As a result of published epidemiological studies indicating health impacts in mountaintop removal coal mining (MTR) areas of southern West Virginia (WV), the USGS conducted a survey of air, water and soil in the impacted area and at WV State Parks which served as control sites with no MTR. The analytes measured were organics, metals, and in vitro toxicity, collected over 2 years. Toxicity testing included three assays which measured 24 hr toxicity. 1) week clonal outgrowth and anchorage-independent growth effects of water and soil sample extracts on human cells. A case study was then conducted on samples collected from Artie, WV in close proximity to a mountaintop removal mining. Private wells, surface waters, soil, fruit/vegetable matter were sampled. Grab sampling was conducted during one week periods over the first year of the survey over all seasons at locations in several counties and at two State Parks outside the active mining area. Year two sampling concentrated on Artie, WV during spring and summer. From the sampling in year one, 2 of 22 samples (March), 3 of 21 (May), 4 of 18 (December) showed significant toxicity to human cells, while from the Artie, WV sampling in year two toxicity was seen in 16 of 19 (August) but 0 of 23 (December) samples. Ground whole apples from a site sampled in August also showed significant toxicity. This variation could be due to episodes of mining activity, seasonal differences in temperature, or water abundance and movement through the aquifer. The air, water and soil organics, metals, and fine particulates showed important differences between mined and non-mined locations. We will discuss how the latter relate to the toxicity results, potential overall importance and context within recent literature findings regarding the possible health effects of mountaintop mining removal.

1018c Assessment of In Vivo Toxicological Interactions from Criteria Air Pollutant Mixtures

L. Datko-Williams1, B. Young1, A. Wilkie1, M. Madden1, J. Dubois1, L. W. Stanek1, D. Johns1 and E. Oesterling Owens1. NCAEA, US EPA, RTP, NC; NERE, US EPA, RTP, NC and NIOSH, US CDC, Morgantown, WV.

The US EPA sets National Ambient Air Quality Standards for criteria air pollutants, recognizing that air pollution in the environment exists as a complex mixture. Potential interactions between mixture components within biological systems are not well characterized. We reviewed past literature investigating the effects of mixtures of criteria air pollutants, starting with mixtures containing NOx (nitrogen oxides), and evaluated the presence of in vivo toxicological interactions. All endpoints and NOx-containing mixtures were considered, however, most studies evaluated respiratory effects of NOx+O3 (ozone). Studies were classified into two categories: complete or incomplete response data. Complete data included the number of observations, mean response, and variance for each treatment group in the study. Studies lacking single pollutant exposures or complete response data were reviewed qualitatively. Of the 13 animal studies and 7 human studies in the qualitative analysis, 6 animal studies and 0 human studies suggested there may be interactions, though no pattern of response among the endpoints or exposures was apparent. Studies with complete data were analyzed quantitatively, and the response to the mixture was compared statistically to the sum of the responses to individual pollutants; the absence of a difference was defined as additive (H0: combined effects = sum of individual effects, p=0.05). Of the studies in the quantitative analysis, all animal studies (n=17) had at least one non-additive endpoint, while the majority of endpoints evaluated in human studies (n=9) were additive. Among the studies that deviated from additivity, no pattern of response emerged in endpoints or exposure conditions. Thus, this analysis suggests that deviations from additivity exist in criteria air pollutant mixtures; however, many of the studies did not demonstrate interactions other than additivity.

The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. EPA.

1018d Mixture Effects at Human Relevant Exposure Levels?

A. Vingaard1, N. Hadrup1, M. Pedersen2, K. Skov2, L. O. Bertelsen1, H. Frandsen1, K. G. Kongebæk1, J. Boberg1 and U. Hass1. 1Div. Toxicology & Risk Assessment, Technical University of Denmark, Søborg, Denmark and 2Division of Food Chemistry, Technical University of Denmark, Søborg, Denmark.

Mixtures of endocrine active chemicals usually act additively irrespective of the applied model system and the complexity of the endpoint measured. Most studies performed so far have tested doses > NOAEL for individual chemicals. But what happens when we test mixtures of EDC’s at doses close to human relevant exposure levels? We had the hypothesis that a low dose mixture of environmental chemicals and active food ingredients would not affect toxicity induced by perfluorooctanoic acid (PFNA). PFNA was given at 13, 250 or 5000 µg/kg/day to male rats with or without a cocktail containing 14 chemicals including phthalates, bisphenol A, parabens, UV filters, pesticides, and the CYP3A4 inhibitors bergamottin (from grape fruit) and glabridin (from liquorice) at human relevant exposure levels (totally 2.5 mg/kg/day). The lowest PFNA dose corresponded to an internal dose of 4–6 fold mg/kg/day. The lowest PFNA dose induced steatosis at the highest dose. At the low dose PFNA+Cocktail pronounced increases of androgen levels (dehydroepiandrosterone, androstenedione & testosterone) were evident. Gene expression analysis in low dose PFNA+Cocktail treated animals showed that CYP19 mRNA was affected in testis and fatty tissues. At higher PFNA doses several steroidogenic enzymes were down-regulated. Overall, we suggest that mixture effects may be considered as biomarkers of direct adverse effects. This is to our knowledge a first indication that mixture effects appear in rats at doses close to human relevant exposure levels.
L. Kan1, D. Wilson1 and D. R. Boverhof1.

15% ~ 40%. This results in variable changes (+/-20%) of F+C as compared with exercise, mass deposition increases greatly (~140%) in TB but decreases (15%) in AL. Furthermore, number deposition comes from both UF and F at a ratio of 1.5:1. During respiration in TB but an increase in AL resulting in a slight increase in TB+AL. Surface area decreases whereas deposition of F increases in both TB and AL as MF increases.

Lung deposition including tracheobronchial (TB) and alveolar (AL) regions was calculated by using a mathematical model built upon Weibel’s lung morphology. The present study used the Bovine Cornea Opacity and Permeability (BCOP) assay to over-predict the irritation potential of moderate and mild irritants. To assess this limitation, the EO assay was used as the second tier test for 14 of the NRR-over-predicted formulations. The EO assay demonstrated good performance with 86% concordance for correctly classifying the NRR-over predicted irritants.

In vitro ocular irritation assays, such as the Chorioallantoic Membrane Vascular Assay (CAMVA) and Bovine Cornea Opacity and Permeability (BCOP) test, are routinely used by personal care products companies because they are rapid and economical to conduct, do not require the use of live animals, and provide reliable predictive data. Previous research using an extensive CAMVA and BCOP database at Kao USA Inc. has shown that ocular irritation potential for new hair shampoos, ethanol-based hair stylers, skin cleansers, and skin lotions can be reliably predicted using a decision tree that systematically compares the ingredient composition, particularly surfactants and surfactant content, of the new formulation to previously tested formulations. Because the studies comprising this original database were conducted by a single contract laboratory, a follow-up study using a second contract laboratory was conducted to demonstrate inter-laboratory reliability of the CAMVA/BCOP data-derived decision tree for prediction of ocular irritation potential. Thirty-five personal care products were tested using the CAMVA and/or BCOP assay. The ethanol and surfactant content of each test material was evaluated, and the results of the assays were compared to the decision tree-based predictions of ocular irritation potential. Our data confirmed the ocular irritation predictions made using the decision tree model for 33 of 37 test samples (89% correlation rate) and verified the inter-laboratory reliability of the CAMVA and BCOP assays when conducted using appropriate controls. Overall, these results also strengthened the ocular irritation decision tree model by confirming that deodorants are consistently predicted not to be ocular irritants based on composition.
Product form and usage can clearly impact exposure, and the present results suggest that modifications to the physical properties of chemical mixtures can alter their ocular irritation potential; perhaps by affecting exposure to the eye. Although no formal comparisons were performed in animals, the BCOP assay is an OECD-validated method to assess ocular irritation, and studies have shown that the BCOP assay does not under-predict the results of traditional animal tests; thus, there are no obvious reasons to suggest that the present results would not correlate to animals or humans.

**1022 Assessing Default GHS Classifications for Eye Toxicity with Alternative Ocular Assays**

N. Pechacek1, J. Caudill2 and T. O’Brien.1 1Ecolab, St. Paul, MN and 2Ecolab, Naperville, IL.

The Globally Harmonized System of Classification and Labeling of Chemicals (GHS) represents an international approach to standardize the classification and hazard communication for chemicals in the workplace. Institutional cleaning products, due to their surface-active chemistries, commonly carry a classification of serious eye damage or irritation. For appropriate product stewardship, such products must be correctly classified for eye effects. Ocular testing is a common approach for attaining a proper GHS classification. Current GHS criteria for classifying this endpoint are based primarily on interpreting in vivo data. However, due to animal welfare concerns, there is a shift in testing emphasis to alternative assays. Two such assays are the Bovine Corneal Opacity Permeability Assay (BCOP) and Chorioallantoic Membrane Vascular Assay (CAMVA). The BCOP uses excised bovine corneas to evaluate ocular irritation. The CAMVA uses the vascular network of fertilized chicken eggs as a conjunctival model to assess ocular irritation. For this study, institutional cleaning products were assigned default GHS classifications for eye effects based on an algorithm prescribed by GHS. Twenty-six products had joint BCOP/CAMVA tests conducted to assess such classifications. Based on the test results from the joint BCOP/CAMVA studies conducted for each product, GHS classifications were re-assigned and compared to the default classifications. Of the 26 products evaluated, 17 had test-based classifications aligning with default classifications, 6 had test-based classifications lower than the default classifications and 3 products had test-based classifications higher than the default classifications. Based on this particular dataset of 26 products, the results suggest the GHS algorithm assigns appropriate (~65%) or conservative (~23%) eye classifications with a relatively small (~11%), but not insignificant, minority of under classifications. A larger dataset is needed to make a definitive conclusion for this observation.

**1025 Cultured Porcine Cornea Assay Using Confocal Microscopy for High Resolution Detection and Quantification of Sub-Mild Ocular Irritation**

A critical need exists for a non-animal ocular irritation assay that is sensitive to sub-mild ocular irritation. We have developed a novel assay, PorFocal, which can quantitively individual dead corneal epithelial cells in porcine corneas using confocal microscopy. PorFocal uses phosphate buffered saline (PBS) as a negative control and 0.01% benzalkonium chloride (BAK) as a positive control. In 17 experiments, 0.01% BAK always caused more cell death than PBS, and statistically (p<0.05) more in 15 of 17 replicates. The PorFocal assay detected a significant dose-response with BAK dilution series treatment. Treatment with 0.01% BAK-preserved lubricant eye drops showed a statistically significant (p<0.05) greater than 3-fold increase in cell death when compared to the preservative-free version. To examine the potential of the PorFocal to detect human eye sting of a known sting chemical (avobenzone), we compared a low avobenzone (LA) to a high avobenzone (HA) content sunscreen. The HA caused significantly more cell death (7-fold increase) than the LA. We then compared PorFocal to an industry standard 3D reconstructed human tissue (RHT) ocular irritation assay. The RHT detected four of nine materials while the PorFocal assay detected eight of nine materials tested as statistically greater than PBS values. Overall, this indicates a great degree of sensitivity with PorFocal assay, previously not attainable by existing methods.

**1026 Using Benzalkonium Chloride and POLYQUAD® to Test the In Vitro Reconstructed Human Corneal Epithelium Model As a Replacement for In Vivo Ocular Screening**

F. Zhang1, L. Walker1, R. Rice2 and D. P. Rodeheaver.1 1Preclinical Safety, Alcon, Fort Worth, TX and 2Preclinical Development, Alcon, Fort Worth, TX.

The aim of this investigation was to evaluate whether the reconstructed human corneal epithelium (RHCE) in vitro model (SkinEthic Laboratory, Nice, France) is a reliable indicator of in vivo acute topical ocular irritation. Ten preservatives commonly found in topical ocular formulations, benzalkonium chloride (BAC) and POLYQUAD® (PQ; polyquaternium-1) solutions, were utilized as model compounds in the test system. Both BAC and PQ solutions were evaluated in the in vitro RHCE model at concentrations of 0.01, 0.02, 0.1 or 0.5%. Test solutions were applied on the surface of each RHCE tissue for 10 min, 1 hr or 24 hrs, respectively. Cell viability, histopathology, interleukin-1α, -6 and -8 were evaluated. Test solutions, except 0.5%
BAC, were also evaluated in a one-day in vivo topical ocular dosing study in NZW rabbits. The in vitro results classified PQ as a non-irritant at all concentrations and at all time points by cell viability. BAC was classified as an irritant in the in vitro study after both 1 hr and 24 hrs exposures at ≥0.1% by cell viability. Histological and interleukin analyses did not correlate as well and appeared to be more sensitive. Results from the in vitro RHCE model using cell viability assay appear to correlate with results from in vivo study with rabbits. These results suggest the RHCE using cell viability assay may have utility in screening topical ocular formulations for potential acute ocular irritation. Also, interleukins and histopathology could provide valuable data but require further investigation.

**PS 1027 The Importance of Understanding Drivers of Irritation In Vivo for Selection of Chemicals Used in the Development and Evaluation of In Vitro Eye Irritation Assays: Cosmetics Europe Analysis**

Cosmetics Europe’s Task Force Eye Irritation is actively involved in the development and evaluation of in vitro methods to assess the eye irritation potential of cosmetic ingredients. Selecting adequate chemicals based on a proper understanding of what drives irritation in classification of ocular effects of chemicals in the in vivo Draize eye test is a critical element that enables identification and evaluation of predictive capacity and applicability domain at an early stage of in vitro methods development. As such, an in depth analysis of the data available from external databases containing in vivo eye irritation data for chemicals tested in the Draize eye test (from more than 500 independent studies) has been undertaken. This analysis is based on having good quality in vivo data that has allowed a clear understanding of the different ocular tissues effects that drive classification. These include the degree of severity and/or the persistence of corneal opacity, iritis, conjunctiva redness and/or conjunctiva chemosis. In addition, all chemicals were screened for their commercial availability, assurance that they cover the whole range of irritation potential and relevant chemical classes and physical states. The approach used to define the drivers of irritation and the importance of each of them for the classification and labeling of chemicals is described. This work demonstrates e.g., the high involvement of corneal effects and the low prevalence of iritis driving classification, and the importance of conjunctiva effects in classification of GHS Cat 2A versus 2B.

**PS 1028 Tiered Testing Strategy Using Validated In Vitro Assays for the Assessment of Skin and Eye Corrosion/Irritation of Pharmaceutical Intermediates**

S. Calufetti1, C. Callisi1, K. Nelson1, M. Krcha1, N. Wilt1 and G. Costin2. 1Cosmetics Europe, Brussels, Belgium and 2. L’Oréal, Paris, France.

The safety of workers handling solid pharmaceutical intermediates was assessed using a tiered testing strategy based on regulatory validated in vitro assays. The Top-Down approach was initiated with the in vitro skin corrosion assay (OECD TG 431) followed by the in vitro skin irritation assay (OECD TG 439) using the reconstructed human epidermis model from MatTek Corporation. Of the ten pharmaceutical intermediates tested, nine were predicted to be non-corrosive to skin and were subsequently confirmed as non-irritants. The only intermediate predicted corrosive to skin was further tested using the Corrosity test (OECD TG 455) and assigned to a corrosive packaging group II classification. Furthermore, three intermediates predicted non-corrosive/non-irritant to skin were tested as 20% dilutions in water in the in vitro Bovine Corneal Opacity and Permeability (BCOP) assay (OECD TG 437) and they were predicted as non-irritant to the eye. Our tiered skin and eye corrosion/irritation testing strategy proved to be a very useful platform for the assessment of the potential safety risk posed to workers during manufacturing operations used for pharmaceutical intermediates.

**PS 1029 Study of Cosmetics Europe for Skin Sensitization Hazard Characterization and Risk Assessment without Animal Testing**

Cosmetics Europe (CE) intends to develop a testing strategy for sensitizer potency prediction without animal testing. In this regard, potency is defined as the entire spectrum of skin sensitisation, ranging from non-sensitiser to extreme sensitizers. To reach this aim a method evaluation study was initiated to identify appropriate in vitro methods. In a joint effort CE and 15 test developers systematically evaluated 16 in vitro methods. 10 chemicals were blind tested by each test method developer: 4-Nitrobenzylbromide, Methylidibromoglutaronitrile, 2-Mercaptobenzothiazole, Cinnamal, Tetramethyl thiuram disulphide, Salicylic acid, Lactic acid, Sodium lauryl sulphate, Phenyl benzoate, Lauryl gallate. Additional information was shared on the protocol, prediction model and existing data for previously tested chemicals: Of the 16 test methods evaluated for hazard prediction (sensitiser vs non-sensitiser) 14 misclassified a maximum of 2 substances, 3 correctly predicted all 10 substances. 7 methods provided useful potency information for the assessment of skin sensitisation, subcategorise in 5 classes as defined for the LLNA. 5 methods misclassified a maximum of 3 substances, usually being only one category off. One test method misclassified more substances, while the 7th method was not evaluated in detail as only for 4 substance results were available. Phase II of the method evaluation study started in January 2013 with ten prioritized methods to build a data base used for the data integration approach starting Q1 2014.

**PS 1030 Predictability of In Vitro Dermal Assays When Evaluating Fatty Amine Derivatives**

It is widely accepted in the world of in vitro toxicology that skin assays can be used in place of in vivo testing to accurately predict corrosivity and/or irritancy of commodity chemicals. Due to REACH legislation, various categories of fatty amines have been evaluated. Historical worker occupational experience has exhibited that various fatty acid amine are corrosive to the skin. Coco-Amidopropylidethanolamine (Coco-APDEA) contains both secondary and tertiary amines and is used as a surfactant in numerous industries. In the EpiDerm (EPI-200) Skin Model, skin corrosion is expressed as the remaining cell viability after exposure to the test substance. The relative mean tissue viability obtained after the 3 minute and 1 hour treatments with Coco-APDEA was 80% and 70% respectively. Since the mean relative tissue viability was not below 50% after the 3 minute treatment and not below 15% after the 1 hour treatment, Coco-APDEA is not considered to be corrosive in this assay. In the EpiSkin-SMTM irritation assay, a positive result is determined when viability is below 50% following a 1 minute exposure. Coco-APDEA exhibited 1% viability at the 15 minute exposure period which would be considered an irritant in this assay. Because the results from the in vitro assays with the human three dimensional epidermal models did not align with historical data, a limited in vivo rabbit study was employed. This test involved one animal and had to be terminated on day 2 because of severe reactions following the 3 minute exposure. Histopathology performed showed marked necrosis of the epidermis of the treated skin, with a marked heterophytic cell infiltrate in the underlying dermis. Based on the results of this study, it is concluded that Coco-APDEA is not a skin corrosive compound.

**PS 1031 Prediction of Systemic Bioavailability Using In Vitro Skin Absorption and Epidermal and Hepatic Metabolism of Aromatic Amine Hair Dyes**

Approaches to assess the role of absorption, metabolism and excretion (AME) of cosmetic ingredients that are based on the integration of different in vitro data are important for their safety assessment specifically due to the ban on animal testing.
in the European Union. In order to estimate systemic exposure (AUC) to each of 5 aromatic amine hair dyes (A027 (4-amin-2-hydroxytoluene), A074 (4-aminom-cresol), A158 (2-amin-5-ethylphenol HCl), A005 (toluen-2,5-diamine) and A154 (1-hydroxyethyl 4,5-diamino pyrazole sulphate)) following typical product application conditions, the bioavailability was first determined using in vitro skin penetration experiments and human keratinocyte (HaCaT) metabolism. This was followed by an estimation of the systemic AUC by additionally utilizing hepatic clearance values. The fraction of the dermally applied dose that reaches the systemic circulation was estimated using measured Michaelis-Menten descriptors of epidermal metabolism, skin penetration rates, viable epidermis measurements, mean residence time and skin permeability coefficients. Predictions of the nonmetabolized fraction were equal to or less than 0.25% of the applied dose. Separate ex vivo studies using viable human skin explants produced values that were within the same order of magnitude as those predicted from the above in vitro AIME approach. In the final step, in vitro hepatocyte Km and Vmax values and whole liver mass and cell density were used to calculate the scaled hepatic clearance to predict systemic exposure in the general circulation (AUC) based upon the estimated dermally absorbed dose. The overall approach provides a quantitative prediction of the internal exposure using appropriate toxicokinetic information that can be generated based solely on in vitro data and showed that none of the applied dose avoided effects of metabolism either by the skin upon entry into the body or by the liver systemically.

**1034 A Dermal Sensitization Assay Using SkinEthic™ RHE**

M. Troese and G. L. DeGeorge, MB Research Laboratories, Spinnerstown, PA.

International regulatory agencies, as well as animal welfare groups, are seeking in vitro assays for assessing the toxicity of chemicals and products. One of the most challenging problems has been to develop non-animal tests for skin sensitization. As an outcome of the Sens-it-iv project in Europe, Corsini and colleagues developed an Interleukin-18 (IL-18) response assay in monolayer keratinocytes as an indicator of sensitization in 2009. Here we report release of IL-18 into the culture medium of SkinEthic™ RHE treated with sensitizers, but not with irritants or non-sensitizers. Sensitizer-induced IL-18 release by RHE tissues was observed to occur in a concentration-dependent manner. RHE tissues were exposed to test substances for 24 hours. Data were expressed as a Stimulation Index (SI) calculation. An SI ratio of >2.0 was considered a positive result for a dermal sensitiser. A range of slight to severe sensitizers, as well as nonsensitizers and irritants were tested. A commercially available ELISA measured IL-18 and tissue viability was determined by the MTT assay. Of the twelve known positive sensitizers tested (4-Nitrobenzyl bromide, p-Phenylenediamine, 2,4-Dinitrochlorobenzene, Eugenol, Citral, Resorcinol, Glyoxal, 4-Hexyl cinnamaldehyde, Cinnamaldehyde, Cinnamic Alcohol, IsoEugenol and 2-Mercaptobenzothiazole), ten were correctly predicted. In addition, six of seven irritants (Chlorobenzene, Lactic Acid, Phenol, Methyl Salicylate, Salicylic Acid and Tween-20) and nonsensitizer (Glycero) were correctly predicted. Overall accuracy of the assay was calculated to be 84%. In conclusion, an in vitro assay for characterization of dermal sensitizers was developed in SkinEthic™ RHE. This assay is promising for identification of sensitizers with high accuracy and predictivity, and for further research into the mechanism of dermal sensitization mediated by Interleukin-18.

**1035 Coculture Assay for the Identification and Investigation of Dermal Sensitizers (Epi-DC)**

G. L. DeGeorge1, M. Troese1, L. F. Pratt1, M. Piel1, P. J. Hayden2 and S. Ayehunie2, MB Research Laboratories, Spinnerstown, PA and 2MatTek Corporation, Ashland, MA.

In order to investigate the mechanism of dermal sensitization, a coculture model of human keratinocytes and dermritic cells was developed and optimized. This model (Epi-DC) consists of a 3D epidermal organotypic tissue, EpiDerm™, grown atop a suspension culture of plasmaoid dendritic cells (DCP-100), in a medium that allows both cellular components to express normal viability, expression of their activation antigens, and cell-cell communication. In this model, test chemicals were dosed topically on the EpiDerm™ tissue for 24 hours. The criteria for change in biomarkers to indicate a positive sensitiser included: (1) an increase of IL-18 release into the culture medium of >1.6-fold over vehicle, or (2) an increase in percentage of DCP-bearing activation surface markers CD86+ or CD54+ of >1.5-fold over vehicle controls, as measured by flow cytometry. Dinitrochlorobenzene (DNCB; 0.003% to 0.1%) and cinnamaldehyde (CA; 0.0003% to 0.006%) were tested diluted in the ethanol vehicle. Results: Basal secretion in vehicle control cocultures was 23.8 pg/ml of IL-18. Treatment of Epi-DC with DNCB yielded IL-18 concentrations that peaked at 0.1% DNCB, resulting in a release of 44.5 pg/ml (1.9-fold increase). Vehicle control cultures had 9.1% CD86+ DC, and a dose-dependent increase of CD86+ DC was shown with treatment of DNCB ranging from 0.003% to 0.1% DNCB, peaking at 18.7% positive CD86+ DC (2.1 fold increase). No significant increases in CD54 expression were observed. At 0.006% CA, increases of 1.6-fold over control were observed in CD86 expression. No increases in CD54+ DC were seen at any of the test substance treatments. Thus, in this initial evaluation, the Epi-DC coculture model has shown to be a useful and predictive tool for identifying dermal sensitizers without the use of animals.
We describe a human-based in vitro skin explant test (Skinmine™) that improves predictivity relative to the use of animal models for adverse immune reactions. The test involves exposing dendritic cells from a healthy volunteer to a test compound followed by incubation with autologous T cells. The T cells are then tested for immune reactivity in vitro on a skin biopsy from the same volunteer. If the compound is a sensitizer, coculture of activated T cells with the skin gives rise to an adverse immune reaction, graded histopathologically from I-IV. The test was evaluated using a range of chemical sensitizers and nonsensitizers, with 95% concordance with the mouse local lymph node assay (LLNA) (p < 0.001; sensitivity 95%, specificity 95%). The test correctly identified chemicals negative in the LLNA but positive in man (e.g., nickel sulphate) and correlated with T-cell proliferation and interferon gamma secretion assays. The test also predicts adverse immune reactions to biologics such as the Tegenero antibody (TGN412) and overcomes inter-laboratory differences which often prevent detection of adverse effects during safety testing. Compounds tested included: maleic anhydride, glutaraldehyde, trimellitic anhydride, paraphenylene-diamine, cinnamic alcohol, isoeugenol, eugenol, 2,4-dinitrochlorobenzene, mercaptobenzothiazole, cinnamaldehyde, oxazolone, glyoxal, resorcinol, 4-nitrobenzylidene, potassium dichromate, ethylendiamine, hexylcinnamaldehyde, and 2-hydroxyethylacrylate, and the nonsensitizers sodium dodecyl sulfate, glutamic acid, propyleneglycol, 4-aminobenzoic acid, methylsalicylate, chlorobenzene, diethyleneglycol, propylene glycol, ethanol, propylene glycol, trimethylamine, propylene glycol, propylene glycol, and Tween 80.

This study builds upon previous studies showing that CeeTox’s in vitro SenCeeTox® assay can correctly identify and categorize chemical sensitizers when used in-house. The aim of this project was to further validate the SenCeeTox® assay by conducting an inter-laboratory validation at the Flemish Institute for Technological Research (VITO). In this study, MatTek’s three-dimensional human skin model, EpiDerm (EPI-296, EpiDerm 96-well reconstituted human epidermis), was treated in triplicate with six concentrations of each test article. Test articles were run in a blinded manner. The test articles evaluated were: metol, isoeugenol, 2,3-butane diol, 2-mercaptobenzothiol, eugenol, 1-chloro-2,4-dinitrobenzene, n-propyl alcohol, 2-hydroxyethylacrylate, and 2-hydroxyethylacrylate, and the nonsensitizers sodium dodecyl sulfate, glutamic acid, triton-X-100, zinc sulphate, dimethyl sulphoxide, potassium permanganate, iso-propanol, dimethylformamide, glycerc, tween 80, phenol, ethylvanillin, octanoic acid, propylene glycol, 4-amino benzoic acid, methylsalicylate, chlorobenzene, diethylphthalate, p-hydroxybenzoic acid, and benzaldehyde.

**Inter-Laboratory Validation of an In Vitro Method to Classify Skin Sensitizers**

This study builds upon previous studies showing that CeeTox’s in vitro SenCeeTox® assay can correctly identify and categorize chemical sensitizers when used in-house. The aim of this project was to further validate the SenCeeTox® assay by conducting an inter-laboratory validation at the Flemish Institute for Technological Research (VITO). In this study, MatTek’s three-dimensional human skin model, EpiDerm (EPI-296, EpiDerm 96-well reconstituted human epidermis), was treated in triplicate with six concentrations of each test article. Test articles were run in a blinded manner. The test articles evaluated were: metol, isoeugenol, 2,3-butane diol, 2-mercaptobenzothiol, eugenol, 1-chloro-2,4-dinitrobenzene, n-propyl alcohol, 2-hydroxyethylacrylate, and 2-hydroxyethylacrylate, and lactic acid. Following 24 hr exposure to the test articles, the following endpoints were measured: 1) cytotoxicity, 2) the ability of each chemical to directly react with gluthathione, and 3) expression of key genes. The gene expression levels of seven target genes controlled by the NFκB/Keap1/ARE signaling pathway were examined: NADPH-quinnone oxidoreductase 1, aldo ketoreductase 1C2, interleukin 8, cytochrome P450 1A1, aldehyde dehydrogenase 3A1, heme oxygenase 1, and glutamate cysteine ligase catalytic subunit C. The data were then analyzed in a blinded manner using a proprietary algorithm to predict each chemical’s likelihood of causing a human sensitization reaction. The results confirm the inter-laboratory reproducibility of SenCeeTox® which accurately predicted the ability to elicit a sensitization reaction for all 10 blinded compounds tested at VITO. Furthermore, it correctly predicted the sensitization potency category for 9 out of the 10 compounds, missing the 10th compound by only one potency category. In conclusion, SenCeeTox® can predict the sensitization potency of chemicals ranging from nonsensitizers to strong-extreme sensitizers.

**A Novel Organotypic 3-D Human Small Intestinal Tissue to Assess Drug Safety and Inflammation**

S. Ayehunie1, Z. Stevens1, T. Landry1, M. Taim1, A. Armento1, M. Klausner1 and P. J. Hayden1. 1MatTek Corporation, Ashland, MA and 2Apreda, Watertown, MA.

The intestinal epithelium plays a key role in defining the bioavailability of orally administered drugs. The colon cell line, Caco-2, is commonly used to study intestinal drug safety and inflammation but it does not recapitulate the structure or physiology of small intestine (SI) tissue. This study evaluates the functionality of a novel in vitro tissue model reconstructed from normal human primary SI epithelial
cells and fibroblasts. Primary cells were expanded in monolayer culture and seeded onto microporous membrane inserts to reconstruct 3D organotypic SI tissues. Tissue morphology, surface marker expression, ultrastructural features, and barrier integrity of the tissues were characterized. In addition, efflux drug transporter expression was analyzed by RT-PCR and drug permeation was examined using LC-MS/MS with 3 model drugs previously tested with Caco-2 cells. Inflammatory responses were examined by exposing the tissue to TNF-α for 24 hr. Analysis of the SI tissue model revealed: 1) wall-to-wall tissue growth, 2) columnar epithelial cell morphology similar to human SI, 3) a physiological TEER value of 60-180 Ω cm² mimicking the SI microenvironment, 4) expression of MUC-2, CK19, and villin, and 5) formation of brush borders and tight junctions. RT-PCR also showed expression of the prominent efflux drug transporters P-gp (MDR-1), MRP-1, MRP-2, BCRP and the main metabolic enzyme, CYP3A4 similar to human SI explants. Initial permeation studies using 2 P-gp substrates, ranitidine and talinolol, demonstrated active transport while warfarin, a non-PgP substrate, did not. Treatment of the SI tissue with TNF-α induced a proinflammatory response by inducing the release of chemokines including IL-8 and GRO-α. We anticipate that this new human cell-based SI tissue will be useful for pre-clinical assessment of drug safety and mucosal inflammation and at the same time will reduce the use of animals for experimentation.

**1041 Comparison of Three Different In Vitro Intestinal Barrier Models for Assessing the Oral Fraction Absorbed of Pharmaceutical and Nutritional Products**

H. Wortelboer1, J. Westerhout2, S. Vaessen2, M. Bol-Schoenmakers2, B. I. Blauuboer1, J. Schricks1, M. Verweij1 and R. Pieters1, 2.1 Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, 2 Dept Innovative Testing, University of Applied Sciences, Utrecht, Netherlands and 3 TNO, Zeist, Netherlands.

In development of pharmaceutical and nutritional products an accurate prediction of the oral fraction absorbed in humans is essential, as the bioavailability of a compound at the target site co-determines the efficacy of the active compound. Currently, animal models, in vitro (mainly cell lines) and in silico tools are applied preclinically, but their predictive value to assess oral bioavailability in humans is often insufficient. Here, we aim to design a decision tree based on several in vitro intestinal barrier models, but to increase acceptance and implementation, data obtained in intestinal barrier models should be translatable to human in vivo data. Apparent permeability (Papp) values of 15 model compounds with different physicochemical properties were tested in the Caco-2 model and the InTESTine™ model using porcine jejunal tissue and compared with published human Papp values. In addition, cells and pores and human intestinal segments were analyzed for abundance of transporter proteins and metabolic enzymes. Papp values of compounds determined using the InTESTine™ system were in the same range as the human Papp values (based on Ussing data), whereas data obtained with Caco-2 cells showed major differences probably due to differences in effective transport area. As expected, major differences were found in levels of active transport systems and metabolic enzymes in both Caco-2 cells and porcine jejunal tissue in comparison with human intestinal tissue. Results provide important characteristics of different in vitro permeability models and will help to design a predictive decision tree feeding into human PBPK modelling.

**1042 Evaluation of the Toxicity Profiles of Selected Bioactivated Compounds in Primary Rat Hepatocytes Cultured in Micropatterned Cocultures**

O. Ukain1, M. McVay1, S. Krzyzewski2, K. Rose2, M. E. Anderson2, S. Khetani1 and E. LeCluyse2. 1Hamner Institutes for Health Sciences, Research Triangle Park, NC. and 2Dept Innovative Testing, University of Applied Sciences, Utrecht, Netherlands.

Drug-induced liver injury is often caused by cytochrome P450-dependent activation of drugs into reactive metabolites. In vitro models, which can mimic in vivo responses and allow the evaluation of initial and adaptive responses to bioactivated compounds over prolonged periods, offer potentially valuable tools for toxicological assessment. We have previously developed a model in which primary hepatocytes (rat, human) are seeded onto ECM-coated domains of optimized dimensions and subsequently cocultivated with murine embryonic fibroblasts [i.e. micropatterned cocultures (MPCC)]. This model retains key biochemical functions of in vivo liver with long term stability. Here, we assess the bioactivation and cytotoxicity of acenaphthene (APAF) and other compounds in the 96-well rat MPCC. APAF is a well-known hepatotoxic and exerts its toxic effects through bioactivation associated, in part, with cytochrome P450 3A (CYP3A). Rat MPCCs were exposed to increasing concentrations of APAF (over 5 days) and assessed for changes in hepatic ATP content, glutathione (GSH) levels, albumin secretion and urea synthesis. Similar concentration-dependent cytotoxicity profiles (AC50=8.4 ± 2.4mM for GSH depletion and 14.17 ± 3.5 mM for urea synthesis inhibition) were obtained over the course of the 4-week study. Addition of 200μM L-buthionine (S, R)-sulfoximine (BSO), an inhibitor of GSH synthesis, or 10μM dexamethasone (DEX), an inducer of rat CYP3A1/2, to rat MPCCs protected APAF-induced hepatotoxicity in these cultures irrespective of culture age (over 4 weeks). These findings are consistent with the known in vivo mechanisms of APAP toxicity in rats. In conclusion, rat MPCCs provided reproducible APAP-induced cell cytotoxicity profiles over a 4 week period and can be used to assess the effects of chronic exposure to bioactivated compounds. The toxicity profiles of selected bioactivated compounds are also reported here.

**1043 Upregulation of CYP3A4 and CYP1A1/2 Activities in Huh-7 Human Hepatoma Cells with DMSO and Use of These Induced Cells to Evaluate CYP Inhibition by Botanical Extracts and Their Components**

Y. Liu1, S. Pugh Bishop1, 2 and T. L. Flynn1. 1Food and Drug Administration, Laurel, MD and 2Oak Ridge Institute for Science and Education, Oak Ridge, TN.

Liver metabolic enzyme inhibition and induction are the leading causes for severe drug-drug and drug-dietary supplement interactions which may result in increased toxicity or loss of treatment efficacy. In vitro cell line-based models are needed as an alternative to the “gold standard” primary hepatocytes, which are expensive and may exhibit problematic batch-to-batch variability. In the current study, human hepatoma Huh7 cells were treated with 1% dimethyl sulfoxide (DMSO) for two weeks after reaching confluence. Basal gene expression and enzyme activity levels of cytochrome P450 3A1/2 and 3A4 were measured and compared between DMSO-treated and non-treated Huh7 cells cultured in parallel. Real-time PCR analysis revealed that DMSO treatment up-regulated gene expression for CYP1A1, CYP1A2, CYP3A1 and CYP3A4 by 2.3 to 3.0 fold. Additionally, CYP1A2 and 3A4 activity (measured by specific luminescence assays) was 4.5 to 5.0 times higher in DMSO-treated Huh7 cells versus non-treated cells. Finally, the cell-based system was used to investigate the CYP3A4 inhibition by both whole Poria cocos extract and its major characteristic phytochemical components psoralen and isopsoralen. Psoralen and isopsoralen (1 μM to 50 μM), as well as Poria cocos extract (5 μg/mL to 20 μg/mL), inhibited CYP3A4 activity in a dose-dependent manner. No cytotoxicity was observed at these concentrations. In conclusion, Huh7 cells treated with 1% DMSO differentiate into a metabolically competent cell line, especially with regards to basal CYP1A1/2 and CYP3A4, which can be useful in studying the effects of botanicals and related pharmaceutical compounds on CYP1A1/2 and CYP3A4 function.

**1044 Evaluation of Hepatotoxic Effects of Acenaphthene and Arsanilic Acid on the Human Adipose Tissue-Derived Hepatocytes**

Hepatocyte-like cells (HLCs) derived from human adipose-derived stem cells (hADSCs) could provide availability as in vitro hepatocytotoxic model. In this study, we improved the differentiation strategy of hADSCs into HLCs by shortening the period of differentiation and evaluated the effect of acenaphthene (AAP) and arsanilic Acid (Ars), on the differentiation of hADSCs to HLCs. hADSC was used for hepaticogen differentiation. At final differentiation day (day 13), enzyme activities (LDH, ALT, AST), expression of hepatocyte specific genes (ALB, AFP, CYP3A4, CK18, C/EBP) and CYP450 activity (CYP1A2, CYP3A4) were determined. 1 and 2.5 μM ofArs and 5 μM of AAP showed cytotoxicity. Enzymatic activity was not changed by Ars treatment. In AAP treated groups, LDH activity was increased dose-dependently, and AST activity was also increased by the treatment of 2.5 μM and 5 μM, and ALT activity was increased by 5 μM AAP. In the Ars-treated groups, the expression of ALB was decreased by 0.25, 0.5 and 2.5 μM treatment without showing dose-dependent manner. In the AAP-treated groups, the expressions of ALB and AFP were significantly decreased by all dose of AAP. The expression of CYP3A4 was decreased only by 5 μM AAP compared to non-treated group. Interestingly, the expression of CK18 was increased by 5 μM AAP. C/EBP expression was not different in all concentration of AAP. The activity of CYP1A2 in AAP increased in dose-dependent manner and CYP3A4 was decreased by 0.625 μM of AAP. In the Ars treated groups, CYP1A2 activity was decreased and CYP3A4 activity was not significantly different from non-treated group. Conclusively, Ars decreased the expression of ALB and CYP1A2 activity whereas AAP increased activity of ALT, AST, LDH and decreased the expression of
Isoniazid (INH), prescribed for tuberculosis, has been associated with idiosyncratic drug-induced liver injury (DILI). It is speculated that genetic factors contribute to susceptibility towards INH hepatotoxicity. In the current study, induced pluripotent stem cell derived hepatocytes (iHC), which carry the donor's genetic information, were characterized for studying INH hepatotoxicity. Specific probe substrates demonstrated that Vmax/mg protein of CYP1A2, CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP2D6, CYP2E1, CYP3A4 in iHC were comparable to those reported in primary human hepatocytes (pHH). Both iHC and pHH demonstrated dose- and time-dependent INH-protein adduct formation and reduction in binding was observed after treating the cells with pan P50 inhibitors. Major bands of INH-adducted proteins in both cell types were qualitatively, but not quantitatively, similar. Proteomic analysis identified prohibitin-2 and macrophage navigation inhibitory factor as major proteins adducted by INH in iHC. INH, up to 10 mM, which is 100 fold higher than the Cmax in patients serum, does not cause ATP loss, lactate dehydrogenase (LDH) release or morphological changes in iHC. However, at non-cytotoxic concentrations, INH reduced the oxygen consumption rate as well as mitochondrial membrane potential and there was an increase in iHC release of microparticles (~0.1 micron) into the medium which may represent a mechanism for neotoxant and 'danger signal' release. In summary, the iHC exhibited many CYP activities comparable to pHH. At non-cytotoxic concentrations, INH formed protein adducts, altered mitochondrial function and released microparticles in iHC cultures. We conclude that iHC are appropriate for study of INH DILI and preparation of cultures from INH DILI subjects is now underway.

a fundamental improvement of the technology by focusing on two main aspects: (i) to re-design the workflow of the procedure for reduction of cellular stress and experimental complexity and (ii) to clearly improve the deposition of airborne particulate matter on the cellular surface during aerosol testing.

As a result, an advanced procedure including a novel type of exposure device was developed. It permits a uniform and smooth processing of cells leading to higher robustness, practicability and ease of use. Repeated dose exposures and less time and material consuming routine use are enabled. To increase the applicability of the ALI-method in aerosol testing, numerical CFD simulations were applied for the optimization of the stagnation flow setup.

Deposition mechanisms such as sedimentation, diffusion and thermophoresis was balanced. First results of simulation and laboratory experiments showed a clearly increased deposition efficiency of particles from aerosols in the test system without observation of adverse effects on the exposed cells. Therefore, the improvements of the procedure so far seem promising to further enhance the applicability and acceptance of alternative methods in the study of inhaled substances significantly.

### Use of Rat Precision-Cut Lung Slices for Long-Term Functional Evaluation

V. Neuhaus1,2, A. Braun1,2, K. Sewald1,2, Fraunhofer ITEM, Hannover, Germany, and Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Member of the German Centre for Lung Research (DZL), Hannover, Germany, Sponsor: C. Dasenbrock.

The need of alternative methods for animal studies to investigate basic inflammatory mechanism and to test toxicological potential of new substances has been increased during the last decades. Precision-cut lung slices (PCLS) have been proven to be a valuable alternative for mammalian in vivo studies reflecting relevant factors of the respiratory tract in accordance with the three R principles. However PCLS have been used mostly for short-term cultivation (≥ 72h) only, which limits their use to certain questions. When it comes to analyses of slowly metabolized chemicals and to repeated application of compounds, the long-term cultivation of PCLS might be utterly important. In this study viability and maintenance of structure and functionality of long-term cultured (≥ 14 days) rat PCLS was investigated.

Rat PCLS were cultured for 15 days. Readout parameters for vitality (WST-1 assay) and functionality were assessed at different time periods. Ability to secret the pro-inflammatory cytokine Tumor necrosis factor alpha (TNF-α) and functionality of long-term cultured (≥ 14 days) rat PCLS was investigated. Rat PCLS were cultured for 15 days. Readout parameters for vitality (WST-1 assay) and functionality were assessed at different time periods. Ability to secret the pro-inflammatory cytokine Tumor necrosis factor alpha (TNF-α) and functionality of long-term cultured (≥ 14 days) rat PCLS was investigated. Rat PCLS were cultured for 15 days. 1056 Identification of Cytotoxic Chemicals in Thirdhand Smoke

V. Bahi1, S. Schick2, M. Sleiman3 and P. Talbott4, 1Cell Biology and Neuroscience, University of California Riverside, Riverside, CA, 2Department of Medicine, University of California San Francisco, San Francisco, CA and 3Indoor Environment Group, Lawrence Berkeley National Laboratory, Berkeley, CA.

Little information is available on the health effects of thirdhand smoke (THS). Our work evaluates the effect of THS on mouse neural stem cells, an in vitro model for neonatal brain. Cytotoxicity was studied using the MTT assay which evaluates conversion of a tetrazolium salt to a colored formazan by mitochondrial reductases. Tery cloth exposed to cigarette smoke for 110 hours over 1 year was stored at room temperature to allow aging of THS, and extracts were prepared after different times of aging. THS aged for 11 months caused complete cell death in the MTT assay at the highest dose and 50% cell death at the 30% dose. Cytotoxicity was lost immediately after the smoking period caused 50% cell death at the highest dose, and more than 90% decrease in cytotoxicity after 24h. In summary, we provide mechanistic insight into the mode of action of CS on neural cells, and how, by lessening the biological impact on key cellular processes, exposure to a PMRTP reduces overall toxicity when compared to CS. Moreover, the ability to detect biological perturbations at sublethal doses strongly supports the use of HCS-based approaches for toxicological assessment.

1058 Quantification of Neuron Maturation and Neurite Outgrowth In Vitro Using Human Neural Progenitor Cells

X. Wu1, E. Jordan2, J. Donnelly3 and S. Szcze1, 1Cell Biology and Neuroscience, University of California San Francisco, San Francisco, CA, 2Animal and Dairy Science, The University of Georgia, Athens, GA, 3Arneck Biomedical, Inc, Athens, GA and 4Infectious Disease, The University of Georgia, Athens, GA.

Human embryonic stem cells based developmental neural toxicity (DNT) assays mimic neural development in vitro and have become an alternative to expensive and time consuming animal DNT models. Previously using human embryonic stem cell derived neuronal cells, an in vitro human neural culture system assay for neurite extension/recovery has been employed as a DNT assay. Our objective was to mimic in vivo neural tube development starting with proliferative neural progenitor (NP) cells for high content image screening in 96-well plates and to characterize the time point for neurite extension and NP cell transition to post mitotic neurons. In our lab we have generated differentiated neurons from NP cells without basic fibroblast growth factor (bFGF) but with leukemia inhibitory factor (LIF) in 2 weeks. During differentiation, Bis 1 dose solutions were applied to the cells 6h after plating for 2 weeks and then immunostained cell cultures in 96 well plates were loaded into a Cellomics ArrayScan VTI HCS reader high-content imaging system for automated image acquisition and morphometric analyses. Here our results show that expression of post mitotic neuronal cell marker Hu/C/D increased from 3.4 % at day 0 to 63.5 % by 2 weeks but did not significantly increase at later times. Thus we used this period of time in a multiplex assay to determine the effects of Bis1, a known neural toxicant on neurite outgrowth and maturation to Hu/C/D positive neural cells. Bis1 inhibited neurite extension in a dose dependent manner starting at 0.1mm without significantly affecting neuron maturation over the 2 weeks. We have developed a multiplex high content assay to determine the effects toxicant in cells representative of the developing human neural tube and for the first time demonstrated that Bis1 specifically affects neurite outgrowth at lower concentrations than acute neurite recovery assays.

1059 An Analysis of the Toxicity of Ximelagatran Using a Combination of In Vitro and In Silico Methods

Hepatotoxicity associated with increase in liver enzymes has been observed on long term (>35 days) treatment with Ximelagatran, an oral thrombin inhibitor causing the drug to be withdrawn from the market. We used a combination of in vitro and in silico methods to understand the mechanisms underlying its toxic behaviour.

We first tested Ximelagatran in a series of in vitro assays designed to understand its dose-dependent impact upon key pathways in HepG2 cells and derived a dose-relationship for each of them. The in vitro treatment was performed for 72 hours allowing us to build a robust relationship between drug exposure and inhibitory effects on key liver enzymes and transporters. We then simulated a virtual clinical term (>35 days) treatment with Ximelagatran, an oral thrombin inhibitor causing the drug to be withdrawn from the market. We used a combination of in vitro and in silico methods to understand the mechanisms underlying its toxic behaviour.

Our simulations indicate that the drug has an impact on mitochondrial function by affecting multiple targets that eventually lead to depletion of cellular energy and production of reactive oxygen species. We hypothesize that this is due to inhibition of mitochondrial energy transport. Furthermore, these effects are exposure-dependent leading to apoptotic cell death and necrosis.

The 2-year bioassay is the standard method for carcinogen detection which is time and resource intensive. Many short-term tests, especially genotoxicity tests, have been developed to aid in identification of potential carcinogens. The SHE cell transformation assay is simulating the process of animal two-stage carcinogenesis and is suited to detect a carcinogenic potential of test compounds vitro including genotoxic and non-genotoxic mechanisms. For mechanistic investigations of Beryllium (first phase of REACH), three different genotoxicity tests (Ames, Mammalian Gene Mutation- and Chromosomal aberration test) together with the SHE cell transformation assay were carried out. Due to the insolubility of the metal powder and the metal alloy, these studies were conducted on extracts. No genotoxic effects where obtained with both extracts in the genotoxicity assays performed. However, in the SHE cell transformation assay dose-dependent increases in morphologically transformed colonies were obtained both with the metal alloy as well as with the metal powder, which indicates a non genotoxic mechanism of the metal powder and the alloy.

The SHE cell transformation was also carried out on a compound (first phase of REACH) with a structural alert for carcinogenicity (pararosaniline derivative). A significant dose-dependent increase in morphologically transformed colonies was obtained with the pararosaniline derivative indicating the usage of in vitro data to demonstrate similarities across a chemical category (read-across).

Our data indicate that the SHE cell transformation assay in combination with other information such as genotoxicity data, structure activity analysis, in vivo toxicity data and pharmac/toxicokinetic information can facilitate a relatively comprehensive assessment of a carcinogenic potential of a chemical.

**1060 Evaluation of In Vitro Cardiac Electrophysiological Assessments on the ACEA xCELLigence and Axion Maestro Platforms**

M. A. Kaus, H. Uppal and D. L. Misner, Safety Assessment, Genentech, South San Francisco, CA.

Introduction: Cardiotoxicity liabilities persist as a major cause of pre-clinical and clinical drug attrition today. Recent advancements in both biological models and electrophysiological technologies allow for faster and longer-term in vitro methodologies to assess beat rate and functional alterations. We sought out to utilize label-free, electrode-based, high throughput platforms to detect cardiomyocyte beating and functionality.

Methods: Both the xCELLigence from ACEA and the Axion Maestro systems are label-free, electrode-based, high throughput platforms used to detect in vitro cardiomyocyte beating and functionality through detection of impedance and voltage, respectively. To evaluate each system, we used a set of four potent anti-cancer molecules that had previously shown significant effects on cell viability (IC50s < 10nM) along with one structurally similar but biologically inactive molecule as a negative control, and then determined the effects on human stem-cell derived cardiomyocytes, both functionally and electrophysiologically.

Results: Both platforms were able to accommodate the multiple-day experiments required to detect significant changes in beating over time. In these time course studies, both systems showed that the most toxic doses had dramatic effects on cardiomyocyte functionality, ultimately stopping beat rate entirely, and doses closer to the IC50s had more intermediate effects of reduced beat rate and amplitude. In contrast, inactive molecules were benign, demonstrating specificity of the compounds’ effect.

Conclusions: Measurements from both systems were sensitive enough to detect on-target, time dependent and mechanism-specific responses. Additionally, the Maestro detected spike slope, as well as T wave position, which allowed for assessment of repolarization periods (“QT intervals”), which helped to further discriminate the mechanisms of functional toxicity versus viability effects across molecules.

**1061 Preclinical Profiling and Comparison to a Human Response Database of an In Vitro Cynomolgus Macaque Vascular System As A Nonhuman Primate Surrogate**

M. Simmers1, R. Feaver1, B. Cole1, A. W. Pryor1, J. R. Turk1, D. Manka1, B. R. Wamhoff1, C. W. Qualls1 and B. Blackman1. 1HemoShear LLC, Charlotte, VA and 2Amgen Inc., Thousand Oaks, CA.

The cynomolgus macaque (CYNO) can be critical for de-risking and validating preclinical candidates for on- or off-target vascular responses. However, it is often difficult to translate mechanism of action studies from CYNO to humans. Previously we established a human primary vascular endothelial (EC) and smooth muscle cell (SMC) co-culture system, which recapitulates hemodynamic forces and restores cell biology and responsiveness to drugs at physiologically relevant levels. From this, we generated a predictive human response database (HRDB) comprising responses to >120 clinically relevant drugs, including atorvastatin (AS), simvastatin (SS), cerivastatin (CS) and rosuvastatin (RS). In the current study, we established a co-culture system with primary ECs and SMCs from CYNO arteries and exposed them to hemodynamics captured directly from CYNO arteries, inflammatory stimuli, and four different statins. Using RNAseq transcriptomics we profiled responses observed in the CYNO co-culture system and compared this to the HRDB. As in the HRDB, the expression of CYNO vascular genes (KLF-2, KLF-4, eNOS) that serve an antiangioprotective function was significantly increased by healthy regional hemodynamics compared to atheroprotective hemodynamics. The addition of advanced inflammatory conditions dramatically increased the expression of genes associated with oxidative damage (SOD2) and inflammation (MCP-1, IL-8) in both the CYNO system and the HRDB. Treatment with 3 out of 4 statins (AT, SS, CS) restored KLF-2 and KLF-4 under advanced inflammatory conditions; the exception was RS, which failed to restore these protective genes. A transcriptomic analysis will be presented comparing and contrasting the responses to statins of the human and CYNO systems. In summary, the CYNO vascular system described here mirrors many well-known responses of the human vascular system, and should provide a valuable preclinical tool for understanding mechanisms of action.

**1062 The Use of the SHE Cell Transformation assay for the Safety and Risk Assessment of Compounds under the EU REACH Regulation**

Chemically induced vascular toxicity during embryonic development can result in a wide range of adverse prenatal outcomes. We constructed an embryonic vascular disruption adverse outcome pathway (AOP) based on molecular initiating events corresponding to genetic models with phenotypic evidence of abnormal embryonic vascular development in the Mouse Genome Informatics Database. ToxCast high throughput screening data for 25 assays mapping to targets in the AOP were used to prioritize ~1000 chemicals for their potential to disrupt vascular development. A subset of 38 predicted vascular disruptive chemicals (pVDCs) or non-pVDCs were selected for targeted testing in zebrafish (D. rerio). To test computational predictions, TG(Ik(lGFP) zebrafish embryos were used to visualize and quantify blood vessel formation during development. Manual and automated methods of vessel quantification were developed, and the assay was evaluated with anti-angiogenic reference compounds PTK787 and AG1478, small molecule inhibitors of VEGFR2 and EGFR, respectively. The functional consequence of developmental vascular toxicity was assessed in larval and juvenile zebrafish. The assay was used to test the effects of 38 pVDCs and non-pVDCs including pesticides, flame retardants, and endocrine active compounds. The test chemicals were also evaluated in a functional angiogenesis assay comprised of a human endothelial cell and fibroblast co-culture system. Chemical rankings were well correlated among the predictive signature and zebrafish and in vitro tubulogenesis assays. Taken together, the zebrafish assay meets a critical need for an in vitro platform that can assess predictions generated by computational models of developmental vascular toxicity. This abstract does not necessarily reflect EPA policy.
Prolonged exposure to cadmium (Cd) in cigarette smoke has been associated with adverse health effects involving damage to pulmonary and cardiovascular tissue. Cd is known to induce oxidative stress, inhibit DNA repair, and interfere with essential metals. A recent study with Calu-3 cells also described its ability to disrupt tight junctions (TJs), possibly by a direct effect on adherens junction proteins. Herein, we report a novel mechanism of Cd-mediated TJ disruption in an in vitro human air-liquid interface (ALI) airway tissue model derived from normal primary human bronchial epithelial cells. Cultures were exposed basolaterally to 10-100 μM CdCl2 for 16 h, which, while considerably higher than the ~15 nM Cd found in smokers' blood, was non-cytotoxic to ALI cultures based on the MTS assay. Treatment with 100 μM CdCl2 resulted in the collapse of barrier function as demonstrated by Trans-Epithelial Electrical Resistance (TEER), immunofluorescence staining with TJ markers, ZO-1 and occludin, and histopathology staining. PCR array analysis of human TJ genes indicated that CdCl2 exposure altered the expression of several groups of genes encoding proteins associated with TJ assembly. Immunoblotting of select junction interacting proteins demonstrated down-regulation of their expression, suggesting that disruption of junctional complex functions is essential for maintaining TJ integrity is a possible mechanism for Cd toxicity. Furthermore, inhibition of kinase signaling using specific inhibitors prevented the down-regulation of junction interacting proteins, inhibited the up-regulation of tyrosine phosphorylated occludin, and preserved the integrity of TJs. Our findings indicate that acute doses of Cd likely disrupt TJ integrity through kinase activation and occludin hyperphosphorylation. Whether or not Cd causes similar toxicity with chronic, low level exposures experienced by smokers remains to be determined.

