

**Impacts of dwarf mistletoe on the physiology of host *Tsuga heterophylla* trees as recorded in tree ring
C and O stable isotopes**

- Dwarf mistletoes, obligate, parasitic plants with diminutive aerial shoots, have long-term effects on host tree water relations, hydraulic architecture, and photosynthetic gas exchange and can eventually induce tree death.
- To investigate long-term impacts of dwarf mistletoe on growth and gas exchange characteristics of host western hemlock, we compared diameter growth and tree-ring cellulose stable carbon and oxygen isotope ratios ($\delta^{13}\text{C}_{\text{cell}}$, $\delta^{18}\text{O}_{\text{cell}}$) of heavily infected and uninfected trees.
- Relative basal area growth was initially greater, but declined more rapidly in infected than uninfected trees. $\delta^{13}\text{C}_{\text{cell}}$ and $\delta^{18}\text{O}_{\text{cell}}$ were significantly lower in infected trees. Lower $\delta^{18}\text{O}_{\text{cell}}$ in infected trees was unexpected given that stomatal conductance and external variables expected to influence $\delta^{18}\text{O}$ values of leaf water were similar for both groups. Estimates of mesophyll conductance (g_m) were significantly lower and effective path length for water movement (L) significantly higher in leaves of infected trees, consistent with their lower values of $\delta^{18}\text{O}_{\text{cell}}$.
- This study reconstructs long-term physiological responses of western hemlock to dwarf mistletoe infection. It further points to limitations of the dual isotope approach for identifying sources of variation in $\delta^{13}\text{C}_{\text{cell}}$ and indicates that changes in leaf internal properties such as g_m and L that affect $\delta^{18}\text{O}_{\text{cell}}$ must be considered.