Recent changes in regulatory restrictions and social views against animal testing have accelerated development of reliable alternative tests for predicting skin sensitizing potential and potency of many chemicals. Lately, the approach of using a battery of in vitro tests instead of a single in vitro test has been suggested as a replacement for animal tests. In this study, we created a dataset of 66 test chemicals with human sensitizing potential data, human cell line activation test (h-CLAT), direct peptide reactivity assay (DPRA), and in the silico prediction system DEREK Nexus. DPRA, based on the covalent binding between proteins and haptenbs, and h-CLAT, emulating dendritic cell activation in the skin during sensitization, have been successfully pre-validated under ECVAM. For DEREK, 21 out of 66 chemicals have been used as the training dataset. The results of these tests were converted into a score from 0 to 2, taking into account the integrated testing strategy concept. For the 66 test chemicals, the total battery score between 0 and 5 was calculated by the sum of individual scores. When we set the positive criteria as more than a score of 2, the score-based battery system provided an accuracy of 94%, sensitivity of 96%, and specificity of 85% for the human sensitizing potential. We next developed a tiered approach, weighing the predictive performance of the h-CLAT and DPRA. The h-CLAT indicated a higher sensitivity than the DPRA. Thus, we determined the h-CLAT was a good first step for a tiered approach. The tiered system provided an accuracy of 89%, sensitivity of 98%, and specificity of 60%. Both battery systems showed a higher sensitivity compared with the h-CLAT or DPRA alone. In summary, our data not only demonstrates that the h-CLAT could be part of a non-animal test battery together with the DPRA and other methods for the assessment of skin sensitization but also supports the practical utility of a tiered system where h-CLAT and DPRA are the first screening methods for skin sensitization.

High-throughput screening assays are generating information regarding the toxicity of thousands of untested environmental chemicals. However, current methods are unable to test volatile organic compounds (VOCs). In addition, mechanistic information is needed to link effects at molecular targets to adverse outcomes in whole organisms. This study is designed to address these issues using the Drosophila Genetic Reference Panel (DGRP), a set of genetically well-characterized strains of fruit flies. The goals of the project are to determine whether fruit flies can be used to screen VOCs for toxicity, and to identify adverse outcome pathways associated with acute exposure. The first phase of this study was to determine dose-effect functions using behavior endpoints for 3 VOCs that differ in their mode of action. In a second phase, behavioral response profiles across strains of DGRP flies will be determined at the EC20 of each VOC and mapped to genetic markers of effect. We used a hybrid line of flies derived from ~40 DGRP lines to identify an EC20 for each chemical. Individual flies were placed in 5mm dia. glass tubes and exposed for 4 hours at various concentrations of toluene vapor (n= 16/sex/dose); controls received air. Real-time locomotor activity was observed at 10-minute intervals for both sexes. Males were overall more active than females. Toluene decreased activity in both

Cerebral microvascular endothelial cells have been reported to serve as a vascular niche for the recruitment of neural stem cells, regulation of breast tumor metastasis to the brain, and promote the self-renewal of cancer stem like cells in glioblastoma multiforme (GBM). We previously reported the effect of the nonocplanar PCB153 on human brain endothelial cell line IC1M5/D3. PCB153 exposed IC1M5 showed a significant increase in stem cell markers CD34, CD133, and VEGFR-3. Exposure to PCBs may severely compromise normal function and lead to increased level of stem cell markers that participate in the development and promotion of brain tumors. We tested our hypothesis using in vitro 3D endothelial spheroid cell model that may serve as a rapid and cost-effective alternative to animal testing. The goal of the current study was to develop a 3D in vitro model to evaluate the effects of another PCB congener 126. PCB126 belongs to the coplanar dioxin-like group of PCBs that act through an aryl hydrocarbon receptor (AhR) mechanism. We show that PCB126 (100ng/ml) significantly increased the size of 3D endothelial spheroids over a 48h time period in the 3D endothelial cell clone. MTT assays confirmed sferoid cell viability and flow assisted cell sorting (FACS) showed significantly less apoptosis in spheroids exposed to PCB126. Both stem markers VEGFR3 and CD133 were significantly increased from PCB126 exposure as shown in FACS studies and Western blot. Our results indicate that PCB126 may contribute to brain tumor angiogenesis by enhancing VEGFR3 signaling. For instance, elevated tissue levels of the isomers VEGF3 and VEGFD have been shown in human brain and tumor derived endothelial cells receiving anti-VEGF therapy. Since these isomers are known to contribute their effects via VEGFR3 signaling, our findings support the hypothesis that environmental pollutants may angiogenically activate the brain microvasculature and exacerbate brain cancer or other brain disorders through their effects on the neurovascular niche.

Biphenol A (BPA) and its analogs (BPAF, BPS) are well-known endocrine disruptor compounds (EDCs). We have previously shown that BPA induces estrogen receptor (ERα) but not androgen receptor (AR) activation in luciferase reporter assays. BPA also represses androgen-induced reporter activity in transiently transfected CV-1 cells. Nuclear receptor (NR) target gene transcription levels are dictated by ligand-binding, altered receptor conformation and subsequently modulation of recruitment of coregulators proteins, which modify chromatin accessibility for RNA polymerase. The NR-interacting surfaces of coregulators contain highly conserved helical LxxLL (NR-box, coactivators) or LxxK (NR-box, corepressors) motifs. In order to study the con-regular expression of the BPA-bound ERxR or AR, we applied MARCoNi which mimics NR-coregulator interaction in vitro. Crude lysate of U2OS cells transfected with EGFP-tagged full-length NR were incubated with a peptide array of 154 CoR- and NR-boxes. The latter serves as a sensor for NR conformation, and hence activity status as a function of ligand. To investigate and compare the mechanisms of action by which compounds modulate ERxR activity we quantified the ERxR binding profile of BPA, BPA, BPF, 17β-estradiol (E2, the natural ligand) or solvent (2% DMSO) only. Compound response profiles, i.e. compound-induced log-fold change of ERxR binding, were subjected to hierarchical clustering and demonstrated clear differences between compounds and their ability to modify ERxR conformation. All four compounds induced repulsion of a similar set of coregulators. ERα interaction with a second set of coregulators is enhanced by E2 and BPS (with partial efficacy), largely unaffected by BPA, and moderately decreased by BPAF.

Biphenol A (BPA) is used to make resilient epoxy coatings for food cans. These coatings are required to protect food quality. Although science-based regulatory bodies, including the U.S. FDA and the European Food Safety Authority, conclude that BPA is safe for use in making food-contact coatings, the market has begun to de-select materials containing BPA because it is has very weak agonist activity in the ERα.
activity toward the estrogen receptor. After years of research, no polymers other than epoxies have been identified that are able to fulfill all integrity demands of light metal food packaging.

Alternate bisphenols that technically could be used to replace BPA in epoxy coatings include bisphenol F, S, M, B, AP and AF. Unfortunately, these and most other common bisphenols, like BPA, are weakly estrogenic. This fact has led some policy makers to believe that all potential BPA replacement bisphenols are estrogenic. Using drug-discovery techniques such as QSAR, followed by rigorous in vitro testing, it was possible to identify and verify that some bisphenols exhibit no estrogenicity whatever, and a subset of these non-estrogenic bisphenols can be used to make robust epoxy food contact coatings. Valspar identified 4,4’-methylenebis(2,6-di-tert-butylphenol), CASN 118-82-1, and 2,2’-methyleneendiphenol, CASN 2467-02-9, as likely to have no estrogenicity using a simple QSAR technique in ChemDraw® that measures the immutability of the methylene bridge angle at low temperature. Molecules selected in this way were negative in the yeast estrogen screen (YES) assay. Bisphenols that were negative in the YES assay, and from which epoxy coatings could be made, were further tested and found to be uniformly negative in the U2OS ER green fluorescent protein redistribution assay, the ER Calux® assay, and even in the low-specificity MCF-7 cell proliferation assay (EScreen).

It can be concluded that not all bisphenols are estrogenic. Furthermore, some of these non-estrogenic bisphenols can be used to make robust food-contact epoxy coatings with performance that is comparable to BPA-based polymers.

**1065 Interpreting Estrogen Screening Assays in the Context of Potency and Human Exposure Relative to Natural Exposures to Phytosterogens**

Indication of exposure to potentially endocrine active substances can be detected in urinary biomonitoring studies. While EPA and OECD have validated in vitro & in vivo screening assays to measure interaction of substances with estrogen, androgen & thyroid pathway components, to date, methods to contextualize such results in terms of potencies & actual human exposures are lacking. Although urinary concentrations of substances can be compared on a mass per volume basis, such comparisons are not biologically meaningful because a receptor response is dependent upon potency and the concentration of the active moiety at the receptor. To understand endocrine screening results in terms of potency & human exposure, we propose a method that entails 1) calculating a benchmark dose (BMD) for a response measured in an endocrine screen; 2) estimating the human urinary concentration upon potency and the concentration of the active moiety at the receptor. Using this method, we can correlate estrogenic activity of chemicals in vitro with urinary biomonitoring studies.

**1066 Adaptation of T47D-KBLuc and MDA-kb2 to Screening and Comparison to Other Receptor Reporter Platforms**

Mineral oils (MO) used as ingredients for many printing inks are complex mixtures of hydrocarbons. Although migration of MO from paper into food has been shown, the toxicological relevance of these findings is elusive. Therefore we investigated the estrogenic potential of mineral oil using different in vitro assays. Proliferative effects of MO in the estrogen responsive human breast cancer cell line MCF7 were assessed in the E-screen, and endogenous estrogen responsive gene expression was quantified by real-time PCR. Transactivation assays were performed in HE-Lu9903 containing the human estrogen receptor (ER) and an estrogen responsive element (ERE)-driven luciferase as well as in yeast containing ERE and an ERE-dependent green fluorescent protein. MO primarily consists of mineral oil saturated hydrocarbons (MOSH) and mineral oil aromatic hydrocarbons (MOAH). These two fractions were separated by preparative HPLC and also assessed in the bioassays. MO in a thousand fold dilution stimulated MCF7 proliferation but did not induce reporter gene expression neither in yeast nor in HE-Lu9903 cells. Furthermore, expression of the estrogen responsive gene PGR and TFF1 in MCF7 cells was induced after 24 h exposure to total MO. The estrogenic effects were derived from the MOAH fraction, as exposure of MCF7 cells to this fraction induced gene expression and increased proliferation. In conclusion estrogenic action of aromatic substances derived from MO could be shown in vitro.

**1067 Estrogenic Activity of Aromatic Substances from Mineral Oil Used in Printing Inks**

Lower chlorinated PCBs undergo oxidative metabolism to hydroxylated PCBs with a higher potential to cause xeno-estrogenic effects. While previous studies have demonstrated that PCBs are substrates of cytosolic phase II enzymes which produce PCB sulfates as a new class of metabolites. Because very little is known about the biological and metabolic disposition of this class of metabolites, 8 sulfat monoesters which are either derived from PCB3, a congener shown to be biotransformed to sulfates, or are derivatives of a paint-specific congener or from OH-congeners shown to interact with sulfotransferases (i.e. 2, 3, 2’, 3’ and 4’PCB3 sulfate, 4PCB11, 4PCB39, and 4PCB53 sulfate) and 4’OH-PCB3 as positive control. These compounds were tested for estrogenic and anti-estrogenic, androgenic and anti-androgenic potential at concentrations from 100 µM to 1 µM in the E-and A-screen as well as evaluated for cytotoxicity. These screens are quantitative assays which identifies potential xenogen-receptors. Only 4’OH-PCB3 is highly cytotoxic, while the 4PCB53 and 3PCB3 sulfates are weakly cytotoxic. Regarding endocrine disruption, our data suggest that there is a structure-activity relationship, with the 4’OH-PCB3 (1 uM) and its sulfate ester (100 µM) as most active estrogenic compounds followed by 4PCB3 sulfate, 4PCB39 and 4PCB53 sulfates (100 µM). The same compounds and 3PCB3 sulfate with lower concentrations also exhibited anti-estrogenic activity. 4’OH-PCB3 is the most potent androgenic compound, visible at the highest concentration tested, followed by 3’PCB3 sulfate and 4PCB53 sulfate. Also weakly androgenic are 4PCB11 sulfate, 4PCB39 sulfate and 4’OH-PCB3. Anti-androgenicity was observed with 2’PCB3 and 3’PCB3 sulfates at very low concentrations. Endocrine-disrupting chemicals often display U-shaped or inverted U-shaped nonmonotonic dose-response curves. Similarly no classical dose-response
curves were seen in our experiments. These preliminary data suggest that these PCB sulfate monoester have very low cytotoxic potential in human breast cancer cells as well as very low potential to act as endocrine disrupting agent.

**1069** Pharmacophore Model of Natural Phytoestrogens Which Induce Estrogen Receptor Alpha/Beta Heterodimerization

C. Corián & W. Xu, Wisconsin-Madison, WI, 1Department of Medicinal Chemistry, University of Wisconsin-Madison, Madison, WI, 2Molecular & Environmental Toxicology, University of Wisconsin-Madison, Madison, WI, 3Cellular & Molecular Pathology, University of Wisconsin-Madison, Madison, WI

Estrogen plays an important role in the normal development and growth of the mammary gland. The binding of 17β-estradiol (E2) and other estrogenic compounds to the estrogen receptor (ER) leads to its dimerization and consequent genomic transcription and cascade of biological activities. ERα and ERβ have been shown to exhibit a “Ying and Yang” relationship in regulating breast cancer cell growth: ERα promotes cell growth while ERβ inhibits it. At the receptor level, ERβ appears to negatively regulate the proliferative role of ERα through the formation of ERαβ heterodimers. The objective of this study is to identify natural estrogenic compounds which promote the formation of ERαβ heterodimers, thereby activating ERβ while dampening ERα activity, which might have a protective effect in breast cancer. We initially screened 37 phytoestrogenic compounds from four flavonoid subclasses in a two-step screening process that include activation of ER gene transcription using an ER-dependent reporter assay and dimerization using the Bioluminescent Resonance Energy Transfer (BRET) assay where 6 slightly selective ERαβ heterodimer inducing compounds were identified. In silico studies were then performed to identify the pharmacophore that confers ERαβ heterodimeric specificity in order to design high affinity ligands. We have proposed to test the cancer preventive effects of compounds that induce the ERαβ heterodimer in the E2-induced breast cancer model of AC1 rats.

**1070** Disruption in the Hypothalamus Neonatally Exposed to P-Tert-Octylphenol Is Essential for Induction of Early Occurrence of Persistent Estrus, a Feature of Delayed Effect in Rats

Neonatal exposure to estrogenic compounds induces delayed effect characterized as early occurrence of persistent estrus (Takahashi et al., 2012), but its mechanism has not been understood. The delayed effect is a big concern for offspring toxicity because reproductive toxicity studies couldn’t detect it. We investigated which organ, the hypothalamus or the ovary, is essential for the delayed effect of estrogenic compound. Female Donryu rats were treated with 100 mg/kg p-t-oc-tylphenol (OP) sc 3 times during 5 days after birth (PND5), which treatment is inducible delayed effect, and 8 times of the same manner as PND5 during 15 days (PND15) to induce typical androgenization. The bilateral ovaries in the PND5 or PND15 OP treated or the control groups were dissected at the 4-week of age, and transplanted into the subcaps of ovarioctomized rats at the same age in each group. Estrus cyclicly were checked up to 17 weeks of age and compared to rats with intact ovaries in the corresponding groups. The transplanted ovaries were morphologically examined. In the control group, most of rats received the donated ovaries from control and all treated groups showed normal cycle within 4 weeks after the transplantation, and corpora lutea (CL) were observed in all donors ovaries. In the PND5 group, normal cyclicly changed to persistent estrus 1.5 months after the transplantation in the rats donated the ovaries from control and PND5 groups, the status being similar to corresponding ovary-intact animals. In the PND15 group, all rats with and without the transplantation showed persistent estrus up to 8 weeks of age. Microscopically, few CL were observed. These results indicate that any disruption in the hypothalamus exposed to OP neonatally at delayed effect inducible dose plays an essential role for early occurrence of persistent estrus.

**1071** Pituitary Proliferation Is Affected by Bisphenol A Exposure, but Recovers upon Its Removal

Endocrine disrupting chemicals (EDC) including alkylphenols, bisphenols, diethylstilbestrol (DES) binds directly to ER LBD and enable ER dimerization and estrogen response element (ERE) mediated transcription of target genes. While these EDCs have the required pharmacophore to induce agonist conformation of ER, many EDCs that are currently classified as weak estrogens produce considerable endocrine damage even at low exposure. Plasticizers, alkylphenols and phthalate esters, do not share estrogen phamacophore but are misclassified as compounds binding to ER-LBD. Here we report our integrated in silico and in vitro structure-activity analyses of phalate esters and their ability to module ER-ERE based transactivation by acting on a non-ligand binding site. Compounds were assessed for their ability to compete with fluorescent-labeled estradiol and FITC-tagged peptides binding to non-ligand binding sites using a fluorescence polarization based high throughput screen. Computational screening of library of 87,000 EDCs against pseudoreceptor-based pharmacophores yielded a focused library of ER binding compounds. We identified 1870 chemicals bound to ER-LBD and 276 bound to a specific non-ligand binding site near the estrogen receptor. Bisphenol A (BPA) impacts the hypothalamic-pituitary-gonadal (HPG) axis, affecting neuroendocrine differentiation, reproductive capacity, and puberty. Although the pituitary gland is a central component, little is known about its response to BPA exposure. We previously demonstrated that environmentally relevant BPA treatment during the embryonic period leads to increased pituitary proliferation and gonadotropin cell numbers in female mice. It is unknown whether the effects of prenatal exposure to BPA would cause persistent increases in progenitor proliferation or if the critical window of postnatal pituitary expansion is directly impacted by BPA treatment. Therefore, we used two hypotheses. First, that embryonic treatment of BPA would have lasting effects into the early postnatal period. To test this, mice were dosed with 0.5 or 50 mg/kg/day BPA from embryonic day 10.5 to postnatal day (PND)0 and collected at PND4. No differences were seen in proliferation or gonadotropin number between groups, indicating removal of BPA restored the pituitary to normal conditions. Second, we hypothesized that BPA would have a direct effect on the postnatal pituitary. To test this, we cultured intact PND0 pituitaries with 0.05 or 50 μg/mL of BPA, 10 nM 17β estradiol, or ethanol for 48 hours. QRT-PCR revealed that mki67 (a proliferation marker) decreased with both doses of BPA, however estradiol raised mki67 levels. Progesterone receptor (Pgr) mRNA, a known target of estrogen signaling, was raised in the presence of estradiol, but unchanged by BPA. Interestingly, levels of Esr1 were decreased with BPA treatment, but unaltered by estradiol. From these data, we conclude that BPA affects proliferation and gene expression in the postnatal pituitary in a manner dissimilar to estradiol. These studies also highlight that Influence of the HPG axis or time of dosing may be contributing to pituitary effects of BPA. Supported by P01 ES022848, R01 DK076647, T32 ES007326.
There is growing concern worldwide on the effect of endocrine disrupting chemicals (EDCs) on aquatic organisms and wildlife. Aquatic organisms are particularly vulnerable to exposure because their ecosystems act as sinks for a wide variety of pollutants. Vitellogenin expression, gonad histological alterations are amongst specific biomarkers for monitoring the effects of EDC’s in fish. Vitellogenin expression in male, female and juvenile fish and gonad histopathological alterations were evaluated in Cichlids: Tilapia zillii, T. guineensis, Sarotherodon melanorham, S. galileaus, Oreochromis niloticus, Hemichromis fasciatus and Chromidotilapia gutentheri from Eleiyele reservoir to assess endocrine disruption in fish. Vitellogenin-B2a (VTG-B2a) gene expression in the liver of fish was detected using RT-PCR. Interssex was observed in 53.3% of sample of fish which of 29.0% were adult and 71.0% juvenile male fish. The highest occurrence of interssex was in T. zillii and histological appearance of interssex included the development of primary oocytes along with mature spermatocytes (juveniles/matured spermatocytes within testicular tissue. A significant expression of Vtg-B2a gene was observed in all adult male and some juvenile male fish suggesting exposure to EDCs. VTG gene expression correlated with pathological presentation of intersex observed in adult/juvenile male fish. Further studies to quantify the level of VTG expression by RT-qPCR is on-going but available data indicate that Cichlids could be sentinel species for evaluating the presence of EDCs in lotic waters because of their commercial importance to the population structure of lakes. This is a first report of responsiveness to EDCs in a man-made lake in Nigeria.
Orally Subchronic Exposure to Benzo[a]pyrene Alters Reproductive Hormone Profile

A. Jeng1, 2 and Y. Chen2, 2

Old Dominion University, Norfolk, VA and 2Department of Nuclear Medicine, Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung, Taiwan.

The objective of this study was to assess whether benzo[a]pyrene (B[a]P) alters reproductive hormones, which in turn leads to decreased spermatozoa quality and spermatogenic cell levels. Hsd: ICR (CD1) 10-week old males were orally exposed to B[a]P at 1, 10, 50, and 100 mg/kg/day of body weight for 30 and 60 days. At the end of the experiment, mice were anesthetized and reproductive tissues, i.e. testes, seminal vesicles, and epididymis, were collected. Spermatogenic cells and mature spermatozoa were recovered from the testes and cauda epididymis, respectively. Spermatozoa quality, including concentration, morphology, motility and viability, was examined. Testosterone, estradiol, follicle stimulating hormone (FSH), and luteinizing hormone (LH) levels in serum were determined using the Enzyme Immunoassay/Enzyme Linked Immunosorbent Assay (ELISA). Mice exposed to B[a]P at 50 mg/kg/day and 100 mg/kg/day for 30 days and 60 days exhibited a significantly decrease in serum testosterone and estradiol levels as compared with the control, while FSH and LH remained stable. The levels of testosterone and estradiol were positively correlated with decreased spermatozoa motility (p<0.025 and 0.014, respectively), viability (p<0.002 and 0.018, respectively), and morphology (p<0.007 and 0.018, respectively), but the hormone levels did not correlate with spermatozoa levels. The testosterone and estradiol levels did not correlate with the levels of spermatogonia, pachytene spermatocytes, round spermatids, and elongated spermatids. Subchronic exposure to B[a]P could modulate the production of testosterone and estradiol, which subsequently influence spermatozoa quality.

Testing Mixtures of Antiandrogens In Vivo at Human-Relevant Exposure Levels

K. Fussell1, 2, S. S. Schneider1, 2, S. Melching-Kollmuss1, 2, S. Gröters1, 2, V. Strauss3, B. Siddiqui1, M. Benahmed1, 2, M. Frericks1, 2 and B. van Ravenzwaay4, 1

1Toxicology, BASF SE, Ludwigshafen/Rhein, Germany and 2INSERM, Nice, France.

Endocrine disruption has become an important topic of public concern. Despite an increasing amount of public attention, little is understood about whether human-relevant doses of endocrine disrupting chemicals (EDCs) affect homeostasis. To address these concerns we performed pre- and post-natal reproductive toxicity studies to measure the developmental toxicity of low single- and mixture-doses of three substances with an anti-androgenic mode of action: vinclozolin, flutamide and prochloraz. Doses were selected to mimic a LOAEL, a NOAEL for endocrine effects, and the acceptable daily intake (ADI) for each compound, which were then combined together into three mixtures of the LOAELs, NOAELs, and ADIs. In addition to standard regulatory parameters, a number of molecular endpoints were also incorporated within the same study design. Thus, single- and mixed-exposures can be compared from molecular to pathological levels in one and the same animals.

1078  Testing Mixtures of Antiandrogens In Vivo at Human-Relevant Exposure Levels

Calçatina and Estrogen Replacement Therapy in Menopausal Women

A. K. Quijada, 2, S. P. Rodriguez2, T. A. Rodriguez2, 2 and E. M. Gómez2, 2

2Institute of Reproductive Medicine, National University of Singapore, Singapore.

Aims: To determine the effects of estrogen replacement therapy (ERT) on the concentration of sex hormone-binding globulin (SHBG) in menopausal women. Methods: We studied 16 postmenopausal women (ages 51 to 71 years) who were randomly assigned to either ERT (Estraderm TTS, Ciba-Geigy, Basle, Switzerland) or placebo. Blood samples were obtained at baseline and after 3, 6, 9, and 12 months of treatment. SHBG levels were measured by a competitive protein-binding assay. Results: SHBG levels increased significantly from baseline to month 3 (p<0.01). There was no significant difference in SHBG levels between the ERT and placebo groups. Conclusions: ERT increases SHBG levels in postmenopausal women. However, the clinical significance of this finding is unknown.

Mechanistic Investigation of Testicular Tumor Formation in Rats Treated with the SGLT2 Inhibitor Canagliflozin

P. Vinken1, 2, S. De Jonghe2, T. Net2, 3, L. Lammers1, 2, M. Sinivas1 2 and M. D. Johnson2, 3

1Janssen Research & Development, a division of Janssen Pharmaceutica NV, Beerse, Belgium, 2Janssen Research & Development LLC, Raritan, NJ and 3Colorado State University, Fort Collins, CO.

Canagliflozin, a sodium glucose cotransporter 2 (SGLT2) inhibitor induced Leydig cell tumors (LCTs) in a 24-month rat carcinogenicity study in male rats at dose levels ranging from 10 to 100 mg/kg/day. There were no corresponding preneoplastic lesions in the 3-month or 6-month repeated dose toxicity studies. No tumor development was present in the mouse carcinogenicity study with this compound. A 7-month repeated dose toxicity study was conducted in two groups of 30 male Sprague-Dawley rats receiving vehicle or 100 mg/kg/day canagliflozin by oral gavage to investigate the potential mechanism of LCT formation. Blood samples were collected monthly for measurement of luteinizing hormone (LH) and testosterone (T) and pathology of testis and secondary sex organs was assessed at the end of the study.

Compared to vehicle, serum LH concentrations were increased after 1 month of dosing and generally remained elevated throughout the dosing period. Circulating testosterone levels were unchanged at all time points in comparison to the vehicle. There was a decrease in the weight of the secondary sex organs in the canagliflozin treated group with no change in testis weights. Histopathological examination showed a slight increase in interstitial cell hyperplasia in the canagliflozin treated rats and this was correlated with the increased LH levels. Disruption of the hypothalamic-pituitary-gonadal axis, resulting in sustained increases in LH levels is an established mechanism of toxicity described for a number of non-genotoxic compounds causing LCT’s in male rats. Clinically, no increases in LH were seen in male subjects treated with canagliflozin for 12 weeks. Therefore the formation of LCT’s in male rats treated with canagliflozin is not relevant to humans.

The Fungicide Prochloraz Induces Transporter Breast Cancer Resistance Protein BCRP (ABCG2) in Human Mammary and Adrenocortical Cells

J. Lundqvist, 2, Å. Ohlsson Andersson, 2, J. Talkkite 3 and A. Ökasson, 1

1Dept of Biomedical Sciences and Veterinary Public Health, Uppsala, Sweden.

The imidazole fungicide prochloraz is widely used in horticulture and agriculture, e.g. as a post-harvest anti-mold treatment of fruits and vegetables. Prochloraz is a known endocrine disruptor causing developmental toxicity with multiple mechanisms of action. In this abstract, we report a new mechanism by which prochloraz may exert toxicity on a wide range of cells. BCRP is an efflux transporter, with a broad substrate specificity ranging from xenobiotics such as chemotherapeutics, antibiotics, and the dietary carcinogen PhIP (2-amino-1-methyl-6-phenylimidazo-pyridine) to endogenous substances such as estrone-3-sulfate and DHEA-S. BCRP is widely expressed, e.g. in the intestine, liver, kidney, testis and brain, where it can restrict the cellular uptake of xenobiotics and facilitate the excretion of endogenous substances. BCRP is also present in the mammary gland, where it may cause secretion of xenobiotics into breast milk and dairy. The aim of the present study was to investigate the effects of prochloraz on BCRP gene expression in two human cell models, representing mammary tissue (MCF-7) and adrenocortical tissue (H295R). Cells were treated with 0.1-10 μM prochloraz for 24 h. RNA was isolated and relative BCRP gene expression measured by real-time RT-PCR. All experiments were conducted using non-toxic levels of prochloraz as determined by MTS assay. We found that prochloraz is able to induce BCRP in both cell lines in a dose dependent manner. The gene expression of BCRP was increased 1.5- to 3-fold. In addition to the previously reported mechanisms for prochloraz-induced toxicity, our results show a novel mode of action for prochloraz, which might be
important in a wide range of tissues. A prochloraz-induced stimulation of BCRP could alter both the milk excretion of BCRP substrates, and the steroid availability via increased efflux of estrone–3-sulfate and DHEA-sulfate from endocrine tissues.

1082 Polybrominated Diphenyl Ether Congener 47 Increases Aldosterone Secretion in a Human Adrenocortical Cell Line

P. G. Kong and B. Dungar. Department of Pharmacology, Midwestern University, Downers Grove, IL.

Elevated circulating aldosterone levels are associated with hypertension, thrombosis formation, cardiac hypertrophy, and congestive heart failure. Polybrominated diphenyl ethers (PBDEs) and their metabolites have been previously shown to alter various endocrine biosynthetic pathways including thyroid hormone, estrogens, and androgens. Additionally, PBDEs have been shown to accumulate in the adrenal gland. Therefore, we characterized the effect of PBDE-47 on aldosterone secretion in a human adrenocortical cell line. HAC15 cells were exposed to vehicle or various concentrations of PBDE-47 (10 nM-100 μM). After 72 h, cell viability, aldosterone secretion, and gene expression of enzymes and cofactors involved in aldosterone synthesis was examined. The only concentration of PBDE-47 that affected cell viability was 100 μM. PBDE-47 induced basal aldosterone secretion at 10 and 100 μM (in ng/mL: vehicle, 9.0±1.7; 10 μM PBDE-47, 70.2±9.8; 100 μM PBDE-47, 78.5±19.8; n=4, p<0.05). PBDE-47 also increased Ang II-stimulated aldosterone secretion at 10 μM, but decreased Ang II-stimulated aldosterone secretion at 100 μM (in ng/mL: 137.9±6.7; 10 μM PBDE-47, 200.4±9.3; 100 μM PBDE-47, 80.1±20.6; n=4, p<0.05). Gene expression of several enzymes and cofactors involved in aldosterone synthesis were increased by 10 μM PBDE-47. These data indicate that PBDE-47 disrupts the regulation of aldosterone secretion and provides further evidence that PBDEs are potential endocrine disruptors.

1083 NQO1, a Component of the Plasma Membrane Electron Transport System, Regulates Redox Status in Clonal Pancreatic Beta Cells and Primary Islets

1Cellular Dynamics, Marine Biological Laboratory, Woods Hole, MA, 2Science, United States Coast Guard Academy, New London, CT and 3Pharmacology, University of Maryland School of Medicine, Baltimore, MD.

Plasma membrane electron transport (PMET) is a ubiquitous system which transports electrons out of cells while re-oxidizing intracellular reduced equivalents NADH and NADPH. Recently, NQO1, NAD(P)H-dependent quinone reductase 1, well known for its role in 2-electron reduction of quinones, was shown to be a mediator of PMET in pancreatic beta cells, where it helps to support glucose metabolism and subsequent insulin secretion following exposure of these cells to elevated glucose levels. Our previous work showed that NQO1 positively regulates glucose-stimulated insulin secretion (GSIS), suggesting a role for NQO1 in glucose metabolism and homeostasis. In the current work, we characterized the role of NQO1 in the PMET pathway of pancreatic beta cells and its role in the alteration of intracellular oxidative state in the presence of the redox cycling pro-oxidant menadione. Adenoviral-mediated over-expression of NQO1 resulted in the increase of the NQO1 protein and NQO1 enzymatic activity, and reduced the level of menadione-dependent ROI production in both clonal INS-1 832/13 cells and isolated islets. In islets isolated from global NQO1 knockout mice, menadione-dependent ROI production was elevated. This is consistent with NQO1’s role in detoxification of menadione in other tissues via two-electron reduction.

According to the environmental obesogen hypothesis, exposure to some environmental contaminants may initiate or exacerbate the development of obesity and its associated health consequences. Obesity is now regarded as a risk factor for colon cancer. Perfluorinated compounds (PFCs) are used in applications such as clothing, carpets, food packaging, fire extinguishers etc. We examined effects of exposure to the PFC chemicals PFOA and PFOS during critical periods of development (in utero) in the intestinal cancer mouse model C57BL/6-Min/+ (multiple intestinal neoplasia). The dams were exposed to PFOA or PFOS (0.01, 0.1 and 3.0 mg/kg bw/day) by oral gavage on gestational days 1-17. Body weight of the pups was recorded from birth until termination at 11 weeks and presented as area under the curve (AUC). The small intestine was fixed, stained with 0.2% methylene blue, and tumors scored by an inverse light microscope. Plasma glucose levels (non-fasted) were measured by glucometer at age 6 and 11 weeks, to study the hypothesis of disrupted glucose regulation as a link between obesity and intestinal tumor development. After 3.0 mg/kg bw/day PFOA very few live pups were obtained, whereas this dose of PFOS and the other two doses of both chemicals gave enough mice for statistical analysis. No obesogenic effect of PFOA or PFOS was observed up to 11 weeks of age. Compared with mice exposed to water, mice treated with 0.1 mg/kg bw PFPOA had significantly lower AUC on days 3-18 and weeks 3-11, and also compared with mice treated with 0.01 mg/kg bw PFPOA on weeks 3-11, indicating a toxic effect of PFOA. None of the doses of PFOA or PFOS increased the plasma glucose levels at either time point or increased the number of small intestinal tumors compared with mice given the vehicle distilled water. Conclusion: Exposure to PFOA or PFOS in utero did not have obesogenic effect, at least not up to 11 weeks of age, and did not increase blood glucose levels or intestinal tumorigenesis in Min mice.
Hydroxylated polychlorinated biphenyls (PCBs) and polychlorinated dibenzylo ether (PBDEs) are detected in human plasma as the metabolites of PCBs and PBDEs, their configuration are similar to that of thyroid hormone, and their effect on thyroid hormone system are concerned. Iodotyrosine deiodinase (IYD) has an ability to salvage iodide from iodotyrosine that is generated as byproducts of thyroid hormone biosynthesis. This enzyme has also been discovered to act as a dehalogenase of bromo- and chlorotyrosine. The aim of this study was to investigate the possible influence of halogenated compounds on thyroid hormone metabolism, IYD-inhibitory activity by 44 halogenated compounds, PCBs, PBDEs, agrochemicals, antiparasitics, pharmaceuticals and food colorants, were examined in vitro using microsomes of HEK-293T cells expressing recombinant human IYD. Among them, 22 halogenated phenolic compounds inhibited IYD activity. Rose bengal was the most potent inhibitor, followed by erythrosine B, phloxine B, benzamorone, 4'-hydroxy-2,2',4,5'-tetraiodobiphenyl ether, 4-hydroxy-2,3',4',5'-tetraiodobiphenyl ether, 4-hydroxy-2,3,4,5'-pentachlorobiphenyl, 4'-hydroxy-2,2',4,5'-tetraiodobiphenyl ether, triclosan, and 4'-hydroxy-2,2',3,4',5'-pentabromobiphenyl ether. However, among PCBs and PBDEs without a hydroxyl group, including their methoxylated metabolites, none inhibited IYD activity. These results suggest that halogenated compounds may disturb thyroid hormone homeostasis via inhibition of IYD, and that the structural requirements for IYD-inhibitory activity include halogen atom and hydroxyl group substitution on a phenyl ring.

Purpose: A previous epidemiological study showed dose-dependent increase in TSH level in the serum of the workers exposed to 1-bromopropane (1-BP). Hyperthyroidism-like signs were observed in rats exposed to 1-BP, such as irritant behavior as well as decreased cholesterol and increased protein levels in plasma. The present study investigated effects of exposure to 1-BP on transthyretin (TTR), which is a carrier of thyroid hormone from blood to cerebrospinal fluid (CSF), as well as the level of thyroid hormone in the CSF and blood to understand the possible involvement of thyroid hormone in the toxicity of 1-BP to the central nervous system. Methods: Forty-eight male F344 rats were divided into four equal groups and exposed to 1-BP at 0, 200, 400 and 800 ppm 8 h/d for four weeks. Distribution of TTR protein in the brain was examined by immunohistochemistry. The levels of TTR mRNA in the choroid plexus and liver were measured by quantitative real time PCR. Free triiodothyronine (Free-T3) in the CSF and plasma was measured using ELISA kit. Total triiodothyronine was also measured in the plasma. Results: Four-week exposure to 1-BP at 200 and 400 ppm significantly increased mRNA of TTR in the choroid plexus of the lateral ventricle and fourth ventricle, but reduced that at 800ppm. The level of TTR mRNA didn’t show any change in hippocampus. Free-T3 increased significantly at 400 and 800 ppm in the CSF after four-week exposure to 1-BP but didn’t change in the plasma. Free thyroxine (T4) in the plasma significantly decreased in all the 1-BP exposure groups. Conclusion: The study showed increase in free T3 in the CSF of the rats exposed to 1-BP, which may explain the irritating behavior as well as low cholesterol and high protein in serum of rat exposed to 1-BP.

**1087a** Enhancement of the Endocrine Disruptor Knowledge Base for Assessing Endocrine Activity of Untested Chemicals

H. Hong1, H. Ng1, H. Fang1, R. Perkins1 and W. Tong1. 1Division of Bioinformatics and Biostatistics, National Center for Toxicological Research, Jefferson, AR and 2Office of Scientific Coordination, National Center for Toxicological Research, Jefferson, AR.

Endocrine disruptors (EDs) are exogenous chemicals with potential to disrupt the endocrine system. EDs came under international scientific discussion and debate some two decades ago, sparking regulatory attention. Accordingly, FDA developed the Endocrine Disruptor Knowledge Base (EDKB) and made it publically available. Since then, the EDKB has been widely used by the scientific community. It was recently updated with more comprehensive data and corresponding predictive models. Effects mediated by the estrogen receptor homodimer complex are a primary ED concern. Since many EDs exhibit estrogenic activities, affecting normal estrogen signaling pathways, we first updated the estrogenic data and augmented the EDKB with a comprehensive database of chemicals assayed for estrogenic activity. The database contains over 21,000 estrogenic activity data points across more than 8,000 compounds assayed among 11 species. It also contains protein subtypes and domains used in the assays. Original data were converted into the same units, such as logRBA for competitive receptor binding. Quality control was performed to ensure data quality. It was built using Instant JChem and subsequently instantiated in a web-based software system for users to browse, search and export data. It enables search across multiple fields such as chemical structure, substructure, chemical name, assay type, species, activity range, and references using logical operators. Additionally, data for binding affinity to α-Fetoprotein (AFP) for 125 chemicals are included. The AFP 3D structure was modeled using homology and molecular dynamics (MD) simulations, and AFP-ligand binding modes elucidated for 13 binders. With the recent enhancements, the EDKB provides the scientific and regulatory communities a free source to search endocrine activity data and to develop predictive models for predicting endocrine activity of chemicals for which no data are available.
1087c International Validation of Two Human Recombinant Estrogen Receptor (ER alpha) Binding Assays

An international validation study has been successfully completed for 2 competitive binding assays using human recombinant ERs. Assays evaluated included the Freyberger-Wilson (FW) assay using a full length human ER, and the Chemical Evaluation and Research Institute (CERI) assay using a ligand-binding domain of the human ER. Twenty three compounds were tested in 6 laboratories for the FW assay and 5 for the CERI assay, which included three controls (used with every run), 9 uncoded, and 14 coded chemicals across 3 subtasks. The overall goal of this validation study was to demonstrate the ability of each of the two assays to reliably classify the test chemicals as binders or non-binders. Laboratories had little trouble with the ER binders that produced a full binding curve when using either the CERI or FW assays. As is typical with all ER competitive binding assays, the weak binders proved to be more challenging. However, overall results from both the FW and CERI assays were consistent and in agreement with expected classifications regardless of the form of the hER (i.e., full length ER versus an ER ligand binding domain) or the subtle differences in the protocols for conducting each assay. The reproducibility and accuracy for classification of chemicals as potential ER binders and non-binders using the FW and CERI hER binding assays were comparable to that of the U.S.EPA’s existing ER binding test guideline OPPTS 890.1250, while providing an improved, higher throughput method that does not require animal tissue as the source of receptor. An OECD test guideline is currently being drafted. This abstract does not reflect US EPA policy. Parts of this work were supported by the German Bundesministerium für Bildung und Forschung (BMBF) under Grant 0311154N.

1087e Triclosan-Induced Cell Growth Was Reversed by a Phytoestrogen, Kaempferol, via Regulating Cell-Cycle Related and Apoptosis-Related Genes in MCF-7 Breast Cancer Cells

S. Kim and K. Choi. Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chonbuk National University, Cheongju, Republic of Korea.

Triclosan is one of endocrine disrupting chemicals (EDCs) which are scattered with environment agents, such as toothpastes, deodorant and cleaning supplies. As a phytoestrogen, kaempferol is one of bioflavonoids, which has been found at various of vegetables including broccoli, tea and tomato. Although kaempferol may have anti-cancer activity, its exact mechanism is under investigation in the induction of apoptosis and inhibition of cell proliferation or angiogenesis. In this study, we examined the anti-proliferative effects of kaempferol in triclosan-induced cell growth in MCF-7 breast cancer cells. A proper concentration of kaempferol or triclosan was determined in MCF-7 cells measured by MTT assay. In this study, kaempferol significantly reduced the viability of MCF-7 cells compared to a negative control treated with DMSO, and that kaempferol reversed triclosan-induced MCF-7 cell growth at 50 μM. To confirm that kaempferol inhibited triclosan-induced cell growth, we examined the transactional levels of cell growth and apoptosis-related markers, i.e., cyclin D, p21, cyclin E, p27 and bcl-2, and bax genes, using reverse transcription (RT)-PCR. The expression levels of cyclin D, cyclin E and bax/bcl-2 ratio were increased, while that of p21 and p27 mRNA was decreased by triclosan in MCF-7 cells. In addition, kaempferol reversed triclosan-induced gene expressions in an opposite manner. Taken together, these results indicated that kaempferol may inhibit the growth of MCF-7 cells via regulating of cell cycle and apoptosis-related genes. In addition, EDCs-induced progression of breast cancer may be suppressed by a phytoestrogen, i.e., kaempferol, in a specific manner. [This work was supported by National Research Foundation of Korea (NRF) grant funded by the Ministry of Education, Science and Technology (MEST) of the government of the Republic of Korea (2013R1A1A2059092)].

1087d Comparison of In Vitro and Ex Vivo Thyroid Hormone Synthesis Inhibition Results and In Vitro Outcomes for a Series of Benzothiazoles

Assessing how in vitro data may be used to predict adverse effects in vivo is critical as efforts are advanced to incorporate in vitro assays into a risk assessment framework. Within the context of a thyroid hormone (TH) synthesis inhibition adverse outcome pathway (AOP), in vitro, ex vivo and in vivo assays were used to study the TH disrupting potential for a series of benzothiazoles: benzothiazole (BTZ), 2-mercaptobenzothiazole (MBT), 5-chloro-2-mercaptobenzothiazole (CMBT), 2-aminothiazole (ABT), 2-hydroxybenzothiazole (HBT), and 2-(methylthio) benzothiazole (MTBT). A thyroid peroxidase (TPO) inhibition assay was used to determine the activity of these chemicals in vitro. The rank order potency for TPO inhibition was MTBT>CMBT>ABT>BTZ>HBT. MTBT did not inhibit TPO activity. The benzothiazoles were tested further in Xenopus laevis thyroid gland explant culture with inhibition of TH release as the endpoint. Toxicity was assessed as decreased glandular ATP, MBT inhibited TH release at non-cytotoxic concentrations and with similar potency to methimazole. The benzothiazoles with greatest potency for T4 release inhibition were MBT, CMBT, and HBT, with IC50s of 3, 30, and 133 μM, respectively, but all benzothiazoles showed some inhibitory activity. Benzothiazoles were further assessed in vivo in a 7-d X. laevis tadpole assay. MBT and CMBT were the most potent for affecting endpoints of thyroid hormone synthesis inhibition, whereas others showed little or no effect. Both MBT and CMBT significantly increased sodium iodide symporter (NIS) mRNA indicative of compensatory TSH stimulation in response to decreased circulating TH. Taken as a whole, these results indicate the utility of in vitro assays for queuing chemicals for further testing, but illustrate the need for caution in interpreting results of in vitro or ex vivo inhibition assays especially where toxicity may be a confounding factor. This abstract does not necessarily reflect U.S. EPA policy.

1087f In Vitro Metabolism of Tamoxifen in Human, Rat, and Fish Microsomes

Results from an in vitro study comparing biologically-active metabolites in the plasma of Wistar rats and cunner fish (Tautogolabrus adspersus) treated with tamoxifen indicate notable differences in circulating metabolite concentrations between these two species. After a single oral dose of tamoxifen (25 mg/kg), the predominant metabolite observed from 1 to 72 hrs in rats was N-desmethyltamoxifen while in cunner it was 4-hydroxytamoxifen. The predominant metabolite in humans has been reported to be N-desmethyltamoxifen. To investigate if these species differences could be predicted using an in vivo assay, hepatic microsomes from cunner fish, Wistar rats, and humans were used. The experiment was designed to measure metabolic activity in all 3 species at 37°C. Toxicity was assessed on Wistar rats and cunner fish using LC-MS/MS. The highest concentrations of N-desmethyltamoxifen and 4-hydroxytamoxifen at all time points were observed in rat microsomes. In rat and human microsomes, N-desmethyltamoxifen was the predominant metabolite at both 18°C and 37°C. While formation of 4-hydroxytamoxifen was minimal with human microsomes, this metabolite doubled from 1 to 2 hrs and in fish microsomes (18°C). Unlike in vivo results, fish microsomes produced about twice as much N-desmethyltamoxifen as 4-hydroxytamoxifen during 4 hrs in the in vitro assays. Thus, though these in vitro results are similar to in vivo studies reported for human and rats, they do not reflect in vivo results observed for cunner fish. This abstract does not necessarily reflect U.S. EPA policy.
1087g  Fenhexamid Regulated the Transcripts of Aryl Hydrocarbon Receptor, Aryl Hydrocarbon Receptor Nuclear Translocator and Cell Cycle Related Genes in Human BG-1 Ovarian Cancer Cells Expressing Estrogen Receptors

R. Go and K. Choi. Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Republic of Korea. Sponsor: M. Cho.

Fenhexamid is antifungal agents used in agricultural applications, which are present at measurable amounts in fruits and vegetables. Fenhexamid has been reported to act as an anti-androgen in an androgen receptor reporter assay in engineered human breast cancer cells. Aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor, which translocates into nucleus and dimerizes with aryl hydrocarbon receptor nuclear translocator (ARNT). In this study, we examined the effects of fenhexamid, a pesticide, on the expression of AhR, CYP1A1, CYP1B1, ARNT, and p21 by RT-PCR analysis. To evaluate the ability of cell viability, BG-1 cells were cultured with a negative control (0.1% DMSO), 17b-estradiol (E2; 1x10^-9 M), 2,3,7,8- tetrachlorodibenzo-p-dioxin (TCDD; 1x10^-8 M), or fenhexamid (1x10^-5 - 1x10^-8 M). E2 as a positive control markedly increased BG-1 cell proliferation compared to DMSO. In addition, TCDD and fenhexamid increased BG-1 cell proliferation at the concentration of 1x10^-8 M and 1x10^-5 M, respectively. The transcriptional level of p21 was reduced at 6 h by E2, TCDD, or fenhexamid, while its level was reversed at 24 h following their treatments. The mRNA expression of AhR was reduced by E2, TCDD, or fenhexamid in a time-dependent manner, while its level was reversed in the presence of alpha-naphthoflavone, an AhR inhibitor. In contrast, the transcriptional level of ARNT appeared to be increased by E2, TCDD, or fenhexamid. Taken together, these results indicate that fenhexamid may regulate AhR, ARNT, and p21 to induce cell growth in BG-1 ovarian cancer cells expressing estrogen receptors. A further study will continue to examine disruptive effects of pesticides in estrogen receptor expressing cells or tissues. [This work was supported by National Research Foundation of Korea (NRF) grant funded by the Ministry of Education, Science and Technology (MEST) of the government of Republic of Korea (2013R1A1A2059092).]

1087f  Effects of In Vivo Exposure to Tamoxifen on a Nontarget Species, the Marine Fish Cunner (Tautogolabrus adspersus)

Tamoxifen is an endocrine-active pharmaceutical that is used worldwide to treat certain breast cancers. Because tamoxifen has been detected in aquatic environments, a study was undertaken to investigate its biological effects in a non-target species, the marine fish cunner (Tautogolabrus adspersus). Effects of a 17-day exposure to two different oral doses of tamoxifen (0.5 and 5 mg/kg fish weight) on reproduction in spawning cunner were examined relative to controls. Results show mean egg production in tamoxifen-treated cunner was significantly less than controls. No significant effects were observed in female or viable eggs relative to controls, although a downward trend for both endpoints was noted. After the 17-day exposure, activity of the steroidogenic enzyme aromatase in brains and ovaries from these fish was also evaluated. Ovarian aromatase activity was significantly increased in cunner treated with 5 mg/kg of tamoxifen. There were no significant differences in brain aromatase activity or gonadosomatic index in either sex compared to controls. In a separate experiment, formation of biologically active metabolites over time (from 1 to 72 hours) after a single oral dose of tamoxifen (25 mg/mg) was compared in Wistar rats versus cunner. The predominant metabolite in plasma from rats was N-desmethyltamoxifen, while in plasma from cunner it was 4-hydroxytamoxifen. This difference suggests that the effects of exposure to tamoxifen could be magnified in cunner, since 4-hydroxytamoxifen is considered to be about 100 times more efficacious than tamoxifen or N-desmethyltamoxifen. Overall, differences in circulating metabolites between species and a significant reduction in egg production in spawning cunner treated with tamoxifen both suggest that exposure to tamoxifen could present a tangible ecotoxological risk to fish such as cunner. This abstract does not necessarily reflect USEPA policy.

1087i  Subchronic Toxicology of Tetrabromobisphenol A (TBBPA) in CD® Rats

This study was conducted to evaluate the subchronic toxicity of the flame retardant tetrabromobisphenol A (TBBPA) in CD® rats. Three treatment groups, ten rats/group, were gavaged daily at 100, 300, or 1000 mg/kg/day for 90 days. Recovery animals (five rats/sex) were included in the control and high-dose groups and evaluated 6-weeks post-treatment. In addition to routine observations, organ weights, hematology, and clinical chemistry, a Functional Observational Battery (FOB) was conducted pretest and at Week 12. Motor activity was also evaluated during Week 12. Moreover, thyroid hormone levels (TSH), T3, and T4, were evaluated at 33 days, termination, and recovery. T4 levels were statistically significantly lower in males in all dose groups relative to controls at Day 33 (-26.2%, -31.0%, -31.7% at 100, 300, 1000 mg/kg, respectively) and at Day 90 (-35.8%, -33.4%, -39.3% at 100, 300, 1000 mg/kg, respectively). T4 levels were comparable to controls in the 1000 mg/kg recovery animals. T4 levels were statistically significantly lower in females in all dose groups relative to controls only at Day 33 (-22.5%, -24.1%, -22.0% at 100, 300, 1000 mg/kg, respectively). No changes were noted at Day 90. No changes in TSH or T3 levels relative to controls were noted in either sex at any time point. No toxicologically significant changes were observed in any of the other parameters. The reduction in serum T4 levels was not accompanied by evidence of toxicity or adverse effects, and the animals were clinically normal. Moreover, because the decrease in T4 levels was not of sufficient magnitude to alter mean serum TSH or T3 levels, thyroid histopathology, thyroid weight, or other parameters indicative of thyroid pathology (e.g., body weight), the decrease in serum T4 levels was not considered adverse. Thus, in this rat 90-day oral toxicity study with TBBPA, the No Observed Adverse Effect Level (NOAEL) was at least 1000 mg/kg/day, the highest dose tested. Supported by the NAIFRA Panel of the American Chemistry Council.

1087j  Adverse Human Reproductive Outcomes and Body Burdens of Endocrine Disrupting Compound—Polychlorinated Biphenyls

D. Roy, M. Morgan and C. Yoo. Florida International University, Miami, FL.

Inconsistent evidence exists for an association between polychlorinated biphenyls and adverse human reproductive outcomes. Therefore, the goal of our study was to determine if risk of reproductive and endocrine dysfunction in humans is increased due to exposure to endocrine disrupting compound - polychlorinated biphenyls. The CDC’s NHANES data was used to examine exposure levels of PCBs and the association between blood levels of PCBs and self-reported reproductive health outcomes among U.S. women. The study population ranged from 3109 to 3192 female participants (12 years of age and older) of the National Health and Nutrition Examination Survey who provided blood samples between 1999 and 2004. Individual levels of 7 PCB congers (PCB 074, 099, 118, 138, 153, 170, and 180), the sum of dioxin-like PCB congers (PCB 074, 118), and the sum of non-dioxin-like PCB congers (PCB 099, 138, 153, 170, and 180) were used in conjunction with data obtained from the medical and reproductive health questionnaires. Self-reported reproductive health outcomes were obtained from the interviews of female participants 12 years of age and older. The following outcomes were evaluated using categorical data: age at first live birth, age at menarche, age at menopause, having undergone a medical procedure, uterine fibroids, endometriosis, parity, having a baby with low birth weight, and menstrual cycle regularity for the past 12 months. Separate analyses showed that body burdens of PCBs in blood were significantly higher among women with breast cancer, women with a history of uterine fibroids, and women who had undergone surgical removal of their uterus and/or ovaries when compared to the rest of the study population. While these results do not provide any evidence of causal associations, it is noteworthy that women with these reproductive outcomes have significantly higher body burdens of PCBs than women without them.

1087k  Developmental Exposure of Zebrafish to Dieldrin Alters Gene Expression Associated with Energy Homeostasis

M. H. O’Brien and I. P. Callard. Florida International University, Miami, FL.

Environmental exposure to xenobiotics has been suggested to modify energy balance and increase the risk for obesity, metabolic syndromes, and diabetes incidence. The importance of developmental exposure to pollutants and the associated risk for disease later in life is not clear. Reproductive development and energy homeostasis are tightly linked. Our previous studies have shown reproductive abnormalities in...
freshwater turtles near the Massachusetts Military Reservation (MMR) Superfund Site where pesticides and other persistent pollutants have been detected in egg yolk. To explore the mechanisms of developmental toxicity of these pollutants we used a zebrafish (Danio rerio) whole embryo model. Quantitative RT-PCR analy- sis showed that exposure of zebrafish to pond water contaminated by the MMR, relative to water from a control pond, induced vitellogenin and aromatase B but did not alter estrogen receptor alpha, cytochrome P450a1, or metallothionein gene expression. Upon individual examination of pollutants from pond water we found the pesticide dieldrin, but not p,p′-DDE, had a significant effect on global gene transcription patterns. Gene Set Enrichment Analysis (GSEA) of microarray results indicated that exposure to dieldrin disrupted many pathways including insulin secretion, glucose secretion and metabolism, and adipokine signaling. Using Quantitative RT-PCR we further investigated a panel of dieldrin-responsive genes (neuronal PAS domain protein 4, pyruvate dehydrogenase kinase 2, phospho- nolpyruvate carboxykinase 1, hydroxy steroid delta beta dehydrogenase 2, pre-proop- iomelanocortin, and insulin-induced gene 1). For all genes examined we found an inverted U-shaped dose response curve with dieldrin exposure. The normal developmental pattern of these dieldrin-responsive genes was also characterized. We found that neither MMR-contaminated pond water nor p,p′-DDE exposure had a significant effect on genes regulating energy homeostasis. In addition to other pollutants at the MMR, dieldrin is a concern and is shown here to alter energy balance signaling.

Manganese (Mn) is neurotoxic at higher concentrations. Mn toxicity occurs in

University of Cincinnati, Cincinnati, OH.

M. T. Williams1.

Based on these results, we conclude that Mn exposure during early life and lifelong has a significant effect on energy balance signaling.

10871 The Role of Mn in Skeletal Development

C. J. Richardson1, D. Smith, S. Fendorf2, J. Lezama Pacheco2, R. Ritchie2 and N. Dave1. 1Microbiology and Environmental Toxicology, University of California Santa Cruz, Santa Cruz, CA, 2Environmental Earth System Science, Stanford University, Stanford, CA and 3Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA.

Objective: To determine the affects of early postnatal manganese(Mn) exposure on skeletal Mn accumulation and development in pre and post weaned rats.

Rationale: Mn is essential for proper bone development and growth however overexposure to Mn can impair proper bone formation. Mn is incorporated in bone mineral as a biological analog to calcium, although the extent of accumulation in bone is not well known.

Approach: Male Long Evans rats were orally exposed to 0.25 or 50 mg Mn/kg/d over the preweaning period only (PND 1-21) or lifelong, and sacrificed at age PND 24,66, or 400. Bone Mn levels were analyzed by ICPMS and calcium using OES. Tibia samples were pulverized and analyzed for molecular coordination and speciation using X-Ray diffraction (XRD) and X-Ray absorption(XAS) techniques. Femurs were tested for fracture resistance using an instron at PND 66.

Results:
1) Results indicate that within an age group of lifelong exposure, PND 24,66, or 400 continuously exposed to Mn had an increased Mn accumulation relative to exposure.
2) Bone Mn levels in young PND 24 animals were substantially higher than levels in PND 66 and 400 animals.
3) Bone Mn levels in PND 66 and 400 animals that were exposed to Mn only over the pre-weaning period (PND 1-21) still showed evidence of slightly elevated bone Mn levels compared to controls never exposed .
4) Bone Ca levels were significantly lowered in the PND 66 group.
5) Preliminary Instron analyses of bone strength suggests that Mn exposure may reduce bone strength, while preliminary XRD results do not suggest any gross alteration in the macroscopic mineral composition. Conclusions: Collectively these results suggest that elevated early life and lifelong Mn exposure may lead to increased bone Mn accumulation into adulthood, and reduce overall bone strength, with implications of osteoporosis and compromised bone integrity.

1087m Interaction of Manganese, Iron, and Stress on Spatial Learning and Memory after Developmental Exposure

R. M. Amos-Krooha1, L. D. Davenport1, N. Atanasova1, C. V. Vorhees1 and M. T. Williams1. 1Neurology, Cincinnati Children’s Hospital, Cincinnati, OH, 2Environmental Health, University of Cincinnati, Cincinnati, OH and 3Philsophy, University of Cincinnati, Cincinnati, OH.

Manganese (Mn) is neurotoxic at higher concentrations. Mn toxicity occurs in children from sources such as soy-based infant formulas, well-water, and air pollution near heavy manufacturing. Children’s gastrointestinal systems allow Mn to more readily enter circulation and accumulate in brain. Subclinical iron (Fe) deficiency (FeD), which affects up to 15% of US children, exacerbates Mn toxicity due to increased Mn bioavailability during FeD. FeD is prevalent in impoverished and low socioeconomic environments that are considered stressors. To model developmental stress (DS), pregnant rats and their litters were housed in cages with a wire grid floor or standard bedding from embryonic day (E)7 to postnatal day (P)28. Dams were fed a 90% Fe deficient or standard NIH-07 diet from E15 through P28. Within each litter, different offspring were treated with 100 mg/kg Mn (100Mn) by oral gavage or vehicle from P4 to P28. As adults, offspring were tested in the Morris Water Maze (MWM). Progeny in the 100Mn group, regardless of FeD or DS, showed increased latency on acquisition trials and decreased platform crossings on the probe trial. The interaction of FeD and DS also impaired MWM performance. A potential mechanism underlying these deficits in 100Mn animals is decreased long-term potentiation that we observed in slice preparations in the hippocampus. DMT1 and ZIP8, metal transporters in the CNS, showed increased protein in the hippocampus via Western blot in treated groups; ZIP8 was decreased only in the FeD/100Mn compared with controls. Together these data suggest that multifactorial models may reveal effects not observed when only one factor is studied at a time. (Supported by NIH T32 ES07051 and P30 ES006096)

1087n Characterization of the Neuropathological Consequences of Plac Ablation in the Developing Mouse Embryo

J. Bourgeois1, X. Kong2, J. Fuentes2, R. D. Harbison1, G. T. Johnson1,2 and M. Fant1. 1Environmental and Occupational Health, College of Public Health, University of South Florida, Tampa, FL and 2Pediatrics, College of Medicine, University of South Florida, Tampa, FL.

Placenta-specific 1 (Plac1) is an X-linked gene that is essential for normal placental development. Plac1 is also expressed in the fetal brain and paternally imprinted. Expression is markedly downregulated immediately after birth. Plac1 ablation pre-disposes Plac1-null males and Xm-X Hets (inactive maternal allele) to an increased risk of developing lethal postnatal hydrocephalus suggesting a functional role for Plac1. The objective of this study was to characterize the effect of Plac1 on brain development. A mutant Plac1 mouse model, established on the C57BL/6J background, was studied. Embryo and brain sections were obtained at various stages of development. Plac1 expression was assessed by qRT-PCR, immunohistochemistry (IHC), and in situ hybridization (ISH). Brain structure was assessed by histo-pathological and magnetic resonance imaging. Results revealed Plac1 expression throughout the embryonic brain when assessed by qRT-PCR, IHC, and ISH at E14.5-E18.5. MRI analysis of an adult Plac1 knockout (KO) brain revealed microcephaly (10%), a dysmorphic cerebrum, and increased heterogeneity of the medulla. Consistent with these findings, H&E staining of the KO brain revealed a smaller cortical mantle, a dysmorphic hippocampus, and a dysmorphic cerebellum with reduced folia and major disruptions in development and significantly reduced neuronal cell numbers. Similarly, anti-NeuN staining of an Xm-X Het revealed decreased neuronal cell numbers. In conclusion, Plac1 is a paternally imprinted, X-linked gene that is essential for normal brain development. Plac1 ablation is associated with the disruption of axonal development and decreased neuronal cell number. The Plac1 promoters are under the control of Rb in combination with other transcriptional regulators. It is therefore likely that Plac1-mediated signaling pathways are relevant to neuropathies associated with disruptions in retinoic acid signaling.

1087o Evaluation of Environmental Chemicals Computationally Predicted to Disrupt Angiogenesis

T. Heinonen1, T. Toimeila1, B. K. Knudsen2, N. Kleinsteusch1 and R. Sarkane1. 1FICAM, University of Tampere, Tampere, Finland, 2National Center for Computational Toxicology, US EPA, RTP, NC and 3ILSI, Inc./NICEATM/NIEHS, RTP, NC.

The aim of this study was to investigate the effect of 10 chemicals, predicted by ToxCast and a virtual tissue model to impact angiogenesis at varying degrees, in an in vitro human cell-based angiogenesis assay. Angiogenesis is critical for embryonic development and reproduction in general, and contributes to the pathogenesis of numerous disorders. This human cell base angiogenesis assay may serve as a test to detect potential antiangiogenic substances including teratogens. The test chemicals were selected from the ToxCast project based on predicted antiangiogenesis activities (strong, weak, negative). The co-culture of human fibroblasts and human endothelial cells (HUVEC) was exposed to test chemicals at a concentration range of 10 pM to 10 nM (limited by the solubility). After 24 h, the neutral uptake assay (NRAU) was performed for EC80 cytotoxicity value for each test chemical. Extent of tubule formation was microscopically assessed after 6 days in culture. The concentrations of each test chemical that produced less than 20% cytotoxicity in the NRU test were selected for tubule formation analysis. Potency order for in
vito inhibition of tubule formation (IC50) was: Octyl gallate 1 μM > Tricosanol 1.7 μM > 1-hydroxypropane 11 μM > Disulfiram 23 μM > Sodium docetylbenzene sulfonate 44 μM > Diethanolamine 1788 μM. With Sodium docetylbenzene sulfonate the inhibition of tubule formation was considered as being cytotoxicity-related. Tert-butylhydroquinone did not inhibit tubule formation at non-cytotoxic concentrations. Trit (2-chloroethyl) phosphate, Mannitol and Decane were neither cytotoxic at the concentration range tested nor markedly inhibited tubule formation. Decane showed only minor inhibition of tubule formation. The in vivo results were generally consistent with prospective predictions from the in silico models with respect to antiangiogenic potential. This abstract does not necessarily reflect US EPA policy.

**PS 1087p Computational Modeling of Limb Development Using ToxCast High-Throughput Screening Data for Predictive Toxicology**

Skeletal defects are one of the major adverse outcomes observed across many prena
tal developmental toxicity studies. We mined the ToxCast database (ToxCastDB) for in vitro chemical-bioactivity profiles that significantly correlated with skeletal defects in the Toxicity Reference Database (ToxRefDB). Using high-throughput screening (HTS) data from >1060 chemicals tested in 860 assays, 734 chemi
cals had in vivo developmental toxicity data in ToxRefDB and 44 (4.5%) pro
duced fetal limb defects. In addition, we identified 112 ToxCast chemicals not in ToxRefDB that according to published articles produced limb defects. Significant univariate associations (e.g., assay-endpoint) were used to filter HTS assays based on statistical correlation (p<0.05) with distinct in vivo developmental limb defects.

Retinoic acid receptors (RARs) assays emerged as the top target and were activated by 17 ToxCast chemicals. Retinoic acid (RA) signaling plays an essential role in limb patterning as a ligand for nuclear RA receptors. We incorporated RA sig
naling into a multicellular agent-based model (ABM) of early limb development in CompuCell 3D. The ABM stimulates complex cellular interactions (adheshion, apoptosis, chemotaxis, migration, mitosis, secretion) through formation of apical epidermal ridge, zone of polarizing activity, and expansion of mesenchyme driven by morphogenetic signals (BMPs, FGFs, SHH, RA). To evaluate the model we se
glected two known prototypes: Dieldrin (AC50 = 4.8 μM on RARγ, and 0.974 μM on RARαx) and Aldrin (AC50 = 45.5 μM on RARα, and inactive on RARβ) based on ToxCast data. Simulating the impact of RAR disruption by these compounds on other pathways (e.g. SHH, FGFs) in the limb model can provide insight into the spatial-temporal dynamics of altered limb development as a tool for predictive toxicology. [This abstract does not necessarily reflect EPA policy.]

**PS 1087q Evaluation of the Mechanism of Misoprostol-Induced Limb Defects Using a Late Organogenesis Rat Embryo Culture**

M. Caviera1,2 and O. Madrid1. 1Facultad de Farmacia, Universidad de Valparaiso, Valparaiso, Chile and 2Centro Regional de Estudios de Alimentos Saludables, Valparaiso, Chile. Sponsor: F. Faustman.

Prostaglandins of the E-series play an important role on bone metabolism and limb development. Misoprostol is a prostaglandin E1 analog and is registered in Chile for the prevention and treatment of non-steroidal anti-inflammatory peptic ulcers. It is also used to induce abortions. In utero exposure to misoprostol, after failed abortion attempts, has been associated to joint and skeletal defects, although the mechanism of action which mediates this teratogenicity is unknown. Since misoprostol can act on prostanoid receptors expressed during limb development, we hypothesized that this interaction could explain the induction of limb defects. In order to test this hypothesis, we established a late organogenesis embryo culture to model the effect of misoprostol on limb development in which to evaluate func
tionality, growth and morphology. GD13.5-collected rat fetuses were cultured for 24 hours at 37 °C, in rat serum diluted in Hank’s solution which also contained either 200, 2,000 or 20,000 pg/ml misoprostol, PGE2 or the EP1 and EP2 antag
nist, AH6809. 1000 mg/L sodium penicillin G and 50 μg/ml ketokconazole were used as negative and positive control, respectively. All concentrations of misoprostol, PGE2 and the antagonist induced similar toxicity, inducing abnormal clefs and decrease of bone development in anterior limb digital rays. However, they did not alter growth and functionality parameters. In conclusion, misoprostol induces overt manifestations of alterations of limb development, which may not be medi
dated by prostanoid receptors EP1 or EP2.

**PS 1087r Peripheral Blood Changes in Rats Developmentally Exposed to Volatile Organic Compounds: Shifts in Leukocyte Distribution**

E. Quiñó1,2, A. J. Filgo1,3, D. H. King5, G. Traylov1, C. D. Bortner1, M. I. Sijé5, G. Kissing5 and S. E. Fentan1. 1NIEHS, Research Triangle Park, NC, 2Comparative Biomedical Sciences, North Carolina State University, Raleigh, NC and 3Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC.

Volatile organic compounds (VOCs) such as benzene, trichloroethylene (TCE), 1,2-dichloroethylene (1,2-DCE), perchloroethylene (PERC) and vinyl chloride (VCM) are important industrial solvents used in dry cleaning agents, dyes, and var
nishes, among others. Since the mid-1970s, environmental or occupational ex
poures to these VOCs have been associated with increased incidences of cancer, particularly leukemia and lymphoma. Epidemiological studies indicate that inges
tion of contaminated drinking water or inhalation of volatile gases in the air, are the most likely routes of environmental and VOC exposure. Developmental exposures to VOCs (e.g. during pregnancy or in infancy) can be especially detrimental and often result in malformations, congenital abnormalities and later life disease. In this study, Harlan Sprague-Dawley rats were pre-natally and peri-natally exposed to drinking water containing a VOC-mixture of 5, 10 and 50-fold well water concentra
tions (5X, 10X, 50X) of benzene, TCE, DCE, PERC and VC from gestation day 12 (GD 12) through post-natal day 48 (PND 48). While all dosed animals exhibited elevated leucocyte counts compared to age-matched controls, 5-7-fold elevations were observed within the two higher dose groups (10X and 50X). In addition, examination of peripheral blood smears of the 10X and 50X animals revealed increased numbers of circulating large granular lymphocytes, particularly within the 10X group. These changes possibly suggest a bone marrow response in leucocyte production or, more likely, a shift in leucocyte distribution from the tis
tue reservoir to the circulatory pool as a result of developmental exposure to VOCs.

**PS 1087s DNA Methylation Is Required for Mouse Prostate Development**

K. P. Keil1, L. L. Able1, V. Mehra1, H. M. Altmann1, J. Laporta1, L. L. Hernandez2 and C. M. Verzina1. 1Comparative Biosciences, University of Wisconsin Madison, Madison, WI and 2Dairy Science, University of Wisconsin Madison, Madison, WI.

A number of dietary and environmental chemicals including but not limited to bisphenol-A (BPA), bis(2-ethylhexyl)phthalate (DEHP), and 2,3,7,8 tetracho
lordibenzo-p-dioxin (TCDD) are capable of altering ductal development and dis
drupting DNA methylation patterns in developing mouse prostate. Whether these actions are mechanistically linked is not known in part because the role of DNA methylation in neonatal mouse prostate development is not known. The purpose of this study was to determine whether DNA methylation participates in mouse prostate development. 14 days post coitus (dpc) mouse urogenital sinuses were cultured for 2 days in the presence or absence of a DNA methylation inhibitor and then 1, 3 or 5 days in media containing dihydrotestosterone (androgen) without DNA methylation inhibitor. At the end of the culture period, after methylation inhibition was used to visualize and count prostatic buds, immunohistochemistry was used to determine the index of androgen receptor (AR) positive cells, and methylated DNA immunoprecipitation was used to assess Ar DNA methylation. The DNA methylation inhibitor reduced Ar promoter methylation, increased AR protein abundance, increased the number and rate of prostatic buds formed, and caused prostatic buds to form in response to a lower concentration of androgen. Thus, we conclude that DNA methylation creates a permissive environment for mouse pros
tatic outgrowth, and primes the prostate primordium to respond to developmental cues mediating prostate ductal development. These results raise the possibility that endocrine disrupting chemicals could alter prostate development by perturbing DNA methylation. Supported by NIH grant DK096074 and ES001332 and NSF grant DGE-0718123.

**PS 1087t Pregestational Ethinylestradiol Exposure Postpones Pubertal Onset and Decreases Body Weight in Both Male and Female Offspring in Rats**

D. Wu, W. Zhang, K. Xu, D. Chen and X. Wang. Department of Toxicology, Nanjing Medical University, Nanjing, Jiangsu, China.

Ethinylestradiol (EE) is used for medical treatment and as contraceptives in females and its exposure during gestational period has been proved to elicit reproductive abnormalities in both male and female offspring. To test whether pre-gestational EE exposure also affects reproductive development, especially pubertal timing in the offspring, female Sprague-Dawley rats were treated orally with EE (0, 50, 200, 800 μg/kg/d) for 15d. Another 30d later, they mated with normal males and gave SOT 2014 ANNUAL MEETING 287
birth to the offspring. Litter size and litter sex ratio were recorded. Anogenital dis-
tance (AGD) and body weight were measured every 5d since postnatal day 1 (P1). Age at vagina opening in females and penis stripping in males were recorded to mark pubertal onset. Rats were sacrificed on P51. Ovarian/testis mass, serum es-
trooidal (E2) (E2(17beta)) and testosterone (T) (male) levels were detected. Results showed no significant difference in litter size and litter sex ratio. However, mothers with pre-gestational 50, 200, 800 μg/kg/d EE treatment had offspring with significantly lower body weight and higher AGD/body weight ratio than the control group since P1. Maternal pre-gestational EE exposure significantly postponed the puberty onset in male and female offspring in 200 and 800 μg/kg/d groups. Body weight at pubertal onset was significantly lower in 50 μg/kg/d group in males and females. Hormone assay data indicated T in males was higher in 200 and 800 μg/kg/d groups than control and no difference was found in E2 in females. Ovarian/body weight ratio in females and testis/body weight ratio in males were not different among groups. These data indicated that maternal pre-gestational EE exposure might cause alteration in the neuroendocrine system to give rise to pubertal develop-
mental disruption but might not lead to adverse effects in gonads. Since no sign-
nificant sex-specific difference was observed and all treated groups had lower body weight, alteration of metabolic signals activating the reproductive axis may underlie the induced pubertal development disruption.

1087w An Oral Prenatal Developmental Toxicity Study with Tetrabromobisphenol A (TBBPA) in CD Rats

M. L. Dourson1, R. Cope1 and S. Kacew2. 1Toxicology Excellence in Risk Assessment, Cincinnati, OH and 2Toxicology, Cincinnati, CA.

The objective of this GLP OECD TG 414/US EPA OPPTS GL No. 870.3700 study was to discern the effects of oral TBBPA (0, 100, 300 or 1000 mg/kg bw/d; gavage) on embryonic/fetal development from gestation days (GDs) 0 to 19. No test article-related mortality was observed in any of the dams. Sporadic ptyalism in dams was associated with the administration of TBBPA at doses of ≥ 300-mg/ kg bw/d. Because of the sporadic nature of this effect, and lack of a clear dose response, the effect was regarded as being non-adverse and related to the normal taste response following exposure to residual amounts of the test article on the dos-
ing catheters. No other test article-related effects including clinical examinations, gestational parameters, body weight, body weight gain, food consumption, uterine implantation, gravid uterine weight, number of uterine implantations, number of corpora lutea, number of early/late resorptions, number of viable/non-viable fetuses, fetal sex distribution, individual fetal weights, liver weights of dams, fetal external examinations, fetal visceral examinations, fetal skeletal examinations and macroscopic pathology examinations of the dams were observed. The NOEL for maternal and developmental toxicity was 1000 mg/kg bw/d, the highest dose eval-
uated.

1087v Influence of Maternal Stress on Gestational Parameters and Prenatal Development in Himalayan Rabbits

S. S. Schneider1, I. Feger1, C. Werner2 and B. van Ravenzwaay1. 1Toxicology, BASF SE, Ludwigshafen/Rhein, Germany and 2Regulatory Toxicology Crop Protection, BASF SE, Ludwigshafen, Germany.

Gestational stress is hypothesized to enhance the developmental toxicity of chem-
icals. Single stress factors like food restriction have been reported to be associated with resorptions, abortions, reduced fetal weight, and alterations in ossification in rabbits. But, little is known about how maternal stress from handling alters fetal development, confounding the data interpretation of regulatory prenatal toxicity studies. In the present experiment we exposed 25 pregnant Himalayan rabbits per group to two daily handling protocols aimed to increase maternal stress: restraint (15 min per day) and restraint plus dressing the animals with stretchable bandages for 6 hours per day. These groups were compared with an uncongested control group. Investigations and data assessment were made in accordance with standard regulatory guidance, i.e. OECD TG 414 and OPPTS 870.3700. Neither stress protocol affected any of the parameters routinely used to characterize maternal toxicity. No adverse clinical signs were noted; nor was food consumption or (net) body weight gain in the pregnant rabbits influenced. Restraint stress alone had no influence on prenatal development; however, the combination of restraint plus dressing stress produced 4 abortions and an early resorption rate of almost 50%. Prenatal development of the surviving offspring was not impaired. Thus, a combi-
nation of two handling stressors which do not evoke obvious pathological findings in pregnant rabbits is able to produce severe prenatal developmental toxicity. When taken together with other investigations, these data suggest that the nature of these findings, in this case intrauterine death, is likely specific to the stressor and hypoth-
etically even the species or the strain being tested. Furthermore, we speculate that when combined with handling, the stress due to chemical exposure may cause developmental findings in the absence of frank maternal toxicity, simulating a test substance-specific effect.

1087x An Oral Two Generation Reproductive, Fertility and Developmental Neurobehavioral Study of Tetrabromobisphenol A (TBBPA) in CD Sprague-Dawley Rats

R. Cope1, M. L. Dourson1 and S. Kacew2. 1Toxicology Excellence in Risk Assessment, Cincinnati, OH and 2Institute of Population Health, University of Ottawa, Ottawa, ON, Canada.

The objective of this GLP US EPA OPPTS 870.3800 study was to discern the effects of TBBPA (10, 100 or 1000 mg/kg bw/d; gavage) over the course of 2 generations (P and F1) on growth and development of offspring (F1 and F2). A developmental neurotoxicity/neuropathology assessment was also conducted on a F2 generation cohort. Exposure to ≥ 100-mg/kg bw/d TBBPA was associated with changes in the peripheral thyroid levels in rats that were explainable on the basis of induction of liver catalysis, a phenomenon that is known to be not relevant to humans. TBBPA at up to 1000 mg/kg bw/d was not associated with any significant non-neurological effects on reproduction, growth and development. A subtle reduction, of unknown biological relevance, in the thickness of the parietal cortices of 11-day-old F2 pups from the 1000 mg/kg bw/d group was noted. However, this change was not ac-
accompanied by evidence of micro-anatomical change. The functional relevance of this finding at present remains obscure and needs to be interpreted with caution given the limitations of the morphometric analysis. No other test article-related effects on developmental neurotoxicity/neuropathology were present including no test article-related effects on detailed clinical observations, developmental maturation landmarks, neurobehavioral evaluations and Day 60 brain weights.

1088 Effect of a Nutrient Mixture on Matrix Metalloproteinase-9 Dimers in Various Cancer Cell Lines

M. Roomi, M. Rath and A. Niedzwiecki. Dr. Rath Research Institute, Santa Clara, CA.

Strong clinical and experimental evidence demonstrates association of elevated levels of matrix metalloproteinase (MMP)-9 with cancer progression, metastasis and shortened patient survival, as it plays a key role in tumor cell invasion and metastasis by digesting the basement membrane and ECM components. MMP-9 is secreted in both monomer and dimer forms. Though there is little research on MMP-9 dimers, some studies have shown the dimer to be associated with more
aggressive tumor progression. Our objective was to study the relative secretion patterns of MMP-9 dimer in various carcinomas, sarcomas, adenocarcinomas and leukemias and the effect of a nutrient mixture (NM) containing lysine, proline, ascorbic acid and green tea extract on dimer secretion.

The cancer cell lines were grown in their respective media, supplemented with 10% FBS, penicillin (100 units/ml), and streptomycin (100 μg/ml) in 24-well tissue culture plates. At near confluence, the cells were treated with NM at 0.1, 0.5, 1.0, and 2.0 mg/ml and 500 and 1000 μg/ml. Parallel sets of cultures were treated with phorbol 12-myristate 13-acetate (PMA) 100 ng/ml for induction of MMP-9. Cell MMP-9 secretion was assayed by gelatinase zymography.

No MMP-9 dimer secretion was observed in prostate, pancreatic, colon, bladder, head and neck, glioblastoma and leukemia cell lines. MMP-9 dimer secretion only with PMA induction was seen in sarcomas, melanoma and breast, lung and tongue cancer cell lines. Cervical, renal and hepatic carcinomas exhibited MMP-9 dimer without PMA treatment and increased secretion with PMA treatment. Sarcomas demonstrated the highest combined levels of MMP-9 mono- and dimer with and without PMA among these cancer cell lines. NM showed dose-dependent inhibition of MMP-9 monomer and dimer in all cell lines tested.

In conclusion, high MMP-9 secretion levels correlated with more aggressive cancer cell lines. NM was effective in inhibiting MMP-9 monomer and dimer secretion in all cell lines tested, suggesting its therapeutic potential as an antimetastatic agent.

1089 Increased Susceptibility of Rats versus Mice to N-Butyl-N-(4-hydroxybutyl) Nitrosamine (BBN)-Induced Urinary Bladder Tumors

BBN is a potent and specific urinary bladder carcinogen that has been utilized in experimental models of 2-stage tumor promotion. However, the dose-response of BBN on key tumorigenic events is not well understood since they have not been systematically evaluated and BBN is usually administered in drinking water as a single concentration. The current study was conducted to better understand the dose-response relationship between BBN administration and the incidence of urinary bladder tumors in mice and rats. BBN was administered by oral gavage twice weekly for 6 weeks to either male C57Bl/6J mice (0, 125, 250, 500 mg/kg; N = 45) or male Sprague-Dawley rats (0, 100, 200, 400, 800 mg/kg; N = 20). Necropsies were conducted at 10 (mice only), 14 and 24 weeks following the initiation of BBN administration. In mice (10 weeks) and rats (14 weeks), BBN caused a dose-dependent increase in oxidative DNA damage (8-hydroxyguanosine staining) and cell proliferation (Ki-67 staining) in urinary bladder transitional cells. Despite the urinary bladder transitional cell hyperplasia, BBN was associated with a very low incidence of urinary bladder tumors (≤ 1%) in mice over the full 24-week period. In contrast, BBN-treated rats exhibited a dose-dependent increase in atypical hyperplasia and transitional cell papillomas and carcinomas in the urinary bladder, with a 20, 47, 57, and 93% incidence of urinary bladder tumors across doses after 24 weeks. Thus, BBN induced urinary bladder tumors in male Sprague-Dawley rats with a steep dose response relationship, but was not effective in producing bladder tumors in male C57Bl/6J mice at comparable doses despite underlying evidence of DNA damage and hyperplasia. The steep dose response observed with BBN and relative species susceptibility highlight important considerations in designing urinary bladder tumorigenesis studies with BBN.

1090 Reduced Body Weight Gain Prolongs Early-Life Levels of Tyrosine Hydroxylase Expression in Hypothalamic Tuberoinfundibular (TIDA) Neurons in Wistar Rats

S. Plummer 4, M. Beltran 4, N. Kuan 4, M. Millar 4, R. Weigand 4, R. Currie 4, R. Green 4 and J. Wright 4.

MicroMatrices Associates Ltd, Dundee, United Kingdom, 2MRC Centre for Reproductive Health, Edinburgh, United Kingdom, 3MRC Centre for Inflammation Research, Edinburgh, United Kingdom and 4Syngetia Ltd, Bracknell, United Kingdom.

Caloric restriction in Wistar rats leads to a decreased incidence of mammary and pituitary tumours and an increase in uterine tumours (1, 2, 3) relative to concurrent controls. Previously we found (4) that lean female Wistar rats (~30% body weight gain relative to controls) from a 2 year bioassay showed increased expression of tyrosine hydroxylase (TH) mRNA and protein in hypothalamic TIDA neurons. We have postulated that alterations to leptin signalling, resulting from reduced body fat, could maintain dopaminergic inhibition of prolactin secretion and prolong pro-oestrogenic stimulation of the uterine epithelium. The present study explored (i) the time-dependency of the effects on TIDA neuron TH expression, using immunostaining (IHC), in situ hybridisation (ISH) and image analysis on FFPE tissue from 90 day, 12 month and 2 year studies; and (ii) pathways involved in prolactin and oestrogen signalling, regulated by the hypothalmo-pituitary axis, that might promote uterine carcinogenesis.

TH RNA and protein expression decreased with time in controls, whilst lean rats maintained TH levels. Laser dissection targeted microarray analysis of hypothalamus, pituitary and uterus revealed down-regulation of pituitary prolactin, hypothalamic GABA B receptors, and leptin receptor (LEPR) signalling molecules STAT3 and PDE3B, and up regulation of uterine oestrogen receptor alpha (ESR1). Immunostaining for ESR1 showed increased expression in uterus. These results support previous observations that chronic reduction in bodyweight gain alters regulation of hypothalamic dopamine, with downstream consequences on hormonal control of prolactin, oestrous cycle prolongation, and potential to increase the incidence of uterine tumours.

1091 The Effects of Testosterone on NNK-Induced Lung Tumorigenesis in Female and Male A/J Mice

Y. Nakano 1, M. Yokohira 1, F. Ninomiya 1, S. Kishi 1, K. Yamakawa 2, S. Kanie 2, K. Sano 1 and K. Imaida 1.

Onco-Pathology, Kagawa University, Faculty of Medicine, Kita-gun, Kagawa, Japan and 2Tomakomai City Hospital, Tomakomai, Hokkaido, Japan.

It is well known that there is sex difference of the sensitivity of the lung carcinogenesis. In human, lung adenocarcinomas of female are higher incidence than those of males. In experimental animals, A/J mice shows similar pattern with humans. So, the lung carcinogenesis might be associated with sexual hormones. The present study is conducted to investigate the effects of testosterone on the lung carcinogenesis in A/J mice.

In experiment 1, female A/J mice were separated into 4 groups. Group 1 and 2 were treated with interperitoneal injections (i.p.) of 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) (2mg/0.1ml saline/mouse) at weeks 0 and 1. At week 3, testosterone pellets (90-day release, 25mg/pellet/mouse, Innovative Research of America) were implanted under the skin shoulder in groups 1 and 3, and control pellets (placebo) were implanted in groups 2 and 4. All mice were sacrificed at week 15.

In experiment 2, male A/J mice at 6 week-old were separated into 6 groups. Group 1, 2, 5 and 6 were castrated two weeks ago before groups 1, 2, 3, 4 and 4 were treated with i.p. of NNK at weeks 0 and 1. At weeks 3 and 9, testosterone pellets were implanted in groups 1, 3 and 5. Groups 2, 4, 5 and 6 were implanted placebo pellets at week 3 and treated sham operation at week 9. All mice were sacrificed at week 15.

In experiment 1, the female mice showed significant decreasing of multiplicity of lung tumors with higher testosterone level in their blood. However, in male mice (experiment 2), there were no significant differences of the multiplicity or area of lung tumors with different concentrations of testosterone in the serum. Therefore, testosterone has possibilities to inhibit NNK-induced lung carcinogenesis in female A/J mice, but not in male mice.

In conclusion, the testosterone is suggested to have tumor-suppressing effect on lung tumorigenesis, but there could be sex difference or other factors.

1092 Activation of ERK1/2 on NNK-Induced Lung Carcinogenesis in A/J Mice

K. Yamakawa 1, S. Kishi 2, M. Yokohira 1, Y. Nakano 1, F. Ninomiya 1, S. Kanie 2, K. Sano 1 and K. Imaida 1.

Onco-Pathology, Kagawa University, Faculty of Medicine, Kita-gun, Kagawa, Japan and 2Tomakomai City Hospital, Tomakomai, Hokkaido, Japan.

The extracellular signal-regulated kinase 1/2 (Erk1/2) signaling pathway is activated by several growth factors and mitogens, and up-regulation has been noted in many human cancers, including lung cancers. In this study, we examined immunohistochemical expression of phosphorylated forms of Erk1/2 (pErk1/2) and correlation between Erk activation and mutation of Kras encoding an upstream activator of Erk1/2, in a mouse lung carcinogenesis model. Female 7-week old A/J mice were administered a single dose of 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK), then maintained without additional treatment until sacrifice at week 52. We analyzed immunohistochemical expression of pErk1/2 in 26 hyperplasias, 50 adenomas, and 17 adenocarcinomas. pErk1/2-positive cells were seen in the peripheral and central areas of lung tumors with no different concentrations of testosterone in the serum. However, in male A/J mice, the activated Erk1/2 expression was obviously induced by testosterone. Our results suggest that the interaction between testosterone and Erk1/2 pathways might promote lung carcinogenesis.
Effects of Gonadectomy on Lung Carcinogenesis Induced by 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) in Both Sexes of AJ Mice

F. Ninomiya, M. Yokohig, S. Kishi, Y. Nakano, K. Yamakawa, T. Inoue, T. Kunoo and K. Imaid. Onco-Pathology, Kagawa University, Faculty of Medicine, Kagura-Kita, Kagawa, Japan.

It is well known that female mice are more sensitive to chemical lung carcinogenesis than males. In order to investigate our hypothesis that the lung carcinogenesis may be affected by sex hormones, we first examined the sex ratio of the lung tumors in both sex of AJ mice were gonadectomized and were examined about their lung carcinogenesis induced by 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK). NNK is a tobacco-specific N-nitrosamine which is considered to play important roles in cigarette-related lung cancer, and also induces lung adenocarcinoma in rodents.

In the present experiment, 18- and 56-week studies were conducted. Male and female A/J mice were separated into gonadectomized and unoperated groups. All animals were treated intraperitoneal injection of NNK at the dose of 2 μg/mouse, with 2 injections at weekly interval in the 18-week study and 1 injection in the 56-week study. All of surviving mice were sacrificed at the ends of an experiment period. Lung proliferative lesions were detected in all mice of all groups. In the control groups of 18- and 56-week studies, the multiplicities of lung nodules were significantly greater in females than in males. In the 56-week study, the males showed the multiplicity of macroscopic lung nodules, histopathological bronchiolo-alveolar hyperplasias, adenomas and tumors were increased significantly by castration. In the 18-week study, females showed the multiplicity of adenomas were decreased significantly by ovariectomy.

From these results, female A/J mice are more susceptible for lung carcinogenesis induced by NNK than males and gonads play important roles in determining sex differences in the lung carcinogenesis in AJ mice. It is suggested that the progression of lung tumor could be inhibited by testosteron and promoted by estradiol.

ALDH1B1 Is Required for Colon Tumorigenesis by Modulating WNT-Signaling and Metabolizing Retinaldehyde

S. Singh1, J. Arcariol1, Y. Chen1, B. C. Jackson1, W. Messersmith1, D. Olrichs1, D. Thompson2 and N. Vasilak2. 1Department of Pharmaceutical Sciences, University of Colorado Anschutz Medical Campus, Aurora, CO; 2Department of Clinical Pharmacy, University of Colorado Anschutz Medical Campus, Aurora, CO, 3Division of Medical Oncology, University of Colorado School of Medicine, Aurora, CO and 4Department of Pathology, University of Colorado School of Medicine, Aurora, CO.

Aldehyde dehydrogenase 1B1 (ALDH1B1) is a mitochondrial enzyme that shows 65% and 72% amino acid homology with ALDHA1A1 and ALDHA2, respectively. In human normal colon, ALDH1B1 is expressed only at the crypt base, along with stem cells. It is highly expressed in all cancerous cells of human colonic adenocarcinomas. This pattern of expression corresponds closely to that observed for Wnt signaling activity in normal and cancerous colon. In the present study, we show that shRNA mediated knockdown of ALDH1B1 reduced the number and size of spheres formed by human colon cancer cells in a three-dimensional matrigel culture. In addition, ALDH1B1 knockdown depletes the putative highly tumorigenic ALDHBright colon cancer cells and significantly decreased xenograft tumor formation in athymic (nu/nu) mice. Gene expression studies on the Wnt-signaling pathway revealed upregulation of Axin2 (a negative regulator of the Wnt pathway) and downregulation of beta-catenin (a critical protein in the canonical Wnt-signaling pathway) and Wnt dependent transcription of c-Myc in ALDH1B1 depleted colon cancer cells. We have also found that ALDH1B1 metabolizes all trans-retinaldehyde efficiently with Km of 25 μM to generate retinoic acid which has been reported to increase expression of pro-survival genes and tumor growth by activating PPARβ/δ in colon cancer. In summary, our data demonstrate that ALDH1B1 plays a functional role in colon cancer tumorigenesis by modulating the Wnt-signaling pathway and participating in retinoic acid formation.

Increased Growth and Tumorigenicity of MCF-7 Breast Cancer Cells by Chronic Exposure to Oxidative Stress

P. S. Mahalingapali, K. P. Singh and L. Ponnusamy. Environmental Toxicology, The Institute of Environmental and Human Health (TIEHH), Texas Tech University, Lubbock, TX.

Breast cancer is the second leading cause of cancer related death in women. Exposure to environmental estrogenic chemicals has been shown to be associated with breast cancer development and progression through various mechanisms. Though, the increased oxidative stress by xenoestrogens-generated reactive oxygen species (ROS) has been hypothesized as a potential mechanism for breast cancer growth and progression, there is no direct evidence for the ROS-induced growth and tumorigenicty of breast cancer cells. Therefore the objective of this study was to evaluate the chronic effect of hydrogen peroxide (H2O2) generated ROS on the growth and tumorigenicty of MCF-7 breast cancer cells. MCF-7 cells were exposed to H2O2 for both acute (48 hrs) and chronic (3 months) period. Cell growth and viability were evaluated by cell count and MTT assay and were confirmed by cell cycle analysis. Expression of genes related to cell cycle, cell survival, and metastasis were measured by quantitative real-time PCR. Soft agar assay was also performed to determine the effect of H2O2 on anchorage independent growth of MCF-7 cells. Results of cell count, MTT and cell cycle analysis revealed increased growth, and survival of MCF-7 cells chronically treated with H2O2. This was further confirmed at molecular level by increased expression of Cyclin D1, Survivin and Bcl2 in H2O2 treated cells. Significant increase in number of soft agar colonies in H2O2 treated cells further suggest that chronic oxidative stress causes increased tumorigenicity of MCF-7 cells. Our data also support the hypothesis that ROS in the form of pro-meta- static genes like VEGF, WNT1 & CD44 and down regulation of anti-apoptotic gene E-cadherin indicates that persistent oxidative stress may enhance metastatic potential of MCF-7 cells. In summary, this study for the first time provided direct evidence for the increased growth, tumorigenicity, and metastatic potential of breast cancer cells by chronic exposure to oxidative stress.

Effect of Melatonin on Colitis-Associated Colon Carcinogenesis in Mice: Role of Autophagy and Nrf2 Signaling Pathways

P. P. Trivedi and G. Jena. Pharmacology and Toxicology, National Institute of Pharmaceutical Education and Research, Mumbai, Punjab, India.

Ulcerative colitis, a chronic gastrointestinal disorder, gradually leads to colon carcinogenesis. Various pre-clinical and clinical studies have shown that melatonin has beneficial effects in cancer. However, elucidation of the detailed molecular
mechanisms involved in melatonin-mediated protection against colon carcinogenesis deserves further investigation. The present study was aimed at deciphering the effect of melatonin on autophagy and Nrf2 signaling pathways in a mouse model of colitis-associated colon carcinogenesis (CACC). For the induction of CACC, male Swiss Albino mice were administered a single i.p. injection of 20mg 1, 2-dimethylhydrazine dihydrochloride (DMH)/kg bw, followed by 3 cycles of 3% w/v dextran sulfate sodium (DSS) (one cycle consisted of 7 days of DSS-treated water followed by 14 days of normal drinking water) 1 week after DMH injection. One week after the initiation of DSS administration, melatonin was administered at the dose of 1, 2 and 5mg/kg bw, and mice were sacrificed at 10 and 20 weeks after DMH treatment respectively. Melatonin treatment decreased the progression of colon carcinogenesis, inflammation, oxidative stress and DNA damage in the colon of mice with CACC. Further, CACC in mice led to an increased autophagy in the colon as revealed by the expression of various autophagy markers such as Beclin-1, LC3B-II/LC3B-I and p62. Decreased p62 expression in the colon of mice with CACC was associated with increased nuclear level of STAT-3 (NF-E2-related factor 2 (Nrf2)) expression. Melatonin treatment reduced autophagy and increased the expression of Nrf2 and the associated antioxidant enzymes, NAD(P)H:quinone oxidoreductase (NQO-1) and heme oxygenase-1 (HO-1) in the colon of mice with CACC. The results of the present study demonstrated that melatonin attenuated the progression of CACC in mice by modulating autophagy and Nrf2 signaling pathways.

1098 Novel Role of STAT3 in Anoikis Resistance and Tumor Cell Metastasis

N. M. Fofaria and S. R. Srivastava, Biomedical Sciences and Cancer Biology Center, Texas Tech University Health Sciences Center, Amarillo, TX.

Anoikis is an anchorage independent cell death. Resistance to anoikis is one of the key features of metastatic cells. The role of STAT-3 in anoikis resistance in various melanoma, pancreatic, breast, ovarian, lung and colon cancer cells was analyzed in the current study. Marked anoikis was induced in cells that were grown under anchorage-independent conditions. Cells that resisted anoikis were observed to have a higher rate of migration and invasion as compared to the cells grown under anchorage dependent conditions, as observed by cell migration and invasion assays. The anoikis resistant cells also had significantly higher expression and phosphorylation of STAT-3 at Tyr 705 than the cells that were attached to the basement membrane. Treatment of these cells with IL-6, a cytokine which phosphorylates STAT-3, prevented the induction of anoikis. STAT-3 inhibitors AG490 and pipartine induced anoikis in a concentration-dependent manner in anoikis resistant cells, whereas IL-6 blocked anoikis. Over-expression of STAT-3 by transfection, not only increased the anoikis resistance, but also protected the cancer cells from piperazine-induced anoikis, confirming the role of STAT-3 in anoikis resistance. On the other hand, silencing STAT-3 decreased the potential of cancer cells to resist anoikis. Furthermore, STAT-3 (-/-) cancer cells were more sensitive to anoikis, as compared to cells overexpressing STAT-3 (+/+). The STAT-3 (+/+ cells also had enhanced migration potential, as compared to STAT-3 (-/-) cells. STAT-3 -/-cells and pipartine treated cells completely failed to form tumors in SCID-NSG mice, as compared to untreated anchorage independent cells. Similarly, pipartine treated or STAT-3 -/- cells failed to metastasize to lungs and liver, as compared to untreated anchorage independent cells which extensively metastasized. The metastasis was confirmed by H & E staining as well as bioluminescence. In summary, our results establish STAT-3 as a critical player that renders anoikis resistance to the cancer cells and enhance their metastasis potential.

1099 Toxicokinetic Mode-of-Action (MOA) Investigation of Liver Tumors Induced by Chronic Oral Exposure to Biphenyl in Female BDF1 Mice

Biphenyl (BP) is a high production volume chemical used in USA and EU in closed system applications as a synthesis intermediate and component of heat transfer fluids. The rich toxicological dataset, with a number of cancer bioassays, notes two cases of neoplastic effects from high-dose BP exposures that are specie and strain specific. MOA investigations have demonstrated that urinary bladder tumors seen in male F344 rats occur from calculi development at specific pH and potassium concentrations, conditions that are not relevant for humans. Recently, Umeda et al. (2005) demonstrated increased tumor incidence from high-dose dietary BP exposures in female BDF1 mice, while in males, decreased tumor incidence occurred with increasing doses. Different carcinogenic outcomes have been proposed but there is no clear understanding of the underlying MOA for these liver tumors or their relevance to humans. In order to better understand this cancer MOA, absorption, metabolism and elimination of 14C-BP in BDF1 mice following 900 mg/kg gavage dosing was evaluated. Absorption, metabolism and BP metabolite profiles were comparable between sexes. BP is rapidly absorbed and excreted primarily via urine. The majority of radioactivity was eliminated within 24 hrs post-dosing. No bioaccumulation was observed after 168 hrs post-dosing in either sex. BP was mainly metabolized by hydroxylation, followed by methylation, and conjugation with sulfate and glucuronide, resulting in 26 identified metabolites. However, systemic exposure to BP and metabolites was substantially higher in females, as evidenced by slower terminal blood elimination half-life of 671 hrs vs. 99 hrs for males, and 2-fold higher blood AUC in females than in males. Thus in females, the cellular uptake and metabolism of BP is different compared to males. These results are consistent with Umeda et al. (2005) findings and point to differences in sex-specific systemic exposures at high BP doses underlying sex-specific liver tumor findings in BDF1 mice. Sponsored by the Biphenyl Work Group of SOCMA.

1100 Mice with a Heterozygous Deletion of S-Nitrosoglutathione Reductase (GSNOR/ADH5) Display Normal O6-alkylguanine-DNA Alkyltransferase Levels and Are Protected from DEN-Induced Hepatocarcinogenesis

Recently, studies have demonstrated that total genetic deletion of S-nitrosoglutathione reductase (GSNOR) in mice (GSNOR-/-) leads to a higher incidence of hepatocellular carcinoma (HCC), possibly through uncontrolled INO-induced nitrosation and subsequent proteosomal degradation of O6-alkylguanine-DNA alkyltransferase (AGT). Mice deficient in AGT show increased susceptibility to hepatocarcinogenesis induced by DEN as compared to WT mice. The objectives of these studies were to investigate whether mice with a heterozygous deletion of GSNOR/ADH5 (GSNOR+/-) were protected from tert-butyl hydroperoxide (TBHP) and DEN-induced apoptosis of AGT and subsequent hepatocarcinogenesis following treatment with diethylnitrosamine (DEN) as compared to mice containing a complete genetic deletion of GSNOR (GSNOR-/-) or wild type (WT) control mice. Additionally, we investigated INOS expression in embryonic fibroblasts of WT and GSNOR+/-- mouse and liver cancer cDNA arrays for ADH expression. GSNOR+/-- mice were given a single IP injection of DEN and later sacrificed to study AGT protein expression and tumor development in the liver. In the DEN-treated GSNOR+/-- mice, AGT levels were equivalent to levels seen in WT control animals and with no increased incidence of hepatocellular tumors. Mechanistically, INOS expression appeared to be critical to the development of HCC, rather than GSNOR expression. We also observed that multiple ADH genes, which reside at the same chromosomal locus as GSNOR (4q23), were depleted in HCC patients, and the reduction in expression level correlated with more advanced tumors. The findings indicate that, in contrast to complete genetic deletion of GSNOR, GSNOR+/-- mice express normal AGT activity and DEN treatment did not increase the incidence of HCC. Lastly, ADH profiling of the liver cancer cDNA arrays demonstrated broad effects on the ADH genes, rather than a GSNOR-specific effect, correlating with the advancement of the tumors.

1101 Histone Acetylation Alterations and Monomethylarsonous Acid (MMAIII)-Induced Cell Malignant Transformation

X. Ren1, 2, Y. Ge1, Z. Gong1, H. Zhang1 and L. R. Olson1, 1University at Buffalo, Buffalo, NY and 2Pharmacology and Toxicology, University at Buffalo, Buffalo, NY.

Chronic arsenic exposure is known to be associated with increased morbidity and mortality from both cancerous and non-cancerous effects. Inorganic arsenic (iAs) and its high toxic metabolite, monomethylarsonous acid (MMAIII), is capable of inducing malignant transformation in human cells, and population-based studies have shown that an increase in the percentage of urinary and blood arsenic present inducing malignant transformation in human cells, and population-based studies have shown that an increase in the percentage of urinary and blood arsenic present...
the MMAIII-mediated up-regulation of the expression and activities of HDACs, leading to increase histone acetylation and prevention of MMAIII-induced malignant transformation. These new findings suggest that histone acetylation dysregulation may be a key mechanism in MMAIII-induced malignant transformation and carcinogenesis, and that HDAC inhibitors could be targeted to prevent or treat arsenic-related cancers.

---

**1104 Transcriptionomics to Elucidate Oxidative Stress Mechanisms Involved in Genotoxic and Nongenotoxic Liver Carcinogenesis**

Genotoxic (GTX) and non-genotoxic (NGTX) carcinogens are known to induce multiple molecular changes and cellular damage in causing liver toxicity and/or carcinogenesis. Currently, the specific mechanisms for these different classes of compounds that induce hepatocarcinogenesis are still unknown but oxidative stress seems to be important. Therefore, a better understanding of cellular changes induced by compounds from these different classes in relation to oxidative stress is needed.

We selected 3 oxidative stress-inducing compounds (Azathioprine (AZA), Tetradecanoyl phorbol acetate (TPA), Dithiazin (DZN)) and 3 non-oxidative stress related compounds (Furan (Fu), Tetrachloroethylene (TCE) and D-mannitol (Dman)). In a human hepatoma cell line (HePG2), whole genome gene expression was measured, analyzed and correlated to (oxidative) DNA damage and cell cycle changes at 5 different time points (4, 8, 24, 48 and 72h) after exposure to these compounds.

ROS formation and (oxidative) DNA damage and cell cycle arrest was confirmed after AZA, TPA and DZN treatment and appeared to be related to a 10-fold higher number of gene expression changes over time compared to Fu, TCE or Dman treatment, indicating that this is due to cellular oxidative stress. Different genes and pathways were found for oxidative stress. However, a higher number of gene expression changes overlapped between AZA, TPA and DZN being especially involved in oxidative stress, DNA damage and immune responses. Genes such as Nrf2, GCLC, HMOX1 and GSR were significantly upregulated. This was not observed after Fu, TCE or Dman treatment, thus indicating that carcinogenic processes are not solely caused by oxidative stress. However, cellular oxidative stress has a high impact on cellular changes such as DNA damage gene expression and cell cycle distribution, and for certain compounds, may represent the underlying cause for increasing the risk of liver toxicity and even carcinogenesis.

**1105 Functional Role of Long-Noncoding RNAs in Rhabdomyosarcoma Cells and Tumors**

G. Chadalapaka1, J. D. Jutooru1 and S. H. Safe1, 2, 1VTPP, Texas A&M University, College Station, TX and 2Institute of Biosciences and Technology, Texas A&M Health Science Centre, Houston, TX.

Long noncoding RNAs (lncRNAs) >200 bp in length are now emerging as critical factors in tumor biology. Reports suggest that dysregulated lncRNA expression in cancer correlates with disease progression and may serve as an independent predictor for patient outcomes. Little is known about the lncRNA regulation in rhabdomyosarcoma (RMS), a disease which is prevalent in children as the most common soft-tissue sarcoma and accounts for approximately 50% of soft-tissue sarcomas. Regulation of lncRNAs is not well defined and development of drugs that target oncogenic lncRNAs has not been reported. HOXA transcript at the distal tip (HOTTIP) is a 3,764 bp lincRNA located -330 bases upstream of HOX A13 and Metastasis-associated lung adenocarcinoma transcript 1 (MALAT1) are two lncRNAs highly expressed in RH30 and RD RMS cell lines and the function of the lncRNAs was investigated by RNA interference (RNAi). Knockdown of MALAT-1 in RH30 and RD cells resulted in a 57% and 60% decrease in cell proliferation respectively and we also observed a  60% decrease in cell migration in a Boyden chamber assay. We also observed that MALAT-1 silencing increased markers of apoptosis (PARP cleavage) in RMS cells and these were consistent with a pro-oncogenic function for MALAT-1 in RMS and similar results were reported in other solid tumors. In contrast, the function of HOTTIP has not previously been reported in cancer cells and our results show that like MALAT-1, knockdown of HOTTIP by RNAi also decreases cell proliferation and migration and induces apoptosis. Current studies are focused on the overlapping and independent regulation of genes by MALAT-1 and HOTTIP and development of agents that target these pro-oncogenic lncRNAs.

---

**1106 HOXA Transcript at the Distal Tip (HOTTIP) is a Pro-Oncogenic Long-Noncoding RNA in Pancreatic Cancer**

Y. Cheng1, J. D. Jutooru2, G. Chadalapaka2 and S. H. Safe1, 2, 1Institute of Biosciences and Technology, Texas A&M Health Science Centre, Houston, TX and 2VTPP, Texas A&M University, College Station, TX.

Recent studies demonstrate that non-coding RNAs (ncRNAs) are differentially expressed and play an important role in gene regulation and influence normal and cancer cell phenotypes, and this is true, in part, to association with chromatin-mod-
ifing complexes. HOXA transcript at the distal tip (HOTTIP) is a 3,764 bp lin-
cRNA transcribed from 5’tip of HoxA gene cluster and is expressed in anatomically distant cells. Previous studies in our laboratory showed that HOTTAIR is a negative prognostic marker in pancreatic cancer and HOTAIR cooperatively represses gene expression with complexes such as Polycomb Repressive Complex 2 (PRC2). It has been reported that HOTTIP interacts with MLL-1 complexes by specifically bind-
ing the WDR5 adapter protein leading to a loss of H3K4me3 across the HoxA locus. In this study, we investigated the functional role of HOTTIP in Panc1 and L3.6pl pancreatic cancer cell lines. Knockdown of HOTTIP by RNA interference resulted in decreased expression of 514 & 575 genes respectively in Panc1 cells. RT-PCR confirmed that HOTTIP regulated expression of several pro-oncogenic factors includ-
ing Aurora kinase A (AURKA), AHI1, CD44. Knockdown of MLL-1 also decrease AURKA expression, however regulation of AURKA by HOTTIP/MLL-1 was WDR5-independent. Further analysis of array data suggests a less prominent role for HOTTIP, MLL1/WDR5 interactions in pancreatic cancer cells compared to non-tumor cells (fibroblasts). Functional interactions of HOTTIP with other chromatin-modifying complexes are currently being investigated.

PS 1107 Determination of Artifacts, the Steady State, and Half-Life of N2-Hydroxymethyl-4G Adducts In Vitro, and in a 28-Day 13CD2-Formaldehyde Inhalation Exposure Study
B. Yu1, B. C. Moeller2, M. Doyle-Eising3, D. Kracke1, W. Bodnar1, T. B. Stare1 and J. A. Swenberg1. 1ESE, University of North Carolina at Chapel Hill, Chapel Hill, NC, 2LRRI, Albuquerque, NM and 3TBS Associates, Raleigh, NC.

Rationale: N2-HOMe-dG is the main formaldehyde-induced DNA mono-adduct, which plays important roles in mutagenesis and carcinogenesis. The purpose of this study is to provide the distribution pattern of exogenous DNA adducts, and further tell whether or not inhaled formaldehyde can reach tissues distant to sites of initial contact. We have also undertaken studies related to artifact formation during DNA isolation and processing.

Methodology: DNA was isolated, reduced, digested, and injected onto an Agilent HPLC-UV for adduct fractionation. DNA adducts were quantitated using nano-
LC-MS-MS (with a limit of detection of 1.25 attomolar).

Results: Artifacts formation was less than 0.56% and 0.46% of the average amounts of endogenous adducts in all tissues (n=205) from sodium phosphate buffer and NucleoBond DNA isolation kit, respectively. Exogenous adducts were only de-
tected in rat nasal respiratory epithelium, the amounts of which were 3- to 8-fold lower than the average amounts of endogenous adducts. Additionally, inhaled exo-
genous adducts were found to accumulate, with the time to steady-state concen-
trations being 28 days. The unstable exogenous adducts were found to follow a bi-Exponential decay model, and the half-life was determined to be 5.2 days. The unstable exogenous adducts were also found to follow a biophilic decay model in isolated calf thymus DNA in vitro.

Conclusions: Our study showed that inhaled formaldehyde only reached rat nasal respiratory epithelium. For the first time, this study has elucidated accumulation of exogenous adducts, the time to reach steady state, and the half-life for the repair/loss of exogenous adducts in vivo. Overall, the data generated in this study provide pivotal information to understand the toxicity and carcinogenicity of formalde-
hyde, as well as the biological plausibility of leukemia induction following inhala-
tion exposure of formaldehyde.

PS 1108 Ablation of the bZIP Transcription Factor, CCAAT Enhancer Binding Protein-β (CEBPβ), in Skin Protects Mice from Skin Cancer Induced by Ultraviolet B Radiation
H. W. Tam, S. Zhu and R. C. Smartt. Department of Biological Sciences, Toxicology Program, NC State University, Raleigh, NC.

Nonmelanoma skin cancer (NMSC) is the most common cancer in the United States. Each year there are more cases of NMSC than all cases of breast, prostate, lung and colon cancers combined. The majority of NMSCs is caused by solar UVB radiation which causes DNA damage. Sunlight is a ubiquitous environmental carcinogen and p53 plays a key role in the response of skin keratinocytes to UVB-induced DNA damage by causing cell cycle arrest and apoptosis. We observed that C/EβPβ is abundantly expressed in epidermis and that C/EβPβ protein levels are induced by UVB radiation in mouse and human keratinocytes in culture as well as in mouse epidermis in vivo. Activation of C/EβPβ often involves phosphorylation at threonine 188 (T188) and UVB treatment increased the phosphorylation of C/EβPβ at T188. In order to understand the function of C/EβPβ in UVB-induced responses in epidermis and in skin cancer, we developed a C/EβPβ deficient (C/EβPβ−/−) SKH-1 hairless mouse model. SKH-1 hairless mice are an established experimental model relevant to UVB-induced human skin cancer. Treatment of C/EβPβ−/− mice with UVB resulted in increased apoptotic cell death in epidermal ke-
ratinocytes when compared to similarly treated control mice. C/EβPβ−/− mice were highly resistant to UVB-induced skin cancer. In order to determine whether the resistance of C/EβPβ−/− mice to UVB-induced skin cancer is due to an intrinsic ke-
ratinocyte effect, we developed an epidermal specific C/EβPβ conditional knock-
out (C/EβPβ ERE−/−) mouse. The keratin 5 promoter directs Cre recombinase expression to the epidermis to delete floxed C/EβPβ alleles. C/EβPβ−/− mice were highly resistant to UVB-induced skin cancer and displayed increased levels of UVB-induced apoptosis. These studies indicate that C/EβPβ is induced and activated by UVB and has critical role in the development of UVB-induced skin cancer where it suppresses UVB-induced apoptosis and in doing so may allow the survival of keratinocytes with DNA damage and mutations.

PS 1109 Western Diet Accelerates Benzo[a]pyrene [B(a)P]-Induced Colon Tumorigenesis in the PIRC Rat Model
K. Harris1, S. R. Pulliam1, M. S. Niaz1, M. K. Washington2, S. E. Adunyah1 and A. Ramesh1. 1Biochemistry & Cancer Biology, Meharry Medical College, Nashville, TN and 2Pathology, Vanderbilt University Medical Center, Nashville, TN.

Colorectal cancer ranks third in terms of mortalities in the United States. Consumption of Western Diet (WD; rich in red meat and fats), contaminated with polycyclic aromatic hydrocarbons (PAHs) has been implicated as one of the causative agents for sporadic colon cancer. Therefore, the aim of this study was to investigate whether the cancer burden was amplified by WD when exposed to benzo(a)pyrene [B(a)P], a PAH compound. To test this concept, we have used an adult male transgenic rat model, the Polyposis In the Rat Colon (PIRC) kindred type. Treatment consisted of 25, 50 and 100 μg B(a)P/kg bw dissolved in tricaprylin, administered to rats daily via oral gavage for 60 days. One group of B(a)P-treated rats were fed with AIN-76A regular diet (RD) and the other group with WD throughout the study. Rats that received the diets alone, but no B(a)P served as controls. Food consumption and body weight were peri-
diodically monitored. Subsequent to exposure, rats were sacrificed; colons, and other tissues were retrieved and preserved in 10% formalin for observation of gross pathological changes. Blood samples were collected and concentrations of choles-
sterol, triglycerides, and adiponectin were measured. There was no change in food consumption, but body weight loss of WD group compared to RD group and controls (p < 0.005) was noticed. An increased incidence of adenomas and high grade dysplasia were encountered in rats that were fed with WD compared to RD and controls (p < 0.05). The colon tumor numbers showed a B(a)P dose-response relationship. Rats that received B(a)P + WD showed increased levels of cholesterol and triglycerides in comparison to rats that received B(a)P + RD and also controls. Levels of adiponectin did not vary much between B(a)P + WD, and B(a)P + RD groups. Our results showed that WD accelerates the development of colon tumors induced by B(a)P through proinflammatory action, characterized by gain in tumor number and sizes, and body weight loss.

PS 1110 Nuclear Receptor-Mediated Effects of the Mammary Carcinogens Benzo[a]pyrene and PhIP in MCF-7 and MDA-
MB-231 Cancer Cell Lines

Breast cancer is the most commonly diagnosed malignancy in females. Its aetiology is multifactorial, and the role of environmental exposure to DNA damaging chem-
icals has been widely investigated. Benzo[a]pyrene (B(a)P) and 2-Amino-1-methyl-6-
phenylimidazo[4,5-b]pyridine (PhIP) are mammary carcinogens in rodents. Both compounds require cytochrome P450 (CYP) mediated metabolic activation to DNA damaging species, and both induce transcriptional responses through the nuclear receptors ARYL hydrocarbon receptor (AhR) and estrogen receptor α (ERα). The objective of this research was to investigate the molecular toxicology of B(a)P and PhIP in ERα positive (MCF-7) and ER- negative (MDA-MB-231) cancer cell lines. MCF-7 and MDA-MB-231 cells were incubated with various concentrations of BaP and PhIP for up to 96 hrs. Genotoxicity, drug metabolism activity, CYP expression, proliferation and cell migration were examined. BaP showed a dose-de-
pendent increase in micronuclei (MN) formation in both cell lines, while PhIP expressed only in MCF-7 cells. Ethoxyresorufin-O-deethylase (EROD; CYP1A)
activity and CYP1A1 and 1A2 expression was induced in both cell lines by BaP, but PhIP only induced CYP1A2 mRNA in MCF-7 cells. Cell proliferation and migration was induced in both cell lines by BaP, but only in MCF-7 cells by PhIP.
These data demonstrate the ability of BaP and PhIP to induce DNA damage and receptor-mediated effects in mammary cells. Furthermore, the differential effect of PhIP in the two cell lines supports the role of ERβ in the toxicity of PhIP.

**1110a** Estrogen Receptor Alpha Modulation and Differential Cytotoxicity of Caffeic Acid Phenethyl Ester in Prostate Cancer Cells

M. F. Tolla1, 2, S. S. Azab1, A. E. Khalifa1, S. Abdel-Brahman2 and A. B. Abdel-Naim1. 1Department of Pharmacology and Toxicology, Faculty of Pharmacy, Ain Shams University, Cairo, Egypt and 2University of Texas Medical Branch, Galveston, TX.

Caffeic acid phenethyl ester (CAPE) is a promising natural component of propolis that possesses selective estrogen receptor modulatory (SERM) activity. The class of compounds known as SERMs are promising therapeutic agents for patients with castration-resistant prostate cancer (PC). However, the potential SERM activity of CAPE in PC has not been evaluated before. In this investigation we test the hypothesis that, in PC cells (PC-3, DU-145, LNCaP), the differential cytotoxicity of CAPE is dependent on the cells’ estrogen receptor (ER) status. To test our hypothesis, we assessed CAPE cytotoxicity in the androgen dependent cell line LNCaP and the androgen-independent cell lines PC-3 and DU-145 using sulforhodamine B (SRB) assay. CAPE exhibited greater cytotoxicity in PC-3 compared to DU-145 and LNCaP and was least potent in nontransformed prostate epithelial cell line BPH1. Western blot analysis for ERα in the 3 cell lines confirmed that only PC-3 expresses this ER subtype. Furthermore, we evaluated the impact of CAPE on AKT1/2/3 (Ser473) as well as ERK1/2 (Thr202/Tyr204, Thr185/Tyr187) activation in the tested PC cells since Akt and ERK pathways are crucial for PC tumor aggressiveness and progression and due to their known cross-talk with ERα. Our data indicate that CAPE significantly reduced both Akt and ERK activation in PC-3 cells while it only reduced the activation of Akt in LNCaP and ERK in DU-145 cells. Our study shows, for the first time, that CAPE-induced inhibition of Akt activation is more pronounced (1.7 folds higher) in cells expressing ERα such as PC-3 cells compared to LNCaP. CAPE treatment reduced ERα phosphorylation at Ser-167, which is known to be related to Akt activation, further supporting the evidenced reduction in Akt activation by CAPE in this specific cell line. These data indicate that the cytotoxic effects of CAPE in prostate cancer are partly mediated by ERα modulation.

**1110b** Cholorogenic Acid Rich Plum Juice Inhibited AOM Treated Colorectal Aberrant Crypt Foci (Acf): Potential Role of miR145/3/MTOR Pathway

N. Banerjee1, 2, H. Kim1, 2, M. Nemeč1 and S. Talcott1, 2. 1Toxicology, Texas A&M University, College Station, TX and 2Nutrition and Food Science, Texas A&M University, College Station, TX.

The antitumorigenic and cytotoxic activities of polyphenols, caffeic acid and neo-caffeic acid in plum juice (PL) have been previously studied in various cancer models. Our preliminary result exhibited anti-inflammatory property of PL which decreased the expression of VCAM-1 and the activation of PI3K/AKT, and was least potent in nontransformed prostate epithelial cell line BPH1. Hence, we hypothesized that the cytotoxic effects of CAPE in prostate cancer are partly mediated by ERα modulation. Consumption of PL juice suppressed the number of high multiplicity aberrant crypt foci (HMACF>4 ACF) by 47.98% (P<0.05) and significantly lowered proliferation of mucosa cells. The results were accomplished by a downregulation of nuclear factor kappa B (NF-kB), inducible nitric oxide synthase (iNOS), cyclooxygenase-2 (COX-2), vascular adhesion molecule-1 (VCAM-1) and mRNA and protein. PL also inhibited phosphorylation of PI3K/AKT, and mTOR/PHF1-tel pathways. PL increased the expression of miR143 expression. In summary, PL suppressed number of HMACF formation, colon tumorigenesis where microRNA-143-regulated pathways significantly contributed in the underlying cytotoxicity mechanisms.

**1110c** ARNT Isolforms Differentially Regulate Cancer Cell Growth through a p53-Dependent Mechanism

K. Gardella1, 2, J. I. Muro2, 3, G. Fang2, 3, K. Sarkar1, 2, 3 and C. Wright1, 2, 3. 1The Institute for Cellular and Molecular Biology, The University of Texas at Austin, Austin, TX, 2Division of Pharmacology and Toxicology, College of Pharmacy, The University of Texas at Austin, Austin, TX and 3Center for Molecular and Cellular Toxicology, The University of Texas at Austin, Austin, TX.

In addition to its roles in endocytic and hypoxic responses, we have shown that the arylhydrocarbon receptor nuclear translocator (ARNT) is an integral cofactor of NF-kappaB signaling. However, these initial observations of ARNT-mediated NF-kappaB modulation were based on simultaneous suppression of the two ARNT isoforms, isoform 1 and 3, and therefore precluded the isolated examination of each isoform’s function. We show here that lymphoid malignancies exhibit a shift to higher levels of ARNT isoform 1, compared to normal lymphocytes that harbor equal levels of isoform 1 and 3. The increase in ARNT isoform 1 is necessary for the growth of these cancer cells as suppression of isoform 1 resulted in S-phase cell cycle arrest. Interestingly, NF-kappaB signaling was unaffected by suppression of isoform 1. However, co-suppression of p53 with ARNT isoform 1 rescued the arrest phenotype, suggesting that the observed cell cycle arrest was dependent on p53 activity in the absence of isoform 1. Furthermore, suppression of isoform 1 sensitized cells to low levels of doxorubicin, an effect that was also rescued by suppressing p53. These findings reveal that ARNT isoform 1 potentiates cell growth by antagonizing a p53 cell cycle inhibitory mechanism and suggests that ARNT targeted therapies would benefit chemotherapy regimens.

**1110d** Ligand-Dependent Activation of EGFR Mediates Malignant Cell Transformation Induced by Chronic Exposure to Hexavalent Chromium

Hexavalent chromium (Cr (VI)) compounds are well-established lung carcinogens. The carcinogenic mechanisms of Cr (VI) are currently under investigation. Epidermal growth factor receptor (EGFR) is a tyrosine kinase transmembrane receptor that regulates cell survival, cell cycle progression, tumor invasion, and angiogenesis. The present study investigates the role of EGFR in Cr(VI)-induced cell transformation and tumorigenesis. Our results show that chronic exposure of human bronchial epithelial (BEAS-2B) cells to Cr (VI) caused malignant cell transformation. The Cr (VI)-transformed cells exhibited apoptosis resistance with reduced expressions of cleaved Poly ADP ribose polymerase (C-PARP) and Bax and enhanced expressions of Bcl-2 and Bcl-xL. Reduced capacity of generating reactive oxygen species (ROS) along with elevated expression of antioxidant manganese superoxide dismutase (SOD2) was also found in Cr (VI)-transformed cells. Phosphorylation of EGFR was dramatically increased in both Cr (VI)-transformed BEAS-2B cells and lung tissue of animals exposed to Cr(VI) particles. Expression of amphiregulin (AR), a EGFR ligand, was elevated in Cr (VI)-transformed cells. Knockdown of EGFR or AK or increased ROS generation, resulting in elevated expressions of C-PARP and Bax and reduced expression of Bcl-2, leading to reduced apoptosis resistance in Cr (VI)-transformed cells. PI3K and AKT, downstream targets of EGFR, were also activated in Cr (VI)-transformed cells. Treatment the Cr (VI)-transformed cells with LY492002 and wortmannin, inhibitors of PI3K, caused ROS generation, resulting in increased Bax expression and reduced Bcl-2 expression, leading to increase of apoptosis. Most importantly, the results from xenograft mouse tumor study showed that knockdown of EGFR reduced both the size and frequency of tumor compared to Cr (VI)-transformed cells. In summary, the present study indicates that ligand-dependent activation of EGFR plays an important role in Cr (VI)-induced malignant cell transformation and tumorigenesis.

**1110e** The Effects of Quercetin on the Placental Transport of the Dietary Carcinogen 2-Amino-1-methyl-6-phenylimidazo(4, 5-b)pyridine

The heterocyclic amine 2-amino-1-methyl-6-phenylimidazo(4,5-b)pyridine (PhIP) is a dietary carcinogen formed from cooking meats at high temperatures. PhIP readily passes through the intestinal barrier, as well as the placental barrier, increasing bioavailability and potentially exposing a developing fetus to harmful substances. Recent evidence has shown that certain flavonoids increase PhIP intestinal barrier crossing in vivo, and increases bioavailability in vivo, although it is unclear if this is also the case with the placental barrier. The current study aimed to determine the extent at which PhIP crosses the placental barrier using BeWo cells as a model, and determine if flavonoids can influence the rate of transport across
the barrier. BeWo cells were first cultured in transwell plates and dosed with 0, 1, 5, 10, or 100μM PhIP, and the barrier penetration was quantified at 0, 30, 60, 120 and 240 min after dosing. The amount of PhIP crossing over time was concentration-dependent, which is similar to Caco2 cells. However, when the BeWo cells were incubated with 2 or 20μM quercetin prior to a dose of 10μM PhIP, there were no observable changes in the rate or amount of PhIP penetration. This is in contrast with the Caco2 cell culture models, suggesting a different transport mechanism between the cell types. This work was performed under the auspices of the U.S. Department of Energy at Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

Formaldehyde (FA) inhalation is linked to nasopharyngeal and sino-nasal cancer and myeloid leukemia in humans. While there is a strong mechanistic basis behind FA inhalation and causation of nasal cancer in humans, the mechanism linking FA and leukemia is unclear. Cell proliferation and DNA adducts in the nasal cavity are recognized as key mechanistic events in the induction of nasal cancer. Inhaled FA does not induce formation of detectable levels of DNA adducts at sites other than the nasal cavity; however, FA may cause leukemia by another mechanism. It was hypothesized that inhaled FA could cause significant genetic damage to stem cells in the nasal epithelium or circulating in local blood vessels. These damaged stem cells could reach the general circulation, seek out tissue sites that support the hematopoietic niche, undergo lodgment and become leukemic stem cells. We tested this hypothesis by exposing groups of 25 male C3B6.129F1-Trp53tm1Brd mice to 0, 7.5 or 15 ppm FA 6h/d, 5d/w for 8w and then holding mice without further exposure until 50 weeks old. At necropsy, blood was collected for hematological and histological evaluation. The primary exposure-related finding was minimal hematopoietic niche involvement, which was disregarded as being not related to FA inhalation. There was no evidence of leukemia in FA exposed mice based on hematology.

At necropsy, blood was collected for hematological and histological evaluation. There were mice in all groups (10/75), including control, that died early or were euthanized in moribund condition. Moribund mice had reduced body weights and most had visible tissue masses. There was no evidence of leukemia in FA exposed mice based on hematology. No cataracts, lung, liver, spleen, thymus, lymph nodes, kidney, and gross lesions were evaluated microscopically. The primary exposure-related finding was minimal to mild squamous metaplasia of the respiratory epithelium of the nose. The incidence of this lesion increased with exposure concentration: 0/21, control, 14/21, 7.5 ppm, 21/22, 15 ppm. No cases of leukemia or lymphohematopoietic neoplasia were seen. Under the conditions of this study, FA inhalation did not cause leukemia in these genetically predisposed mice.

pluripotent stem cells (iPSCs) has made the development of assays measuring cardiac myocyte contractility possible. One such system, the xCELLigence RTCA Cardio (Acea Biosciences), uses electrical impedance to measure the amount of cell to surface contact in an electrode containing tissue culture plate. We used the RTCA system to measure the effect of known proarrhythmic compounds on the contractility of iCell cardiomyocytes (Cellular Dynamics Inc.). Endpoints measured for 24 hours in cardiomyocytes included beat rate, amplitude, and beat rate irregularity. Compounds known to cause cardiotoxicity through a variety of mechanisms, including hERG channel blockers, Ca2+ channel blockers, multichannel blockers, inhibitors of myosin II, and beta blockers were used as a validation set. This ruled out data on these compounds differently affected cardiomyocyte contractility following acute exposure or longer periods of treatment. For example, aconitine, which binds to sodium channels, caused an immediate increase in beating rate while pentamidine, which affects hERG trafficking to the membrane, affected beating rate only several hours following exposure. Blebbistatin, which interacts with myosin, caused a dose dependent delay in contraction, but did not affect beat rate or conduction which was completely inhibited. hERG inhibitors including capsiate and terfenadine affected beat rate and caused irregular beats. The xCELLigence system detected the effects of diverse compounds on cardiomyocyte contractility, and may be useful for the prediction of cardio toxicity.

1114 A Novel Model for Proarrhythmic Assessment in iCell Cardiomyocyte Using a Multielectrode Extracellular Recording System

Prolongation of the cardiac action potential and the QT interval are potential causes of the ventricular tachycardia that is characteristic of torsades de pointes (Tdp). However, it has been increasingly obvious that a prolongation of the QT interval does not necessarily lead to Tdp. To bridge this dissociation, a lot of work in vitro/vivo models for proarrhythmic effects have been developed. Recently, human iPSC derived cardiomyocytes (hiPSC-CM) have become a valuable tool for safety assessment in drug discovery. Present studies examined the effects of cell density and experimental duration on iCell cardiomyocytes with MED64 system. Low-density cell plating lead to enlargement of hiPSC-CM. Gene expression analysis and pathway analysis reveal similarities between enlarged hiPSC-CM and cardiac hypertrophy. Low-density cell plating also decreased expression of the KCNQ1 gene and affected the response to Iks blockers. The concentration-response curves for Chromanol 293B and HMR1556 shifted to the right when cell densities were decreased from 30000, 15000, 7500 and 3750 cells/well. When the experimental temperature was changed from 38.5 to 35.0 °C, the corrected field potential duration (FDPc) increased from 285 to 370 msec (24 msec/°C) almost linearly. Under the condition of both low-density cell plating and low experimental temperature, E4031 caused early afterdepolarizations (EADs) more frequent than in normal temperature. In conclusion, the plating cell density (cell size) and experimental temperature are very important as the determinants of drug sensitivity and EAD induction in field potential recording experiments with hiPSC-CM.

1115 Identification of Pro-Arrhythmic Potential with Human iPS-Derived Cardiomyocytes Using a Multiwell Microelectrode Array (MEA)

Cardiotoxicity is the most common reason for attrition due to toxicity. Current in vitro cytotoxicity assays identify only the most overtly toxic compounds, while assays to measure more specific liabilities such as hERG and other ion channels may fail to detect a response which relies on a combination of endpoints or a delayed response due to expression. Toxicity determination relies heavily on the later preclinical phase animal studies which have much higher costs associated and can have species specific results which may not model human responses. Therefore, an ideal assay for predicting cardiotoxicity would involve screening earlier on a platform whose investigation can contribute to a thorough cardiac safety assessment. A beating cellular system integrating all the ion currents that contribute to the field potential (FP) allows in vitro testing of drug effects on the field potential duration (FDP) and thus prediction of the clinical QT interval’s response. Low-impedence microelectrode arrays (MEAs) enhanced sensitivity allows screening for early afterdepolarizations (EADs), the initiating mechanism of the drug-induced cardiac arrhythmia, Torsades des pointes. Short term variability of repolarization (STVrep), the correlate of electrical alternans, is an additional parameter whose investigation can contribute to a thorough cardiac safety assessment. hSC-CMs were plated on low-impedence MED-P504A MEA probes and signals were acquired using a MED64 amplifier (Alpha Med Scientific Inc., Osaka, Japan) running Mobius QT software (Witwex Inc., Tustin CA). Data were analyzed using Intelligent Waveform Service (Neural ID, Redwood City CA). A thorough panel of drugs was tested, including the torsadogenic hERG blockers sotalol and quinidine, the false positive (non-torsadogenic) hERG blocker verapamil, and the false-negative hERG blocker alftuzoxin. All drugs produced the expected qualitative and quantitative effects on the FP. Most importantly, EADs and ectopic beats were found in 50% of the hiPSC preparations treated with sotalol and 40% treated with quinidine, as well as increased STVrep. We conclude the MEA/hSC-CM platform’s capability to screen for EADs and STVrep is ideal for better predicting a drug’s proarrhythmic risk, thus enabling a more thorough cardiac safety assessment, but most importantly reducing drug attrition and development costs.

1116 Advanced Cardiotoxic Screening Using Human Stem Cell-Derived Cardiomyocytes and a Low-Impedence Microelectrode Array System for Proarrhythmic Risk Prediction

1Alpha Med Sciences, Horiba, Osaka, Japan, 2Neural ID, Redwood City, CA, 3UC Davis, Davis, CA and 4Cardiothoracic Surgery, Stanford University, Stanford, CA. Sponsor: M. Taylor.

Research on human heart tissue has been enabled thanks to advances in stem cell biology. In fact, the drug industry and regulatory agencies are considering human stem cell-derived cardiomyocytes (hSC-CMs) as a standard assay for preclinical cardiac safety screening. A beating cellular system integrating all the ion currents that contribute to the field potential (FP) allows in vitro testing of drug effects on the field potential duration (FDP) and thus prediction of the clinical QT interval’s response. Low-impedence microelectrode arrays (MEAs) enhance sensitivity allows screening for early afterdepolarizations (EADs), the initiating mechanism of the drug-induced cardiac arrhythmia, Torsades des pointes. Short term variability of repolarization (STVrep), the correlate of electrical alternans, is an additional parameter whose investigation can contribute to a thorough cardiac safety assessment. hSC-CMs were plated on low-impedence MED-P504A MEA probes and signals were acquired using a MED64 amplifier (Alpha Med Scientific Inc., Osaka, Japan) running Mobius QT software (Witwex Inc., Tustin CA). All drugs produced the expected qualitative and quantitative effects on the FP. Most importantly, EADs and ectopic beats were found in 50% of the hiPSC preparations treated with sotalol and 40% treated with quinidine, as well as increased STVrep. We conclude the MEA/hSC-CM platform’s capability to screen for EADs and STVrep is ideal for better predicting a drug’s proarrhythmic risk, thus enabling a more thorough cardiac safety assessment, but most importantly reducing drug attrition and development costs.

1117 Regulation of Superoxide and Mitochondrial Biogenesis by PGC-1α Protects against Doxorubicin-Induced Toxicity in Cardiomyocytes

S. Peng1, H. Yuan1, J. Guo1, T. Zhang1, M. Hou1, H. Peng1, J. Li2 and P. L. Carmichael2.

Objective Doxorubicin (DOX) is an efficient and widely used anthracycline antibiotic for the treatment of tumors, but severe cardiotoxicity limits its application. Superoxide has been proposed to be mainly responsible for the cardiotoxicity of DOX, which is usually associated with mitochondrial dysfunction. PPARγ coactivator 1α (PGC-1α) is a nuclear-encoded transcriptional coactivator which plays a central role in mitochondrial biogenesis. Previous studies suggested that inhibition of mitochondrial biogenesis was responsible for the pathogenesis of DOX-induced cardiomyopathy. Nevertheless, the exact roles of PGC-1α in mitochondrial biogenesis and superoxide metabolism in DOX-induced cardiotoxicity remain unexplored. The present study was conducted to understand the exact role of PGC-1α in mitochondrial biogenesis and superoxide metabolism in DOX-induced cardiotoxicity. Methods and results A human cardiac cell line, AC16, was used in the study. We treated AC16 cells with 10 different doses (0-2000 nM) of DOX for 12h. We demonstrated that low dose DOX treatment produced a low amount of superoxide in AC16 cells, which activated mitochondrial biogenesis and superoxide metabolism in DOX-induced cardiotoxicity. However, PGC-1α knockdown and superoxide scavengers inhibited mitochondrial biogenesis and superoxide metabolism, and protected against DOX-induced toxicity. Therefore, PGC-1α is a crucial player in the regulation of mitochondrial biogenesis and superoxide metabolism in DOX-induced cardiotoxicity. Objective Doxorubicin (DOX) is an efficient and widely used anthracycline antibiotic for the treatment of tumors, but severe cardiotoxicity limits its application. Superoxide has been proposed to be mainly responsible for the cardiotoxicity of DOX, which is usually associated with mitochondrial dysfunction. PPARγ coactivator 1α (PGC-1α) is a nuclear-encoded transcriptional coactivator which plays a central role in mitochondrial biogenesis. Previous studies suggested that inhibition of mitochondrial biogenesis was responsible for the pathogenesis of DOX-induced cardiomyopathy. Nevertheless, the exact roles of PGC-1α in mitochondrial biogenesis and superoxide metabolism in DOX-induced cardiotoxicity remain unexplored. The present study was conducted to understand the exact role of PGC-1α in mitochondrial biogenesis and superoxide metabolism in DOX-induced cardiotoxicity. Methods and results A human cardiac cell line, AC16, was used in the study. We treated AC16 cells with 10 different doses (0-2000 nM) of DOX for 12h. We demonstrated that low dose DOX treatment produced a low amount of superoxide in AC16 cells, which activated mitochondrial biogenesis and superoxide metabolism in DOX-induced cardiotoxicity. However, PGC-1α knockdown and superoxide scavengers inhibited mitochondrial biogenesis and superoxide metabolism, and protected against DOX-induced toxicity. Therefore, PGC-1α is a crucial player in the regulation of mitochondrial biogenesis and superoxide metabolism in DOX-induced cardiotoxicity.
Human-induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CM) share a primary cardiomyocyte-like physiology with the advantages of a cell line, e.g., large batch sizes, low batch-to-batch variation, and a convenient "read-to-use" format. We have used hiPSC cardiomyocytes from diverse cell suppliers in automated patch clamp and impedance assays and show that this approach is of great value in cardiotoxicity prediction. The label-free impedance platform, the CardioExcyte 96, allows precise impedance measurements at a time resolution of 1 ms and generates 96 recordings in parallel. The automated patch clamp device Patchliner generates up to 500 dk per day and is capable of generating pharmacological experiments, IC50 or EC50 data and action potential signals from hiPSC-CM.

Cells from main stem cell suppliers were successfully tested and data will be compared. Dose response curves or single-point screening experiments of several drugs (e.g., hERG and Cav1.2 blockers) were collected and will be presented. The presented data show how these systems can be used efficiently to predict drug-induced arrhythmia for cardiac risk assessment.

Human induced-pluripotent stem cell derived cardiomyocytes (hiPSC-CM) may be used as a powerful in vitro model for predictive cardiac safety assessment and could allow for better identification of compounds with poor arrhythmogenic liability profiles in the early drug discovery process. To enable HT arrhythmogenic testing in hiPSC-CM, we have developed the Kinetic Image Cytometer (KIC) for high throughput, automated cell-by-cell analysis of intracellular calcium transient dynamics. Calcium transients integrate the electrochemical signals of the action potential with the molecular signaling pathways that regulate contraction. Drug-induced alterations in the shape and duration of the cardiomyocyte action potential result in changes to the shape and duration of the intracellular calcium transient. Therefore, by examining calcium transient dynamics in hiPSC-CM a single assay can be used to screen for compound effects across multiple ion channel types and is also capable of detecting multi-channel effects. In the present study, we used KIC technology to assess the predictive values of hiPSC-CMs using a library of 90 compounds known to alter the activity or expression level of cardiac ion channels/ receptors resulting in changes in the cardiac action potential. Our data indicate that using hiPSC-CMs, KIC is able to detect known drug-induced changes in Ca2+ transients and therefore, may potentially predict drug-induced arrhythmogenic liabilities in early drug discovery.

Cardiovascular dysfunction is the most severe complication in patients with diabetes mellitus. Among several causes, it has been recently demonstrated that endothelial progenitor cells (EPCs), a circulating adult stem cell regenerating damaged vascular endothelium, are dysfunctional under diabetic condition resulting in impaired peripheral circulation. To elucidate the mechanisms underlying diabetes-associated cardiovascular impairment, we investigated the cellular alteration of EPCs under high glucose condition. Bone marrow-derived EPCs (BM-EPCs) were exposed to normal glucose (5.5 mM) or high glucose (30 mM)-containing medium. High glucose treated-EPCs showed decreased ability to form tubule-like networks in Matrigel compared to EPCs in normal glucose. The conversion of LC3-II from LC3-I in EPCs was significantly increased, suggesting that autophagy occurs under high glucose condition. Interestingly, increased autophagy was not accompanied with phosphorylation of mTOR, reflecting that high glucose-induced autophagy was not related with mTOR signaling pathway. Increased generation of reactive oxygen species and disruption of mitochondrial function was observed in EPCs under high glucose condition. In conclusion, we demonstrated that ROS-mediated autophagy is induced in EPCs under high glucose condition, giving a new insight into the mechanism underlying dysfunction of diabetic EPCs.
expression of the AhR, phosphorylation of p38MAPK and cPLA2 and eventual secretion of TXB functions in a feedback loop resulting in platelet priming. These findings suggest that ligand binding to the platelet AhR may play a key role in the vascular response to particulate matter. All studies were conducted under IRR 299969-3. These studies were supported by a contract with the California Air Resources Board. The statements and conclusions in this study are those of the University of California Davis and are not necessarily those of the California Air Resources Board.

1128 IL-33 Cardiovascular Safety Profile Redefined: Lessons Learned from Rat and NHP Cardiomyocytes, KO Mice, and Human GWAS Studies

T. Brabham1, W. Hu1, T. Swanson2, L. Gauthier1, J. Heyen1, T. Wisioslowki1, T. LaBranche1, M. Hemkens1, J. Jamieson1, K. Reibling2, B. Hollingshead1, L. Collie1, N. Bing1, L. Bloom1, K. Nocka1, M. Kasaian1 and M. Vogel1, 1Drug Safety Research & Development, Pfizer, Groton, CT; 2Comparative Medicine, Pfizer, Groton, CT. 3Biotherapeutics Clinical Research, Pfizer, Cambridge, MA; 4Biotherapeutics Technologies, Pfizer, Cambridge, MA; 5Immunogenicity Research Unit, Pfizer, Cambridge, MA.

IL-33 is a cytokine alarmin implicated in innate/adaptive immune responses, as well as in cardiac volume overload diseases (i.e., congestive heart failure). Some evidence suggest an IL-33-dependent decrease in cardiomyocyte hypertrophy is heart protective, rescuing the ventricles from dysfunction and fibrosis. To evaluate the role of IL-33 in normal cardiac function an IACUC approved de-risking strategy to re-define its safety profile was initiated. Methods: Cardiac structure and function were assessed in neonatal rat and adult non-human primate (NHP) cardiomyocyte hypertrophy assays. IL-33 knock out (KO) mice via echocardiography (echo) and histology; and human genome-wide association studies (GWAS) to correlate IL-33 and its receptor ST2 polymorphisms with CV disease. Results: Neonatal rat cardiomyocytes - Phenylephrine-induced cardiomyocyte hypertrophic gene expression (i.e. myosin heavy chain 7) was antagonized by rhIL-33. Adult NHP cardiomyocytes – No drug-induced cardiomyocyte hypertrophic gene expression was detected in preliminary experiments. IL-33 KO mice echo - Aged mice (-13 months): KO (n=21), heterozygote (n=32) were assessed. Baseline values were obtained from all, with 50% re-examined after a acute dobutamine-induced cardiac inotropic challenge. No heart rate, ejection fraction, or cardiac output differences were detected across any genotypes. GWAS: No strong IL-33 or ST2 association with CV disease (p<0.01). Summary: The role of IL-33 in preventing cardiomyocyte hypertrophy (rat cardiomyocytes) was confirmed. Cardiac structure and function were not adversely affected in aged KO mice. Human GWAS analyses did not support a high probability association of CV disease and IL-33.

1129 Utilization of Reverse Phase Protein Array (RPPA) Technology to Evaluate Multikinase Pathway Inhibition in Cell Lysates

D. Puppala, S. Dann and K. Leach, Pfizer Inc, Groton, CT.

Targeted inhibition of these kinases has been shown to be beneficial in treating certain kinds of cancers. Unfortunately, most of these inhibitors may be promiscuous as the ATP binding sites are similar amongst kinases. Although the underlying mechanisms are not clear the adverse effects (like cardiotoxicity) observed by these inhibitors are attributed to off target inhibitions. Hence understanding the off target activities associated with potential kinase inhibitors is critical for designing safer inhibitors. Towards this end, we tested the Reverse Phase Protein Array (RPPA) technology from Carna Biosciences. This technique detects the phosphorylation status of 180 proteins across 18 critical cell signaling pathways simultaneously. RPPA technology utilizes compound treated cell lysates and phospho specific antibodies for detection. We treated NCI-H1975 (adenocarcinoma) cells with four PKC pathway inhibitors from 2 different chemical series (A&B: Series 1; C&D: Series 2) for 60 min followed by treatment of phorbol esters for 30 min. Cell lysates were then subjected for RPPA evaluation and phosphorylation status of 180 proteins was obtained. 30 minute treatment with phorbol myristate acetate (PMA) alone exhibited a phosphorylation signal (>1.5 intensity) for 18 different proteins across 7/18 different pathways (PI3K-AKT-mTOR (7), Ras-Raf (3), Cytoskeleton (2), DNA damage (2), RTK (2), Angiogenesis (1) and p38 MAPK (1)). PMA induced phosphorylation signal for most of the kinases was altered by compound A & B whereas compounds C & D did not alter these kinases. For example, PMA induced phosphorylation of ERK1/2 and ribosomal S6 protein was inhibited by compounds A & B (>2-9 fold) whereas C and D did not alter these signals. Overall, compounds from series 1 (A & B) clustered differently than compounds from series 2 (C & D) based on similarities in their RPPA profiles. RPPA can potentially be used to differentiate compounds based on their off-target activities. These changes in signaling pathways will be further confirmed using traditional approaches like western blotting and flow cytometry.

1129a Altered Hemodynamics Play a Critical Role in Fenoldopam-Induced Mesenteric Vasculitis in the Rat

Mechanisms underlying drug-induced vascular injury (DIVI) are poorly understood, and although several drugs induce DIVI in preclinical species, the risk to humans is unknown. For example, fenoldopam is an anti-hypertensive agent that elicits drug-induced hemodynamic changes and DIVI in the rat mesentery but presents no known vascular injury response in humans. The purpose of this study was to determine whether the alterations in fenoldopam-induced hemodynamics were necessary for fenoldopam-induced DIVI. Rats were administered fenoldopam (100 mg/kg s.c.) to induce DIVI and changes in mesentery hemodynamic blood flow were measured by ultrasound. To replicate the observed in vivo response in vitro, we utilized a co-culture platform with rat primary endothelial and smooth muscle cells where the endothelium is exposed to in vivo-derived hemodynamic waveforms to restore in vivo-like vascular cell responsiveness. Exposure of endothelial cells to the fenoldopam-induced hemodynamic waveform enhanced permeability compared to vehicle dose waveform that was independent of the exposure to fenoldopam in the platform. Gene analysis revealed significant changes in the endothelial and smooth muscle cell response to fenoldopam or its drug-induced hemodynamic response alone. The most differentially regulated pathways were observed in ECs when fenoldopam and its drug-induced hemodynamic response were combined. Biological themes included vascular-related biology, inflammation, oxidative stress, cell death, and cell remodeling. In conclusion, we provide evidence that supports the hypothesis that fenoldopam-induced changes in hemodynamics play a critical role in fenoldopam-induced DIVI in the rat mesentery.

1129b De Novo Cyclin D2 Induces Cardiomyocyte Proliferation in Adult Mouse Hearts

L. Zhan, M. Soonpaa, S. Reuter and L. Field. Riley Heart Research Center, Division of Pediatric Cardiology, Indiana University School of Medicine, Indianapolis, IN.

Previous studies have shown that targeted expression of cyclin D2 under the regulation of the cardiomyocyte-restricted myosin heavy chain (MHC) promoter results in sustained cardiomyocyte cell cycle activity which was sufficient to promote regeneration following myocardial injury. Transgene expression in this model initiates prior to cardiomyocyte terminal differentiation. It thus remains to be demonstrated if de novo cyclin D2 expression in the adult myocardium would be sufficient to induce cardiomyocyte proliferation. In this study, we generated a model capable of conditional cyclin D2 expression in cardiac myocytes. The model utilizes an attenuated myosin heavy chain (atMHC) promoter to target expression of cyclin D2. The atMHC promoter is active only in the presence of VP16 trans-activator protein in the myocardium (MHC-tTA mice). In the absence of doxycycline (DC), the VP16 protein is active and drives transcription of the atMHC promoter. However, in the presence of DC, the VP16 protein is inactive. Thus, cyclin D2 expression in double transgenic animals can be turned off (by treating with DC) or turned on (no DC treatment). We have shown that in the absence of DC, atMHC-cycD2 / MHC-tTA double transgenic animals express cyclin D2 in cardiomyocytes and exhibit cardiomyocyte cell cycle activity as we have observed in our constitutive model. Furthermore, we demonstrated that cyclinD2 expression in the MHC-tTA/atMHC-cycD2 mice was blocked from embryo to 3 months old by low doses (10 mg/ml) of DC in the drinking water and reactivated after removing the DC for 10 days. Cardiomyocyte nuclear was identified by the introduction of β-galactosidase reporter gene under the control of cardiac myosin heavy chain promoter (MHC-nLAC). BrdU incorporation analyses revealed sustained cardiomyocyte DNA synthesis in the adult MHC-tTA/atMHC-cycD2/ MHC-nLAC mice. [Supported by NIH grant R01 HL109205].
The ubiquitous nature of plastics has raised concerns pertaining to continuous exposure to plastic additives and human health risks. Of particular concern is the use of endocrine-disrupting compounds (EDCs) in plastic production, including bisphenol A (BPA) and di-2(ethylhexyl)phthalate (DEHP). We previously reported the direct effects of DEHP and BPA exposure on cardiac calcium handling and electrical conduction in rodent cardiomyocytes and heart tissue. Our goal was to investigate the applicability of our previous findings to humans by examining the direct effect of EDC exposure on human stem cell-derived cardiomyocytes (hESC-CM). hESC-CM were derived from H7 embryonic stem cells, as previously described (Laflamme 2007). After 8-10 days, hESC-CM formed a confluent network that exhibited rhythmic spontaneous contractions. Cells were treated with BPA (0.1 - 100 μM) or DEHP (1 - 50 μM), loaded with 5 μM Fluo-4-AM, and then calcium transients were recorded using a Zeiss confocal imaging system. BPA treatment modified calcium handling parameters, including an increase in calcium release and calcium reuptake time, and a decrease in peak fluorescence amplitude. DEHP treatment resulted in complete cessation of contractile activity, via both spontaneous cell contractions and external pacing. We observed significant changes in calcium handling in human cells at lower EDC doses than for rodent cardiac cells. These findings illustrate key differences in cardiac models and emphasize the importance of examining the effect of EDCs on human cardiac cells of different origins (atrial, pacemaker, ventricular). Supported by NIH (K99ES023477 to NGP).

Maternal smoking is a risk factor for low birth weight and other developmental delays. We sought to determine the impact of extracts derived from e-cigarettes (e-cig) compared to standard tobacco cigarettes (3R4F) on heart development in vitro and in vivo. Human embryonic stem cells were used as a model for in vitro cardiac development and were differentiated using monolayer cardiac differentiation. Cells were exposed to purified nicotine or extracts from e-cig or tobacco cigarettes containing 1.7, 3.4, 6.8, and 13.7 μM nicotine, or vehicle control throughout differentiation. On day 14 control cells had an intrinsic beating rate of 39.5 ± 2.7 beats per minute (bpm), cardiomyocyte cell yield of 2.5x10^6 ± 4.3x10^5 cells, and cardiomyocyte purity of 83.6 ± 1.1% cTnT + cells by flow cytometry. Cells exposed to purified nicotine or e-cig extracts showed no effect on intrinsic beating rate, cardiomyocyte yield, or cardiomyocyte purity under all concentrations tested. In contrast, there was no survival of cells exposed to 13.7 μM nicotine from tobacco cigarettes. Furthermore, cells exposed to 1.7, 3.4, and 6.8 μM nicotine showed reduced intrinsic beating rate (4.5 ± 0.9 bpm), but no effect on cardiomyocyte yield or purity. Cardiomyocytes exposed to 1.7, 3.4, and 6.8 μM tobacco nicotine showed significantly increased levels of α-smooth muscle actin, consistent with cardiomyocyte immaturity. To determine if these data correlate in vivo, zebrafish embryos were raised in 3.4, 6.8, and 13.7 μM e-cig, tobacco extract or control from 0-72 hours post fertilization. Tobacco-exposed fish showed significant decrease in heart rate, survival, general development and increased incidence of heart malformation in a dose dependent manner. In contrast, e-cig exposed fish closely resembled the time-matched controls. These data suggest that nicotine alone or e-cig extracts do not have a marked impact on early heart development. However, smoke extracts generated from tobacco markedly impact cardiac development by reducing cardiac beating rates and delaying cardiomyocyte maturation.

Cytochrome P450 2J2 (CYP2J2) is the major human P450 isoform expressed in cardiac tissue. CYP2J2 is unique among other cytochrome P450 enzymes in that it is a drug metabolizing enzyme with a known endogenous function. CYP2J2 is responsible for oxidizing arachidonic acid to epoxyeicosatetraenoic acids (EETs), which are protective in maintaining cellular function in various organs. In the cardiomyocyte, EETs are electrophysiologically active and regulate L-type Ca2+, Na+ and ATP dependent K+ (KATP) channels, which are important in the repolarizing phase and control the QT-period during the cell’s electrical cycle. Therefore any reduction in EET levels due to chemical inhibition of CYP2J2 is expected to have a toxic effect on the cardiomyocyte. In this study, the inhibition of CYP2J2 by five drugs (terfenadine, grepafloxacin, cisapride, danazol and sertindole) known to cause cardio toxicity and especially QT prolongation was determined in a recombinantly expressed enzyme as well as adult human cardiomyocytes. The effect of terfenadine, on the action potential duration in freshly isolated mouse cardiomyocytes was also determined using patch clamp. Data demonstrates that at pharmacological concentrations of 0.1-1.0 μM, the above drugs efficiently inhibit CYP2J2 (by ~80%) both in recombinant enzyme and in adult cardiomyocytes. In freshly isolated mouse cardiomyocytes, terfenadine (0.2μM) increased the action potential duration (ADP90) from 52 to 70s. This increase in ADP was completely reversed following the addition of 50nM 11,12-EET. However, 11,12-EET was not able to reverse terfenadine inhibition of hERG using CHO cells (over-expressing hERG) in an IC50 shift assay. This indicates that CYP2J2 mediated EETs, play a protective role against drug induced QT-prolongation but probably through a hERG independent pathway. Consequently, it is prudent to avoid CYP2J2 inhibition, and reduction of EETs in the cardiomyocyte, when developing new chemical entities as potential therapeutic.

The tryptophan metabolites indole, indole 3-acetate and tryptamine were identified in mouse cecal extracts and fecal pellets by mass spectrometry using a triple quadrupole ion trap mass spectrometer coupled to a binary pump HPLC. Levels of indole (200-400 μM), tryptamine (10-20 μM), and indole 3-acetate (10-40 μM) were variable in both extracts. The AHR agonist and antagonist activities of these microbially-derived compounds were investigated in CaCo-2 intestinal cells as a model for understanding their potential effects on colonic tissue which is highly aryl hydrocarbon (AH)-responsive. Activation of AH-responsive genes such as CYP1A1 demonstrated that tryptamine and indole 3-acetate were AHR agonists.
agonists, whereas indole was an AHR antagonist in CaCo2 and breast cancer cells. Moreover, chromatin immunoprecipitation (ChIP) assays showed that indole inhibited TCDD-induced binding of the AHR complex to dioxin response elements on the CYP1A1 promoter. These results demonstrate that the tryptophan metabolites indole, tryptamine and indole 3-acetate modulate AHR-mediated responses in CaCo2 cells, and concentrations of indole that inhibit AHR antagonist activity (100-250 μM) are detected in the intestinal microbiome and impacts on intestinal function are being investigated.

**1131 NR4A1 Antagonists Inhibit Breast Cancer Cell Growth, Survival, and Migration**

E. Hedrick1, U. Lin2, S. H. Safe1, 2 and S. Lee1, 1Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and 2Institute of Biosciences & Technology, Texas A&M Health Science Center, Houston, TX.

The orphan nuclear receptor NR4A1 (Nur77/TR3) is overexpressed in many solid tumors, and results of RNA interference (RNAi) studies suggest that NR4A1 functions as a pro-oncogenic factor. However, previous studies in breast cancer cells on the activity of NR4A1 are equivocal and we have investigated the function of this receptor in breast cancer cells by knockdown of NR4A1 (siNR4A1) or treatment with a C-DIM/NR4A1 antagonist activates caspases-8 and -7 and induced cleaved PARP expression in MCF-7, MDA-MB-231 and SKBR3 breast cancer cells. Transfection of erbB2-overexpressing SKBR3 cells with siNR4A1 also decreased cell proliferation by >30% after 72 hr and cell migration in a Boyden chamber assay was decreased by >80%. NR4A1 regulates cell survival and mTOR pathways and maintains low levels of oxidative stress in pancreatic and lung cancer cell lines, and treatment with C-DIM/NR4A1 antagonists or transfection with siNR4A1 decreased survival (induced apoptosis), inhibited mTOR, and induced stress in breast cancer cells. However, it was also evident that the expression of these well-characterized NR4A1-regulated pathways and the effects of NR4A1 inactivation were also highly cell context-dependent among a panel of breast cancer cell lines (MCF-7, SKBR3 and MDA-MB-231). Nevertheless, the C-DIMs/NR4A1 antagonists were effective antineoplastic agents in breast cancer cell lines and inactivated one or more NR4A1-regulated pathways.

**1132 AhR Knockout Rats Are Insensitive to Changes in Tissue Pathology and Serum Chemistry Markers following 4-Week Repeated-Dose Exposure to TCDD**

R. Budinsky1, R. Hukkanen1, M. Lawson1, A. Nyska2, R. Manno3, A. Grassetti1, D. Layko1, J. Rowlands1, J. A. Harrill3 and R. S. Thomas4, 1The Dow Chemical Company, Midland, NC, 2Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, 3Research Toxicology Centre S.A., Pomezia, Rome, Italy and 4The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

Persistent activation of the aryl hydrocarbon receptor (AhR) is believed to play a key role in the mode-of-action for TCDD-induced rat liver tumorigenesis. To evaluate the AhR-dependence of early pathological changes prior to tumour formation, we conducted a four-week TCDD repeated-dose study in adult female AhR knockout (AhR-KO) and wild type (WT) rats and investigated alterations in target tissue pathology and serum chemistry markers. Beginning at 8 weeks of age, AhR-KO and WT rats (n = 20 rats/dose/genotype) were dosed by oral gavage (4-5 doses / week, 19 total doses) with varying concentrations of TCDD in corn oil (0, 3, 22, 100, 300, 1000 ng/kg/day). Liver, lung, thymus and kidney were examined for treatment- and genotype-related gross and histopathological effects. Serum was isolated from blood samples and analyzed using a standard rat clinical chemistry panel. Treatment-related increases in the severity of hepatic and thymic pathology were observed in WT rats only. In the liver, these included hepatocytic vacuolization and hypertrophy and increased inflammation. Treatment-related increases in serum ALP, AST, cholesterol, globulin, total bile acids and total bilirubin as well as decreases in serum triglycerides, glucose and A/G ratio were also observed in WT, but not AhR-KO rats. These data demonstrate that AhR-KO rats are insensitive to early changes in liver function and histopathology induced by repeated exposure to TCDD.

**1133 Epithelial Aryl Hydrocarbon Receptor Contributes to Intestinal Host-Microbe Homeostasis**

I. A. Murray, K. J. Smith, A. Patterson and G. H. Perdew. Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA.

Recent evidence demonstrates a role of the aryl hydrocarbon receptor (AHR) within the immune compartment of the intestine in establishing tolerance to commensal microbes and suppressing pathogenic infection. However, the contribution of epithelial AHR in maintaining host-microbe symbiosis has thus far not been examined. Using C57Bl/6j mice Ahrfx/fx & epithelial Ahr knockout (IEAhr) models together with 16s quantitative PCR (qPCR), we have investigated the effect of epithelial Ahr ablation upon the composition of the intestinal microbiota. The data reveal a 2-fold increase in ileal bacteria of IEAhr mice when compared to Ahrfx/fx counterparts. ELISA data revealed that bacterial outgrowth observed with IEAhr mice was associated with a 50% increase in fecal IgA, suggesting a humoral response to the increased bacterial population. qPCR analysis supports the notion of a humoral response in IEAhr mice with increased expression of Iif together with its receptors Tnfsf13c, Tnfsf13a and Tnfsf17. Furthermore, ileal expression of the acute phase proteins Saa2/3 were increased in IEAhr mice. Additionally, elevated hepatic Scl1 was observed, indicative of a systemic response. Coincident with the elevated bacterial population and the inflammatory response, we observed a 10-fold decrease in segmented filamentous bacteria (SFB). The association of SFB with the ileal epithelium educates the immune system with regard to commensal bacteria, prompting tolerance through the Th17/Treg system, limiting outgrowth/pathogen expansion. We therefore examined ileal Il17a mRNA expression in IEAhr and Ahrfx/fx mice. Data revealed that Il17a expression reflected the decrease in SFB. The deficit in Il17a expression suggests that IEAhr mice may exhibit a reduced capacity to respond to opportunistic pathogens. Here, we propose that ablation of epithelial Ahr restricts SFB colonisation, thereby decreasing microbial tolerance, which leads to bacterial expansion, dysbiosis and an inflammatory response. Funding:NIHES004869/019964.

**1134 Characterisation of the Hepatic Effects of Phenobarbital in Constitutive Androstane Receptor (CAR, NR113) Knockout Rats**

M. Chamberlain, C. Haines and C. R. Elcombe. CXR Biosciences, Dunfermline, United Kingdom.

The administration of Constitutive Androstane Receptor (CAR, NR113) activators to rats and mice induces hepatomegaly that is characterised by hepatocellular hypertrophy (due to the proliferation of smooth endoplasmic reticulum and concomitant induction of enzymes belonging to the CYP2B and 3A families) and hyperplasia (increased semi-conservative DNA synthesis and cell proliferation). Previous studies utilising CAR knockout (KO) mice have demonstrated that the presence of an active CAR is necessary for the induction of this hepatomegaly. This study was designed to investigate the effects of the CAR-activator phenobarbital (PB) in CAR KO rats (SAGE Labs, Boyertown, PA). Male Wild Type (WT) and CAR KO rats (n=5 per group), which had been implanted with osmotic pumps containing BrdU to allow determination of replicative DNA synthesis (S-phase), were administered PB (500 ppm) in the diet for 7 days. Other groups of WT and CAR KO rats received control diet. PB treatment of WT rats resulted in a 1.2-fold increases in liver weight and livet/ body weight ratios, centrilobular hepatocellular hypertrophy, a 5-fold increase in hepatocellular S-phase labelling index and a 3-fold increase into total microsomal P450. The microsomal CYP2B catalysed reactions pentoxyresorufin-O-depentyl- hepatic S-phase labelling index and a 3-fold increase into total microsomal P450. The microsomal CYP2B catalysed reactions pentoxyresorufin-O-depentylation (PROD) and benzyloxyresorufin-O-debenzylation (BROD) were induced 100-fold and 40-fold respectively. These changes were accompanied by increases in CYP2B1 (2600-fold) and CYP2B2 (1120-fold) mRNA. None of these PB-induced effects were observed in the CAR KO rats. The use of Whole Genome Expression Microarrays demonstrated 343 differentially expressed genes in the PB-treated WT rats versus the WT control group (selection criteria of ≥1.5 fold change and a p value < 0.05). There were 200 differentially expressed genes in the PB-treated CAR KO rats compared to the untreated control CAR KO rats. In conclusion, an active CAR is required for phenobarbital-mediated hepatomegaly in rats and only 40% of the genes regulated by PB appeared to be CAR-dependent.
1135 Effects of Perfluoroalkyls on the Activations of Human CAR3, PXR, and TR Receptors In Vitro

1Vet. & Biomed. Sci., The Pennsylvania State University, University Park, PA and 2Penn State College of Medicine, Hershey, PA.

Research studies have shown that several perfluoroalkyl substances (PFASs) have the potential to activate certain xenosensor nuclear receptors (NR) involved in regulating metabolic processes. Pleiotropic responses following activation likely are responsible for many effects observed in toxicological studies, and key differences in expressions and responses on activation are known to exist. Although many studies have investigated the potential of PFASs to activate NR1C1 (PPARα), few studies have examined potential for activation of NR1I3 (CAR3) and NR1I2 (PXR). Notably lacking are investigations into the ability of PFASs to activate the thyroid receptors, NR1A1 (TRα) and NR1A2 (TRβ). We investigated the potential of 5 PFASs (perfluorooctanesulfonate (PFOS, 2 samples), perfluorohexane-sulfonate (PFHxs), perfluorobutanesulfonate (PFBS), perfluorobutyrate (PFBA), and perfluorooctanoate (PFOA)) to activate human CAR3, PXR, and TRα using chimeric systems with a luciferase reporter plasmid at PFAS concentration ranging from 0.4 to 100 μM. The same PFASs as well as perfluorononanoate (PFNA) and perfluorodecanoate (PFDA) were tested for human TRα and TRβ activation in another similar system with luciferase reporter plasmid at PFAS concentrations of 10 μM. In these assays, PFOS, PFNA, and PFDA were also tested for activation at 1, 10, and 100 μM. No human TTR or TRα activation or repression was observed with any PFAS at any concentrations tested. Weak activations that were lower in magnitudes than the respective positive controls were observed with CAR3 (PFOS, 100μM) and PXR (PFHxs, 33 and 100 μM; and PFOS, 100 μM). These PFAS concentrations (equivalent of 13,000 – 50,000 ng/mL) were several orders of magnitude higher than general population. Based on these observations and in light of known human exposure levels, the PFASs included in this study are not expected to act via direct activation of the studied NR1 sub-family receptors.

1136 Activation of Aryl Hydrocarbon Receptor (AHR) Synergistically Induces Lipopolysaccharide (LPS)-Mediated Transcription of Proinflammatory Chemokine (c-c motif) Ligand 20 (Ccl20)

T. S. Lahoti1, J. A. Boyer, J. M. Hughes, J. A. Murray and G. H. Perdew.

Vet. & Biomed. Sci., The Pennsylvania State University, University Park, PA.

Chemokines, a family of chemotactic cytokines, dictate recruitment of leukocytes, and play a critical role in immune homeostasis and tumorigenesis. Ccl20, a pleiotropic chemokine, also known as macrophage inflammatory protein-3α or Eotaxin-1, was originally identified as a chemoattractant for lymphocytes and dendritic cells. Ccl20 is highly expressed in pathological conditions such as rheumatoid arthritis, colon and pancreatic cancers and sepsis. It is the ligand for CC chemokine receptor 6 (Ccr6), which is expressed on the surface of dendritic cells, memory T cells and naïve B cells. LPS, a component of outer membrane of gram-negative bacteria, activates inflammatory signaling in macrophages, leading to enhanced secretion of pro-inflammatory cytokines and chemokines, such as Ccl20, via NF-kB-mediated activation. It is known that during inflammation, AHR can crosstalk with p65 (NF-κB) via NF-κB. Therefore, we examined the role of AHR in LPS-mediated activation of Ccl20. Primary peritoneal macrophages (1×10⁶ cells) from C57BL/6 (Ahrb) and Abr null mice (Abr-/-) were isolated and treated with AHR agonists 2.3.7,8-pentachlorodibenz-α-p-dioxin (TCDD) or indolo[3,2-b]carbazole (ICZ), followed by stimulation with pro-inflammatory LPS. Quantitative real time PCR revealed that the activation of Ahr in LPS-mediated activation of Ccl20. Primary peritoneal macrophages (1×10⁶ cells) from Ahrb or Abr-/- mice not only induces the basal levels of Ccl20 but also synergistically promotes LPS-mediated activation of Ccl20 mRNA. Studies performed in 1×10⁶ cells from Abr-/- mice revealed that the basal/synthetic effects to be Ahr-dependent. ELISA performed on supernatants from Ahrb 1×10⁶ cells exposed to TCDD and LPS mirrored the mRNA expression, albeit without synergy. Overall, these findings suggest that activation of AHR plays an underlying role in regulating the Ccl20 transcription in 1×10⁶ cells, and likely contribute towards AHR agonist-mediated inflammation. (Funded by: ES004869 and ES019964)

1137 Aryl Hydrocarbon Receptor: Insights into Its Role in Metabolic Homeostasis

N. Grier, J. A. Murray and G. H. Perdew.

Dept. of Vet. and Biomed. Sci., Penn State University, State College, PA.

Obesity is a multi-factorial disease governed by a complex combination of genetic, lifestyle, and environmental inputs. Obesity is often associated with hyperglycemia, hypertension, hepatic steatosis, endotoxemia, inflammation, and cancer. Numerous studies indicate these pathologies are influenced by the Aryl Hydrocarbon Receptor (AHR). Recent evidence demonstrates that AHR has the capacity to attenuate de novo cholesterol and fatty acid synthesis in the liver. However, AHR's role in obesity appears to be complex and requires further investigation. Here, we have examined the effect of different allelic variations and conditional knockout murine models of Ahr upon metabolic homeostasis and associated gene expression. We identified that male mice harboring the low-affinity Ahrb allele are 20% more glucose tolerant than their high-affinity Abr-/- counterparts. Additionally, Abr-/- mice exhibit a 2-fold increase in liver triglyceride content, accompanied by a relevant increase in the expression of fatty acid synthesis genes (Fasn, Acaca, Srd1, and Sreb1L1). Furthermore, we observed a 3-fold increase in hepatic Fgf21 (fibroblast growth factor 21) expression among AHR-deficient mice in comparison with Abr-/- mice. Similarly, liver-specific, conditional AHR-knockout mice recapitulated the effect seen in Abr-null mice, exhibiting a 2.7-fold increase in Fgf21 expression when compared to their Abr-/- counterparts. This suggests that AHR exerts liver-specific control over Fgf21 gene expression. Fgf21, an important regulator of the response to fasting, is known to ameliorate obesity when administered to various genetic and diet-induced murine models of the disease. Interestingly, the Fgf21 promoter contains several putative dioxin response elements (DREs). We hypothesize that AHR is involved in the regulation of this key hormone through direct repression on the promoter. This project is supported by NIH grants ES004869 and ES019964.

1138 Selective Aryl Hydrocarbon Receptor Modulator (SAHRM) SGA360 Attenuates Lipopolysaccharide (LPS)-Mediated Septic Shock

G. H. Perdew1, T. S. Lahoti1, J. M. Hughes1, J. A. Murray1, K. Gowda2 and S. Amin2.

Vet. and Biomed. Sci., The Pennsylvania State University, University Park, PA and 2Penn State College of Medicine, Hershey, PA.

Septic shock is a pathological condition predominantly associated with endotoxin (LPS) producing gram-negative bacteria. It requires immediate medical attention since it is the leading cause of death in patients admitted to intensive care units worldwide. LPS activates Toll-like receptor 4 leading to enhanced secretion of proinflammatory cytokines and chemokines. Overexpression of these proinflammatory mediators contributes to multi-organ dysfunction syndrome, leading to death. Aryl hydrocarbon receptor (AHR), a ligand activated transcription factor, has recently been implicated to possess immuno-modulatory effects. We have previously shown that SGA360 can be used to mitigate cytokine-mediated pro-inflammatory gene expression. Thus this study was conducted to evaluate the role of AHR in both in vivo and in vitro models of septic shock. C57BL/6J (Ahrb), Abr-/-, and Ahrb-/- mice were injected with SGA360 at -1h and +12h relative to a lethal dose of LPS. Animals from all three genotypes exposed to LPS alone showed median survival of 28h, 29h and 30h respectively. However, Ahrb mice exposed to SGA360 followed by LPS showed a significant increase in median survival to 42h. Abr-/- and Ahrb-/- mice exposed to SGA360 followed by LPS showed poor median survival rate (27h and 20h). Macrophages have been shown to play a critical role in LPS-mediated inflammation. Thus, in order to study the ability of SGA360 to selectively modulate AHR, primary peritoneal macrophages (1×10⁶ cells) isolated from Ahrb and Abr-/- mice were pretreated with SGA360 followed by activation with proinflammatory LPS. Quantitative real-time PCR revealed that SGA360 mitigated expression of multiple inflammatory genes induced by LPS only in Ahrb mice. These findings suggest that selective modulation of AHR may be a viable therapeutic approach to mitigate inflammatory signaling associated with septic shock. (Funded by: ES016964)

1139 Adaptation of the Human Ah Receptor to Bind Simple Indoles

T. D. Hubbard1, D. Desai1, W. Bisson2, S. Amin3 and G. H. Perdew1.

Vet. and Biomed. Sci., Pennsylvania State University, State College, PA and 2Env. & Mol. Tox., Oregon State University, Corvallis, OR and 3Penn State College of Medicine, Hershey, PA.

Recent evidence has shown that specific tryptophan catabolites are ligands for the aryl hydrocarbon receptor (AHR) and are important for the maintenance of intestinal health. The activation of AHR promotes gut immunological homeostasis.
and increased epithelial barrier function. Through characterization and analysis of multiple tryptophan catabolites, we have identified a discrepancy between the ability of mouse versus human AHR to bind simple indole molecules. Computer modeling of the ligand-binding domain (LBD) of the mouse and human AHR reveal significant differences, consistent with a 10-fold decrease in affinity for TCDD observed with the human AHR, relative to the murine Ah allele. The abundant microflora tryptophan catabolite indole (20 μM) was found to increase relative luciferase activity 6-fold in a dioxin response element driven luciferase reporter human HepG2 assay, similar to results observed with 10 nM TCDD. Conversely, in a mouse axolotl reporter line, indole failed to exhibit agonist activity compared to TCDD. qPCR analysis revealed tryptophan catabolite 3-methyl indole to display agonist activity specific to human AHR similar to that of indole, while isomers 1-methyl indole and 2-methyl indole failed to exhibit agonist activity. These results suggest that the human AHR has evolved to bind simple indoles produced in the gut. This project is supported by NIH grants ES004869 and ES019964.

1142 An Aryl Hydrocarbon Receptor from the Salamander Ambystoma mexicanum Exhibits Low Responsiveness to 2, 3, 7, 8-Tetrachlorodibenzo-p-Dioxin

J. Shoots and W. H. Powell, Biology Department, Kenyon College, Gambier, OH.

Sequence and structural features of the aryl hydrocarbon receptor (AHR) can underlie species- and population-specific differences in its affinity for 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and other agonists. These differences often explain the varying degrees of TCDD toxicity exhibited by distinct animal groups. Frogs, for example, are dramatically less sensitive to TCDD toxicity than many other vertebrates, and we have previously demonstrated that frog AHRs bind TCDD with low affinity. In Xenopus laevis AHR1B, weak TCDD binding results from the combination of three residues in the ligand binding domain: A354 and A370, along with N325. In the current study we seek to determine whether this mechanism of low TCDD responsiveness is shared by AHRs of other amphibian groups. To this end, we used RT-PCR to isolate a cDNA encoding an AHR from a salamander, the Mexican axolotl (Ambystoma mexicanum). It encodes a polypeptide of 95.5 kDa that shares 59% identity with Xenopus laevis AHR1B and 50% identity with mouse AHR. Phylogenetic analysis reveals that the axolotl AHR is orthologous to vertebrate AHR1s. Ambystoma AHR contains the same amino acid residues in the positions that confer low TCDD affinity to frog AHRs (N335, A364 and A380), suggesting that it also binds TCDD weakly. We tested this hypothesis with transactivation assays employing a luciferase reporter gene governed by the enhancer region from mouse CYP1A1 (pGudLuc6.1). For axolotl AHR, the EC50 for reporter gene induction by TCDD was 45 nM, even lower than frog AHR1B (23 nM) and dramatically less than a chimeric frog AHR containing the mouse ligand binding domain (0.2 nM). Taken together, the low TCDD responsiveness and the sequence conservation with the frog AHR ligand binding domain suggest that axolotl AHR binds TCDD with low affinity. We predict that Ambystoma mexicanum salamanders will exhibit resistance to the toxic effects of TCDD and other xenobiotic AHR agonists. Funded by the NIH (R15 ES011130) and the Kenyon Summer Science Scholars Program.

1143 1, 1-Bis(3′-indolyl)-1-(aromatic)methanes Are NR4A1 Antagonists That Inhibit Rhabdomyosarcoma Cell Growth and Survival

A. Reeder1, G. Chadalapak1, S. Lee2 and S. H. Safi1, 3, 4 1Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and 3Institute of Biosciences & Technology, Texas A&M Health Science Center, Houston, TX.

Rhabdomyosarcoma (RMS) is the most common tissue sarcoma that is primarily observed in children and adolescents. Cytotoxic drugs are the major chemotherapies used for RMS treatment and these are accompanied by toxic side-effects. The nuclear orphan receptor NR4A1 (Nur77/TR3) is a pro-oncogenic factor that is expressed in RMS cells, and we investigated the effects of a series of 1,1-bis(3′-indolyl)-1-(p-substituted phenyl)methane (C-DIMs) analogs that exhibit NR4A1 antagonist activity on the growth and expression of selected pro-oncogenic factors in RD and RH30 RMS cells. EC50 values for growth inhibition (2 days) by the p-hydroxyphenyl (DIM-C-pPhOH), p-cyanophenyl (DIM-C-pPhCN), and p-carboxymethyl (DIM-C-pPhCO2Me) were 14, 6.4 and 10 μM, respectively, for RH30 cells and 16, 4.4 and 11 μM, respectively, for RD cells. NR4A1 regulates multiple pro-oncogenic pathways/genes and acts as a coactivator for multiple specificity protein 1 (Sp1)-regulated genes through NR4A1-Sp1 interactions, and several Sp-regulated genes are critical for RMS cell and tumor growth. Treatment of RMS cells with 15-22.5 μM DIM-C-pPhOH significantly decreased expression of bcl-2, survivin, epidermal growth factor receptor (EGFR), cyclin D1 and c-Myc proteins, and the mechanisms of NR4A1-Sp1 interactions and their inactivation by C-DIMs are being investigated. Thus, NR4A1 antagonists are a novel class of relatively non-toxic agents for clinical treatment of RMS and for application of combined drug therapies.
The aryl hydrocarbon receptor (AhR) is expressed in many tissues and is mainly studied in the context of environmental chemicals and toxins. For example, benzo[α]pyrene (BaP) and TCDD are well-established activators of the AhR, whereas endogenous ligands of the AhR are still uncertain. In its function as an antioxidant, vitamin E (VE as alpha-tocopherol) is oxidized to alpha-tocopherylquinone (TQ), which is widely considered to be biologically inert. Our early studies suggested that TQ may be biologically active as an activator of the AhR in prostate cancer cells (i.e. LNCaP cells). Thus, the rationale for this study was to examine TQ as an activator of the AhR and the completion of gene expression analyses, TQ was found to produce more than 3,800 gene expression changes (greater than 2-fold), whereas VE treatment resulted in 1,200 gene expression changes. Gene expression pathway and network analyses identified a clustering of AhR-responsive genes affected by TQ, but not VE, which was validated using qPCR for specific AhR-responsive genes (e.g., CYP1A1). Activation of AhR by TQ was further examined using an XRE/DRE-responsive luciferase reporter system where TQ, but not VE, stimulated activity. Experiments using RNAi to down-regulate AhR activity showed that the TQ-induced up-regulation of CYP1A1 expression was indeed mediated by the AhR. Finally, primary cultures of AhR knock out mouse embryonic fibroblasts (MEFs) were established. CYP1A1 expression in AhR wild-type (WT) and knock out (KO) MEF cells was determined after treatment with TQ. KO MEF cells showed little change in the expression of CYP1A1, while WT MEF cells responded to TQ treatment with increased CYP1A1 expression, establishing that the AhR is necessary for TQ-mediated up-regulation of CYP1A1. Details on the mechanism of TQ’s activation of the AhR remain unclear. However, we have shown that quinone structures, as present in TQ, are effective at activating the AhR. Results from these studies provide intriguing support for TQ as an endogenous agonist of the AhR.

1145 Pharmacological and Electrophysiological Characterization of Ascaris suum Homopentameric Nicotinic Acetylcholine Receptors in Xenopus laevis Oocytes
Department of Biomedical Sciences, Iowa State University, Ames, IA.

Nicotinic acetylcholine receptors (nAChRs) belong to the family of ligand-gated ion channels (LGICs) and are found in both vertebrate and invertebrate species. The nAChRs in nematode parasites are pharmacologically different from mammalian host nAChRs allowing nematode selective compounds (anthelmintics) to be used for treatment and prophylaxis. Unfortunately, the widespread use of anthelmintics has given rise to the development of resistance. There is then, an urgent need to characterize the different nAChRs present in parasitic nematodes to provide a better understanding of their pharmacology for drug development and to find ways of overcoming resistance. Using molecular cloning and the two-electrode voltage clamp electrophysiological techniques, we have cloned and expressed two nAChR subunit genes (acr-16 and acr-21) from Ascaris suum in Xenopus laevis oocytes. Our results showed that ACR-16 or ACR-21 on their own can reconstitute a functional nAChR in the presence of an ancillary factor, RIC-3. Pharmacological characterization of homomeric receptors produced by ACR-16 or ACR-21 revealed that these receptors have distinct properties. The homomeric ACR-16 receptor is more sensitive acetylcholine than to nicotine and insensitive to levamisole and pyrantel. On the other hand, the homomeric ACR-21 receptor is more sensitive to nicotine than to acetylcholine but also insensitive to levamisole and pyrantel. These previously uncharacterized receptors are potential target sites for new anthelmintic compounds and are not anticipated to show cross-resistance with existing anthelmintics.
sylated proteins. Correspondingly, ensemble FRET spectroscopy measurements indicate that glycosylated and non-glycosylated proteins induce ‘open’ and ‘closed’ P-domain conformations respectively. The co-chaperone Erp57 influences substrate-binding kinetics and induces a ‘closed’ P-domain conformation, even in the presence of a glycosylated substrate. Together with analysis of the interactions of CRT with cellular proteins, these findings indicate that recruitment of monoglycosylated proteins to CRT is kinetically driven, while the P-domain and co-chaperone binding contribute to stable CRT-substrate interactions. Substrate sequestration in the cleft between the glycan binding site and P-domain is a likely mechanism for CRT-assisted protein folding.

**1149 Quantitative Profiling of Environmental Chemicals and Drugs for Farnesoid X Receptor Activity**

C. Hu1, J. Zhao1, R. Huang1, J. Hsieh1, J. T. Hamm1, X. Chang1, K. Houck3 and M. Xie1.

Farnesoid X receptor (FXR), a bile acid sensor, exerts protective function in numerous diseases including cholestasis, diabetes, liver regeneration, and cancer. Despite the extensive interests in FXR ligands in drug discovery, little is known regarding potential FXR-mediated toxicity effects from xenobiotic chemicals. Here we describe the profiling of approximately 10K environmental chemicals and drugs in modifying FXR signaling and associated cytotoxicity. The FXR beta-lactamase assay was used to screen the Testox10K compound library, containing environmental chemicals, clinically-approved drugs and known bioactive small molecules, in a 1536-well plate format at 15 concentrations in triplicate runs. 435 potent and reproducible hits were identified and grouped into several clusters based on their chemical structure similarity and known biological function. Many environmental chemicals including synthetic hormones, pesticides, and industrial chemicals showed FXR antagonist activity. Some drugs acted as agonists, antagonists, or partial agonists of FXR. Several clusters of compounds identified from the screening were also found to be active against other functionally related nuclear receptors. These results not only provide directions for prioritizing chemicals for further testing FXR-mediated toxicity but also suggest novel signaling pathways for future mechanistic studies. Supported by EPA Interagency Agreement Y3-HG-7026-03. This work was reviewed by EPA and NTP and approved for publication but does not necessarily reflect official agency policy.

**1150 Thalidomide Increases Cytochrome P450 Activity and Drug Metabolism in Liver through Direct Activation of Nuclear Receptor CAR and PXR**

R. van Beuningen1, N. Murayama2, D. Melchers1, H. Suemizu3, C. Guillouzo4, and M. Xia1.

Thalidomide (TC) is a widely used antiangiogenic drug in the treatment of several cancers, including multiple myeloma. However, the mechanism of TC action in liver cancer is not well understood. Previously, we have shown that TC is a potent activator of both CAR and PXR in human liver cancer cells. In this study, we investigated the effects of TC on the expression of CYP3A4, a key enzyme involved in the metabolism of many drugs. Our results indicate that TC significantly increases the expression of CYP3A4 in a dose-dependent manner. This effect is not mediated by classical CAR activation, but rather by direct activation of PXR. These findings suggest that TC may have potential therapeutic applications in liver cancer, and that the modulation of CYP3A4 activity by TC may be a target for further investigation.

**1151 Novel Interaction between PXR and CAR1 in Cytochrome P450 Induction**

B. C. Ho1, J. Zhao1, J. Johnson1, P. C. Wilgie2 and M. I. Morano1.

PXR and CAR are nuclear receptors that regulate the expression of genes involved in drug metabolism. In this study, we investigated the interaction between PXR and CAR1, two key nuclear receptors that participate in the induction of several CYPs including CYP2B6, CYP3A4, and CYP2C9. More than 20 splice variants of CAR transcripts have been identified. CAR1 is the main isoform found in hepatocytes; however, CAR1 shows strong constitutive activity when expressed in cell lines. In contrast, two other less abundant splice variants, CAR2 and CAR3, display no constitutive activity and can transactivate CYP2B6 and CYP3A4 upon ligand binding. In order to investigate the molecular mechanism of CAR1-mediated induction in hepatocytes, we assembled secreted alkaline phosphatase (SEAP) reporter gene constructs using native promoter sequences from CYP genes. These reporters were co-transfected in HepG2 cells with combinations of CARs, PXR, and HNF4α/β by STEP reverse transfection. The reporter constructs were functionally verified by expressing PXR or CAR3 and stimulated with corresponding ligands. In the presence of CAR1, both the CYP2B6 and CYP3A4 reporters exhibited the expected strong constitutive activity which masked the induction effect of CAR ligand C7TC7. Interestingly, the co-expression of PXR and CAR1 drastically suppressed the basal constitutive activities of CAR1 on both reporter genes. As a result, the effect of C7TC7 activation of CAR1 on CYP2B6 reporter became much more prominent (>5-fold). Although C7TC7 binding to CAR1 or CAR3 triggered only around 2-fold induction of CYP3A4 reporter gene, the co-activation of CAR1 and PXR led to a much more robust (>11-fold) induction of CYP3A4 than by activation of either nuclear receptor alone indicating a synergistic effect. This study emphasizes the significance of nuclear receptor interactions in the regulation of gene expression and illustrates the importance of using native promoter sequences instead of short synthetic regulatory elements in reporter gene assays. (Supported by NIH grant ES019807)

**1152 Effects of PPAR-Alpha Activation on Liver Toxicity in Mice Exposed to Trichloroethylene**

H. Yoo, V. Soldatov, O. Kooy, W. Bodnar and J. Rouyn.

Trichloroethylene (TCE) is an environmental and occupational toxicant and is classified as 'carcinogenic to humans' by both the US EPA and IARC. It has been hypothesized that peroxisome proliferator-activated receptor alpha (PPARα) activation, mediated by oxidative metabolites of TCE, is an important mechanistic event for liver cancer in mice. Although it is known that trichloroacetic acid (TCA), a major metabolite of TCE, may activate PPARα, uncertainties remain regarding the association between the extent of oxidative TCE metabolism, PPARα activation, and toxicity pathways that may be independent of PPARα. This study investigated oxidative TCE metabolism in the context of PPARα status (wild-type, Ppara-null, and humanized Ppara) in the mouse. Male and female mice of each genotype were treated with TCE (400 mg/kg/day in 5% Alkamuls EL-620 in saline vehicle) by oral gavage for 4 weeks. Liver and serum were collected at 5 hrs after the last dose. Quantification of TCA, trichloroacetic acid (TCA), and trichloroethanol (TCHO) was performed. In addition, ALT, liver-to-body weight ratio, hepatocellular proliferation, expression of peroxisome proliferator marker genes (Ppara, Acox1, and Cyp4a10), inflammation, and steatosis were evaluated. We found that (1) there were significant differences in TCE metabolism between different genotypes; (2) expression of Acox1 and Cyp4a10 significantly increased in both wild-type and pPpara mice, but not in Ppara-nulls; (3) spontaneous steatosis was observed in Ppara-null vehicle-treated, but not in mice treated with TCE; (4) mild increase in inflammation in TCE-treated group compared to vehicle was observed in Ppara mice. In conclusion, these data provide additional mechanistic information for understanding the linkages between oxidative TCE metabolism, PPARα activation, and liver toxicity of TCE. This work was supported by the Superfund Basic Research Program grant P42 ES005948.
1153 A Central Role of Aryl Hydrocarbon Receptor in High-Fat Diet-Induced Hepatic Steatosis

C. Xu1, C. Wang1, K. Bottum2, S. Krager2, C. Jaeger2 and T. Sichak1
1 Pharmacology, SIU School of Medicine, Springfield, IL and 2 Internal Medicine, SIU School of Medicine, Springfield, IL.

The aryl hydrocarbon receptor (AhR) is a ligand-activated basic helix-loop-helix/period-AhR nuclear translocator-single minded transcription factor which mediates a wide range of physiological and toxicological effects upon exposure to endogenous and exogenous ligands. Recent studies have shown that activation of AhR induces hepatic steatosis through upregulation of fatty acid translocase that is responsible for fatty acid transportation into the liver. The aim of this study is to determine whether AhR knockout protects against high-fat diet-induced hepatic steatosis.

6-week old wild-type (WT), AhR heterozygous (AhR+/−) and AhR knockout (AhR−/−) male mice were exposed to a normal chow diet (NCD, 10% fat diet) or a high-fat diet (HFD, 60% fat diet) for 14 weeks. AhR+/− as well as AhR−/− mice were protected from HFD-induced hepatic steatosis, impairment of the insulin signaling pathway, and inflammation, as well as systemic insulin resistance. In addition, the expression of Cyp3a fatty acid translocase, key lipogenic genes, fatty acid synthase (Fas) and acetyl-CoA carboxylase (Acc), peroxisome proliferator-activated receptor-ε (PPARε) and fatty acid oxidation key enzymes, carnitine palmitoyl transferase-1 (CPT-1) and acyl-CoA oxidase (ACO) were lower in AhR−/− and AhR+/− mice compared to WT mice after HFD feeding. Since fatty acid oxidation was decreased as an adaptation to decreased de novo fatty acid synthesis, the expression of fatty acid oxidation markers suggested that the protective effects on HFD-induced hepatic steatosis in AhR−/− as well as AhR+/− mice resulted from upregulation of Cyp3a fatty acid translocase expression, thereby increasing fatty acid transportation into the liver. These findings elucidate an important role for the AhR in HFD-induced hepatic steatosis, and the AhR signaling pathway could become a potential therapeutic target for fatty liver disease.

1154 Profiling of Compound-Induced Modulation of CAR-Coregulator Interactions As a Means to Differentiate between Direct and Indirect CAR Activation

J. P. Groten1, D. Melchers1, R. van Beuningen1, B. Chorley2, C. Corront3 and R. Houtman1
1 PamiGene International BV, Den Bosch, Netherlands and -EPA, Research Triangle Park, NC.

The nuclear receptor (NR) superfamily member constitutive activated receptor (CAR) controls the expression of a large battery of genes encoding xenobiotic metabolizing enzymes and transporters. CAR can be activated by at least two mechanisms: direct binding (e.g. CITCO) and subsequent recruitment of coregulator proteins which regulate target gene chromatin accessibility, or an indirect mechanism involving interference with a signaling pathway that inhibits the ability of CAR to translocate to the nucleus (e.g., phenobarbital (PB) and phenytoin (PN)). Although a large number of chemicals activate CAR, use of structure-activity relationships to predict CAR activation has been hampered due to the lack of an assay that in conjunction with classical trans-activation assays, allows chemicals to be classified as indirect or direct activators. As a potential solution for this caveat, we applied a peptide microarray with 154 coregulator-derived NR-interaction motifs, (CoR)NR boxes, which serves as a sensor for CAR conformation and activity status as a function of ligand. Human CAR LBD-coregulator interactions were profiled in the presence of PB, PN, or CITCO, clomizolamze (antagonist) or solvent (2% DMSO). Compound response profiles, i.e. compound-induced log-fold change of CAR binding, were subjected to hierarchical clustering and demonstrated clear differences between compounds and their ability to modify CAR conformation. A large number of significant interactions between CAR and coregulators were stimulated with CITCO. Many of the same interactions were significantly decreased with clomizolamze. PB and PN exposure led to very few significant interactions indicating that they do not activate CAR directly. In summary, coregulator-NR interaction assays are promising new tools to identify chemicals that activate nuclear receptors by different mechanisms. (This abstract does not reflect EPA policy)

1155 Ethanol-Induced Hepatic Expression of Cytochrome P450 (Cyp) 2b10 Is Dependent on PPAR/B/D

T. Koga1, G. Balandaram1, M. Goudarzi2, A. Fornace1, H. Li1, B. J. Bytusuki1, T. Mak1 and J. M. Peters2
1 Pharmacology, SIU School of Medicine, Springfield, IL and 2 Internal Medicine, SIU School of Medicine, Springfield, IL.

Because of the significant morbidity and lethality due to alcoholic liver disease (ALD), there remains a need to elucidate the mechanisms how ALD is caused. This will allow for the development of new non-invasive biomarkers of ALD that could lead to new approaches for the prevention and treatment of ALD. It was previously shown that PPARβ/δ has an important function in the ALD, and that PPARβ/δ could prevent some ethanol-induced hepatic effects as shown by differences in the urinary metabolome. Thus, the present study global gene expression patterns to begin to identify potential genes that may contribute to the differences in urinary metabolites modulated by PPARβ/δ. Chronic ethanol treatment causes increased hepatic Cyp2b10 mRNA and protein in wild-type mice, but this was not observed in Pparβ/δ-null mice. This suggests that induction of CYP2B10 by ethanol is regulated by PPARβ/δ, and this could be involved in the etiology of ALD modulated by PPARβ/δ. Interestingly, nuclear and cytosolic sub-localization of ethanol inducible (CAR), a trans-activation factor known to regulate Cyp2b10 expression, was different between each wild-type or Pparβ/δ-null mice. However, peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC1α), a transcription factor which participates in CAR transactivation of the Cyp2b10 gene, was up-regulated in wild-type mice, and this effect was not observed in Pparβ/δ-null mice. These results suggest that PPARβ/δ regulates CYP2B10 expression independently of CAR activation, not by affecting CAR translocation directly. Ongoing studies are evaluating the role of Cyp2b10 in ALD and how PPARβ/δ influences the metabolism of endogenous compounds due to this drug metabolizing enzyme (Supported by AA018863 and ES016013).

1156 Compromised Adaptive Upregulation of Mitochondrial Metabolism and Accumulation of Hepatic Lipids Associate with Alcoholic Liver Damage in PPARα/-/- Mice

A. Fornace1, H. Li1, B. J. Bytusuki1, T. Mak1 and J. M. Peters1
1 Department of Biochemistry, Georgetown University, Washington, DC and 2 Department of Veterinary and Biomedical Sciences, Pennsylvania State University, University Park, PA.

Alcohol alters hepatic metabolism, and chronic alcohol consumption can result in alcoholic liver disease (ALD). Peroxisome proliferator-activated receptor-ε (PPARε), a ligand activated transcription factor modulates expression of genes that regulate fatty acid catabolism. The specific PPARα target genes that modulate ALD are unclear. There is remarkable similarity between the histopathology of ALD in Pparα-/- and in early ALD in humans. Importantly, PPARα expression and activity are thought to be lower in human liver than mouse liver. Hence, the Pparα-/- mouse is a good model to investigate ALD. In this study, Pparα-/- mice were used to elucidate whether PPARα is activated or repressed by chronic alcohol consumption. Hepatic transcriptomic and metabolomic analyses were used to examine the alterations of genes and metabolites associated with pathological changes associated with ALD. The changes triggered by chronic alcohol consumption in Pparα-/- mice were compared with those in wild-type mice. The results showed that in the presence of PPARα, energy metabolism pathways in mitochondria, namely the fatty acid β-oxidation, the TCA cycle and electron transfer chain, were induced transcriptionally in response to two-month alcohol feeding. In contrast, these responses were greatly reduced in the absence of PPARα expression. In line with the transcriptional modifications of these metabolic pathways, lipidomics profiling results showed consistent accumulation of triglycerides in Pparα-/- mice as compared to controls. A significant increase in the number of metabolites and a strong induction of fibrogenesis genes were also observed exclusively in alcohol-fed Pparα-/- mice as compared to controls. These observations indicate that PPARα plays a protective role in response to chronic alcohol consumption by adaptive transcriptional activation of this receptor.

1157 A Novel Pregnane-X-Receptor (PXR) Knockout Rat Model: Characterization and Evaluation of the Role of PXR in Hepatic Lipidosis

1 Angen, Thousand Oaks, CA.

The PXR plays a well-established role in drug metabolism and protection against toxic metabolites such as bilirubin, however its role in lipid metabolism is less well understood. Previous studies in mice have linked PXR activation to induction of hepatic lipidosis, although the consequences of PXR activation in the rat and human remain unclear. To further understand the role of PXR in lipid metabolism, we evaluated the phenotype a novel Sprague Dawley rat PXR knockout (KO) model constructed using zinc finger nuclease technology. PXR KO rats were fertile and were of similar body weight to age-matched wild type rats. There were no differences observed by light microscopy in the majority of tissues examined, however there was a consistent decrease in hepatosplenomegaly and lymphopoeisis, which was reflected by a decrease in hematocrit and circulating red and white blood cells (all lineages), decreased bone marrow cellularity and decreased lymphocytes in the spleen. Altered basal energy metabolism in the PXR KO rats was indicated by mild decreases in serum glucose and cholesterol but no change in serum triglycerides or non-esterified fatty acids. Consistent with published studies in mice, treatment of...
wildtype rats with a PXR activator (pregnenolone-16alpha-carbonitrole (PCN)) induced centrilobular hepatic hypertrophy consistent with enzyme induc- tion and peripoportal hepatic microvesicular vacuolation, which stained posi- tively for adipophilin confirming the vacuoles contain lipid. An increase in hepatic triglycerides further confirmed accumulation of hepatic lipid by PXR activation in the rat. When the PXR activator PCN was administered to PXR KO rats, no hepaticcellular hypertrophy or vacuolation (and no increase in hepatic triglyc- eride content) was evident, thus confirming that PXR induction is associated with increased hepatic lipid in rats. These results are similar to those reported in mice, and further suggests PXR activation is associated with changes in hepatic lipids in rodents.

**1158 Aryl Hydrocarbon Receptor-Dependent Induction of Liver Fibrosis by Dioxin**

X. D. Coutomoi$^{1, 2}$, S. Pierre$^{1, 2}$, A. Chevallier$^{1, 2}$, F. Texieria-Clerc$^{1}$, L. Bui$^{1, 2}$, A. Barouki$^{1, 2}$, 3, P. Fernandez-Salgueiro$^{2}$, M. Aggerbeck$^{1, 2}$, S. Letort$^{1, 2}$ and R. Barouki$^{1, 2}$ 4.

The contribution of environmental pollutants to liver fibrosis is an important and poorly explored issue. In vitro studies suggest that the environmental pol- lutant 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and other Aryl hydrocarbon Receptor(AHR) ligands induce several genes that are known to be up-regulated during liver fibrosis. Our aim was to determine whether exposure to such pollutants can lead to fibrosis and to characterize the mechanisms of action. Mice were treated for 2, 14, or 42 days, once a week with 25µg/kg of TCDD. Gene and pro- tein expression, in vitro and in vivo, as well as liver histology were investigated for each treatment. Treatment of mice with TCDD for 2-weeks modified the hepatic expression of markers of fibrosis such as collagen-1a1 and -smooth-muscle-actin. This is not observed in Ahr KO mice. Following 6-weeks of treatment, histol- ogical features of murine hepatic fibrosis became apparent. In parallel, the levels of inflammatory cytokines and of markers of activated fibroblasts were found to be up-regulated. Interestingly, we also found increased expression of genes of the TGF beta pathway and a concomitant decrease of miR-200a levels. Since the transcription factors of the Snail family were shown to be involved in liver fibrosis, we stud- ied their regulation by TCDD. Two members of the Snail family were increased, whereas their negative targets, the epithelial marker E-cadherin and Claudin1, were decreased. Further, the expression of mesenchymal markers were increased. Finally, we confirmed that Snai2 is a direct transcriptional target of TCDD in the human hepatocarcinoma cell line, HepG2. The AHR ligand, TCDD, induces hepatic fib-rosis by directly regulating pro-fibrotic pathways.

**1159 Identification of Environmental Chemicals Which Could Contribute to Nonalcoholic Fatty Liver Disease by Nuclear Receptor Activation**

L. Al-Eryani$^{1, 2}$, B. Wahlang$^{1}$, K. C. Falkner$^{3}$, H. Clair$^{1}$, R. A. Prough$^{4}$, L. C. States$^{1}$ and M. Cave$^{1}$ 5.

Environmental chemical exposures have previously been associated with nonal- coholic fatty liver disease (NAFLD). Activation of xenobiotic receptors includingpregnan-xenobiotic-receptor (PXR) and constitutive androstane receptor (CAR) by environmental chemicals may influence energy metabolism. We hypothesize that PXR activation is a mode of action for toxicants in NAFLD. The purpose of this study is to identify and validate environmental chemicals which interact with PXR or CAR and could thus contribute to NAFLD. EPA-ToxCast Phase I (320 chemicals) was screened for compounds associated with receptor activation. Human (h) and murine (m) PXR and CAR activation were examined for selected compounds from ToxCast Phase I in addition to organochlorine pesticides which were previously associated with human NAFLD. These compounds were validated in vitro for PXR/CAR activation using transient transfection assays in HepG2 cells. Nearly 2/3 of chemicals screened positive for PXR activation. 67 compounds and 102 compounds were found to activate hPXR by NGCG and Attagene assays respectively. The CelleDirect assay identified 202 compounds that were found to change CYP3A4 (PXR target gene) expression. Among chemicals selected for validation in cell-based reporter assays, trans-nonachlor, chlordane, DDE, DDT, lindane and alachlor activated h/m PXR. Diedrindrin activated mPXR only. Diedrin, trans-nonachlor, DDT, lindane and alachlor also activated hCAR but not nCAR. Potential PXR interactions were identified for nearly 2/3 of ToxCast Phase 1 chemicals. However, not all chemicals identified by the ToxCast screening assays proved to be xenobiotic receptor agonists. We postulate that the environmental chemicals that activate PXR may contribute to NAFLD through the effect of this receptor on energy metabolism which may differ in humans and rodent models.

**1160 Involvement of Constitutive Androstane Receptor (CAR) in the Liver Hypertrophy and Hepatocarcinogenesis Induced by Three Fibrates in Mice**

K. Inoue$^{1}$, D. Suzuki$^{1}$, Y. Ogasaw$^{2}$, J. Maeda$^{3}$, T. Morikawa$^{1}$, R. Ichimura$^{1}$, M. Takahashi$^{1}$, Y. Kodama$^{1}$ and M. Yoshida$^{1}$.

Fibrates are known as PPARα agonists and induce hypertrophy and tumors in mouse liver. To clarify the involvement of CAR in the mechanisms of liver hyper- trophy and tumors induced by fibrates, 6-week-old male C3H (wild) and CAR knockout (KO) mice were fed a diet containing 2,000 ppm clofibrate (Clo), 2,400 ppm fenofibrate (Feno) or 5,000 ppm bezafibrate (Beza). Four-week-treatment of three fibrates induced centrilobular (Clo) or diffuse (Feno and Beza) liver hyper- tropy in wild mice, while CARKO inhibited the hypertrophy of Clo only. In all treated groups of both genotypes, Cyp2b10 expression was markedly increased in the liver. All fibrates increased Cyp2b10 expression in wild mice and the expression significantly decreased by CARKO in all treated groups. However CYP2P10 pro- tein was clearly observed in the centrilobular areas only in wild Clo group, indicat- ing a discrepancy between mRNA and protein expression. These data suggest that CAR might involve in Clo-induced liver hypertrophy. In 27-week-feeding treat- ment with characteristic three fibrates after diethylstilbestrol initiation, the numbers of basophilic altered foci and/or adenomas were significantly increased in wild mice, but not CARKO, indicating that CAR might involve in induction of basophilic foci and adenomas induced by these three fibrates. On the other hand, CARKO did not affect the increased numbers of eosinophilic altered foci and/or adenomas, which were induced by each fibrate in wild mice. In conclusion, not only PPARα but also CAR plays an important role in liver hypertrophy of Clo and in the hepa- tocarcinogenesis process of Clo, Feno and Beza.

**1161 Ginkgo biloba Extract Is Nongenotoxic In Vivo and Constitutive Androstane Receptor Is Involved in Its Hepatocarcinogenesis**

J. Maeda$^{1}$, K. Inoue$^{1}$, R. Ichimura$^{1}$, T. Morikawa$^{2}$, Y. Ogasaw$^{2}$, Y. Kodama$^{3}$ and M. Yoshida$^{1}$.

Ginkgo biloba extract (GBE) is commonly used as a herbal supplement aiming to improve brain function and memory. A recent National Toxicology Program (NTP) study of GBE (TR578) reported concerns of genotoxicity and clear evid- ence of liver hypertrophy and hepatocarcinogenicity in mice. To understand the mode of actions of hepatocarcinogenesis of GBE, we investigated the genotoxicity of GBE in vivo and constitutive androstane receptor (CAR) involvement in liver hypertrophy/carcinogenesis, using wild-type and CAR knockout (CARKO) mice. Our studies of liver comet assay and bone marrow micronucleus assay showed negative results, even at 2,000 mg/kg GBE by gavage for 3 days. This indicates that GBE is non-genotoxic in vivo.

In a 4-week GBE dietary treatment of doses up to 10,000 ppm, a dose-dependent hepatic hypertrophy accompanied by CYP2B10 expression was induced in wild-type mice. In CARKO mice, only the highest dose of GBE induced same alterations as wild-type mice, indicating that GBE-induced liver hypertrophy is mainly CAR-mediated.

In a two-stage hepatocarcinogenesis model initiated by diethylnitrosamine administration, a 27-week treatment with GBE at 10,000 ppm resulted in an increased number of liver tumors and altered foci in wild-type mice. In contrast, the lesions were far less frequent in CARKO mice. These results demonstrate that GBE has a certain potential to induce mouse liver tumors through a non-genotoxic mechanism, and that the mode of action for hepa- tocarcinogenesis of GBE is CAR-mediated.

PS

SOT 2014 Annual Meeting 307
Bile acid (BA) homeostasis is dysregulated during pregnancy as a result of reduced signaling of the Farnesoid X Receptor (Fxr), which can lead to hypercholesterolemia and liver diseases such as intrahepatic cholestasis. To determine whether Fxr function could be pharmacologically rescued during pregnancy, pregnant C57BL/6 mice were treated with vehicle or 100 mg/kg GW4064 (GW), a synthetic Fxr agonist, on gestation days 13 and 14, and livers and intestines were collected for qPCR and western blot analysis. In pregnant mice, the mRNAs of hepatic transporters Ntcp, Oatp1a1/4, Mrd2, Bsep and Oatp mRNAs as well as Cypl7a1 and Mrpl mRNAs by 20 to 150%. Expression of Cyp7a1 mRNA was reduced in GW-treated pregnant mice to levels lower than virgin controls. In addition, GW restored expression of Cyp7a1, Bsep and Cypl7a1 proteins. In the ileum, treatment of pregnant mice with GW increased Fgf15 and Ostb mRNAs between 2- and 3-fold. Pregnancy also decreased the expression of the Fxr target gene and transcription factor, Shp, in liver and ileum by 65% and 98%, respectively. GW returned Shp expression to levels of virgin controls in the liver, and elevated expression by 4-fold in the ileum. These data demonstrate that pharmacological activation of Fxr during pregnancy may partially restore the down-regulation of key bile acid and xenobiotic transporters, as well as additional target genes in the Fxr pathway. Supported by R01ES020522, T32ES007148, and P30ES050522.

**1162 Activation of the Farnesoid X Receptor Restores Hepatic and Intestinal Bile Acid Synthetic Enzyme and Transporter Expression in Pregnant Mice**

J. E. Moscovitz1, B. Kong1, G. L. Guo2, and J. M. Alekunes1,2.1 Department of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ and 2Environmental and Occupational Health Sciences Institute, Rutgers University, Piscataway, NJ.

Fetal complications of Intrahepatic Cholestasis of Pregnancy (ICP) frequently include perinatal mortality. The severity is positively related to maternal serum total bile acids, but the genetic etiology remains unresolved. Respiratory Distress Syndrome (RDS) occurs in 28.6% of newborns of ICP patients. ABCB11 is a hepatic export pump for bile acids. Abcb11 KO mice showed elevated serum bile acids. Therefore, we hypothesized that Abcb11 KO female mice might be a model for ICP.

Offspring from KO dams showed 100% mortality, regardless of paternal genotypes. Necropsy only revealed atelectasis in neonates from KO dams. Gene and protein expression of pulmonary cell type markers did not change. Histopathological analysis did not reveal any defect in developmental lungs of neonates from KO dams. However, electron microscopy revealed super-coiled surfactant in the lungs of neonates from KO dams. The lipid components of pulmonary surfactant did not differ between neonates of WT and KO dams. But serum bile acids were significantly higher in KO dams during pregnancy and accordingly, higher in their neonates. However, only taurine conjugated muricholic acid (T-MCA) was elevated in the lungs of neonates from KO dams. Our data suggests that elevated T-MCA affects pulmonary surfactant, leading to poor oxygenation. This is consistent with our findings that secretion of total bile acids in postnatal newborns is significantly elevated after birth.

To rescue the mice, we backcrossed Abcb11 KO into either CAR or PXR-null background. Abcb11/CAR double KO mice rendered 100% neonatal mortality rates. In contrast, maternal absence of PXR with Abcb11 produces strong neonatal rescue with about 60% of neonates. The studies have identified Abcb11 as a major gene that accounts for neonatal RDS of cholestatic mothers. The Abcb11 KO female mice could be animal model to develop therapeutic approach.

**1163 An Animal Model of Intrahepatic Cholestasis of Pregnancy**

**1163a Exposure to Aryl Hydrocarbon Receptor Antagonist Alpha-Napthalene Blocks Diet-Induced Obesity and Nonalcoholic Fatty Liver Disease**

B. Moyer, 1. Rojas and C. Tomlinson. Medicine, Dartmouth College, Hanover, NH.

Previous studies have indicated a role for the aryl hydrocarbon receptor (AHR) in mediating obesity. Mice with the Ahdr variant low-affinity allele have been shown to become less obese when fed a high-fat diet compared to mice with the high-affinity Ahdr allele. In the current study, we hypothesize that high doses of known AHR antagonist alpha-napthalene (NF) will also prevent diet-induced obesity. To test this, C57BL/6 mice were fed either a standard mouse diet, a “Western diet” containing additional cholesterol 45% of kilocalories come from fat, or these two diets containing 2% NF. Following 26 weeks of diet exposure, no adverse response to the NF was observed, and no differences in food consumption were associated with the NF diet. At 26 weeks’ diet, 16 mice per group per sex were sacrificed. NF had a near-complete effect on blocking obesity. Body weights at sacrifice for females were 22.0 ± 1.4 g (control), 28.7 ± 3.3 g (Western), 23.6 ± 1.8 g (control + NF), and 24.5 ± 2.2 g (Western + NF). The difference between Western diet and Western diet + NF was significant, P value < 0.05. Furthermore, histological examination of livers indicate fat accumulation indicative of non-alcoholic fatty liver disease (NAFLD) was widespread in Western diet groups, but was not widely detected in any other group. Differences in fat accumulation were also detected via MRI imaging and fat pad weights taken at sacrifice. From these data we conclude that inhibition of the AHR via dietary exposure to high levels of a known antagonist can block pathologies associated with the Western diet, including obesity and NAFLD. This further affirms a possibly major role of the AHR in regulating the body’s response to diet.

**1163b Amphiregulin (AREG) and Transforming Growth Factor-alpha (TGF-α) Play Opposing Roles in 2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD)-Induced Proliferation and EGFR Signaling in Skin**

C. Campion1, C. H. Sutter1, T. R. Sutter1,2 and J. A. Cole1. 1Biological Sciences, University of Memphis, Memphis, TN and 2W. Harry Feinstone Center for Genomic Research, Memphis, TN.

In the epidermis, the balance between differentiation and proliferation is modulated by epidermal growth factor receptor (EGFR) signaling. EGFR activation promotes proliferation and is dampened under differentiating conditions. Previous studies show that TCDD, calcium (Ca), and TCDD/Ca cause time- and treatment-dependent down-regulation of [125I]-EGF binding, however the mechanism and implications of this down-regulation on epidermal homeostasis and EGFR signaling have not been fully addressed. In this study, we sought to identify whether secreted ligands drive EGFR down-regulation and the impact of these ligands on EGFR signaling, ligand responsiveness, and cellular proliferation in primary neonatal human epidermal keratinocytes (NHEKs). A 72 h treatment with TCDD, Ca, or TCDD/Ca reduced [125I]-EGF binding to 77%, 41%, and 32% of control cells respectively without loss of EGFR protein. TCDD and TCDD/Ca-treated NHEKs showed no change in basal ERK activity but significantly enhanced responsiveness to exogenous ligand. TCDD, Ca, or TCDD/Ca caused elevated secretion of TGF-α compared to control cells while all NHEKs secreted AREG in a time-dependent manner. Using neutralizing antibodies, we showed that altering secreted ligands had no effect on total EGFR protein. TGF-α had an anti-proliferative effect and neutralization led to significantly decreased [125I]-EGF binding. Conversely, neutralization of AREG led to decreased cell number in TCDD, Ca, and TCDD/Ca-treated NHEKs. Neutralization of both ligands reversed treatment-dependent EGFR down-regulation in TCDD-, Ca-, and TCDD/Ca-treated cells, supporting that this down-regulation is modulated through the secretion of both TGF-α and AREG, which leads to an alteration, though not a loss, of EGFR signaling. TGF-α and AREG play opposing roles in downstream NHEK proliferation suggesting that TCDD pathology is in part due to imbalancing ligand-driven EGFR signaling.
This study was conducted in male Swiss Webster mice to further confirm our previous findings on heteroprotection of thioacetamide (TA)-primed mice against acetaminophen (APAP)-induced lethality. The objective was to examine the role of annexin A1, an endogenous inhibitor of phospholipase A2, in heteroprotection by TA against APAP-induced liver failure and mortality. Male Swiss Webster mice were primed with a low dose of TA (40 mg/kg in 10 ml normal saline/kg, intraperitoneally (i.p.)) 36h before challenge with a lethal dose (600 mg/kg 0.4% NaCl pH 8.2, i.p.) of APAP. Plasma alanine aminotransferase (ALT), aspartate aminotransferase (AST) were measured as biomarkers of liver injury, and plasma secretory phospholipase A2 (sPLA2) activity was measured to monitor the expansion of APAP-initiated liver injury. Hepatic glutathione (GSH) depletion following APAP treatment was measured in TA primed and non-primed mice. TA priming resulted in marginal decrease (~25%) in Cyp2e1 enzyme level, but the extent of rise in ALT and AST and decrease in hepatic GSH after APAP overdose was not affected due to TA priming. Moreover, TA priming did not affect the rise in plasma sPLA2 level at 2h following APAP treatment; however, no further rise in sPLA2 was observed at later time points in TA primed mice as compared to non-primed mice. TA priming resulted in overexpression of annexin A1 at 24 to 48h. Inhibition of annexin A1 biosynthesis using protein synthesis inhibitor cycloheximide (CHX) (40 mg/kg in 5 ml distilled water/kg, i.p.) at 1h before TA priming resulted in unabated expansion of APAP-induced liver injury and led to 100% mortality in stark contrast to 100% survival in APAP-overdosed TA primed mice that did not receive CHX intervention. In conclusion, annexin A1 overexpression in proliferating hepatocytes abolishes the expansion of liver injury after a lethal APAP overdose in mice.

This study was designed to test whether inhibiting secreted phospholipase A2 (sPLA2), a death protein, with a specific inhibitor, BPPA [5-(4-benzoxylphenoxy)-4S-(7-phenylheptanoylamino) pentanoic acid], prevents the expansion of liver injury initiated by a lethal overdose of acetaminophen (APAP) in mice. Male Swiss Webster mice (25-30g) were treated with a lethal dose of APAP (600 mg/kg, ip, in warm 0.45% NaCl pH 8.2) followed by a single dose of either BPPA (20 mg/kg, ip, in DMSO 3 ml/kg) or DMSO vehicle (3 ml/kg, ip) alone injected at 2, 4 or 8h after APAP administration. Survival and mortality were recorded over the next 14 days. Plasma alanine aminotransferase (ALT) and sPLA2 activities were measured in the mice on alternate days from days 1 to 13. ALT and sPLA2 activities increased sharply in the mice treated with TA either alone or followed by DMSO (3 ml/kg, ip) led to 80% mortality. In contrast, mice treated with BPPA at 2 and 4h after the APAP administration exhibited similar rise in sPLA2 and ALT activities on day 1 declining thereafter and suffered only 10 and 30% mortality, respectively. Covalent binding of 14C-APAP-derived reactive metabolite to liver protein, hepatic glutathione (GSH) depletion, and hepatic GSH:GSSG ratio did not change after the APAP overdose in the mice receiving the BPPA intervention. Ninety, 70, and 60 percent of the mice treated with BPPA at 2, 4, and 8h after the lethal dose of APAP, respectively, survived. We conclude that timely intervention by the administration of the sPLA2 inhibitor, BPPA, prevented the expansion of APAP-induced liver injury and death of the mice after the lethal challenge with APAP.
Nuclear factor erythroid 2-related factor 2 (Nrf2) is a transcription factor that pos-positively regulates the expression and activity of cytoprotective genes during periods of oxidative stress. Literature has shown that some of these genes are highly expressed in livers of female than male mice. This may explain previous reports of greater tolerability by female mice to acetaminophen (APAP) hepatotoxicity than males. The hypothesis for this study is that resistance to APAP toxicity by female mice is due to higher basal and inducible expression of Nrf2 and Nrf2-dependent genes. Here, we examined differences in basal mRNA and protein expression for Nrf2 and Nrf2-dependent genes in naïve (fed) male and female mice and overnight-fasted mice following vehicle or APAP treatment. Alamine aminotransferase (ALT) activity was also measured as an indicator of hepatotoxicity. Hepatic mRNA and protein levels were measured by quantitative PCR and western blotting, respecti-respectively. Contrary to our hypothesis, results show that basal Nrf2 mRNA expression was significantly lower in livers of fed female than male mice. Consistent with this, basal Nrf2 protein expression was lower in livers of both fed and over-night-fasted female than male mice, with significance observed in livers of fed mice. However, greater induction of the Nrf2-dependent gene NAD(P)H quinone oxidoreductase 1 (Nqo1) and multidrug resistance-associated protein transporter 4 (Abcc6 or Mrp4) was observed in livers of overnight-fasted female than male mice. Similarly, Nqo1 protein expression was significantly higher in livers of both fed and overnight-fasted female mice. As expected, ALT activity was significantly elevated in both WT and Nrf2-null male mice following APAP treatment, but no significant increases in ALT were observed in either genotype of female mice. This unaltered tolerance by female mice lacking Nrf2 indicates that other factors, rather than Nrf2, are responsible for the lower susceptibility of female mice to APAP hepatotoxicity. Supported by NIH DK069557.
ALF using an incremental dose model. C57BL/6 mice were treated with either 300 mg/kg (APAP300, regenerative dose) or 600 mg/kg (APAP600, non-regenerative dose) APAP. Liver injury and regeneration were studied over a time-course of 0 to 96-hr. Mice treated with APAP300 developed extensive liver injury followed by significant regeneration resulting in resolution of injury by 48-hr. In contrast, APAP600 group exhibited significant progression of injury with substantial decrease in regeneration. The inhibition of regeneration in APAP600 group was associated with decreased cyclinD1 mRNA and protein expression. Further analysis of upstream signaling revealed that growth factors signaling pathways (EGFR/c-Met, downstream MAPKs) were dose-dependently activated and remain highly activated even at APAP600, where regeneration was inhibited. However, canonical Wnt/β-catenin and NF-κB signaling were activated only in APAP300 where regeneration was stimulated. Next, we investigated role of Wnt/β-catenin in further detail. ChIP analysis revealed increased binding of β-catenin to cyclinD1 promoter specifically at APAP300 correlating with higher cyclinD1 induction. Furthermore, over-expression of stable form of β-catenin (M565) in mice resulted in induction of cyclinD1, improved liver regeneration and decreased progression of injury following APAP overdose. Overall, our study identified several potential pathways and confirmed role of Wnt signaling in regulation of liver regeneration after APAP overdose.

1174 Strain Difference in Carbamazepine-Induced Hepatotoxicity

Carbamazepine (CBZ) is a widely used antiepileptic drug, and severe hepatotoxicity is reported in a small population of the patients who took CBZ. Recent publications suggest that the CBZ-induced hepatotoxicity is immunity-mediated. The present study investigated effects of mouse strain-specific immunological back ground on CBZ hepatotoxicity. CBZ was administered to 5 strains mice, ICR (frequently used in general toxicology study), C57BL/6 (Th1 dominant) and BALB/c (Th2 dominant). These mice were given CBZ at 400 mg/kg/day for 4 days and 800 mg/kg for subsequent 1 day. After 24 hr of the final dosing, all survived animals were necropsied and laboratory tests were performed. Hepatotoxicity, such as necrosis of hepatocytes along with increases in plasma AST, ALT or LDH, was observed in 0/10, 5/10 and 8/10 mice in ICR, C57BL/6 and BALB/c, respectively, among which the severity was worst in BALB/c. Blood TCR-β values were comparable in all 3 strains. However, RT-PCR analysis using liver revealed highly increased gene expression of pTCRβ, CCL2 in C57BL/6 and BALB/c. Furthermore, there was also increased gene expression of TNF-α, IL-6 and IL-10 also increased. These responses were strongest in BALB/c. In addition, an increased gene expression of liver Hemeoxygenase-1 (HO-1) was observed in the hepatotoxicity-induced mice. Since HO-1 is reported to present in dendritic cells in the liver, HO-1 might play some role for CBZ-induced hepatotoxicity. Taken together, there were clear strain differences in incidence and severity of CBZ-induced hepatotoxicity. The different hepatotoxicity responses between the strains were correlated to different immunological responses in the liver and BALB/c was most sensitive.

1175 Assessment of the Effects of Perfluorononanoic Acid on Hepatic Homeostasis

K. G. Kongbak1, 2, K. Skov1, N. Hadrup1 and A. Vinggaard1.1 National Food Institute, Technical University of Denmark, Søborg, Denmark and 2Department of Systems Biology, Technical University of Denmark, Kgs. Lyngby, Denmark.

Polyfluorinated compounds (PFC) are compounds where all or most hydrogen atoms are replaced by fluorine atoms. Due to their physical-chemical properties, PFCs are used in more than 200 industrial and consumer applications of which lubricants, fire-fighting foams, and emulsifiers for the production of fluoropolymers are a few examples. Perfluorononanoic acid (PFNA) is a nine-carbon perfluorinated compound, used as a surfactant and emulsifier. Due to the long half-life and occurrence in both human and animal serum, PFNA is a frequently detected PFC’s in human serum. Over the last decade (1999-2010), researchers have found a three-fold increase in PFNA concentrations in blood from the US population. Due to the long half-life of PFNA and thus the tendency to bio-accumulate, there is an increased concern about the human exposure to these compounds. PFNA is between the four most frequently detected PFC’s in human serum. To study the potential effects of PFNA on hormonal and hepatic homeostasis, we dosed adult male Wistar rats with three doses of PFNA (0.0125, 0.25, and 5 mg/kg bw/day) once daily for 14 days by gavage. After euthanization, we sampled blood and various tissues and isolated mRNA from liver samples for Agilent rat gene expression microarrays. A metabolomics analysis was performed on the blood samples using LC MS/MS. The identified perturbed targets/signaling pathways were validated using RT qPCR and immunohistochemical staining of liver slices. The highest PFNA dose caused steatosis and general toxicity. We found significant changes in plasma levels of androstenedione and testosterone at the highest dose and corticosterone at the lowest dose. Initial overrepresentation analyses of the gene expression microarray data using Gene Ontology categories suggested effects of PFNA on energy metabolism and peroxisome proliferation along with mitochondrial and endoplasmic reticulum function. This is e.g. indicated by misregulation of genes involved in mitochondrial fatty acid β-oxidation. This is in agreement with the findings from the metabolomics analysis, showing decreased levels of lipids in the plasma samples.

1176 Tolerance to Acetaminophen (APAP) Hepatotoxicity in a Mouse Model of Autoimmunization

APAP overdose is the leading cause of acute liver failure in the U.S. Rodents treated with low hepatotoxic doses of APAP become resistant to toxicity from subsequent treatment with higher doses of APAP (APAP autoprotection). Although this phenomenon is also seen in patients who repeatedly take supratherapeutic doses of APAP, the underlying mechanism(s) is not known. Previous gene microarray studies revealed a pronounced induction of liver Fmo3 mRNA expression in our mouse model of APAP autoprotection. Here, we characterized the gene regulation and protein expression of liver Fmo3 during APAP hepatotoxicity. The functional consequences of Fmo3 induction were also investigated. Plasma and livers were collected from male C57BL/6 mice over a period of 72h following a single dose of APAP (400 mg/kg) to measure Fmo3 mRNA and protein expression. Although Fmo3 mRNA levels increased significantly following APAP treatment, its protein expression marginally changed. By contrast, both Fmo3 mRNA and protein expression were significantly higher in mice pretreated with APAP (400 mg/kg) and re-exposed to a higher dose (600 mg/kg). In contrast to naïve C57BL/6 male mice, females mice have about 80-times higher basal Fmo3 mRNA and are highly resistant to APAP hepatotoxicity. Co-administration of APAP with the Fmo3 inhibitor methimazole rendered female mice susceptible to APAP hepatotoxicity, with no changes in susceptibility detected in male mice. Furthermore, a human hepatocyte cell line (HC-04) clone overexpressing human FMO3 showed enhanced resistance to APAP cytotoxicity. Taken together, these findings establish for the first time induction of Fmo3 protein expression and function by xenobiotic treatment. Our results also indicate that Fmo3 expression and function plays a role in protecting the liver from APAP-induced toxicity. Although the mechanism(s) of this protection remains to be elucidated, this work describes a novel function for this enzyme. Supported by NIH DK069557.

1177 Altered Expression of Hepatic Xenobiotic Metabolism Systems in Transport Deficient (TR-) Rats

L. LeCureux, V. Bhaskaran and L. D. Lehman-McKeeman, Discovery Toxicology, Bristol-Myers Squibb, Lawrenceville, NJ.

TR- rats are characterized by a spontaneous mutation in the biliary transporter, multidrug resistance-associated protein 2 (Mrp2; Abcc2), and generally recognized that there is a compensatory increase in the expression of the basolateral transporter Mrp3 (Abcc3) in these rats. The purpose of this work was to characterize global hepatic gene expression changes in TR- rats, with emphasis on xenobiotic metabolizing systems. Liver mRNA profiles were evaluated in TR- and control Wistar rats (AllDirex®; Rat Genome 230, 2.0 GeneChips; p < 0.01), and results were confirmed by RT-PCR. For Phase I metabolic enzymes, Cyp450 reductase, Cyp2b1, and Cyp2a2 increased (≥ 1.5x), whereas Cyp2c40, Cyp2b2, and Cyp7a1 decreased (≤ 2.7x). For phase II conjugating enzymes, Ugt1a1 increased along with several glutathione transferases including, Gsta5, Gstm2, Gstp1, and Gstt1. Gsta5 was the most significantly increased in this family (9.6x). As expected, Abcc3 mRNA was increased, along with an increase in Abca1 (3.9x). Hepatic expression of numerous solute carriers (Slc family) was altered, with 7 members significantly up-regulated. Of these transcripts, expression of Slc35c2, a transporter for GDP-fucose, was elevated (6x). An additional 11 Slc genes were down-regulated, including the sucrose transporter Slc5a6 (4.4x) and the Na+/phosphate exchanger, Slc34a2 (8.8x). These results indicate that hepatic expression of numerous genes involved in Phase I, II and III metabolism are altered in Mrp2-deficient TR- rats. The potential contribution of these changes (e.g. altered enzyme activity or transport of solutes) to the disposition of endogenous and exogenous compounds should be considered when this model is used to assess the role of Mrp2 in biliary excretion and toxicity of drugs and environmental chemicals.
Acetaminophen (APAP) overdose causes severe and occasionally fatal liver injury. Numerous drugs that attenuate APAP toxicity have been described. However, these compounds frequently protect by cytochrome P450 inhibition, thereby preventing the initiating step of toxicity. We have previously shown that pretreatment with allopurinol can effectively protect against APAP toxicity, but the mechanism remains unclear. In the current study, C57BL/6 mice were administered allopurinol 18h or 1h prior to APAP overdose. Administration of allopurinol 18h prior to APAP overdose resulted in an 88% reduction in liver injury (serum ALT) 6h after APAP, however, 1h pretreatment offered no protection. APAP-cytochrome adducts and glutathione depletion kinetics were similar with or without allopurinol pretreatment. The phosphorylation and mitochondrial translocation of c-Jun-N-terminal kinase (JNK) has been implicated in the progression of APAP toxicity. In our study we showed equivalent early JNK activation (2h) however late JNK activation (6h) was attenuated in allopurinol treated mice, which suggests that later JNK activation is more critical for the toxicity. Additional mice were administered oxypurinol (primary metabolite of allopurinol) 18h or 1h pre-APAP, but neither treatment protected. This finding implicated an aldehyde oxidase (AO)-mediated metabolism of allopurinol, so mice were treated with hydralazine to inhibit AO prior to allopurinol/APAP administration, which eliminated the protective effects of allopurinol. We evaluated potential targets of AO-mediated preconditioning and found increased hepatic metallothionein 18h post-allopurinol. These data show metabolism of allopurinol occurring independent of P450 isoenzymes preconditions the liver and renders the animal less susceptible to an APAP overdose.

The role of allopurinol in APAP-induced liver injury is well documented. However, the mechanism of its protective effect is unclear. In our study, we investigated the protective effect of allopurinol using freshly isolated PHH, isolated from either unused tissue or surgical waste. PHH were exposed to 5mM, APAP hepatotoxicity using freshly isolated PHH, isolated from either unused tissue from donor livers or material from liver resections. PHH were exposed to 5mM, 10mM and 20mM APAP over a period of 48 hours, and multiple parameters were assessed. As evidenced by the release of alanine aminotransferase (ALT), APAP dose-dependently induced significant hepatocellular necrosis starting from 24h, which correlated with the clinical onset of human liver injury after APAP overdose. Interestingly, cellular glutathione was depleted rapidly during the first 3h, which was similar to the murine model. APAP also resulted in early formation of APAP-protein adducts (measured in whole liver homogenate and in mitochondria) and mitochondrial dysfunction as shown by the loss of mitochondrial membrane potential after 12h. Furthermore, APAP time-dependently activated c-Jun N-terminal kinase (JNK). More specifically, JNK phosphorylation occurred in the cytosol and mitochondria 1h after APAP exposure, while phosphorylated JNK subsequently translocated to the mitochondria. Both pretreatment and co-treatment with JNK inhibitor SP600125 reduced JNK activation and partially attenuated cell death at 24h and 48h after APAP. Our data demonstrate for the first time detailed mechanistic events in human hepatocytes and mitochondrial dysfunction, in addition to the role of JNK in determining the progress of APAP induced hepatotoxicity. TLR4 are major receptors for extracellular histone mediated sterile inflammation, injury and death in mouse model of APAP. The aim of this study was to elucidate the possible role of TLR4 blockers in preventing APAP induced hepato-fetal injury. TLR4 blockers were used in APAP-induced rat hepatotoxicity in order to elucidate the protective role of TLR4 in APAP-induced liver injury.

Acetaminophen (APAP) overdose is the most prevalent cause of drug-induced liver injury in western countries. Extensive studies have been conducted to investigate the mechanism of injury after APAP overdose in various biological models, including mice, rats and hepatoma cell lines. However, it remains ill-defined as to how the injury progresses in humans. Primary human hepatocytes (PHH) represent the gold standard model of studying drug toxicity, and here we investigated APAP hepatotoxicity using freshly isolated PHH, isolated from either unused tissue from donor livers or material from liver resections. PHH were exposed to 5mM, 10mM and 20mM APAP over a period of 48 hours, and multiple parameters were assessed. As evidenced by the release of alanine aminotransferase (ALT), APAP dose-dependently induced significant hepatocellular necrosis starting from 24h, which correlated with the clinical onset of human liver injury after APAP overdose. Interestingly, cellular glutathione was depleted rapidly during the first 3h, which was similar to the murine model. APAP also resulted in early formation of APAP-protein adducts (measured in whole liver homogenate and in mitochondria) and mitochondrial dysfunction as shown by the loss of mitochondrial membrane potential after 12h. Furthermore, APAP time-dependently activated c-Jun N-terminal kinase (JNK). More specifically, JNK phosphorylation occurred in the cytosol and mitochondria 1h after APAP exposure, while phosphorylated JNK subsequently translocated to the mitochondria. Both pretreatment and co-treatment with JNK inhibitor SP600125 reduced JNK activation and partially attenuated cell death at 24h and 48h after APAP. Our data demonstrate for the first time detailed mechanistic events in human hepatocytes and mitochondrial dysfunction, in addition to the role of JNK in determining the progress of APAP induced hepatotoxicity.
Acorinel accumulation, activation of pro-apoptotic stress kinase-JNK, ER stress, and apoptotic cell death was examined in vitro in alcohol-exposed rat hepatic cells (H4IIEC), and in vivo in a mouse model of alcohol consumption. Exposure to alcohol led to substantial accumulation of acorinel adducts both in vitro and in vivo. This was accompanied by phospho-activation of JNK and upregulation of ER stress transcription factors ATF3 and ATF4, and the pro-apoptotic protein, GADD153/CHOP. Cellomics analysis revealed that accumulation of acorinel adducts correlated with (i) disruption of mitochondrial membrane potential; (ii) release of free calcium; and (iii) cell death in hepatocytes. This study demonstrates that acorinel is likely to be a major culprit in the ER stress and hepatotoxicity associated with alcohol consumption. Acorinel scavengers may have therapeutic potential in alleviating the adverse effects of alcohol consumption, and we are actively investigating this concept.

1183 Mechanism of Altered Metformin Distribution in Diabetic Nonalcoholic Steatohepatitis
A. L. Dzielewski, J. Clarke, N. Nelson, S. Werts and N. J. Cherrington, Pharmacology & Toxicology, University of Arizona, Tucson, AZ.

Metformin is an anti-hyperglycemic agent that is widely prescribed for type-2 diabetes and is currently being investigated for the treatment of other insulin resistance-related disorders including nonalcoholic fatty liver disease (NAFLD). NAFLD is a highly prevalent chronic liver disease with stages ranging from simple steatosis to nonalcoholic steatohepatitis (NASH). NASH, which contains various cellular stress responses including lipid accumulation, inflammation, oxidative stress and fibrosis, alters transporter expression and drug disposition. Metformin elimination is transporter-dependent, mediated by Oct2, Oct1 and Matel in the liver and kidney. The purpose of this study was to determine whether metformin demonstrates altered expression and tissue distribution in diabetic and NASH mouse models. A single oral dose of [14C]metformin was administered to C57BL6 and diabetic ob/ob mice, each fed either a control diet or a methionine and choline deficient (MCD) diet to model NASH. ob/ob (diabetic) mice exhibited increased hepatic Matel1 and decreased renal Oct1 expression compared to WT, and diet-induced NASH in diabetic mice increased mRNA expression of hepatic Oct1. Both diabetes and NASH decreased Oct2 and Matel mRNA expression in the kidney. For metformin distribution, diabetic mice had increased plasma area under the curve (AUC) and liver and kidney metformin levels compared to WT. In both WT and ob/ob mice, presence of NASH increased metformin exposure, with NASH mice exhibiting increased plasma AUC and muscle concentrations compared to WT, and diabetic NASH mice exhibiting increased plasma AUC, muscle and liver concentrations compared to diabetic alone. Overall, diabetes and NASH additively increased plasma AUC and retention of metformin in liver and muscle compared to WT control. These results indicate that diabetes and NASH alter transporter expression and shift the disposition profile of metformin, potentially increasing the risk of drug toxicity.

1184 Altered Transcription Initiation and Exonization of the First Intron of the Human Liver ABC4 Gene in Tissue Specimens from Cases of Acetaminophen Overdose
X. Gu and J. E. Manautou, University of Connecticut, Storrs, CT.

Liver injury caused by overdose of the analgesic and antipyretic drug acetaminophen (APAP) is a serious human health problem. The precise molecular events mediating initiation, progression and recovery from APAP liver injury remain unclear. In our previous studies, mRNA and protein induction of the eflux transporter ABC4 gene was found to be associated with APAP liver injury and recovery. In this study, we examined potential changes in transcription start site (TSS) profile and intronic exonization of the ABC4 gene in human liver specimens from APAP overdose cases. Using 5’RLM-RACE analysis (RNA ligase mediated rapid amplification of cDNA 5’-end) and genotyping of ABC4 mRNA intronic exons, we found multiple ABC4 TSSs distributed in a dispersed fashion in liver samples from APAP overdose patients. Similarly, multiplicity and dispersion of ABC4 TSSs was also observed in normal livers. However, the frequency and location of ABC4 TSSs in APAP livers were noticeably different from those in normal livers. We also found two types of ABC4 mRNA variants with different exonisation of intron 1 in both normal and APAP livers. Lower levels of 5’ unapped mRNA variants containing a longer intronic exon, while higher levels of 5’ capped mRNA variants containing a shorter intronic exon were identified in APAP livers. This indicates that during APAP toxicity, degradation of ABC4 mRNA variants containing a longer intronic exon is enhanced while degradation of variants containing shorter intronic exon is repressed. In silico analysis showed that ABC4 mRNA variants containing the shorter intronic exon encode for a 39-amino acid peptide that is approximately1/35th the length of the full peptide. The biological significance and function of these ABC4 mRNA variants remains to be further investigated. Taken together, our findings provide new insights into the mechanism of ABC4 gene regulation at the transcriptional and posttranscriptional level in association with APAP hepatotoxicity. Supported by NIH Grant DK069557.

1185 Nr2f Protects against Furosemide-Induced Hepatotoxicity
Q. Qi1,2, L. Li2, H. Zhou3 and G. D. Klaassen1, 1Department of Internal Medicine, University of Kansas Medical Center, Kansas City, KS and 2Institute of Clinical Pharmacology, Xiangya Medical School, Central South University, Changsha, Hunan, China.

Furosemide is a diuretic drug, but its reactive intermediates lead to acute liver injury in mice. Given the essential role of Nr2f as a cellular defense regulator, we investigated whether Nr2f would protect against furosemide-induced liver injury using the Nr2f 2-gene dose response’ mice model (Nr2f-null, wild-type, Keap1-KD and Keap1-HKO mice). Twenty-four hour after furosemide administration (250mg/kg, i.p.), serum ALT activities and histopathological analysis indicated severe hepatotoxicity in Nr2f-null and WT mice, but significantly less in the Nr2f-overexpressed Keap1-KD and Keap1-HKO mice. Furosemide increased the mRNA of genes involved in the acute phase response (Hlo-1 and MT-1), ER stress (Chop10 and Gadd45), inflammatory cytokine (IL-1B), chemokines (Mip-2 and mKC), as well as apoptosis (Egr1 and Bax) in livers of Nr2f-null and wild-type mice, but increased less in mice with more Nr2f. The two genotypes of over-expressed Nr2f mice had increased expression of the Nr2f target genes Gclm, Gclc and Nqo1 prior to furosemide administration, and were increased further after furosemide administration. Thus, our findings provide strong evidence that over-expression of Nr2f in Keap1-KD and Keap1-HKO mice and the increases in mRNA of a number of genes involved in anti-oxidative stress, anti-inflammation, anti-ER stress and anti-apoptosis protect against furosemide-induced hepatotoxicity.

1186 Acetaminophen (APAP)-Induced Hepatic Protein Adducts in Liver and Mitochondria of C57/B6 Mice Are Reduced by S-Adenosylmethionine (SAMe)
A. Schnellre1, M. S. Wright1, H. Hedrick1, J. Brown1, J. G. Ball1 and M. Valentinov1, 1Pharmacology, Physiology and Toxicology, Marshall University School of Medicine, Huntington, WV and 2Wheeling Jesuit University, Wheeling, WV.

Hepatotoxicity is associated with an overdose of the antipyretic drug, acetaminophen (APAP). APAP toxicity requires biotransformation to a toxic metabolite and increased oxidative stress. S-Adenosylmethionine (SAMe) protects mice from APAP overdose. The overall hypotheses for this study is that SAMe reduces APAP hepatic toxicity by preventing oxidative stress and post-translational modifications of proteins including the antioxidant enzyme, Manganese Superoxide Dismutase (MnSOD). Male C57Bl6 mice were divided into 4 groups (N=5-10/group) and injected intraperitoneal (ip) as indicated: vehicle (VEH, 15 ml/kg water ip), SAMe (1.25 mmol/kg 5 ml/kg, ip), APAP (250 mg/kg, ip) and SAMe and APAP (SAMe administered 1h after APAP). Livers were collected 4h following APAP. Subcellular fractions were isolated from mitochondria and cytosol. Equal amounts of protein were processed for Western analysis and immunoprecipitation. SAMe administered 1h after APAP reduced APAP hepatic toxicity when measured 4h post APAP injection. Protein carbonylation was increased by APAP and attenuated by SAMe. 3-Nitrotyrosine (3-NT) formation was increased in mitochondria by APAP and reduced by SAMe. Mitochondrial MnSOD nitrosylation was increased by APAP and reversed in the APAP+SAMe group. In conclusion, APAP induced protein carbonylation and nitrosylation of proteins which was reversed by SAMe treatment 1h post APAP. (Supported by NIH Grant 5P20RR016477 to the West Virginia IDeA Network for Biomedical Research Excellence).

1187 Hepatic Vascular Endothelial Dysfunction in Environmental Toxin-Induced Nonalcoholic Steatohepatitis Is Regulated by TLR4-miR21-GRHL3 Axis
S. Das, R. K. Seth and S. Chatterjee, University of South Carolina, Columbia, SC.

The liver sinusoidal endothelium is very specialized and phenotypically differentiated. The aims of this study were to investigate the role of TLR4-linked upregulation of miR21 and its effect on the target; grainyhead-like 3 (GRHL3), in inducing the changes in liver histology and liver microvasculature. We used a murine model of environmental toxin-induced nonalcoholic steatohepatitis (NASH) where diet-induced obese (DIO) mice were exposed to disinfection byproduct bromochloromethane (BDCM). In addition, CYP2E1 and TLR4 gene deleted mice (KOs), exposed to BDCM were used for the study; to establish the role of metabolic
oxidative stress and TLR4 in hepatic endothelial dysfunction. qRTPCR was used to detect the changes in mRNA levels for vascular endothelial dysfunction markers, GRHL3 (regulates eNOS phosphorylation and hence endothelial dysfunction), TLR4; and in levels of miR21 (targets GRHL3). Western blot, oil red O, H&E, immunofluorescence staining and microscopic techniques were also used to test the experimental endpoints. mRNA and protein levels for vascular endothelial dysfunction markers were significantly increased in DIO+BDCM group compared to DIO, CYP2E1 KO and TLR4 KO groups. GRHL3 protein expression was significantly decreased (implying degradation of mRNA by miR21); whereas miR21 and TLR4 mRNA levels were significantly increased in DIO+BDCM group compared to DIO, CYP2E1 KO and TLR4 KO groups. The mRNA levels of inflammatory markers were significantly high in DIO+BDCM group compared to the other groups. CYP2E1 KO and TLR4 KO mice were protected from hepatic vascular endothelial dysfunction along with other NASH pathology as evidenced by decreased inflammation. In summary, our finding for the first time identifies the role of TLR4-miR21-GRHL3 axis in modulating hepatic vascular endothelial dysfunction and resultant inflammation. This forms a basis for a potential therapeutic target in the treatment of environmental toxin-induced NASH. (4R00ES19875-02 to Saurabh Chatterjee).

1188 Serum and Hepatic Fibroblast Growth Factor 21 Levels Are Increased in Subjects with Alcoholic Liver Diseases and in Mice Exposed to Alcohol by Decreased Transcriptional Suppression

C. Zhao1, Y. Liu1, K. C. Falcner2, M. Cavo3, C. McClain1, 2 and W. Feng1, 2

1Hepatology and Nutrition, University of Louisville, Louisville, KY and 2Pharmacology & Toxicology, University of Louisville, Louisville, KY.

Liver-derived FGF-21 is a novel metabolic regulator of glucose and lipid metabolism. Alcohol exposure affects lipid metabolism by increasing lipogenesis and decreasing fatty acid β-oxidation. However, it is currently unknown whether alcohol exposure affects FGF-21 expression. Serum FGF-21 levels were measured in 24 consenting subjects (16 subjects with acute alcoholic hepatitis, 20 patients with alcoholic cirrhosis, and 9 subjects with alcohol abuse, and were compared to 26 healthy, non-drinking controls by ELISA. C57BL/6 mice were fed Lieber DeCarli diet containing 5% alcohol or maltose dextrin for 4 weeks (chronic), or for 12 days and then given one dose of alcohol at 6 g/kg by gavage 6 hours before sacrificing (chronic-binge), or only one dose of alcohol by gavage (acute). Serum and hepatic FGF-21 levels and hepatic FGF-21 mRNA levels were measured. Liver triglyceride and serum FFA were also measured. Serum levels of FGF-21 were markedly increased in both human subjects with ASH and alcohol abusers without ALD, but unchanged in AC vs. non drinking controls. Serum levels of FGF-21 were also markedly increased in mice exposed to alcohol, and the hepatic expression of FGF-21 were increased by both mRNA and protein levels. The increased FGF-21 expression was positively correlated with increased hepatic levels of triglyceride and serum levels of FFA. The expression of PGC-1α and Rev-Erb, which are important transcription suppressors of FGF21, were decreased in mouse livers exposed to alcohol. Alcohol exposure increased hepatic and circulating FGF-21 expression likely through an inhibition of transcriptional suppression mediated by the PGC-1α-Rev-Erbβ pathway. The regulation of FGF-21 expression may be associated with hepatic lipid metabolism in alcoholic steatohepatitis. The observed increase in circulating FGF-21 was conserved between animal models and human subjects with ALD.

1189 FGF21 Deficiency Exacerbates Chronic Alcohol-Induced Fatty Liver Disease

Y. Liu, C. Zhao, M. Zhang, C. McClain and W. Feng. University of Louisville, Louisville, KY.

Alcoholic fatty liver disease (AFLD), is considered as the earliest pathological alteration in ALD. Studies demonstrated that inhibition of fat accumulation and promotion of fat clearance prevents hepatic steatosis and slows or halts the progression of ALD. Previous studies have identified extrahepatic hormones are important in alcohol-induced alteration in liver lipid metabolism, little is known whether the paracrine and endocrine signal for metabolic regulation of hepatic itself participates in alcohol exposure associated lipid accumulation. Fibroblast growth factor 21 (FGF21) is a member of the endothelium FGF subfamily and a major metabolic regulator, which plays a critical role in the glucose and lipid metabolism. Here we demonstrated that FGF21 deficiency exacerbate chronic alcohol-induced AFLD. Global FGF21 knockout mice and their controls were fed Lieber DeCarli diet containing 5% alcohol or pair-fed isocaloric diet for 4 weeks. Alcohol feeding increased hepatic fatty acid and triglyceride contents and fat accumulation. There was no obvious alteration in hepatic fat accumulation in FGF21 deficiency mice under pair feeding. However, a markedly increased hepatic fat was detected in FGF21 knock-out mice when fed chronic alcohol. Further studies showed that FGF21 deficiency exacerbated alcohol-induced liver injury. The FGF21 exacerbated-fat accumulation was associated with upregulation of the genes involved in fatty acid de novo synthesis, such as PPS and SCD-1, and the decrease in the gene expression responsible for fatty acid β-oxidation, such as CPT-1. Mechanistic studies showed that FGF21 knockout decreased SIRT1 which deacetylates SREBP-1c. In addition, we showed that FGF21 deficiency also decreased LKB1 which activates AMPK. The downregulation of SIRT1 and LKB1/AMPK in FGF21 deficiency livers of mice exposed to chronic alcohol lead to SREBP-1c and PGC-1a-mediated increased fatty acid synthesis and decreased fatty acid β-oxidation. In conclusion, FGF21 is likely required for cellular defense against hepatic lipogenesis and cellular capacity for fat clearance in subjects exposed to chronic alcohol.

1190 Uric Acid Inhibits Lipid Metabolism through Suppression of Autophagy

K. Lee1, Y. Choi1, S. Oh2 and B. Lee3

1College of Pharmacy, Seoul National University, Seoul, Republic of Korea and 3Research Center for Oral Disease, Regulation of the Aged, College of Dentistry, Choons University, Gwangju, Republic of Korea.

Fructose which is reported to be lipogenic is rapidly phosphorylated to fructose-1-phosphate by fructokinase using ATP. It results in AMP accumulation causing activation of AMP deaminase and generation of uric acid. Patients with hyperuricemia or gout usually accompany hyperglycemia and hyperuricemia is also prevalent in patients presenting nonalcoholic fatty liver disease (NAFLD) that develops hepatic steatosis in the lack of alcohol abuse. In this context, we hypothesized that uric acid which comes from the fructose metabolism promotes triglyceride accumulation and development of fatty liver. Today, it is well demonstrated that fatty liver mainly results from increased de novo lipogenesis, increased transport of triglyceride into the liver and decreased lipolysis. In this paper, we tried to characterize the role of uric acid in lipolysis. A newly found function of autophagy is the degradation of lipid droplets in hepatocytes. Accordingly, we hypothesized that uric acid contributes to the pathogenesis of development of fatty liver by regulation of autophagy. We found that uric acid inhibits autophagy in concentration- and time-dependent manner in HepG2 cell line. Although uric acid did not suppress the expression of autophagy related proteins but activated Akt followed by inhibitory phosphorylation of TSC2, subsequently increased phosphorylation of mTOR and decreased autophagy. It was well known that starvation-induced autophagy degrades lipid droplet and releases fatty acids for mitochondrial β-oxidation. Pretreatment of uric acid suppressed starvation-induced autophagy and decreased intracellular lipid utilization by starvation. In addition, long-term treatment of uric acid itself increased intracellular lipid content and cells incubated with oleate in the presence of uric acid deposited more lipid than those only treated with oleate. In conclusion, this study first demonstrated a novel mechanism that uric acid regulates lipid metabolism through suppression of autophagy.

1191 Platelet Function Inhibits Liver Injury and Fibrosis Induced by a Bile Duct Toxicant

N. Ishii1, A. K. Konop2, K. L. Towery2, H. Cline2, K. Williams3, M. J. Flick1 and J. P. Luyendyk2

Chronic liver disease in humans and animal models is associated with hemostatic changes including platelet activation and deposition of cross-linked fibrin in the liver. Previous studies have suggested that hepatic platelet accumulation inhibits liver fibrosis and promotes liver repair. Complete fibrinogen deficiency worsens liver injury in mice with chronic liver disease. However, the pathways linking coagulation to platelet activation during chronic liver disease are not known. We hypothesized that elements of platelet activation and function, including thrombin mediated protease activated receptor (PAR)-4 signaling and fibrin engagement of the gIIbIIIa integrin on platelets inhibit hepato cellular injury and fibrosis in a mouse model of xenobiotic-induced chronic liver injury and fibrosis. To test this hypothesis, mice expressing a mutant form of fibrinogen (ogen) incapable of binding gIIbIIIa (FibTA5 mice) and mice lacking PAR-4 (PAR-4/-/- mice) were used. FibTA5 mice, PAR-4/-/- mice and wild-type (WT) mice were fed a purified diet (AIN-93M) containing the bile duct toxin alpha-naphthylisothiocyanate (ANTT) (0.025%), or control diet (AIN-93M) for four weeks. PAR-4 deficiency did not increase liver necrosis in mice fed ANTT diet. However, compared to WT mice, portal inflammation and peribiliary fibrosis increased significantly in PAR-4/-/- mice fed ANTT diet. Focal hepatocellular necrosis and serum alanine aminotransferase activity were markedly increased in FibTA5 fed ANTT diet compared to WT mice and this corresponded with a significant induction of proinflammatory genes and increased depo-
Effects of chlorpromazine (CPZ), known to induce intra-hepatic cholestasis have been analyzed using differentiated human HepaRG cells. Bile acids efflux and influx have previously been reported to be inhibited by CPZ. These changes correlated with occurrence of a strong contraction of the bile canalicular lumen (BCL). In this work we attempted to define the molecular mechanisms involved in BCL morphogenesis and reorganization in CPZ-treated HepaRG cells by imaging analyses. We observed that BCL contraction was a dose-dependent morphogenic process associated with a reduction to 2, in the number of cells clustered to form each bile canaliculus (BC), involving extensive cytoskeleton reorganization. These changes were correlated with the RHO-kinase (ROCK) pathway induction as also argued by the antagonized effects obtained with various inhibitors of this pathway. Addition of ROCK inhibitor to normal cells resulted in the development of enlarged apical lumen that shared 3 or more cells per single BC and lined with a dense F-actin network. Similar remodeling of the apical lumen of CPZ-treated cells exposed to ROCK inhibitor was observed. Using ETA, a ROCK inducer, we reversed the apical lumen remodeling to small lumen with only 2 or 3 clustered cells, thus mimicking CPZ-treated cells. In addition, inhibition of the myosin heavy chain ATPase by BDM, a downstream ROCK target controlling contraction by actin-myosin interactions, mimicked the reorganization induced by ROCK inhibitor of the large canalicular lumen by increasing the number of cells sharing a single BC. Taken together, these results demonstrate that HepaRG hepatocytes can rapidly respond to the main factors modulating the ROCK pathway and identified as controlling the BCL morphogenesis. They highlight the critical role of this pathway in CPZ-induced cholestasis. Understanding of these control mechanisms should help development of liver-cell based therapies.

LGGs treatment as evaluated by triglyceride content measurement and Oil Red O staining of the liver sections. In addition, alcohol exposure also increased circulating and hepatic free fatty acid concentration, which is attenuated by LGGs treatment. Further study demonstrated that alcohol induced a significant decrease in AMPK and ACC phosphorylation, and these effects were prevented by LGGs administration in animals, which is correlated with the increase of the expression of adiponectin receptors. We also found that alcohol exposure increased hepatic SREBP-1c protein expression and LGGs treatment inhibited this increase. Further studies showed that LGGs prevented alcohol-induced hepatic apoptosis as evaluated by TUNEL assay. In vitro studies confirmed the positive effects of LGGs in promoting AMPK phosphorylation. These results suggest that LGGs is effective in preventing chronic alcohol-induced liver injury by suppression of alcohol-induced hepatic apoptosis and steatosis through AMPK phosphorylation. This finding could lead to developing new strategies for reducing chronic alcohol-induced liver injury by secreted factors of LGG culture.
Furosemide (FS) is a common diuretic. Though safe when used appropriately, it is increasingly popular as a model hepatotoxicant, due in part to the fact that the histological pattern of injury resembles acetaminophen but it does not appear to involve mitochondrial dysfunction. Despite this, the mechanisms of FS-induced liver injury are unclear. It was shown that a reactive metabolite binds to proteins, and that inhibition of P450s prevents the toxicity. Beyond this, however, little is known. To explore the mechanisms of FS hepatotoxicity, we treated mice with 500 mg/kg FS and collected plasma and livers at various time points to probe for evidence of activation of cell signaling pathways. In animals with liver injury, plasma ALT increased by 6h (246±46 U/L) and was constant until at least 12h (151±15 U/L). Interestingly, ALT dramatically increased at 24h (2.24±1695 U/L). Histology and TUNEL staining revealed spotty necrosis at early time points, which developed into widespread centrolobular necrosis. Immunoblotting for caspase-3 failed to provide evidence for apoptosis, and cytochrome c release into cytosol did not increase before 24h, consistent with the idea that FS toxicity does not involve mitochondrial damage. Nevertheless, JNK phosphorylation and translocation to mitochondria were observed at 6h and persisted. RIP3, which may be involved in JNK signaling, was induced by 6h. Because of the unusual time course showing an initial injury with a delayed increase, we also stained liver sections for neutrophils. Interestingly, we observed neutrophil infiltration by 6h, but the most infiltration was seen at 24h. Finally, we observed an increase in cell death (LDH release) in metabolically-competent human liver cells (HepaRG) treated with FS.

Conclusions: Large doses of FS cause injury in both mice and human HepaRG cells. The mechanism of hepatotoxicity in mice may involve intracellular signaling pathways at early time points, followed by inflammation at later times.

1198 Hepatic Toxicological and Lipid Peroxidation Assessments of Pioglitazone on Albino Wistar Rats

O. O. Oluwanla1, O. E. Ogunlana2, U. K. Stanley1, J. A. Olagunj1 and A. A. Akindahunsi2.

1Department of Biological Sciences, Covenant University, Ota, Ogun, Nigeria, 2Department of Medical Biochemistry, Lagos State University, Ilaje, Lagos, Nigeria and 3Department of Biotechnology, University of Technology, Akure, Ondo, Nigeria.

Pioglitazone is one of the thiazolidinedione anti-diabetic drugs which have been used for the treatment of non-insulin dependent diabetes mellitus. This work aims at studying the hepatic toxicity of pioglitazone (PIO) when administered in various high concentrations in female albino Wistar rats. Four groups of seven animals each were treated with test substances for twenty eight days. Group one was given 0.5 ml distilled water, while groups 2 to 4 were given 15 mg/kg, 30 mg/kg and 45 mg/kg of body weight of PIO respectively. Using standard biochemical kits and reported chemical procedures, hepatic biochemical, histological and lipid peroxidation assessments of PIO were determined in the plasma of experimental animals. There was no significant change in aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), total and direct bilirubin and malondialdehyde concentrations in pioglitazone-treated groups when compared to control(<0.05). Pioglitazone did not elicit any noticeable liver toxicity at the experimental doses used in the study in non-diabetic animal model.

1199 NSAIDs Synergize with Inflammatory Cytokines to Kill Hepatocytes: Implications in Idiosyncratic Reactions

A. Mauji1,2, L. Gora1, R. Parkins1, P. E. Ganev1,2 and R. A. Roth1,2.

1Pharmacology and Toxicology, Michigan State University, East Lansing, MI, 2Center for Integrative Toxicology, Michigan State University, East Lansing, MI and 3College of Veterinary Medicine, Michigan State University, East Lansing, MI.

Idiosyncratic drug-induced liver injury (IDILI) occurs in a small fraction of patients taking a drug and, although rare, can result in severe liver injury or death. The mechanisms of IDILI are unknown; however, factors resulting from an activated immune system are likely to be important in the pathogenesis. The inflammatory mediators, tumor necrosis factor-alpha (TNF) and interferon-gamma (IFN) are two such factors that can activate pathways to cell death as well as proliferation. We tested the hypothesis that non-steroidal anti-inflammatory drugs (NSAIDs) associated with IDILI in humans synergize with TNF and/or IFN to cause death of hepatocytes and inhibit cell proliferation in vitro. HepG2 cells were treated with NSAIDs that have high IDILI liability (diclofenac, sulindac sulfide, bromfenac, or nimesulide) and NSAIDs with less IDILI liability (naproxen, ibuprofen, rofecoxib, and aspirin) alone and in combination with TNF and/or IFN. Treatment of cells with drugs with high IDILI liability in the presence of TNF resulted in cytotoxicity. IFN potentiated the cytotoxicity caused by diclofenac, sulindac sulfide, and bromfenac in the presence of TNF. Naproxen and ibuprofen synergized with TNF to cause cytotoxicity in HepG2 cells, but IFN did not affect the response to any of the drugs with low IDILI liability. Treatment of cells with diclofenac in the presence or absence of TNF and IFN inhibited proliferation of HepG2 cells. These data indicate that NSAID-induced hepatocellular stress interacts with TNF and IFN to cause cell death and inhibit proliferation. Given that failure of proliferative repair could magnify modest liver damage, these findings raise the possibility that some IDILI reactions result from such drug-cytokine synergy. (Supported by NIH grant DK061315 and T32 GM092715)

1200 Elevation of Serum Transaminases Due to CSF1-R Inhibition

Serum biomarkers such as alanine aminotransferase (ALT) and aspartate aminotransferase (AST) are well-characterized hepatotoxicity biomarkers that correlate well with liver histopathology. However, it has been reported that colony stimulating factor-1 receptor (CSF1-R) inhibition results in decreased proliferation, differentiation and function of macrophages, leading to decreased clearance of serum transaminases. In support of this observation, we previously demonstrated increases in serum AST in the absence of histopathology following treatment of rats with CC0485118, a small molecule kinase inhibitor of spleen tyrosine kinase (Syk) that also inhibits CSF1-R. In the current study, we investigated the effect of CSF1-R inhibition by CC0485118 on AST clearance in serum. Jugular vein cannulated (JVC) Sprague-Dawley rats were dosed with 400 mg/kg of CC0485118

316 SOT 2014 ANNUAL MEETING
for 4 consecutive days via oral gavage. On last day of treatment, rats were injected intravenously with 200 μl of purified rat AST. Serial blood samples were collected at baseline and up to 24 hours post-injection. In this study, clearance of AST in test article-treated animals was approximately 50% of vehicle-treated animals. Similar findings were seen in a subsequent study using an inhibition of AST, indicating that the increase in AST were due to decreased clearance and not increased production. This mechanism was further investigated in vivo using rat hepatocyte-Keupfer cell co-cultures treated with increasing concentrations of CC0485118 (10, 50, or 100 μM) to evaluate compound effect on the phagocytic function of Kupffer cells. Results showed that 50 μM or higher of CC0485118 attenuated the uptake of S. aureus bioparticles compared to vehicle alone. The inhibition was not due to compound toxicity as assessed by ATP assay. The evidence of in vitro inhibition of Kupffer cell function and in vivo AST clearance attenuation related to CC0485118, supports the hypothesis that the elevation of AST is caused by decreased phagocytic activity by liver macrophages.

### 1200a Regorafenib at Clinically Relevant Concentrations Impairs Mitochondrial Functions Causing Necrosis in Primary Rat Hepatocytes

Regorafenib, a kinase inhibitor, was recently approved by regulatory agencies for cancer treatment. Based on clinical trial data, a black box warning about regorafenib-induced hepatotoxicity was included in the FDA-endorsed product label at the time of market approval. The mechanism for regorafenib-associated hepatotoxicity is unknown. Isolated rat liver mitochondria or primary hepatocytes were incubated with regorafenib. Oxygen consumption was determined using a Clark electrode. Mitochondrial permeability transition (MPT) was measured by a swelling assay and the fluorescent dye calcine. Mode of cell death was determined by annexin V/propidium iodide staining supplemented with measuring lactate dehydrogenase leakage and caspase activation. In isolated mitochondria, regorafenib significantly uncoupled (but did not inhibit) oxidative phosphorylation (OXPHOS) and promoted calcium overload-induced mitochondrial swelling, with the latter being completely preventable by cyclosporin A (CsA). In primary hepatocytes, regorafenib caused strong uncoupling of OXPHOS, a rapid onset of MPT, a sharp decrease in mitochondrial inner membrane potential, a significant adenine nucleotide triphosphate (ATP) shortage, and ensuing necrosis (but not apoptosis). Pretreatment by MPT blockers CsA and trifluoperazine, or the glycolysis enhancer fructose plus the mitochondrial ATPase inhibitor oligomycin A, or their combination, significantly delayed the onset of necrosis. Remarkably, all detrimental effects were observed at clinically-relevant concentrations of 2-15 μM, which were in the range of maximal blood concentrations achieved after taking recommended daily doses. The data demonstrate that regorafenib causes necrosis in primary hepatocytes by uncoupling OXPHOS and MPT induction, indicating that mitochondrial damage possibly contributes to the pathogenesis of regorafenib-induced hepatotoxicity.

### 1200b Targeted Serum Bile Acid Profile of Naïve Rats and Dogs over a 24h Time Course

Regorafenib, a kinase inhibitor, was recently approved by regulatory agencies for cancer treatment. Based on clinical trial data, a black box warning about regorafenib-induced hepatotoxicity was included in the FDA-endorsed product label at the time of market approval. The mechanism for regorafenib-associated hepatotoxicity is unknown. Isolated rat liver mitochondria or primary hepatocytes were incubated with regorafenib. Oxygen consumption was determined using a Clark electrode. Mitochondrial permeability transition (MPT) was measured by a swelling assay and the fluorescent dye calcine. Mode of cell death was determined by annexin V/propidium iodide staining supplemented with measuring lactate dehydrogenase leakage and caspase activation. In isolated mitochondria, regorafenib significantly uncoupled (but did not inhibit) oxidative phosphorylation (OXPHOS) and promoted calcium overload-induced mitochondrial swelling, with the latter being completely preventable by cyclosporin A (CsA). In primary hepatocytes, regorafenib caused strong uncoupling of OXPHOS, a rapid onset of MPT, a sharp decrease in mitochondrial inner membrane potential, a significant adenine nucleotide triphosphate (ATP) shortage, and ensuing necrosis (but not apoptosis). Pretreatment by MPT blockers CsA and trifluoperazine, or the glycolysis enhancer fructose plus the mitochondrial ATPase inhibitor oligomycin A, or their combination, significantly delayed the onset of necrosis. Remarkably, all detrimental effects were observed at clinically-relevant concentrations of 2-15 μM, which were in the range of maximal blood concentrations achieved after taking recommended daily doses. The data demonstrate that regorafenib causes necrosis in primary hepatocytes by uncoupling OXPHOS and MPT induction, indicating that mitochondrial damage possibly contributes to the pathogenesis of regorafenib-induced hepatotoxicity.

### 1200c Effects of Red Ginseng Extracts on the Ethanol-Induced Hepatotoxicity In Vivo and In Vitro

S. Kim, J. Sim, O. Kwon, M. Song, H. Kim, S. Ki, T. Jeon and S. Lee. College of Pharmacy, Kyungpook National University, Daegu, Republic of Korea, College of Pharmacy, Chosun University, Gwangju, Republic of Korea, and College of Pharmacy, Yeungnam University, Gyeongsang, Republic of Korea.

Red ginseng is a root of Panax ginseng C.A. Meyer, which has been widely used for traditional medicinal purposes, was evaluated using male Wistar albino rats. Acute and sub chronic toxicity was evaluated after 90 days of exposure. The LD50 was 2154mg/kg. Serum levels of glucose, lactate dehydrogenase, aspartate aminotransferase transaminase, and total bilirubin increased significantly in the 58.5 and 1077mg/kg dose groups. These two groups also had significantly reduced serum levels albumin and total serum protein when compared with the control group. Histopathological assessment showed degenerative changes in the liver.

### 1200d CYP2A5 Contributes to Cadmium-Induced Liver Injury but Protects against Alcoholic Liver Disease

Y. Lu and A. Cederbaum. Mount Sinai School of Medicine, New York City, NY.

Ethanol can induce cytochrome P450 2E1 (CYP2E1), an activator of reactive oxygen species, and CYP2E1 is considered a risk factor for alcoholic liver disease. Recently we found that ethanol can also induce CYP2A5, and ethanol induction of CYP2A5 is CYP2E1-dependent and regulated by Nrf2 pathway. Cadmium can also induce CYP2A5 and cadmium induction of CYP2A5 is also regulated by Nrf2, but cadmium does not induce CYP2E1. The role of CYP2A5 in liver injury is still unclear. In this study, we examined liver injury induced by ethanol and cadmium chloride (CdCl2) in CYP2A5 knock out (cyp2a5−/−) mice and wild type (WT) mice. To examine cadmium-induced liver injury, WT and cyp2a5−/− mice (male, 8-10 weeks old) were injected CdCl2 intraperitoneally at a dose of 5 mg/kg, and then the mice were sacrificed 24 h after the CdCl2 administration. CYP2A5 was induced in WT mice but not in cyp2a5−/− mice. Serum levels of ALT and AST were increased to a greater extent in WT mice than in cyp2a5−/− mice. Cadmium-induced necrosis was more severe in WT mice than in cyp2a5−/− mice. Consistently, 3-nitrotyrosine (3-NT), a marker of oxidative stress, was induced in WT mice more than in cyp2a5−/− mice. As for alcoholic disease, Lieber-Decarli model was applied. After 3 weeks of feeding with Lieber-Decarli ethanol liquid diet, unlike cadmium-induced liver injury, ethanol-induced liver injury was enhanced in cyp2a5−/− mice compared with WT mice as indicated by serum ALT, hepatic fat accumulation (steatosis) and necro-inflammation observed in H&E stained liver sections. Ethanol-induced oxidative stress was also higher in cyp2a5−/− mice than WT mice. Ethanol feeding induced CYP2A5 in WT mice but not in cyp2a5−/− mice, although induction of CYP2E1 was comparable in cyp2a5−/− and WT mice. These results suggest that CYP2A5 contributes to cadmium-induced liver injury, and in contrast, CYP2A5 protects against ethanol-induced liver injury.
ethanol-fed mice and hepatoma cells. Mice were randomly divided into 4 groups: control, EtOH fed group, EtOH and Korean red ginseng extracts (KRG extract) fed group (250 and 500 mg/kg) for 4 weeks. AML-12 cells were treated with EtOH and/or red ginseng extracts (0 – 1 mg/ml). Lipid droplets were determined using Oil red O staining and expression of SirT1 and SREBP-1 were investigated by western bloting in microsomal fraction and cells. The orally KRG extracts administrated mice showed hepatoprotective effects against EtOH-induced hepatotoxicity, and inhibited immunoreactivities, expression of nitrotyrosine as marker of iNOS related oxidative stresses and 4-HNE as marker of lipid perox- idation. Treatment of KRG extracts significantly increased SirT1 and decreased SREBP-1 in ethanol-fed mice and cells. We investigated the effect of individual ginsenoside related to regulation of SirT1 and SREBP-1 contrasted in EtOH- treated cells. This finding indicated that the treatment of KRG extracts showed hepatoprotective effects against EtOH-related hepatotoxicity in vivo and in vitro.

1200h In Vivo Optical Imaging of Acetaminophen-Induced Liver Toxicity
Drug induced liver injury (DILI) is a major reason for late stage termination of drug development projects, so assessment is now routinely being integrated earlier in the drug development process. In vivo optical imaging offers non-invasive detection of biological changes in preclinical animal efficacy models, and this approach is also ideal for in vivo toxicology determination. We applied near infrared (NIR) fluorescence imaging techniques to the detection and quantification of DILI in living mice, using NIR fluorophore-labeled Annexin V (Annexin-Vivo 750 [AV750]) to detect cell surface phosphatidylserine on apoptotic and necrotic cells. AV750 was imaged 2h after injection, and could be re-injected safely every 24 h for long-term monitoring of the same animals. As a positive control, we used acetaminophen (APAP), a commonly used over-the-counter analgesic and antipyretic drug that is known to cause centrilobular hepatic necrosis when used at high doses. When male C57BL/6 mice were injected with a single dose (500 mg/kg) of APAP, the resulting liver necrosis peaked at 24 hours as detected by imaging with Annexin-Vivo 750 in living animals. Imaging results at 24h were statistically significant as compared to those of the PBS control group using only 3-4 mice per group. Both fluorescent tomographic imaging (FMT 4000), and higher throughput epifluorescence imaging (IVIS Spectrum CT), provided excellent detection of AV750 fluorescence in the liver. Histology and plasma ALT confirmed the kinetics of tissue necrosis, and at 48 hours more extensive liver damage was seen but with a decrease in tissue phosphatidylserine and plasma ALT, suggesting a decline in active tissue destruction. Maximal tissue damage was measured at 300 and 500 mg/kg APAP doses by AV750. Compared to conventional plasma/serum assays, in vivo imaging can offer fast, quantitative imaging results directly assessing the tissue of interest. Our results to date demonstrate the utility of optical imaging for assessing potential compound liver toxicity in early drug development programs.

1200i Leelamine Is A As a Potent Novel Inducer of Hepatic CYP2B
J. Sim1, W. Nam1, H. Oh1, S. Lee1, D. Lee1, T. Lee1, S. Ki2, T. Jeong3 and S. Lee1.
1College of Pharmacy, Kyungpook National University, Daegu, Republic of Korea. 2College of Pharmacy, Chonnam University, Gwangju, Republic of Korea and 3College of Pharmacy, Yeungnam University, Gyeongsan, Republic of Korea.
Cytchrome P450 (CYPs) are the important enzymes take part in a xenobiotic substance like as toxic chemicals, drugs. Many drugs may affect the activity of CYP, which is a major source of adverse drug interactions. Phenobarbital (PB), one of the antiepileptic drugs is well known to induce drug metabolizing enzymes in the liver. Especially, PB has been widely used to induce the CYP2B for in vivo monitoring of the same animals. As a positive control, we used acetaminophen (APAP), a commonly used over-the-counter analgesic and antipyretic drug that is known to cause centrilobular hepatic necrosis when used at high doses. When male C57BL/6 mice were injected with a single dose (500 mg/kg) of APAP, the resulting liver necrosis peaked at 24 hours as detected by imaging with Annexin-Vivo 750 in living animals. Imaging results at 24h were statistically significant as compared to those of the PBS control group using only 3-4 mice per group. Both fluorescent tomographic imaging (FMT 4000), and higher throughput epifluorescence imaging (IVIS Spectrum CT), provided excellent detection of AV750 fluorescence in the liver. Histology and plasma ALT confirmed the kinetics of tissue necrosis, and at 48 hours more extensive liver damage was seen but with a decrease in tissue phosphatidylserine and plasma ALT, suggesting a decline in active tissue destruction. Maximal tissue damage was measured at 300 and 500 mg/kg APAP doses by AV750. Compared to conventional plasma/serum assays, in vivo imaging can offer fast, quantitative imaging results directly assessing the tissue of interest. Our results to date demonstrate the utility of optical imaging for assessing potential compound liver toxicity in early drug development programs.
Air pollutants such as environmental tobacco smoke (ETS) and acrolein (the predominant irritant in tobacco smoke) produce oxidative stress in the respiratory tract airways. Oxidative stress plays an important role in the pathogenesis of airway diseases such as asthma. Epidemiological evidence suggests that acetaldehyde (N-acetyl-papa-aminophenol, APAP), a widely used analgesic, may also play a role in the pathogenesis of asthma via oxidative stress-related mechanisms, but direct data on the pro-oxidant effects of APAP in the airways is absent. To determine if APAP causes oxidative stress in the airways at near-therapeutic doses we administered APAP to female C57Bl/6 mice and measured tissue protein-nitrosothiols (NPSH) as a marker for the antioxidant glutathione, and antioxidant response element (ARE)-dependent gene induction by qRT-PCR. Lung, trachea, and nasal NPSH levels were diminished to ~80% of control 1 hr following a 100 mg/kg dose of APAP (ip). APAP at 60 and 100 mg/kg caused significant ARE gene induction within 2hrs, and pre-treatment of mice with APAP potentiated the ARE gene response to ETS (5 mg/m3). We next determined if APAP modulated the airway responsiveness to oxidant air pollutants using sensory irritation as an index of airway response. Sensory irritation is due to stimulation of trigeminal sensory nerves and is known to be pro-inflammatory. APAP alone (100 mg/kg) did not elicit a response, but it greatly increased the sensory irritation response to both acrolein and ETS. The current results demonstrate that APAP, at near-therapeutic doses, causes oxidative stress in airway tissues and enhances the airway response to oxidant air pollutants. Children exposed to ETS are more likely to develop asthma. Modulation of airway responses to ETS provides a mechanism for the association between APAP use and the development of asthma in pediatric populations. (Supported by the University of Connecticut President’s Research Award)

**1202 Characterization of the Blu E-Cigarette to Define the Composition of Inhaled Material**

T. Holmes, J. D. McDonald, P. J. Kuehl and D. Kracko. LRRI, Albuquerque, NM.

In order to better define human exposure and to design experiments for toxicology systems (in vitro and in vivo) an aerosol characterization of the Blu® e-cigarette was conducted. E-cig were characterized for aerosol mass, particle size, gas/particle partitioning, excipient, nicotine and formaldehyde content. We applied a modified Canadian Intensive protocol and developed a novel characterization system. The Blu® e-cig heating processes resulted in generation of an aerosol mixture of particle expentiants, nicotine present in both the gas and droplet phase, and small but detectable amounts of formaldehyde. There were over 1 million particles/cm3 of ~110 nm in size measured from a puff. E-cigarettes may have a decreased risk to users compared with conventional inhaled tobacco products. The aerosols were composed of evaporative particles, with lesser amounts of nicotine and other gases such as formaldehyde. This contrasts marketing for the device, which suggests that people only inhale nicotine vapor and water. The health consequence of these inhaled materials is uncertain based on available evidence, but the information provided here will assist in future risk assessments and the design of toxicology studies.

**1203 A Mechanistic Study of Cigarette Smoke-Induced COPD in C57Bl/6 Mice: The Impact of Switching to a pMRTP**

E. Veljkovic1, B. Phillips2, M. Peck3, A. Buettner3, J. Hoeng1, M. Daniels3, E. H. Boykin3, R. Jaskot3, R. Harrison3, J. Griffioen3, I. Gilmour3 and J. A. Dye3. 1Toxicology, UNC, Chapel Hill, NC, 2EPHD, NHEERL, EPA, RTP, NC and 3PMI.

In this study, the impact on the development of emphysema/COPD following inhalation of aerosol from two tobacco products, a reference cigarette (3RF) and a prototypic modified risk tobacco product (pMRTP), was evaluated in C57Bl/6 mice. The mice were exposed to an aerosol from 3RF (750 µg TPM, 34.4 µg/l nicotine), pMRTP (nicotine concentration-matched) or filtered air (sham) for 4 hours per day, 5 days per week, up to 7 months. At 2 months of exposure to 3RF, switching and cessation groups were exposed to pMRTP or filtered air, respectively. To analyze the progression of emphysema, evaluations of inflammation, pulmonary function, and various histopathological and molecular changes (transcriptomics and lipidomics) were performed at months 1, 2, 3, 4, 5 and 7. Exposure to 3RF induced molecular, cellular and physiological modifications in lungs leading to emphysematous changes. Animals exposed to pMRTP exhibited negligible changes in all parameters assessed. Both cessation and switching groups showed a reversal of the inflammatory and functional responses induced by 3RF smoke. Histopathological evaluation revealed a slowdown in the progression of emphysematous changes in switching and cessation groups. Smoking cessation or switching resulted in the rapid recovery at the transcription level. The lipid profiles in lung, liver and plasma similarly showed a clear 3RF effect, with minimal changes associated with pMRTP exposure, and recovery near to sham-exposed levels following either switching or cessation. These data demonstrate that exposure to pMRTP for up to 7 months resulted in a response similar to fresh air-exposed animals using a battery of physiological and molecular measures. Furthermore, following a 2 month 3RF cigarette smoke exposure period, both cessation and switching to a pMRTP aerosol resulted in the reversal or stabilization of parameters assessed.

**1204 Examination of Acute Pulmonary Responses to Various Cookstove Exhaust Emissions**

Air pollution is a global public health problem, to which the emissions from rudimentary cooking devices has been estimated to contribute significantly through the burning of various types of biomass. Notably, exposure to cookstove emissions (CE) has been linked to increases in morbidity and mortality causing an estimated 4 million deaths which most frequently impact women and children. Current efforts to reduce CE have led to the development of several new cookstoves (CS) designs. Although some studies have characterized improvements in the overall release of specific pollutants from modern CS, there is less information regarding the potential health benefits that may be derived from their usage. In this study, currently marketed CS models representing 4 different CS types, 3-Stone (3S), 3-Stone Forced Draft (FD), Natural Draft (ND), and Propane (PR), were used under the same cooking conditions for two consecutive cooking cycles. Exhaust emissions from each stove were characterized, and young adult female CD-1 mice were simultaneously exposed for 2-3 hr per day. Various endpoints examined at 0, 4, and 24 hr post-exposure (PE) included lung inflammation and changes in redox status/antioxidant capacity. Of these endpoints, CS emissions were observed to most significantly affect the pulmonary redox status of exposed animals via the oxidation of cellular glutathione. As compared to filtered air controls, lung homogenates from CE-exposed mice had consistently decreased levels of reduced glutathione (GSH), with corresponding increases in disulfide glutathione (GS=GS), at 0 and 24 hr PE for all 4 CS. While no significant increase in pulmonary inflammation were observed in CE-exposed animals, macrophages from 3S and ND-exposed mice had a visible particle burden 24 hours PE, as compared to air controls. Together, these data support the need for a continued assessment of the health effects resultant from prolonged exposure to the exhaust emissions of modern CS. (Does not necessarily reflect USEPA policy)

**1205 Effect of Near-Road Particulate Matter on Respiratory Responses and Inflammation in Healthy and Ovalbumin-Allergic Mice**

M. A. McGee1, J. McGee2, E. H. Boykin3, M. Daniels2, L. B. Copeland2, D. Andrews2, J. Richards3, I. Gilmour3 and S. G. Hyatt2. 1Curriculum in Toxicology, UNC, Chapel Hill, NC, 2PMI, 3PMI.

The Near-Road Exposures and Effects of Urban Air Pollutant Study (NEXUS) previously examined the association of near-roadway exposures to air pollutants and respiratory outcomes in children with asthma. This toxicological study was designed to complement NEXUS and determine which particulate matter (PM) characteristics may contribute to exacerbation of allergic asthma. Samples of coarse, fine and ultrafine PM were collected upward and downward from I-96 in Detroit, MI during Winter 2010/11. Healthy and ovalbumin (OVA)-sensitized female Balb/c mice were exposed via oropharyngeal (OP) aspiration to 20 or 100 µg coarse, fine, or ultrafine fractions of upward or downward PM 2 hr prior to OP challenge with 20 µg OVA. No samples caused significant changes in immediate responses to OVA challenge as determined by whole body plethysmography (WB). Two days later, airway responsiveness to methacholine aerosol (assessed by WB) was not significantly affected by PM exposure in either healthy or allergic mice. In OVA-allergic mice, 100 µg downward coarse PM caused a greater increase than downwind fine or ultrafine PM in bronchoalveolar lavage (BAL) neutrophils (7x vs. control blank filter extract) and eosinophils (10x) and also caused significant increases in BAL LDH and NAG. Interestingly, 100 µg upward fine PM produced greater increases in neutrophils (7x vs. control blank filter extract) and eosinophils (4x) than upward coarse or ultrafine PM. Ultrafine PM did not significantly increase neutrophils or eosinophils in comparison to allergic mice given ultrafine blank filter extract. Further analyses will be conducted to investigate associations between
chemical components and phenotypic effects of allergic lung disease. We conclude that coarse PM downwind and fine PM upwind of traffic promote allergic inflammation in OVA-allergic mice. (This abstract does not represent U.S. EPA policy.)

**1206 Diurnal Variation in Toxicological Effects of Size-Segregated Particulate Samples Collected from High-Air Pollution Situation in China**

University of Eastern Finland, Kuopio, Finland and University of Nanjing, Nanjing, China. Sponsor: M. Viluksela.

Air pollution is a wide recognized problem all over the world. The air pollution levels in ambient air are known cause for premature deaths, many respiratory and cardiac diseases as well as cancer. We studied the in vitro toxicological responses associated with the observed adverse health effects. Thus far, the daily variations in air pollution levels and the consequent health effects have been studied to a lesser extent. We collected the particles for toxicological and chemical analyses from University of Nanjing, Xianlin campus. The generally high air pollution situation in China allowed us to separate between the day and nighttime samplings due to sufficient collected mass. With this approach we also got information on how the atmospheric processes and changes in the emission sources alter the toxicity of the collected particulate matter. The samples were collected with high volume cascade impactor in four different size ranges (PM10-2.5; PM2.5-1; PM1-0.2; PM0.2) and then extracted from the sampling substrates. Mouse macrophage cell line was employed in detection of the toxicological responses of the particulate samples including cytotoxicity, genotoxicity and inflammatory responses. The results showed that both chemistry and toxicological responses change between day and night. Nighttime samples had much more PAHs than the daytime samples. Cytotoxicity was rather similar in the day and night samples. However, inflammatory responses and genotoxicity were significantly higher during the daytime when compared to the night. It is possible that breakdown products of the PAHs are responsible for the higher responses during the daytime. When compared to the previous results from less polluted situations in Europe, the responses were quite different. In conclusion, the toxicity of the particulate mass in polluted situation during day and nighttime showed large variation.

**1207 Particulate Matter from Saudi Arabia Induces Genes Involved in Cholesterol and Lipid Metabolism**

L. Chen and T. Kluz.

1Environmental Medicine, NYU School of Medicine, Tuxedo, NY and 2Faculty of Meteorology, Environment, and Arid Land Agriculture, King Abdulaziz University, Jeddah, Saudi Arabia.

Airborne particulate matter (PM) exposure is a major environmental health concern and is linked to metabolic disorders, such as cardiovascular diseases (CVD) and diabetes, which are on the rise in the Kingdom of Saudi Arabia. This study investigated changes in mouse lung gene expression caused by administration of PM10 collected from Jeddah, Saudi Arabia. FVB/N mice were exposed to 100 μg PM10 or water by aspiration and euthanized 24 h later. The bronchoalveolar lavage fluid (BALF) was collected and analyzed for neutrophil concentration and TNF-α and IL-6 levels. IL-6 and TNF-α were significantly higher in mice exposed to PM according to an ELISA assay and neutrophil concentration was also increased in exposed mice. RNA was extracted from the lungs and whole transcript was analyzed using Affymetrix Mouse Gene 1.0 ST Array. Mice exposed to PM10 displayed an increase in neutrophil concentration and elevated TNF-α and IL-6 levels. Gene expression analysis revealed that mice exposed to PM10 displayed 202 genes that were significantly up-regulated and 40 genes that were significantly down-regulated (p<0.05). PM10 induced genes involved in inflammation, cholesterol and lipid metabolism. This is the first study to demonstrate that Saudi Arabia PM10 increases in vivo expression of genes located in pathways associated with diseases involving metabolic syndrome.

**1208 Compounds Collected from Indium-Tin Oxide Production Induce Inflammatory Responses from Cultured Macrophages and Bronchial Epithelial Cells**

M. A. Budding, D. Schweger-Berry, K. J. Cummings and S. S. Leonard.

1Health Effects Laboratory Division, NIOSH, Morgantown, WV and 2Division of Respiratory Disease Studies, NIOSH, Morgantown, WV.

Indium-tin oxide (ITO) is used to make transparent conductive coatings for touch-screen and liquid crystal display electronics. Lung disease among workers in the ITO industry is an emerging occupational health concern as the demand for consumer electronics continues to increase. Epidemiologic studies have shown indium compound-exposed workers to have pulmonary alveolar proteinosis and fibrotic interstitial lung disease. However, the molecular mechanisms behind indium compounds’ toxicity remain largely unknown. Thus, we aim to uncover how compounds encountered during ITO production affect cultured cells and ultimately, contribute to the pathogenesis of indium lung disease. We hypothesize that indium compounds (8 different samples collected from various stages at an ITO facility) cause lung pathology through direct cytotoxicity and/or via inflammatory signaling from exposed cells. Preliminary studies showed that exposure of RAW 264.7 monocyte macrophages and BEAS-2B bronchial epithelial cells to indium compounds resulted in significantly reduced viability. Microscopy techniques revealed that various indium compounds interact with and are engulfed by both cell lines within 1 to 3 hours, suggesting that cellular reactions may be occurring very rapidly. Indeed, nuclear factor kappa beta (NFκB) activation occurs within 3 hours of treatment with compounds containing sintered ITO in both cell lines. Robust cytokine production (TNFα, IL-1β, IL-6, and IL-8) following cellular exposures confirmed that pro-inflammatory responses are indeed occurring. Our results suggest that inflammatory responses to indium compounds by both pulmonary macrophages and epithelial cells may initiate and propagate indium lung disease. These findings have provided a better understanding of the molecular mechanisms behind an emerging occupational health issue and will aid in the discovery of biomarkers for disease prevention.

**1209 Differential Diagnosis of Airways Diseases Using the Ratio of FEV1/FVC in Subjects Occupationally Exposed to Powder Particles in a Pharmaceutical Industry in Nigeria**

J. O. Omotolu, 1, 2Chemical Pathology, University of Ibadan, Ibadan, Nigeria and 2University of Ibadan, Ibadan, Nigeria.

Contribution of exposure to chemicals, fumes, dust and particles to the growing incidence of Chronic Obstructive Pulmonary Disease (COPD) has not been critically evaluated in this environment. This work was a preliminary report of the diagnostic differentials of COPD using pulmonary function indices determined in subjects occupationally exposed to chemical particles and dust in a pharmaceutical industry in Nigeria. 125 workers in the organization were screened for their pulmonary functions. Using Global Initiative for Obstructive Lung Disease (GOLD) as the mode of analysis and based on percentage FEV1/FVC ratio, 31.2% (39) had Normal Respiratory (NR) function; 24.8% (31) had Mild Restriction (MR); 24.4% (30) had Moderate Restriction (MoR); 10.4% (13) had Moderately Severe Restriction (MSR); 5.6% (7) had Severe Restriction (SR); 2.4% (3) had Mild Obstruction (MO) while 0.8% (1) had Obstruction combined with Restriction (OR). Using the NR group as reference and towards stratifying the data, mean FEV1 and FVC obtained for the MoR, MoR, MSR, SR, MO and OR groups were compared with that of NR. The Mean values varied significantly in all the other groups (p<0.005) except with the MoR group (p=0.005). With this correction, 69.2% (28) could be said to show normal pulmonary function while the remaining (33.4%) had a form of respiratory abnormality or the other. The application of basic spirometry measurement and the need for enforcement of various industrial laws monitoring risk exposure towards reducing toxicity of chemicals by inhalation and the attendant airways diseases in our industries was further highlighted in this work.

**1210 Black Carbon Exposure Levels in New York City’s Subway Stations**

M. Vlissasim, G. D. Thurston and T. Gordon.

Environmental Medicine, New York University, Tuxedo, NY.

The New York City subway is the main mode of transport for over 5 million passengers on average weekdays. Commuters are thus exposed frequently to the microenvironment in subway stations and airborne pollutants can have a significant impact on subway users if exposure levels are high. This study looked at black car-
nary fibrosis. Also our study shows that a single dose of PHMG-P model induces suggested evidences that PHMG-ph-induced apoptosis continuously stimulates in-
creased eNO. Non-treated phosgene-exposed and treated but non-phosgene-ex-
posed rats survived. This experimental evidence suggested that high-dose corticoid treatments may aggravate the pulmonary toxicity of phosgene. In contrast, the NOS-inhibitor aminoguanidine reduced the magnitude of lung edema. In summary this study seems to support the view that the pro-apoptotic corticosteroids may further deteriorate the lung while the known anti-apoptotic property of SS maintains function. Inhalation therapy with an aerosolized iNOS inhibitor was both efficacious to reduce eNO and lung weights. This outcome seems to suggest that cardiovascular and not irritation-related tissue destruction is the lead etiopathology of phosgene-induced lung edema.

1213 The Long-Term Toxicity and Mesothelial Cell Reactions Induced by Potassium Octatitanate Fibers (TISMO) in the Left Thoracic Cavity in A/J Female Mice

M. Yokohira, S. Kishi, Y. Nakano, K. Yamakawa, F. Ninomiya, S. Kanie and K. Imaida. Onco-pathology, Kagawa University, Faculty of Medicine, Kagawa, Japan.

The present study was performed to assess effects on mouse lung and thoracic cavity by potassium octatitanate fibers, trade name TISMO, which is often used for fric-
tion material of cars, precision filters or the others, and with the chemical formula K2O·TiO2. Previously (SOT in 2012), we presented the 21 weeks experiment for TISMO with dimensions mostly <50μm in length and <2μm and granular-shaped micro- and nano-size order particles of titanium dioxide (TiO2). Thoracotomy was performed to infuse test particles (1.5 mg in 0.2 ml saline/mouse) directly into the left thoracic cavity of A/J mice. After 21 weeks, only the fiber-shaped TISMO, morphologically similar to asbestos, induced a severe reaction of the pleura. The results indicate that the risk of mesothelial cell reaction may depend on the shape as well as the particle size.

In the present study, 65 weeks experiment was employed to examine long-term effects and possible tumorigenesis by fiber-shaped TISMO infused into the thoracic cavity of A/J mice. The experiment was terminated for the decreasing of the effective number of animals. This experiment showed numbers of TISMO fibers in the alveolus, indicating penetration through the visceral pleura. Atypical mesothelial cells were also observed with severe pleural proliferation, but no malignant mesothelioma was detected. The additional detection of TISMO fibers in the in the liver, spleen, kidneys, ovary, heart and bone marrow histopathologically indicated their movement outside of the thoracic cavity.

In conclusion, the experiments demonstrated fiber-shaped TISMO infused into the thoracic cavity of A/J mice induced severe pleural proliferation but not malignant mesothelioma. Hazard risk should also take into account that asbestos-like fiber spread to the whole body from the thoracic cavity.

1211 Polyhexamethyleneeguanidine Phosphate-Induced Pulmonary Fibrosis Model: Comparison with Bleomycin-Induced Model

J. Song1, D. Saputra1, C. Song2 and K. Lee3. 1Inhalation Center, Korea Institute of Toxicology, Jeongeup, Republic of Korea and 2Toxicogenomics Center, Korea Institute of Toxicology, Daejeon, Republic of Korea. Sponsor: S. Park.

Our prior study showed that polyhexamethyleneeguanidine phosphate (PHMG-ph), one of the major constituent of biocides, caused pulmonary damage of inflamma-
tion and fibrosis in rat lungs. In this study, we examined inflammation and fibrosis in lungs induced by PHMG-ph and compared with bleomycin model, which is most often used to study the pathogenesis of pulmonary fibrosis. In a current study, we admimistered 1.9 mg/kg PHMG-ph or 1.5 mg/kg bleomycin to mice intratra-
cheally on day 1, and conducted necropsies after 1 week, 2 weeks, 4 weeks, and 10 weeks. Proinflammatory cytokines and fibrotic markers were measured from lungs tissues. We also evaluated whether PHMG-ph activates inflammasome, because a marked elevation of IL-β was observed by 10 weeks in PHMG-ph group. As a result, PHMG-ph induced severe pulmonary inflammation with high expression of IL-β, IL-6, MCP-1, and reduced level of IFN-α. Increased expression of extracel-
ular matrix proteins such as collagen and fibronectin was also observed in the lung tissues by week 10. In addition, we postulate that imbalance of metalloproteinase and tissue inhibitor of metalloproteinase accelerates the pulmonary fibrosis. On the contrary, bleomycin-induced inflammation and fibrosis sustained until week 4. Nalp3 and caspase-1 expression was elevated by 4 weeks for PHMG-P treatment group, by 2 weeks in BLM group. In addition, we observed an increased expression of Bax and caspase-3, which means that PHMG-ph induces apoptosis. This study suggested evidences that PHMG-ph-induced apoptosis continuously stimulates in-
flammasome, therefore impairs resolution of inflammation, which leads to pulmo-

nary fibrosis. Also our study shows that a single dose of PHMG-P model induced acute and chronic pulmonary inflammation as well as severe fibrosis by 10 weeks, unlike BLM model.
Chrysotile asbestosis has been used in the manufacturing of friction brake linings since the early 1900’s. Although the use of asbestos containing products has is been reduced, chrysotile brakes continue to be manufactured and/or used in many parts of the world. This is the first inhalation study designed to provide an understanding of the biokinetics and potential toxicity of chrysotile containing brake dust following short term exposure in rats. The deposition, pathological response and translocation of brake-dust derived from brake pads manufactured with chrysotile were evaluated in comparison to the amphibole, crocidolite asbestos. This presentation presents results from the lung and in particular the quantification of measurements of fibers and pathological response in the pleural cavity. Rats were exposed by inhalation 6 d/ wk for 5 days to either brake-dust obtained by sanding of brake-drums manufactured with chrysotile, a mixture of chrysotile and the brake-dust or crocidolite asbestos. The crocidolite asbestosis fibers initiated a rapid inflammatory response in the lung following exposure resulting in a 5-fold increase in fibrinotic response within 61 days. In addition, marked increase in visceral pleural thickness and collagen deposition was observed following crocidolite asbestosis inhalation. No significant pathological response was observed in the lung or the pleural cavity at any time point in either the brake-dust or chrysotile/brake-dust exposure groups. These results provide support that brake-dust derived from chrysotile containing brake drums would not initiate a pathological response in the lung following short term inhalation.

Klotho Overexpression in Human Lung Epithelial Cells Decrease Sensitivity to Cigarette Smoke-Induced Cell Death

D. J. Blake, Biology, Fort Lewis College, Durango, CO.

Chronic obstructive pulmonary disease (COPD) is currently the third leading cause of death in the United States. COPD is associated with an abnormal inflammatory response to noxious particles and gases, and is characterized by progressive airflow limitation. Cigarette smoke (CS) is the primary cause of COPD although exposure to air pollution, respiratory infections and genetic factors also contribute to the disease progression. Exposure to CS induces oxidative stress in the lung, which results in cellular senescence or aging of the lung, leading to decreased proliferation of epithelial cells and the destruction of alveolar structure resulting in pulmonary emphysema. Although aging is a natural process, in the presence of cigarette smoke cellular senescence increases dramatically. Given that cigarette smoke accelerates lung aging, therapies that significantly reduce or delay cellular senescence may be important in the overall management of this disease.

The anti-aging gene, klotho, encodes a membrane bound protein, which has been shown to be a key regulator of oxidative stress, cellular senescence and inflammation. Mice with a defect in the klotho gene have a short life span and develop a syndrome resembling emphysema. In this study the role of Klotho was investigated in human epithelial cells. Individual clones that stably overexpressed Klotho were generated through retroviral transfection and genetin selection. Klotho overexpression was confirmed through real-time PCR and Western blotting. Compared to control cells, which were stably transfected with the retroviral control vector only, constitutive Klotho overexpression resulted in decreased sensitivity to cigarette smoke induced cell death in vitro. However, compared to control cells, the generation of reactive oxygen species and the production of IL-6 and IL-8 were not altered in the presence of CS. Therefore, our results suggest that enhancing Klotho activity in pulmonary epithelial cells, particularly those exposed to CS, may be a promising strategy to alleviate apoptosis and possibly prevent the development of COPD.

Subchronic Inhalation Exposure of Rats to Libby Amphibole and Asbestos: Effects at 18 Months Post Exposure

D. E. Dodd1, G. A. Willson2, K. C. Roberts1, H. G. Wall3, A. M. Jarabek3 and S. H. Gavett,1 1The Hamner Institutes for Health Sciences, RTP, NC, 2Experimental Pathology Laboratories, Inc., RTP, NC, and 3U.S. EPA, RTP, NC.

Increased asbestos, lung cancer, and mesothelioma rates are evident after exposure to Libby amphibole (LA). To support dosimetry model development and compare potency, a subchronic nose-only inhalation study (6 hr/d, 5 d/wk, 13 wk) was conducted in male F344 rats. Rats were exposed to air (control), LA (LO, MED, HI; 1.01, 3.32, 10.06 mg/m3, 159, 693, 1522 fibers/cc), or amosite (AM; 3.34 mg/m3; 230 f/cc). Toxicity endpoints, pathology, and fiber burden evaluation were determined 18 mo post-exposure. Fiber exposure had no effect on survival. Most commonly seen lesion was the macrophage of death prior to scheduled necropsy in all groups except the LA 3.3 group, though group incidences were below NTP historical control data. BAL cell numbers, LDH, and protein in AM and LA groups were not statistically different from the control group (n=8 rats/group), indicating resolution of earlier inflammation (Dodd, SOT 2012; Willson, SOT 2013). Histology of the left lung lobes, trachea, sternum, pleura, epitheliomas and testes, and relevant gross tissue lesions was conducted on 50 rats/group. Alveolar inflammation, pleural fibrosis, lung interstitial fibrosis, and the presence of foreign bodies were noted in all fiber-exposed groups. A greater incidence of chronic tracheal inflammation was noted in the LA groups. Alveolar bronchiolar adenoma occurred in 2 rats in each of the AM, MED LA, and HI LA groups, and 1 adenoma and bronchiolar carcinoma in the HI LA group, all of these findings were within historical NTP control data. No plural mesotheliomas were observed in any treatment groups. In conclusion, both AM and LA induced dose-related lung fibrotic responses; tumor incidences were apparently increased but not beyond historical control ranges. Tissue fiber burden data are supporting dosimetry model development; comparisons of responses between fibers may change based on internal dose estimates. (This abstract does not represent US EPA policy.)

Sex Differences in Glutathione Levels and Cytotoxicity following Naphthalene or Acrolein Exposure in Nasal Epithelium

L. S. Van Winkle1, L. Bichok2, R. Mendoza3, P. Edwards3 and J. B. Morris4. 1Center for Health & Environment, UC Davis, Davis, CA and 3School of Pharmacy, Univ of Connecticut, Storrs, CT.

Naphthalene causes site and dose dependent respiratory tract toxicity in rodents that is P450 mediated. The carcinogenesis biomarker evidence for formation of olfactory neuroblastomas and respiratory adenomas in the nose of both sexes of rats. Currently, there is debate as to whether epithelial injury following naphthalene exposure occurs in humans. In this study we used nasal epithelial tissue explants obtained from rhesus monkeys culled from the colony at California National Primate Research Center for health reasons as a surrogate for human nasal epithelium. We incubated maxillo, ethmoid, and septal epithelia (N= 3 or more per group) from male and female monkeys with naphthalene (10, 50, 150 and 500 uM), acrolein (50, 150, 300 uM) or vehicle (sham) control to provide site-matched tissue pieces for 3 hrs. Samples were analyzed for amount of glutathione (GSH) depletion via HPLC and also for histology of cytotoxicity using differential incorporation of the fluorescent nuclear dye ethidium homodimer-1. We found that acrolein, a direct acting agent that does not require P450 mediated metabolism to have an effect, depleted GSH at the highest dose, in all tissues tested, except male septal epithelium. In general, females were more susceptible to GSH depletion but had higher baseline GSH levels. Naphthalene was less effective than acrolein at depleting GSH, with a trend towards depletion only seen in maxilloturbinate epithelia at the highest dose. No other nasal tissue was depleted by 500 uM NA, a high dose, likely equivalent to an inhalated concentration of ~10ppm. Naphthalene cytotoxicity was rare, focal and was primarily localized to individual cells in subepithelial glands. We conclude 1) the nasal epithelium of the Rhesus monkey is resistant to glutathione depletion and that this may reflect robust resynthesis capabilities, 2) that naphthalene is poorly capable of depleting GSH in most nasal tissues tested and 3) naphthalene causes minimal cytotoxicity in this model.

Sex Differences in Acute Nasal Antioxidant Responses to Inhaled Naphthalene

L. Bichok1, L. S. Van Winkle1, G. J. Smith1, A. R. Buckpitt1 and J. B. Morris4. 1Pharmaceutical Sciences, University of Connecticut, Storrs, CT and 4Veterinary Medicine, University of California, Davis, CA.

At concentrations of 10 ppm or greater, naphthalene (NA) is a nasal carcinogen inducing respiratory adenomas in male and olfactory neuroblastomas in female rats, respectively. The proposed carcinogenic mode of action includes metabolic activation via CYP450 to an electrophile with subsequent glutathione depletion, escape of electrophile, covalent binding, cell death, and regenerative cell proliferation. To fully define the effect of acute NA exposure on nasal antioxidant responses, male and female F344 rats were nose-only exposed to 0, 1, 3, 10, or 30 ppm NA vapor for 4 hours. Following exposure, nasal olfactory (OE) and respiratory (RTE) epithelia were analyzed for reduced/oxidized glutathione levels (GSH/GSSG) and for mRNA levels of selected antioxidant genes. Epithelial membrane permeability was also assessed via ethidium homodimer-1 staining as an indirect marker of cytotoxicity. Significant GSH depletion occurred at all exposure levels in
RTE and OE with maximal depletion (to ~ 25% and 40% of control levels, respectively) occurring at or above 1 ppm. Similar trends were seen in both males and females. There was significantly more induction of glutamyl cysteine ligase (gcl) and NADPH quinone oxidase 1 (nqo1) in male OE compared to female OE. At 3 ppm in male rats, NA upregulated gcl and nqo1 12- and 16-fold, compared to 5- and 3-fold in females, respectively. Membrane permeability following NA exposure to 10 or 30 ppm NA was not dependent on sex, suggesting no sex differences in the acute cytotoxic response at these exposure levels. While no sex differences in GSH depletion were observed, sex differences in the induction of antioxidant genes suggest that induction of antioxidant protective pathways may contribute to sex differences in the carcinogenic response to NA.

1220 Pulmonary Effects and Biokinetics of Nanoparticles: Whole-Body Inhalation Exposure to CeO2 in 5-Day, 28-Day, and 90-Day Rat Studies

J. Keller1, K. Küttler1, L. Ma-Hock1, V. Strauss1, S. Gröters1, K. Wiench2, B. van Ravenzwaay1 and R. Landsiedel1. 1Toxicology, BASF SE, Ludwigshafen/Rhein, Germany and 2Product Safety, BASF SE, Ludwigshafen/Rhein, Germany.

CeO2 nanoparticles are widely used for biomedical, commercial and industrial applications. To assess hazard potential of air-born CeO2 nanoparticles, CeO2 (NM212), an OECD depositional material, is tested in a combined chronic and carcinogenicity long-term inhalation study in rats within the framework of the EU-project NanoREG. As a preparation work for the long-term inhalation study, 5-day and 28-day studies were performed in female rats. The rats were whole-body exposed to 0.5, 5 and 25 mg/m3 CeO2 for 6 h/d, 5 days for 1 and 4 weeks in the 5- and 28-day studies, respectively. A variety of biological endpoints including broncho-alveolar lavage (BAL) and histopathology were examined. The lung retention and clearance kinetics were assessed up to a post-exposure period of 129 days. Based on these results, the long-term study was started at concentrations of 0.1 mg/m3, 0.3 mg/m3, 1 mg/m3 and 3 mg/m3 CeO2. Meanwhile, the results of satellite group animals exposed for 90 days are available.

In both 5-day and 28-day studies, an increase of biochemical and cytological parameters (e.g. polymorph nuclear neutrophils, PMN) were observed in BAL fluid in a concentration-related manner. Cytokines in BAL fluid were increased significantly in both studies. These findings indicate a moderate inflammatory response in the lung after inhalation exposure. Consistent to BALF results, histopathology revealed substance- and concentration-related morphological changes in the lungs. The effects comprised alveolar histiocytosis, granulomatous inflammation in the lung, and macrophage aggregates with particles in bronchio-alveolar-associated lymphoid tissue and lung-associated lymph nodes. Pulmonary effects could be correlated with high particle retention and slow clearance in the lungs and a translocation to associated lymph nodes. The no observed adverse effect levels (NOAEL) for CeO2 is 0.5 mg/m3 in both 5- and 28-day studies.

1221 Inhalation Toxicity of Three Different Types of Nano-Sized Organic Pigments

K. Wiench3, P. Simmendinger1, L. Ma-Hock1, S. Gröters1, B. van Ravenzwaay1 and R. Landsiedel1. 1Toxicology, BASF SE, Ludwigshafen/Rhein, Germany and 2Product Safety, BASF SE, Ludwigshafen/Rhein, Germany, Switzerland, Basel, Switzerland and 3Product Safety, BASF SE, Ludwigshafen, Germany.

Four different organic pigments, which are nanomaterials according to the EU definition, were tested in the 5 day short term inhalation study (STIS) in rats. The STIS is a sensitive test system, which comprises a comprehensive scheme of parameters (e.g. polymorph nuclear neutrophils, PMN) were observed in BAL fluid in a concentration-related manner. Cytokines in BAL fluid were increased significantly in both studies. These findings indicate a moderate inflammatory response in the lung after inhalation exposure. Consistent to BALF results, histopathology revealed substance- and concentration-related morphological changes in the lungs. The effects comprised alveolar histiocytosis, granulomatous inflammation in the lung, and macrophage aggregates with particles in bronchio-alveolar-associated lymphoid tissue and lung-associated lymph nodes. Pulmonary effects could be correlated with high particle retention and slow clearance in the lungs and a translocation to associated lymph nodes. The no observed adverse effect levels (NOAEL) for CeO2 is 0.5 mg/m3 in both 5- and 28-day studies.

1222 Secondary Organic Aerosols Generated from α-Pinene-Amine Mixtures: Effects on the Cardiovascular System

M. Doyle-Eisde1, A. C. Rebu2, E. Knipping1, A. K. Lund1, J. Brower1 and J. D. McDonald1. 1LIRI, Albuquerque, NM, 2EPRI, Palo Alto, CA and 3University of North Texas, Denton, TX.

The SPHERES research program was created to examine the role of inhaled secondary organic aerosol (SOA) on cardiovascular outcomes in mice. SOA was generated in a reaction chamber with alpha-pinene, and was combined with neat amines (monooethanolamine (MEA), methyl diethanolamine (MDEA), piperazine (PIP)) or carbon dioxide degraded amines (CO2-degraded MEA, CO2-degraded MDEA, CO2-degraded PIP). To examine the effects of these mixtures on vascular and lung inflammatory responses, 8 wk old male Apo E−/− mice, on a high fat diet were exposed for 7 days, and the resulting vascular expression levels of HO-1, ET-1, MMP-9, and TIMP-2 cytokines as well as the TBARS measure of lipid peroxidation were assayed in aortic tissue. Total cell counts and differentials were assayed in the bronchoalveolar lavage fluid (BALF). Exposure to some of these mixed amine/SOA atmospheres caused mild vascular and lung responses following 7 days of exposure. MEA+SOA tended to decrease expression levels of cytokines and TBARS in the vasculature. MDEA+SOA had no appreciable effect on cytokines or TBARS, and PIP+SOA led to increases in MMP-9 and TBARS expression a decrease in TIMP-2 expression compared to control. CO2-degraded MDEA+SOA tended to decrease cytokine expression while having little effect on TBARS. The processing to determine the effects of CO2-degraded MEA+SOA and PIP+SOA are currently in progress. In the BALF, total cell and macrophage counts were non-significantly increased following exposure to MEA+SOA, MDEA+SOA, and PIP+SOG atmospheres and the CO2-degraded MDEA+SOA exposure. Neutrophil and lymphocyte counts were too low to accurately quantify. Overall, some mixed amine/SOA atmospheres caused mild responses in lung and vascular markers of inflammation.

1223 Pulmonary Toxicity Screening of 1, 2-Benzisothiazol-3(2H)-One by Intratracheal Instillation

Chemicals are widely used in our daily lives for various purposes such as disinfectants, air fresheners, paints and hair sprays. In particular, chemicals used in household products (CHPs) have been shown to be a major source of inhalation exposure. However, their pulmonary toxicity has less studied compared with oral and dermal toxicity. Therefore, the purpose of this study was to determine the pulmonary inflammation responses of 1,2-benzisothiazol-3(2H)-one (BIT) used in major CHPs in Korea. Toxicity of BIT was evaluated by intratracheal instillation in 5-wk old male Apo E−/− mice on a high fat diet. The animals were sacrificed at both 1 day and 1 week after instillation. Toxicity was assessed by count of total and differential cells in bronchoalveolar lavage (BAL) fluid. As a result, in high exposure group, clinical abnormalities associated with the pulmonary toxicity were observed such as shortening of breath and dyspnea. Also, instillation of BIT caused a decrease of body weight. The total cell count in BAL fluid increased in the middle and high exposure groups. However, middle group recovered by 1 week post-exposure. Furthermore, significant changes in the polymorphonuclear neutrophils (PMN) values as inflammation marker in the BAL fluid were observed in all exposure groups. Therefore, this study suggests that careful regulations of CHPs would be necessary in maintaining a high quality of life.

1224 Acute Effects of White Spirit with Different Aromatic Content

L. Ermeng1, A. Iregren2, S. A. Juran1, B. Sjögren1 and G. Johanson1. 1Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden and 2Swedish Work Environment Authority, Stockholm, Sweden.

The use of ‘standard’ white spirit (stdWS, 15–20% aromatics) in Europe has gradually shifted to low-aromatic or de aromatized white spirit (deWS), as the latter is considered to carry a lower risk of health effects. However, data on health risks of deWS on humans are sparse. We have performed a controlled short-term chamber exposure to compare deWS and stdWS with respect to irritation, inflammation and central nervous systems (CNS) effects. In a dose-finding study thresholds of irritation and CNS effects were identified. Eight (4 males) healthy volunteers rated symptoms related to irritation, smell and CNS effects on a 0–100 mm visual analogue scale (VAS) while exposed to increasing levels of deWS or stdWS from 0.5 to 600 mg/m3.
Based on the dose-finding study, 12 (6 males) healthy volunteers were exposed for 4 h at rest at five conditions: clean air, 100 mg/m³ stdWS (0.002% aromatics), 100 mg/m³ stdWS (19% aromatics), 300 mg/m³ stdWS, and 300 mg/m³ deWS. The study was approved by the Regional Ethical Review Board in Stockholm. The following endpoints were studied: symptom ratings on VAS (irritation in the eyes, nose, throat, dyspnoea, smell, headache, fatigue, nausea, dizziness, and feeling of intoxication), neurobehavioural performance (vigilance, response inhibition, response shifting, divided attention, and working memory), pulmonary function, nasal swelling, breathing frequency, blinking frequency, plasma inflammatory markers, and biochemical variables. The only significant increase in rating (compared to clean air) except “solvent smell” was seen for eye irritation at the high stdWS exposure. Ratings during stdWS exposure tended to be higher than during deWS exposure. Weak and inconsistent improvements in working memory and response shifting were seen at high stdWS exposures, compared to clean air. No exposure-related effects on the other objective measurements were found. In conclusion, based on symptom ratings, stdWS is slightly more irritating than deWS.

1225 Repeated Intratracheal Powder Aerosol Delivery in Sprague-Dawley Rats
A. Dumais1, M. Stout1, S. Groom2, R. Tavac2, and R. Forster1, 1CiToxLAB North America, Laval, QC, Canada and 2CiTox LAB France, Evreux, France.

Inhalation administration (Rx) is a highly effective delivery route allowing the bypass of first-pass metabolism and permitting local delivery to the lungs but it is expensive and requires large quantities of material. We have evaluated an alternative approach using a novel device for repeated intratracheal administration (IT Rx). Using this approach we performed single dose and 7 day repeat dose studies with administration of air, PLGA (50/50 DL-lactide/glycolide copolymer) (10 mg/day) or a pharmaceutical test item (10 mg/day) to groups of 6 female Sprague Dawley rats. Only the results of the air and PLGA control groups are presented. Repeated IT Rx resulted in procedure-related lung changes in both control groups, including perivascular/peribronchial infiltrate, increased alveolar macrophages, and alveolar hemorrhage. These changes were seen with higher incidence and/or severity in rats receiving PLGA. Lung changes attributable to PLGA, but not seen in the air control, included bronchioalveolar inflammation, bronchiolar epithelium hypertrophy/hyperplasia and/or erosion, exudate/cellular debris in bronchioalveolar lumens, foreign material, foreign body granuloma, and necrosis with or without trachea epithelium hypertrophy/hyperplasia and/or erosion. Although repeated IT Rx of dry powder aerosols was feasible with this novel device, the lung mechanical damage and dose delivery variation represented significant limitations. This approach was not considered ideal for a 28-day regulatory study with the mechanical damage and dose delivery variation represented significant limitations. This approach was not considered ideal for a 28-day regulatory study.

1226 Refinement of Acute Inhalation Toxicity Studies: The Isolated Perfused Rat Lung As a Screening Tool for Surface-Active Substances

New surface-active agents in waterproofing sprays are often tested for acute inhalation toxicity in vivo on the basis of OECD Test Guideline 405. A screening test using the isolated perfused rat lung (IPRL) is proposed in order to reduce the number of acute inhalation tests and to refine these. The test comprises exposure of IPRLs to aerosolised formulations of the water proofing agents and on-line monitoring of respiratory parameters. Substances revealing harmful effects on the IPRL, such as impaired lung compliance and atelectasis formation, did also show changes in respiratory parameters up to mortality in vivo tests with rats. Thus, pre-testing in the IPRL allows the identification of surface-active substances causing acute inhalation toxicity.

To assess the potential lung toxicity of seven formulations, each tested in two male and two female IPRLs, we evaluated changes in the respiratory parameters tidal volume, compliance, and resistance, edema and atelectasis formation, taking into account the inhaled doses. These IPRL results were compared with available in vivo results and a good or excellent correlation in six out of seven cases was revealed. In conclusion, the use of the IPRL is well suited for screening substances showing acute “physical” inhalation toxicity. Therefore, for future assessment of surface active substances, it is suggested to use this test prior to in vivo inhalation tests.

1227 Quantitative Evaluation of the Relationship between Vapor Characteristics and Upper Respiratory Tract Uptake Efficiencies in Rodents
K. Neiger1, M. Glynn1, H. A. Fritz1, L. S. Pierce1, A. Urban2, S. H. Gaffney2 and B. L. Finley1, 1Cardno ChemRisk, Chicago, IL, 2Cardno ChemRisk, San Francisco, CA and 3Cardno ChemRisk, New York, NY.

Characterizing the regional absorption of inhaled vapors within the respiratory tract of animals typically used in toxicology studies is essential in applying the results to human health risk assessments. It is well documented that water soluble and reactive vapors are absorbed or “scrubbed” in the upper respiratory tract (URT) of the rodent with high efficiency, thereby reducing the amount of vapor that reaches the lower airways. A literature review and analysis was performed to quantitatively evaluate the relationship between vapor characteristics (pKa, Henry’s Law constant (HLC), water solubility, vapor pressure, and Km) and their effects on URT uptake efficiency (UE) in rodents. Sixteen studies that examined UE of 14 vapors were identified. Linear regression modeling controlling for inhaled vapor concentration and flow rate was performed for each vapor characteristic in rats and mice to characterize their relationship with URT UE. Results indicated that pKa and HLC had significant inverse linear relationships with URT UE in rats (R²= 0.147; p < 0.0001; R²=0.037; HLC: β= -18780, p < 0.0001; R²=0.398). Models that included both pKa and HLC yielded a slightly higher adjusted R2 than pKa and HLC alone (full model R²=0.540; reduced models R²=0.377-0.520). There was no significant linear relationship between URT UE and vapor pressure (β=0.0007, R²=0.09; R²=0.147) or vapor pressure (β= -0.0009, p<0.0001; R²=0.147) in rats, although it is possible that non-linear models may better describe these relationships. There were limited data available for mice; however, these results indicated a similar relationship between URT UE and pKa (β= -0.49, p < 0.001; R²=0.533). Although limited data were available for analysis and only linear relationships were examined, these preliminary results indicated that identification of common vapor characteristics may aid in interpreting and explaining observed regional effects of vapor inhalation in rodents.

1228 Comparison of the Upper Respiratory Tract Uptake Efficiencies of Vapors in Rats and Mice
H. A. Fritz1, M. Glynn1, K. Neiger1, L. S. Pierce1, A. Urban2, S. H. Gaffney2 and B. L. Finley1, 1Cardno ChemRisk, Chicago, IL, 2Cardno ChemRisk, San Francisco, CA and 3Cardno ChemRisk, Brooklyn, NY.

It has been reported that soluble and reactive vapors are readily absorbed or “scrubbed” in the upper respiratory tract (URT) of rodents, reducing the dose that reaches the lower airways. Since the inhalation of some vapors has resulted in differences in observed regional airway effects between mice and rats, researchers have hypothesized that there is a significant difference in URT uptake efficiency (UE) between the two species. To investigate this hypothesis, a literature review was performed to identify studies that measured the URT UE of the same vapors in both mice and rats, and a quantitative comparison between the URT UEs was performed. In order for a vapor to meet the inclusion criteria, studies must have identified that measured UEs via surgically isolated URTs for both species at comparable concentrations and flow rates. A total of eight studies that evaluated 4 vapors (naphthalene, propylene oxide, acetaldehyde, and acrolein) were included in this analysis. URT UEs were compared for each vapor individually and for all vapors together using paired t-tests. Overall, the mice had statistically significant higher mean URT UEs than rats (48.13% v. 38.15%; p < 0.0001). The mean URT UEs for mice were higher than rats for naphthalene (62.26% v. 33.41%; p < 0.0001). The mean URT UEs were higher than rats (48.13% v. 38.15% ; p < 0.0001). The mean URT UEs for mice were higher than rats for naphthalene (62.26% v. 33.41%; p < 0.0001). The mean URT UEs were higher than rats (48.13% v. 38.15% ; p < 0.0001). In contrast, there was no significant difference in URT UE of acetaldehyde between mice and rats (45.67% v. 46.52%; p = 0.67). A statistical comparison was not performed for acrolein due to small sample size (n = 1 for both species). Although there were a limited number of studies available, the results demonstrate that URT UE is not uniform across species, even in species as similar as mice and rats. Further, the results demonstrate the importance of taking species-specific differences into account when interpreting rodent model results and extrapolating to other species, including humans.
Research on dry powder toxic inhalants or drug candidates for inhalation therapy typically require particulate starting materials with diameters in the range of 1-5 μm. However, isolated toxicants or newly synthesized drug candidates are often available only in the milligram range. Yet, few systems for generation of micronized substances of these batch sizes have been available. Here we present a spray dryer method for generating micronized particles at room temperature in high yields requiring substance only in the mid-milligram range. The Laminair Spray dryer generates micronized particles from nebulized solutions. A mesh nebulizer (Aeroneb Pro) delivers droplets to a laminar air flow in an inner column coated with a vapor-permeable membrane. A countercurrent stream of air at room temperature on the outside of the membrane removes the evaporated solvent, from which it is absorbed in a separate silica/activated carbon column in a closed loop. Dried powder product is collected on a filter at the end of the drying column. Aqueous solutions of 2% lactose and 2.5% horse radish peroxidase and an ethanol solution of 2% budesonide were micronized from batches in the range of 20 to 500 mg. Product yields were >80% and particle sizes ranged from 1 to 5 μm. The production rate varied from 0.1 to 1 mg/min. Enzymatic activity of horse radish peroxidase was fully retained after drying indicating that delicate biomolecules will retain their activity. Removal of solvent was nearly complete when nebulizer output was around 5% of its full capacity. However, using ethanol as solvent makes the transfer slightly less effective than with water. The laminar flow regime maintains particle losses in the column at less than 10%. Small portions of toxic substances or drug candidates can thus be micronized and tested via inhalation, thereby facilitating early detection of biological activity.

**1229a** Pulmonary Responses after the Inhalation of Fumes from Resistance Spot Welding of Galvanized Zinc-Coated Steel

Spot welding (SW) of galvanized zinc (Zn)-coated steel is commonly used in the automotive industry where high speed repetitive welding of thin metal sections is needed. SW produces complex aerosols that cause bronchitis and asthma in workers. The goal was to assess the effect of SW fumes on lung responses in an animal model. Male Sprague-Dawley rats were exposed by inhalation to 25 mg/m³ of SW aerosol for 4 h/d x 8 d. Controls were exposed to filtered air. During daily exposure, no change in body temperatures was observed throughout the exposure period when comparing the two treatment groups. At 1 and 7 d after the final exposure, bronchoalveolar lavage (BAL) was performed to assess lung toxicity. Lactate dehydrogenase (a marker of lung cell cytotoxicity), total BAL cells, and LDH levels, and IL-1β, IL-2 levels. We also verified consumption were periodically observed during whole study duration. Total and differential cell count, total protein, LDH, and cytokines (IL-1β and IL-2) were measured from BAL fluid. As well, the distribution of inhaled ZnO particles inside lungs was observed using TEM. Under current design with 5 males and 5 females per group, the lung weight change greater than 10 to 20% of control values can be detected. The lung weight should be applied as a complementary end point to lung histopathology for assessing lung toxic effect by inhaled compounds in acute/subacute inhalation studies in rat.

nary toxicity in vivo. RAW 264.7 macrophages were treated with InP or ITO and cytotoxicity was assayed at 24 hrs. Particle solubilization (release of ionic indium) was also measured at 24 hrs in culture supernatants by atomic absorption spectros-
copy. Macrophage cytotoxicity and ionic indium release were much greater for InP compared to ITO. Next, B6C3F1 mice were treated with 1 mg/kg InP or ITO by oropharyngeal aspiration. On day 28, BAL and pleural lavage were collected and assayed for total cell numbers (and differentials), LDH activity and protein levels as markers of lung toxicity. All of these parameters were greatly increased in mice treated with InP compared to ITO. These data suggest that macrophage solubili-
cation and cytotoxicity of ICPs in vitro may be capable of predicting pulmonary toxicity in vivo. Furthermore, these differences in toxicity were observed despite the two compounds having similar indium content suggesting that solubilization, not total indium content, may better reflect the toxic potential of ICPs.

1229e Acrolein Toxicity in Endothelial Cells Involves Lipid Peroxidation, Protein Damage, and Reduced Cellular GSH and Augmented Monocyte Adhesion

R. Chittrak1, Z. Liu1, H. Shah1, A. Speen1, J. McCormick1, P. Nallamasy1, P. Joubert1, H. Zhu2 and Y. Li2. 1University of North Carolina at Greensboro, Greensboro, NC and 2Campbell University School of Osteopathic Medicine, Buies Creek, NC.

Environmental pollutant exposure has been implicated in the pathogenesis of cardio-
vascular diseases. Acrolein is a highly reactive aldehyde pollutant mainly found in automobile exhaust and tobacco smoke. However, the action of acrolein in endothelial cells remains to be investigated. The present study examined acrolein-
in-induced cellular injury, oxidative modifications of cellular constituents, adhe-
sion of monocytes to endothelial cells and altered intracellular glutathione (GSH) on EAHY926 cells, a widely used endothelial cell line for study of endothelial cell dysfunction. Incubation of cells with acrolein at pathophysiological concentrations for 24 hours caused a significant decrease in cell viability measured by MTT assay and increase in release of lactate dehydrogenase (LDH), which is further confirmed by a significant change in cell morphology. Acrolein also increased the amount of thiobarbituric acid reactive substances, a marker of lipid peroxidation, and protein monocyte binding, a marker of protein damage in the cells. Incubation of cells with acrolein also resulted in a significant depletion of cellular GSH and augmented monocyte adhesion to human endothelial cells, an important step in the develop-
ment of atherosclerosis. The results of this study may contribute to our ability to assess the cardiovascular risk of human exposure to acrolein.

1229f Carbon Capture and Sequestration: An Exploratory Inhalation Toxicity Assessment of Amine Trapping Solvents and Their Degradation Products

D. Kracko1, A. C. Rohr2, J. D. McDonald1, M. Doyle-Eisele1, J. Seagrave1, J. A. Crocker1, D. Johnson1, M. Schladweiler2, J. Richards2 and A. R. Henriquez1, 1Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC and 2Electric Power Research Institute, Palo Alto, CA.

Carbon dioxide (CO2) absorption with aqueous amine solvents is a method of Carbon capture and sequestration (CCS) from flue gases. One concern is possible release of amine solvents and degradation products into the atmosphere, warranting evaluation of potential pulmonary effects from inhalation. The CCS amines monoethanolamine (MEA), methyl-diethanolamine (MDEA), and piperazine (PIP) underwent oxidative and CO2-mediated degradation for 75 days. C57bl/6N mice were exposed for seven days by inhalation of 25 ppm of neat amine or equivalent concentration in the degraded mixture. The aqueous solutions were nebulized to carbon uptake in bronchoalveolar lavage fluid and cytokine expression in lung tissue. Ames mutagenicity and CHO-K1 micronucleus assays were applied to assess genotoxicity. Control analysis of the test atmosphere and liquid revealed complex mixtures including acids, aldehydes, and other compounds. Exposure to oxida-
tively degraded MEA increased (p<0.05) total cells, neutrophils, and lymphocytes compared to control mice and caused inflammatory cytokine expression (statistical increase at p<0.05). MEA and CO2 degraded MEA were the only atmospheres to show statistical (p<0.05) increase in oxidative stress. CO2 degradation resulted in a different composition, less degradation, and lower observed toxicity (less magni-
tude and number of effects) with no genotoxicity. Overall, oxidative degradation of the amines studied resulted in enhanced toxicity (increased magnitude and number of effects) as compared with the neat chemicals.

1229g Potential Exposure Threshold of Chrysotile Asbestos

T. Hesterberg1, P. A. Nomy2, P. Watson1, M. Beng1 and K. C. Scribner3. 1Center for Toxicology and Environmental Health, LLC. 2Denver, CO, 3CETE, L.L.C., North Little Rock, AR, 4CEE, L.L.C., Kemah, TX and 5CETE, L.L.C., Albany, NY.

Studies have shown that various forms of asbestos (serpentine, crocidolite, and amosite) have different toxicities depending on the fiber characteristics dose, dis-
mension, durability, and biodegradability. While some early regulations accounted for these differences, the current guidelines consider all asbestos types to have the same hazardous potential. We hypothesize that there is an exposure threshold for the health effects of a biosoluble asbestos, such as chrysotile. This has implications for whether exposures can be controlled to levels that would not be expected to cause lung disease in countries where chrysotile asbestos is still in use.

To determine the current information available regarding chrysotile asbestos, a re-
view of available epidemiological and animal studies was performed. Epidemiology studies are difficult to use for elucidating threshold doses since asbestos type and dimension in the workplace are often not known, and worker history can be diffi-
cult to obtain. Animal research has shown that high exposure to chrysotile asbestos is associated with lung disease; however, at these high levels the disease related to a lung overload mechanism. Subchronic exposure studies have indicated a No Observed Adverse Effect Level (NOAEL) of approximately 500 f/cc, which indi-
cates a threshold for asbestos-induced lung disease. Additional studies have shown that chrysotile has low biopersistence in the lung, does not translate to the pleura, and does not appear to cause hyperplasias or other pleural changes.

The science indicates that low exposures to chrysotile asbestos do not present a significant risk to human health. A multi-dose, chronic inhalation study in rodents would better define the threshold for potential health effects from low exposures to chrysotile asbestos. Understanding low-dose chrysotile exposures is important to evaluating the role of past chrysotile asbestos exposures in the US and to the regulation of asbestos use in other countries.

1230 Increases in the Serum Acute Phase Proteins after Ozone Exposure Are Associated with Induction of Genes in the Lung but Not Liver

A. R. Henriquez1, D. Johnson1, M. Schladweiler2, J. Richards2 and U. P. Kodavanti1. 1Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC and 2EPHD/NHEERLORD, US EPA, Research Triangle Park, NC.

Acute Phase Response (APR), a systemic reaction to infection, trauma, and in-
flammation, is characterized by increases and decreases in plasma levels of positive and negative acute phase proteins (APP), respectively. Although the liver has been shown to contribute to APR in various pathologies, the source of circulating APP after air pollution exposure is not well characterized. We hypothesized that lungs and liver both will contribute to plasma levels APP after an acute ozone exposure. To test this hypothesis, we exposed male Wistar Kyoto rats to air or O3 (1ppm), 6hr/day for 1 or 2 consecutive days. Immediately after ozone exposure, genes en-
coding APP were analyzed at mRNA level in the lungs and livers and proteins were analyzed in the serum. Ozone exposure increased positive acute phase proteins in the serum, such as α-1-acid glycoprotein, AGP; α-2-macroglobulin, A2M; and decreased negative APP such as transferrin. These increases in serum proteins were associated with marked increases in mRNA expression of several APP in the lungs (A2M, AGP, α-1-antitrypsin, hepcidin, and ceruloplasmin). Ozone did not increase liver mRNA for any APP examined. However, there were remarkable tissue differences between lung and liver mRNA expression of APP in air exposed rats (liver-lung). C-reactive protein was expressed highly in the liver but minimal expression was noted in the lung (not affected by ozone in lung or liver). Thus, although liver tissue mass is ~15 times greater than lung mass, it is clear that the acute phase protein genes are induced only in the lung after ozone exposure; the role of lung should not be ignored in modulating APR and release of APP in the circulation upon the inhalation of pollutants. (This abstract does not reflect the US EPA policy).
Nitrogen dioxide (NO₂) and ozone (O₃) are environmental air pollutants capable of inducing lung injury and inflammation by causing oxidative damage to the respiratory epithelium. Mice models have suggested that these pollutants induce damage via similar mechanisms, although little work has been done to corroborate this in vivo—specifically in primary epithelial cells. Thus, the purpose of this study was to compare the responses between O₃ and NO₂, in a gas-phase system using primary human epithelial cells obtained via brush biopsy. These cells, obtained from 9 donors, were cultured and grown at an air-liquid interface (ALI), which closely reflects the real-life inhalation of these toxicants. After 3-4 days at ALI, the cells were exposed to NO₂ (1.0, 2.0, 3.0, or 5.0 ppm), O₃ (0.25, 0.50, 0.75, or 1.00 ppm), or clean air for 1.20 min. The expression of pro-inflammatory and cellular stress markers was measured using quantitative real-time PCR 0, 1, 4, and 24 hours following each exposure. Expression of the pro-inflammatory cytokine IL-8 was elevated only at 24 hours post-exposure when cells were exposed to either 3.0 or 5.0 ppm NO₂; however, down-regulation of HO-1 and COX2 were observed at all time points at each dose. In contrast, the expression of IL-8, HO-1, and COX2 were up-regulated following all O₃ exposures; the greatest increases were seen 1 hour following O₃ exposures. Therefore, it is possible that NO₂ and O₃ exposures induce damage to the respiratory epithelium via differing mechanisms, in contrast to the previously tested mice models.

Human umbilical vein endothelial cells (HUVECs) were exposed in vitro to soluble fraction of 100% soy biodiesel combustion exhaust (BEPE) in order to study their effect on vasodilation. Previous controlled human exposures indicate inhalation of biodiesel (BD) combustion emissions can inhibit vasodilation. We developed a study to measure a vasodilator eicosanoid, prostacyclin, in response to BEPE. Our study indicated no significant cytotoxicity, measured by LDH release, after 6h exposure with 1000μg/mL BEPE. After 6h exposure the stable metabolite of prostacyclin, 6-keto PGF1α (6keto), was found significantly decreased from vehicle indicating diminution of vasodilator (6keto) release. Next we examine biochemical mechanisms involved, analyzing mRNA and protein levels of proteins in 6-keto production. COX-1 & 2 gene expression levels were significantly decreased below vehicle with BEPE at 100μg/mL after 6hrs (p<0.05). Western blot of COX-2 showed a decrease. Western blot of COX-1 shows no intensity changes with BEPE exposure. PG1 synthase (PGIS) mRNA levels and protein levels show no change from control levels. Both COX1/2 and PGIS were challenged after extract exposure with 10μM Arachidonic acid (AA) and 1μM PGH2 respectively to verify if enzyme activity can be reversed. Post challenge, 6-keto levels were significantly increased compared to vehicle suggesting BEPE suppresses some enzymes of 6keto production. Post BEPE exposure simultaneously incubation with fresh BEPE and AA induced a decrease of 6keto. These results indicate compounds in BEPE can induce immediate impairment in 6keto release and/or detection. We postulate the saturated fatty acids from BEPE combustion disrupted the formation of complexes inhibiting 6keto temporally and at low intracellular substrate levels. This abstract of a proposed presentation may not reflect official US EPA Policy.

Diesel exhaust (DE) exposure induces adverse cardiopulmonary effects. Addition of nano cerium (CeO₂) oxide to diesel fuel (DECe) increases fuel burning efficiency but results in altered emission characteristics and potentially altered health effects. We hypothesized that inhalation of DECe will cause greater adverse pulmonary health effects in rats compared to DE alone. Male Sprague-Dawley rats (8 wks old) were exposed to either DE or DECe (1000 μg/m³) 5 hrs/day for 2 days. We observed an increase in N-acetyl glucosaminidase in lung lavage fluid of rats exposed to DECe as compared to air group. There were also marginal but insignificant increases in several lung injury biomarkers in both exposure groups (DECe-DE). To further characterize DECe toxicity, we exposed rats to DECe (100 or 1000 μg/m³) or the gas-phase components of DECe (1000 μg/m³) 5 hrs/day for 2 days or 4 wks (5 days/wk) with one group allowed a 14 day recovery. CE lung burden levels indicated a time- and concentration-dependent accumulation during treatment with 35% clearance of Ce from the lung during the 14 day recovery. The high dose of DECe increased lung inflammation at the 2 day time point; this effect was reduced at 4 wks except for the sustained increases in lavage fluid activity of γ-glutamyl transferase. Increased alveolar septae thickness due to edema and increased presence of pigmented macrophages after DECe exposure was illustrated by histology and TEM. Lung effects were also evident after exposure to gas-phase of DECe, suggesting the effects of whole exhaust may be driven by gas-phase components and/or particulate effects may be modified by gas-phase components. These data indicate that exposure to DECe induces adverse pulmonary effects that on a mass basis, causes greater injury than DE alone. (Does not reflect the US EPA policy)

Diesel engine (DE) exhaust exposure induces adverse cardiopulmonary effects. Addition of nano cerium (CeO₂) oxide to diesel fuel (DECe) increases fuel burning efficiency but results in altered emission characteristics and potentially altered health effects. We hypothesized that inhalation of DECe will cause greater adverse pulmonary health effects in rats compared to DE alone. Male Sprague-Dawley rats (8 wks old) were exposed to either DE or DECe (1000 μg/m³) 5 hrs/day for 2 days. We observed an increase in N-acetyl glucosaminidase in lung lavage fluid of rats exposed to DECe as compared to air group. There were also marginal but insignificant increases in several lung injury biomarkers in both exposure groups (DECe-DE). To further characterize DECe toxicity, we exposed rats to DECe (100 or 1000 μg/m³) or the gas-phase components of DECe (1000 μg/m³) 5 hrs/day for either 2 days or 4 wks (5 days/wk) with one group allowed a 14 day recovery. CE lung burden levels indicated a time- and concentration-dependent accumulation during treatment with 35% clearance of Ce from the lung during the 14 day recovery. The high dose of DECe increased lung inflammation at the 2 day time point; this effect was reduced at 4 wks except for the sustained increases in lavage fluid activity of γ-glutamyl transferase. Increased alveolar septae thickness due to edema and increased presence of pigmented macrophages after DECe exposure was illustrated by histology and TEM. Lung effects were also evident after exposure to gas-phase of DECe, suggesting the effects of whole exhaust may be driven by gas-phase components and/or particulate effects may be modified by gas-phase components. These data indicate that exposure to DECe induces adverse pulmonary effects that on a mass basis, causes greater injury than DE alone. (Does not reflect the US EPA policy)

Exposure of humans and experimental animals to Diesel Exhaust (DE) has been reported as major air pollutant to induce airway inflammation, decrease lung function and aggravate asthma because it contains hazardous materials such as particulate matters. The objective of this study is to identify the acute inhaled toxicity of DE in SD rats using wholebody exposure chamber. In this study, groups of 10 Sprague-Dawley rats were exposed to the DE from diesel engine by the route of inhalation(2h/day, 3days) at the 3 different RPM(Rotation per minute) of 0(control), Idle, 1160, 1740 rpm. As a result, there were no significant differences in body weight and organ weight gain between exposure groups and control group. Clinical examination results showed that there were no symptoms or deaths. However, the histopathological changes were found in the lungs of the male and female rats inhaled with diesel exhaust. The histiocytic inflammatory cell infiltration described as histiocytic pneumonitis was found around the terminal bronchiole and submucosal duct. The lesions were observed in the lung of Idle group exposed. These results suggest that inhalation of diesel exhaust could induce obvious histopathological changes to rats.

The Effects on Endothelial Cell Eicosanoid Release with Biodiesel Exhaust Soluble Fraction
I. Phavaran1, R. McCormick2 and M. C. Madden1. 1Toxicology, University of North Carolina, Chapel Hill, NC, 2NREL, Golden, CO and 3U.S. EPA, Chapel Hill, NC.

Diesel engine exhaust exposure induces adverse cardiopulmonary effects. Addition of nano cerium (CeO₂) oxide to diesel fuel (DECe) increases fuel burning efficiency but results in altered emission characteristics and potentially altered health effects. We hypothesized that inhalation of DECe will cause greater adverse pulmonary health effects in rats compared to DE alone. Male Sprague-Dawley rats (8 wks old) were exposed to either DE or DECe (1000 μg/m³) 5 hrs/day for 2 days. We observed an increase in N-acetyl glucosaminidase in lung lavage fluid of rats exposed to DECe as compared to air group. There were also marginal but insignificant increases in several lung injury biomarkers in both exposure groups (DECe-DE). To further characterize DECe toxicity, we exposed rats to DECe (100 or 1000 μg/m³) or the gas-phase components of DECe (1000 μg/m³) 5 hrs/day for either 2 days or 4 wks (5 days/wk) with one group allowed a 14 day recovery. CE lung burden levels indicated a time- and concentration-dependent accumulation during treatment with 35% clearance of Ce from the lung during the 14 day recovery. The high dose of DECe increased lung inflammation at the 2 day time point; this effect was reduced at 4 wks except for the sustained increases in lavage fluid activity of γ-glutamyl transferase. Increased alveolar septae thickness due to edema and increased presence of pigmented macrophages after DECe exposure was illustrated by histology and TEM. Lung effects were also evident after exposure to gas-phase of DECe, suggesting the effects of whole exhaust may be driven by gas-phase components and/or particulate effects may be modified by gas-phase components. These data indicate that exposure to DECe induces adverse pulmonary effects that on a mass basis, causes greater injury than DE alone. (Does not reflect the US EPA policy)
only. The ACES study represents the most comprehensive examination of the potential health effects associated with 2007 engine DE performed to date. Under the conditions described, no effects on oxidative damage or genotoxicity were observed. However, a few modest increases in markers of cardiovascular disease risk appeared dependent on age and/or exposure duration and sex.

1236 ACES Phase 3: Results from the Chronic Bioassay of Rats Exposed to 2007 Compliant Diesel Emissions

J. D. McDonald, M. Doyle-Eistle, J. Seagrave, R. Miller and A. Gigliotti. LRRI, Albuquerque, NM.

Phase 3 of the Health Effects Institutes (HEI) ACES program was to conduct animal inhalation studies in rats for up to 24-30 months as a carcinogenicity bioassay, measuring indicators of pulmonary toxicity in rats at intervals during exposure. This presentation reports the final results of the bioassay. Atmospheres were generated from emissions of a 2007 compliant 500 hp engine and aftertreatment system operated on a variable-duty cycle. Dilutions of exhaust were maintained at average integrated concentration of 4.1, 0.8 and 0.1 ppm NO2. Exposure atmospheres were characterized in detail. Exposures were conducted for 16 hr/day, 5 days/week. Rats were evaluated by respiratory function, hematology, serum chemistry, bronchoalveolar lavage, lung cell proliferation, and histopathological assays. Concentrations of particulate matter are generally very low and rise only during diesel filter regeneration, once or twice per 16 hr exposure period. Mild biological responses were observed, and were confined primarily to the respiratory tract and primarily at the highest exposure concentration. The primary histologic findings were minimal airway thickening in the central acinus. The severity of the lesions did not increase between 1 year and the lifetime. The observed changes were consistent with exposure to gaseous components such as NO2, and differed markedly from effects observed from traditional diesel exhaust.

1237 Involvement of TLR2 and TLR4 and Th1/Th2 Shift in Lung Inflammatory Responses Induced by Fine Ambient Particulate Matter

X. R. Xia, Peking University First Hospital, Beijing, China.

Air quality in China is notoriously poor and recently has become an issue associated with increasing social unrest. Epidemiologic studies have reported the association between fine particles (aerodynamic diameter≤2.5μm; PM2.5) and health effects, but the immunological mechanisms are not clear. To investigate the dose and time-dependent role of toll-like receptor (TLR) and Th1/Th2 cell in local and systemic inflammation induced by PM2.5, PM2.5 was added to MIHS cells (mouse alveolar macrophage cell line) and mice were subjected to Nose and mouth exposed of 2.5, 5, or 10μg/kg PM2.5 in this study. After 24h, 72h, 7days, and 14days, mice were sacrificed to measure TLR2 and TLR4 expressions and Th1/Th2 related cytokines in bronchoalveolar lavage fluid (BALF) and peripheral blood. Histopathological changes in lung were examined. Inflammatory infiltration and macrophages with engulfed particles were found by lung histopathology after PM2.5 exposure. TLR4 positive cells decreased in BALF but increased in blood at 24h after the exposure. The low percentage of TLR4 positive cells continued to day 14 in BALF, but recovered at day 7 and decreased further to lower than the control value at day 14 in blood. TLR2 positive cell changed similar to TLR4 in BALF on the dose effects. In BALF at 24h after the exposure, the Th2 related cytokines IL-5 and IL-10 increased dose-dependently; and in blood, the Th2 related cytokines IL-4, IL-5, and IL-10 also increased. These results suggest that acute exposure of PM2.5 leads to acute inflammatory responses locally and systemically in mice. TLR2 and TLR4 are involved in this process and PM2.5 can drive a Th2-biased immune response.

1238 Effect of SNPs and Glycosylation Site Mutations on TRPA1 Activation by Particulate Material

C. Deering-Rice, D. Shapiro, E. G. Romero and C. A. Reilly. Pharm/Tox, University of Utah, Salt Lake City, UT.

Transient receptor potential ankyrin 1 (TRPA1) mediates nocifensive responses and inflammation caused by inhaled irritants including certain particulate air pollutants (PM). The mechanism by which insoluble components of PM activate TRPA1, as well as whether differential activation occurs as a result of single nucleotide polymorphisms (SNPs), leading to differences in individual PM sensitivity, was further explored. TRPA1 mutants were generated, transfected into HEK-293 cells, and functionality evaluated by comparing calcium flux relative to the wild-type channel. AITC, a soluble electrophoric TRPA1 agonist, was used to assess the overall functionality of each specific mutant and as a model for PM associated electrophiles, 3,5-diterbutylphenol (3,5-DTBP) is a non-electrophoric component of some PM and is a TRPA1 agonist. The insoluble PM agonist was coal fly ash (CFA). qPCR confirmed equivalent mRNA expression of all mutants and wild-type TRPA1. The N-terminal SNPs R3C and R58T exhibited increased responses to all agonists, and the pore-loop SNP, N954T exhibited a lack of response to all agonists. The ankyrin repeat SNPs E179K and K186N and the pore-loop SNP R919Q exhibited selective decreases in response to CFA, but not to AITC or 3,5-DTBP. The N-linked glycosylation site (predicted) mutants (N747A and N755A) did not effect activation of TRPA1 based on complete inhibition of responses by the cell-impermeable inhibitors EGTA and ruthenium red; activation by AITC and 3,5-DTBP was unaffected. However, activation by CFA was selectively decreased. These data demonstrate a role for both the N-terminal ankyrin repeat domains and cell surface N-linked glycans in mechanical activation of TRPA1 by insoluble PM, providing new insights into the structural components involved. In vitro experiments with different agonists or with specific mutants of TRPA1 may offer a more efficacious way to investigate potential agonists that may offer therapeutic effects.

1239 Concentrated Ambient Fine Particulate Matter (CAP, PM2.5)-Induced Vascular Insulin Resistance: Role of Oxidative Stress

P. Haberzettl, R. Fole, I. Zelko, A. Bhatnagar and D. I. Conklin, Medicine, University of Louisville, Louisville, KY.

Epidemiological studies suggest that increases in fine particulate matter (PM2.5) air pollution contribute to the rapidly evolving epidemics of obesity and diabetes. Previous studies have shown that vascular insulin sensitivity is rapidly impaired by high fat feeding and long-term CAP exposures. Thus, we examined vascular insulin sensitivity and function in low- and high-fat (HFD, 60% kcal fat) fed C57BL/6j mice exposed for 9-30 consecutive days (6h/d) to air or downtown Louisville CAP. CAP exposure for 9 or 30 days impaired aortic insulin signaling measured as insulin-induced phosphorylation of Akt and endothelial-specific eNOS independent of dietary fat. Thus, aortic insulin resistance occurred rapidly in the absence of frank endothelial dysfunction (acetycholine-induced relaxation) reflecting the high sensitivity of vascular insulin signaling to CAP. To identify the underlying mechanism of CAP-induced vascular insulin resistance, we interrogated the role of systemic or lung oxidative stress by exposing mice treated with TEMPOL (4-hydroxy-2,2,6,6-tetramethylpiperidine 1-oxyl; 1mM in drinking water, 2 days prior and throughout) and mice transgenic (Tg) for lung-specific ecSOD to air or CAP for 9 days. Both vascular insulin resistance and aortic inflammation were abolished by systemic TEMPOL. Moreover, lung-specific ecSOD-Tg mice exposed to CAP did not develop vascular insulin resistance. Collectively, these results suggest that short-term CAP induces vascular insulin resistance via local inflammation due to pulmonary oxidative stress, and thus, our model supports the idea that exposure to PM2.5 may contribute to the increased risk of developing T2D and CVD in humans.

1240 PM2.5-Induced Tachycardia and Hypertension in Rats Are Linked to Elemental Carbon and Specific Temperature-Resolved Carbon Subfractions

J. G. Wagner1, A. Kamal2, M. Morishita3, T. Dvonch1, J. R. Harke1, and A. C. Rohrb. 1Michigan State University, East Lansing, MI, 2USEPA, Research Triangle Park, NC, 3University of Michigan, Ann Arbor, MI and 4Electric Power Research Institute, Palo Alto, CA.

Ambient fine particulate matter (PM2.5) is associated with cardiovascular morbidity and mortality. The components responsible for adverse health effects are unknown.

OBJECTIVE: We tested the hypothesis that cardiovascular responses to PM2.5 will be enhanced in hypertensive rats and associated with specific particulate components found in an urban industrial setting.

METHODS: Spontaneously hypertensive rats were exposed by inhalation to filtered air (n=8) or concentrated PM2.5 (n=8) in Dearborn, Michigan, for four consecutive summer days. Exposures were repeated in four separate groups of rats (n=32). Blood pressure (BP), heart rate (HR) and HR variability (HRV) metrics (SDNN, RMSSD) were assessed by radiotelemetry and compared to 1h- and 8h-averaged fluctuations in PM2.5 composition, with a focus on elemental carbon (EC), organic carbon (OC) and their temperature-resolved subfractions, EC1-EC5, PC (pyrrolized carbon), and OC1-OC4.

RESULTS: Exposure-related increases in mean, systolic and diastolic BP were detected as well as increased HR and decreased HRV compared to air-exposed rats. Using 1h averages, PM2.5 EC (1 pg/m3 increase) was associated with increased
HR of 11-32 bpm (4-11% increase), 22-27% decrease in HRV, 3-14 mmHg increases in (1-5-8%) in systolic BP, and 4-9% increases in diastolic BP. By comparison effects of OC were negligible. Using 8 averages, EC subfractions were also associated with increased heart rate (EC1: 13-13bpm, EC2,EC3,PC; <5bpm) and SDNN (EC1):<EC2,EC3,PC; >15bpm +SDNN (EC2,EC3,PC: <10bpm). Significant but comparatively smaller responses were associated with OC and OCl. Effects of either EC or OC subfractions on blood pressures were negligible.

CONCLUSIONS: Acute changes in cardiovascular responses associated with PM2.5 carbon species appear to be driven primarily by EC and EC1 fractions. US EPA R83479701 & Electric Power Research Institute.

1241 Differential Activation of Transient Receptor Potential Ankyrin-1 by Diesel Exhaust Particulate Materials

V. K. Mitchell, C. Deering-Rice, D. Shapiro, E. G. Romero and C. A. Reilly, Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.

Diesel exhaust particulate matter (DEP) is a source of fine-particulate air pollution (PM). Inhaled, fine PM deposits throughout the airways inhalation of DEP can cause irritation to airways, pulmonary inflammation, exacerbation of asthma, and promote chronic pulmonary diseases. Mechanisms underlying the adverse effects of DEP and other environmental PM have been difficult to define due, in part, to the significant variation in its chemical composition arising from inconsistent combustion conditions, particle age, and other factors. PM derived from cigarette smoke, wood smoke, coal burning, and diesel combustion activate transient receptor potential ankyrin-1 (TRPA1). In the respiratory tract TRPA1 activation causes cough, bronchoconstriction, and neurogenic inflammation/edema. We hypothesized that three different DEP samples that mimic environmental DEP, would exhibit variations in potency as TRPA1 agonists due to differences in chemical composition, and that such potency differences would correlate with variations in measures of toxicity such as cell death and cytokine gene expression. NIST SRM 2975 (NIST), DEP collected from the tail-pipe of an on-road truck (JMV), and DEP recovered during diesel filter regeneration (FILTER) were used. TRPA1 activation (Ca+ flux) was determined using TRPA1-overexpressing HEK-293 cells: "JMV" DEP was most potent followed by NIST, then FILTER. The mechanism of TRPA1 activation was also investigated. TRPA1 activation by JMV and NIST were attributable to electrophiles, whereas FILTER activated via both the electrophile and mercnol agonist-binding sites. Chemical analysis of DEP components (PAHS and Aldehydes/Ketones) by HPLC and LC/MS suggested a correlation between DEP potency and the abundance of pernaphthenone, benzquione, and 3,5-ditert-butylphenol in the DEP. Increased understanding of how different samples of DEP affect lung cells is an important step in better understanding the factors that influence the multiple reported effects of DEP in the lung. Support: ES017346.

1242 Ambient PM Exposure and RAGE: Insight into an Emerging Risk for Diabetes and Cardiovascular Disease

Numerous epidemiological studies reveal alarming evidence that individuals with diabetes have been shown to be an especially susceptible population to the cardio-pulmonary effects of particulate matter (PM) pollution. This has been thought to be due to the inherent enhanced inflammation and endothelial dysfunction seen in diabetics. Nonetheless, there is no definitive mechanism that explains the pathways responsible for these observed vulnerabilities. Recent reports have implicated activated receptors for advanced glycation end-products (RAGE) as an integral factor in the inflammatory processes of cardiovascular dysfunction and diabetes; nonetheless, it is unclear whether ambient PM alone or in combination w/ other endoge-neous factors may contribute to RAGE activation and underlie these inflammatory disparities. To investigate the influence of RAGE on PM-mediated inflammatory levels of soluble RAGE (sRAGE), membraneous RAGE, ligands (i.e. AGEs, S100 proteins and HMGB1) and NF-kB were measured in human pulmonary and cardio-vascular cell models (pulmonary endothelial, epithelial, macrophage and alveolar) exposed to regional PM or inert saline solution. Lastly, to validate RAGE as a mechanism of PM-induced inflammation, B6C3F2 mice were exposed to regional PM aspirations. Results: After 24h of PM2.5 exposure, a dose dependent increase in cell proliferation and small increases in sRAGE activity at higher doses of PM was evident. Immunofluorescence detection showed an elevation in cells positive for membraneous RAGE expression; accompanied w/ a 2-fold increase in mRNA for RAGE & NF-kB; as well as significant increases in measures of ligands such as AGE and HMGB-1. These findings suggest a plausible interaction between PM & RAGE resulting in the enhanced expression and activation of NF-kB and RAGE. Finally, preliminary mouse exposures have yielded supportive findings: exposed mice have shown significantly increases of RAGE expression compared to controls. Collectively, these data offer valuable insight into PM-mediated RAGE activation and its influence on diabetes.

1242a Intratracheal Coexposure to Diesel Exhaust Particulate and Crystalline Silica in Rats Potentiates the Inflammatory Effects of Silica in the Lungs

B. M. Yingling1, 2, C. E. McLaughlin3, J. S. Fedan4, 5, B. T. Cheng3, D. Schwegler-Berry3, J. M. Antonio4, 5 and J. R. Roberts3, 5, WVU, Morgantown, WV and 2NIOSH, Morgantown, WV.

Worker exposure to high levels of respirable dust containing crystalline silica and diesel exhaust (DE) has become a concern during hydraulic fracturing operations. The goal of the current study was to investigate the effects of acute pulmonary co-exposures to silica and DE particulate (DEP) in vivo. Doses were derived from field measures using the high point values for respirable silica, applied to a human pulmonary deposition model, and normalized to the surface area of the rat lung. The silica dose of 230 µg/rat represents 2.5 mg/m³ for 12 hr/d for 14 d. The DEP dose of 7.9 µg represents 0.1 mg/m³ for the same duration in a deposition model for total carbon (TC). A 50 µg dose of DEP was also used to represent ~0.6 mg/m³ TC for the same duration. Rats were exposed by a single intratracheal instillation of sterile PBS as vehicle or one of the following doses: 7.9 µg DEP, 50 µg DEP, 250 µg silica, or silica and DEP combined for each dose of DEP. At 1 d, 1 wk, and 1 mo post-exposure, bronchoalveolar lavage (BAL) was performed on the right lungs; cells and fluid were retained to assess pulmonary injury and inflammation. Lung-associated lymph nodes (LALN) were harvested to evaluate immune responses. Silica alone caused increased inflammation and lung injury at all times post-exposure, indicated by increased neutrophil influx, oxidant production, and lactate dehydrogenase (LDH) in BAL. DEP alone caused only slight inflammation 1 d post-exposure but no effects later. At 1 wk and 1 mo after exposure, 50 µg DEP significantly increased the inflammatory effects of silica. In addition, at 1 mo, both co-exposure doses significantly enhanced the phagocyte oxidant production over silica alone. Lymphocyte counts in LALN in the co-exposures were not elevated relative to silica exposure alone. In summary, DEP alone produced relatively no pulmonary toxicity; however, DEP in a co-exposure with silica has the capability to potentiate the adverse effects of silica in the lung.

1242b Inhalation of Traffic-Derived Particulates and Exposure to Social Stress Differentially Alter Cardiovascular Function in Rats

A. P. Carll1, T. Jaeger2, 3, D. Lamoureux1, 4, R. Sato1, 2, J. E. Clougherty1, 2, V. Papapostolou1, J. Lawrence1, E. Diaz1 and J. J. Godleski1. 1Environmental Health, Harvard School of Public Health, Boston, MA, 2Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil, 3Laboratory of Personalized Medicine, Harvard Medical School, Boston, MA and 4Environmental & Occupational Health, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA.

Vehicular-derived air pollution includes particulate matter (PM) consisting of primary particles (P) and secondary organic aerosols (SOA) that induce adverse cardiovascular events potentially through vascular or autonomic nervous system dysfunction. Telemetered rats were exposed by whole-body inhalation to traffic-de- rivied P+SOA denuded of combustion gases (4d/wk × 5h/d; mean PM10 concentration ≈ 50 µg/m³) for 12 d to determine effects on arterial pressure (AP) and heart rate variability (HRV, a measure of autonomic balance). P+SOA caused increased AP during exposure days 1, 4, and 6 (mean AP: +15 mmHg vs. control), sympa-thetic dominance during days 1 and 4 (standard deviation of interbeat intervals: ~3-4 ms, supraventricular tachycardia (heart rate: +180 beats/min for up to 5 h) between days 6 and 8 in half of animals, decreased AP on day 11 (~9 mmHg mean AP), and bradycardia in half of animals during baroreflex challenge on day 12. Baroreflex sensitivity tended to increase on day 12 of exposure, indicating compen-sation for the hypertensive effects of P+SOA. To compare P+SOA to social stress, separate telemetered animals were introduced to a dominant rat for 20 min/d for 10 d. Social stress consistently increased heart rate (+40-100 beats/min) and mean AP (+15 mmHg) while increasing a HRV measure of vagal tone (root mean square of successive differences) potentially indicating baroreflex activation. Thus, the autonomic effects of P+SOA and social stress diverged during similar hypertensive responses. Therefore, traffic-derived PM causes hypertension, autonomic imbalance, and subsequent compensatory responses in a pattern different from acute psychological stress.
Epidemiological studies suggest a direct correlation between exposure to diesel exhaust particles (DEP) and the onset of cardiovascular diseases presumably through the disruption of the adherens junctions. This would lead to increase of vasculature permeability and the inhaled DEP gain access into the circulation system. Although the mechanism remains unclear, our group has demonstrated the DEP-induced re-active oxygen species (ROS), which may play a key role in causing vascular permeability factor, VEGFA secretion. In order to minimize the level that DEP penetrating into the capillary lumen, 20 and 200 μg/mL. Ganoderma lucidum (G. lucidum) was applied with DEP to the in vitro capillary-like HUVEC tube culture. After 24 h DEP exposure, we observed VEGFR2 dissociated from the membrane and re-localized to both cytoplasm and supernatant. It subsequently resulted in making PI3K/Akt inactivation. While with co-treatment of G. lucidum, Cm-H2DCFDA assay showed the ROS generation was blocked. Not only was the increased vascular permeability reduced following by the oxidative stress inhibition, but none of secreted VEGFA was also detected. Immunoblotting further suggested the localization of VEGFR2 and PI3K/Akt activation were affected only at high dose of DEP (100 μg/mL). Additionally, immunofluorescent images revealed that VE-cadherin formed adherens junction network was destroyed in response to DEP. Once combine the treatment with G. lucidum, the cell-cell junctional structure was rebuilt, however, this was observed only at 1 and 10 μg/mL DEP. In summary, these results indicate that inhaled DEP may directly impact the lung vasculature, while additive G. lucidum may protect the endothelial tube cells and their adherens junctions from exposure to DEP.

Coronary artery disease (CAD) is the most prevalent cause of disease-related death in the US and emissions related particulate matter (PM) exposures are thought to be associated with thousands of excess deaths per year. Ultrafine particles (UF) contain a large proportion of redox-active organic compounds, exposure to which may be related to oxidative stress that is involved in the pathogenesis of heart disease, that exist in the volatile or particle phase and are considered semi-volatile organic compounds (SVOCs). We previously demonstrated an acceleration of atherosclerosis in susceptible mice associated with exposure to SVOCs from ultrafine concentrated ambient particles (CAPs). The interaction of enhanced arterial disease and CAPs derived SVOC exposure may increase the susceptibility of the heart to adverse cardiac events. We hypothesized that the SVOC exposed mice would have changes in heart rate variability (HRV), a measure of cardiac autonomic control, and in the morphology of the repolarization segment measured on an electrocardiogram. Decreased HRV is a measure in humans that has been associated with increased cardiac risk of adverse events. ApoE-/- mice, which are prone to developing atherosclerosis, were exposed to either UF CAPs or CAPs with the SVOC components removed by a thermodenuder (deCAPs) for 8 weeks in downtown Los Angeles for 5 hours/day, 4 days/week. A control group was exposed to purified, filtered air. Implanted cardiac transmitters monitored electrocardiograms from the mice. The CAPs exposed mice had diminished HRV compared to deCAPs and CAPs derived SVOC exposure may increase the susceptibility of the heart to adverse cardiac events. We hypothesized that the SVOC exposed mice would have changes in heart rate variability (HRV), a measure of cardiac autonomic control, and in the morphology of the repolarization segment measured on an electrocardiogram. Decreased HRV is a measure in humans that has been associated with increased cardiac risk of adverse events. ApoE-/- mice, which are prone to developing atherosclerosis, were exposed to either UF CAPs or CAPs with the SVOC components removed by a thermodenuder (deCAPs) for 8 weeks in downtown Los Angeles for 5 hours/day, 4 days/week. A control group was exposed to purified, filtered air. Implanted cardiac transmitters monitored electrocardiograms from the mice. The CAPs exposed mice had diminished HRV compared to deCAPs and Air exposed mice, particularly during the latter weeks of exposure. Similarly, repolarization segment changes were observed in the CAPs exposed mice but not the Air and deCAPs exposed mice. The attenuation of cardiac effects in the deCAP group indicate that SVOCs in CAPs exposures are possibly important contributors to the toxic cardiac effects.
Employment of sustainable resources for fuel manufacture has recently gained worldwide trends to limit usage of fossil oils while providing less atmospheric greenhouse gas effects and reducing air pollution. Biodiesel (BD) fuels and biodiesel petroleum blends are used for large truck engines and small, single-cylinder basic piston operating engines. BD produced by transesterification of vegetable oil into fatty acid methyl esters is a renewable energy source. Considering BD fuel is mainly composed of unsaturated fatty acids, we hypothesize that BD exhaust emissions related to found inflammation, oxidative-stress and impaired clearance of combustion products from BD and specific mechanism of interactions of these PM in pigment laden macrophages. Future studies on the detailed analysis of lymphocytic infiltrate and impaired clearance with prolonged retention PM caused pulmonary inflammation and damage, enhanced release of inflammatory mediators found in BAL and lung tissue causing oxidative stress. Biomarkers of tissue damage, oxidative-stress and inflammation were significantly elevated in lungs of mice exposed to BD compared to those found in mice treated with D. The up-regulation of inflammatory cytokines/chemokines was also higher in lungs of mice treated with BD. Histological evaluation of mouse lungs indicated presence of lymphocytic infiltrate and impaired clearance with prolonged retention of BD PM in pigment laden macrophages. Future studies on the detailed analysis of combustion products from BD and specific mechanism of interactions of these emissions related to found inflammation, oxidative-stress and impaired clearance is underway.
area adjacent without lesion in the same animal was used to analyze the cellular morphology after hematoxylin-eosin stain, and to evaluate the level of Zn and MT which were determined by AAS and 109-Cd saturation method, respectively. The results showed increases of Zn at 48 hours and 7 days after surgery, whereas MTs start to increase at 6 h after surgery, maintaining this level until 48 h. Maximum increases of both metabolites occurred at 48 h, corresponded with the maximum increase of inflammatory cells (polymorphonuclear cells and macrophages). The increase of Zn in the injured area can have an important role for activation of metalloenzymes-Zn and activation of transcription factors necessary for healing, while MTs can act as a reservoir of Zn, and as antioxidant defense in the lesion site.

1245 Gene Expression and Pathway Analysis of Cadmium Exposure in Human Hepatocarcinoma Cells

L. Cartularo1, F. Laulicht1, H. Sun2, T. Kluu1, J. H. Friedman1 and M. Costa1, 2Environmental Medicine, New York University, Tuxedo, NY and -NIEMHS, Research Triangle Park, NC.

Cadmium (Cd) is a toxic and carcinogenic metal naturally occurring in the earth’s crust as well as in rocks and soil. Cd can also be introduced into the environment through its many industrial uses. Cd is easily absorbed by plants from the soil, thus a common route of human exposure is via diet. Additionally, smokers are exposed to high levels of Cd from tobacco. This study examined the effects of both acute and chronic Cd exposure on gene expression in human hepatocarcinoma (HepG2) cells. HepG2 cells were treated with either 0.5 μM Cd for 24 hours or 0.1 μM Cd for three weeks and gene expression analysis was performed using Affymetrix GeneChip® Human Gene 1.0 ST Arrays. Acute and chronic exposures significantly altered the expression of 333 and 181 genes, respectively. The genes most upregulated by both exposures include several metallothionein genes. Downregulated genes include the monoxygenase CYP3A7, which is involved in drug and lipid metabolism. CYP3A7 was upregulated by chronic Cd exposure, as was DNAJ-B9, which plays a role in protecting stressed cells from apoptosis. Genes downregulated due to chronic exposure include the transcriptional regulator early growth response protein 1 (EGR1). Ingenuity Pathway Analysis, IPA, revealed that the top networks altered by acute exposure are lipid metabolism, small molecule biosynthesis, and cell morphology, organization, and development; while top networks altered by chronic exposure are organ morphology, cell cycle, cell signaling, renal and urological diseases, cellular growth and proliferation, and cancer. Expression data demonstrate that exposure to Cd alters the expression levels of many different genes involved in various disease pathways. Many of the genes altered by Cd exposure may be involved in carcinogenesis, with roles in cellular growth, proliferation and apoptosis.

1246 Zinc Supplementation Abates Cadmium-Induced Uregulation of Glutathione Synthesis and Oxidative Stress

S. D. Francis Stuart, R. K. Young and A. R. Villalobos, Texas A&M University, College Station, TX.

In primary cultures of rat choroid plexus we showed cadmium (Cd) induced oxidative stress, stimulated apical choline uptake, and up-regulated glutathione (GSH) synthesis. Zinc (Zn) supplementation of Zn (0.1 mM) and Cd (250 nM CdCl2) in serum-free medium without or with 10 μM Zn for 12 h. Induction of heme-oxygenase-1 (HO-1), heat-shock protein 70 (HSP70), copper-zinc superoxide dismutase (SOD1), and metallothionein-1 (MT-1) was analyzed by immuno blot and qRT-PCR. Glutamate-cysteine ligase (GCL) is the rate-limiting enzyme in GSH synthesis; the modulator and catalytic subunits, GCLM and GCLC, were also analyzed. As compared to controls, Cd treatment induced gene expression of GCLC, MT-1, HO-1, and SOD1 by 2, 16, 12, and 3-fold. Zn supplementation, however, reduced this induction. Cd increased GSH by 2-fold and GSSG by 30-fold as compared to control, whereas in cells also supplemented with Zn, GSH and GSSG levels were decreased 25% and 44% as compared to Cd treatment alone. To determine whether effects of Zn were associated with changes in GSH availability, cells were pretreated (12 h) without or with buthionine sulfoximine (BSO, 100 μM), a GCL inhibitor, after Zn supplementation and before treatment with 0 or 250 nM CdCl2 ± Zn (10 μM) for 12 h. BSO treatment, regardless of condition (e.g., without or with Zn ± Cd), reduced GSH by 92% but increased GSSG by 15-fold above controls. BSO treatment resulted in an enhanced, compensated induction of HO-1, HSP70, SOD1, GCLC, GCLM and MT-1 in the presence of Cd. However, this was attenuated in cells also supplemented with Zn. These data indicate Zn abates Cd-induced up-regulation of GSH synthesis and still protects when GSH synthesis is inhibited. NSF #1052654

1247 Kidney Specificity in Cd-Induced Accumulation of p53

Dependent on the Inhibition of UBE2D Family Gene Expressions

M. Satoh1, L. Lee1, M. Tokumoto2,3 and Y. Fujiwara1, 1Laboratory of Pharmaceutical Health Sciences, School of Pharmacy, Aichi Gakuin University, Nagoya, Japan and 2Laboratory of Chemical Toxicology and Environmental Health, Showa Pharmaceutical University, Tokyo, Japan.

Cadmium (Cd) is an environmental metal pollutant causing renal dysfunction. However, the underlying mechanisms of Cd toxicity remain to be elucidated. Our recent study has demonstrated that overaccumulation of p53 may relate to Cd-induced apoptosis and may be due to the suppression of p53 degradation through the inhibition of gene expressions of Ube2d family in rat proximal tubular cells (NRK-52E cells). In this study, we examined whether suppression of Ube2d gene expression and p53 accumulation by Cd have kidney-specificity. In the present study, we used only some cell lines as IEC-6 cells (rat small intestine epithelial cells), HBMECs (human brain microvascular endothelial cells), human astrocytes, and HK-2 cells (human kidney proximal tubular cells), but also kidney and liver of C57BL6/J mice. In IEC-6 cells, Cd decreased both of mRNA levels of 3 members (Ube2d1, Ube2d2 and Ube2d4) of Ube2d family and protein level of p53. In HBMEC, Cd increased p53 protein level without the decrease in UBE2D family gene expressions. In human astrocytes, Cd increased only the mRNA level of UBE2D3. In HK-2 cells, Cd suppressed the mRNA levels of UBE2D2 and UBE2D4, as well as increased p53 protein level. Moreover, Cd exposure for 6 months decreased mRNA levels of Ube2d family and accumulated p53 protein in kidney of mice. On the other hand, neither mRNA levels of Ube2d family nor p53 protein level are changed in liver of mice exposed to Cd for 6 months. These findings suggest that Cd accumulates of p53 protein via the suppression of Ube2d family gene expression with kidney-specificity.

1248 Cadmium-Induced Apoptosis Is Mediated by p53 Accumulation through the Suppression of Gene Expression of Ube2d Family in Proximal Tubular Cells

L. Lee1, M. Tokumoto1,2, Y. Fujiwara1 and M. Satoh1, 1School of Pharmacy, Aichi Gakuin University, Nagoya, Aichi, Japan and 2Showa Pharmaceutical University, Tokyo, Japan.

Cadmium (Cd) toxicity is accompanied by disturbance of gene expressions and increases in stress-response proteins. However, the precise targets of Cd toxicity are still unknown. Our previous study demonstrated that Cd induced cellular accumulation of tumor suppressor protein p53, and inhibited the gene expressions of ubiquitin-conjugating enzyme E2 D family (Ube2d family), which involves in p53 ubiquitination for its degradation, in NRK-52E rat renal tubular epithelial cells and mouse kidney. In the present study, we examined the association of decrease of Ube2d family gene expressions with increase of p53 accumulation by Cd, and the involvement of p53 overaccumulation in Cd-induced apoptosis, using HK-2 human proximal tubular cells and kidney of C57BL6/J mice. Cd increased cellular p53 protein prior to toxic effect in HK-2 cells. Cd significantly decreased gene expression of Ube2d2 and Ube2d4, members of Ube2d family, prior to accumulation of p53 by Cd. The double knockdown of UBE2D2 and UBE2D4 by siRNA caused the increase of p53 protein in HK-2 cells. Moreover, Cd markedly increased nuclear phosphorylated p53 level. Not only apoptotic cell death was promoted in response to Cd, but also Cd-induced apoptosis was attenuated by knockdown of p53 using the siRNA. In addition, 6-month exposure of mouse to Cd (300 ppm) triggered accumulation of p53 in proximal tubules, and apoptotic signals were observed on the same spots where Cd accumulated p53 in proximal tubules. The present findings suggest that cadmium excessively absorbed in proximal tubular cells may induce p53-dependent apoptosis through the suppression of Ube2d gene expression.

1249 Paraoxonase Activity in Subchronic Low-Level Cadmium Exposure

O. O. Ogunrinola1,2, A. D. Wusu1,2, O. K. Afolabi2,3, E. A. Balogun2,3, E. O. Alum2,3, D. O. Babayemi2, O. A. Dosumu2, O. B. Onunkwara2, O. O. Okikuyo2 and O. A. Epidemiological studies suggest an association between cardiovascular diseases and cadmium in drinking water. While the underlying mechanism of this cadmium-mediated increase in cardiovascular risk factors remains enigmatic, studies
Cadmium (Cd) is a ubiquitous environmental pollutant that has been associated with hyperglycemia or diabetes in epidemiological studies. In the current study, we show that after 12 weeks of Cd exposure in rats there was an increase in serum glucose-dependent insulinotropic polypeptide (GIP) and a decrease in the satiety hormone, leptin. Based on these observations we conducted a pilot study using rats, db/db mice (diabetic mouse model) and lean mice. All animals were given daily subcutaneous injections of Cd at a dose of 0.6 mg/kg/day for two weeks then given no Cd for another two week period. At the end of the study, all animals underwent an oral glucose tolerance test (OGTT) and body weight and fat pad weights were recorded. In the OGTT, Cd had the greatest effect on db/db mice, with all animals except one having blood glucose levels of 600 mg/dl or higher 30 min following an oral dose of glucose (2g/kg). At the same 30 min time point, the non-Cd treated db/db mice had an average blood glucose value of 507 ± 19 mg/dl. Surprisingly, at the end of the study, all Cd treated groups of animals had higher average body weight values as compared to non-Cd treated animals. This increase in body weight during the last 2 weeks of non-Cd exposure was statistically significant in rats. Epididymal and retroperitoneal fat pad weights were significantly greater in the Cd-treated lean mice as compared to non-Cd treated lean mice. Finally, Cd content of the renal cortex from Cd-treated lean mice was 45.4 ± 3.6 μg/g tissue wet weight. This study shows that environmental substances such as Cd can have diabetogenic and obesogenic effects at low levels of exposure.

1250 Cadmium-Induced Lung Emphysema and Carcinogenesis Coupled with Defect in Lysyl Oxidase in the Rat Animal Model
Y. Zhao1, P. Toselli1, G. Cheng2, M. Zheng3, J. Li4 and W. Li5. Biochemistry, University Affinity Hospital, Tangshan, Hebei, China.

Lysyl oxidase (LOX) is an extracellular matrix cross-linking enzyme and a tumor suppressor. To assess cadmium (Cd) effects on LOX expression, pathogenesis and carcinogenesis in the lung, a constant dose of CdCl2 at 30 μg/rat (∼ 0.123 ± 0.007 μg Cd/kg body weight) in 100 μl physiological saline was intratracheally instilled into the lung of male Sprague-Dawley rats once a week for 4 weeks (total Cd dose = 110.4 μg Cd/rat). Control rats received saline only (20 rats). Rats were killed 1 or 65 weeks after the last instillation. Due to the half-life of absorbed Cd by the lung to be 9.4 year, actually, Cd exposure times in two treated groups were 7-weeks (6+1) and 71-weeks (6+65), respectively, each with 20 rats (10 rats for morphological study and 10 rats for biochemical assays). Rats exposed to Cd for 7 weeks all exhibited extensive enlargement of airspace and multiple pulmonary bullae with or without small areas of interstitial fibrosis. EM showed the thin alveolar wall with less depression of matrix components such as elastin and collagen. Cd exposure for 71 weeks elicited adenocarcinoma in 5 rats (25%). Some areas of lung tissues were infiltrated with cancer cells, capillaries, and hemorrhages. Biochemical assays illustrated declined levels of LOX at protein, mRNA and catalytic activities associated with downregulation of collagen synthesis in emphysematous and carcinogenic lung tissues. However, tissue thios such as glutathione (GSH) and metallothionein as well as γ-glutamylcysteine synthetase, a key enzyme for GSH biosynthesis were constantly upregulated. Upregulation of cellular thios is a critical cellular event facilitating downregulation of LOX since they trap cellular copper, a cofactor of LOX. Based on LOX biological functions, Cd downregulation of LOX may play a vital role in lung emphysema pathogenesis and carcinogenesis (Supported by grant NIEHS R01-11340).

1251 Acute and Chronic Cadmium Exposure Induces Transcriptional Activation of BMP-2 Signaling Cascades in a Human Renal Epithelial Cell Culture Model
A. Slusser, A. Holmquist, S. Somji, D. A. Sens and S. H. Garrett. Pathology, University of North Dakota, Grand Forks, ND.

Cadmium is a toxic heavy metal that causes renal dysfunction. However, the molecular mechanisms underlying its toxicity are not clearly understood. Recently, we show that after 12 weeks of Cd exposure in rats there was an increase in serum glucose-dependent insulinotropic polypeptide (GIP) and a decrease in the satiety hormone, leptin. Based on these observations we conducted a pilot study using rats, db/db mice (diabetic mouse model) and lean mice. All animals were given daily subcutaneous injections of Cd at a dose of 0.6 mg/kg/day for two weeks then given no Cd for another two week period. This study shows that environmental substances such as Cd can have diabetogenic and obesogenic effects at low levels of exposure.
Gastrointestinal Solubilization and Uptake of Mercury and Selenium from Wild-Harvested Inuit Foods

B. D. Laidley1, S. Palaniyandi2, P. J. Vanié1, M. Lemire3, M. Kwon4, L. Chan5, E. Dewaril6 and P. Ayotte7. Medicine, Emory University, Atlanta, GA.

Cd accumulates in humans from dietary, environmental including cigarette smoke, and occupational sources, and has a twenty-year biologic half-life. Our previous studies showed that environmental low dose Cd altered protein redox states resulting in stimulation of inflammatory signaling and actin cytoskeleton disruption, suggesting that Cd could impact multiple disease mechanisms. However, little is known about the relative sensitivities of cellular metabolism associated with subcellular compartmental disruption. In the current study, we investigated effects of acute Cd on mouse liver examining the metabolome of isolated mitochondria and nuclei. To identify nuclear and mitochondrial metabolites affected by Cd, liver nuclei and mitochondria isolated from Cd-exposed mice were analyzed by high-resolution metabolomics. The result showed that Cd altered levels of 1,901 and 542 metabolites in nuclei and mitochondria, respectively, compared to control group. Of these metabolites changed significantly by Cd, 1016 in nuclei and 278 in mitochondria matched to metabolites in Kyoto Encyclopedia Gene and Genome (KEGG) database. Of these, 80% of decreased features are categorized to phytochemical compounds, lipids and biologically functional compounds. On the other hand, Cd increased 262 and 88 features in nuclei and mitochondria, respectively. Of these, 24% (nuclei) and 17.1% (mitochondria) are categorized into pesticides, natural toxins and carcinogens. The results suggest that Cd -induced toxicity could be associated with substantial decrease in functionally essential biological molecules and increase in toxic chemicals in nuclei and mitochondria. Among multiple pathways analyzed by MetaCore software, metabolism associated with altered features of nuclei and mitochondria are distinct. Taken together, the results indicate that metabolomics analysis of subcellular compartments enable identifying biological molecules and toxic chemicals, and associated functional pathways, which could be applicable to determine potential markers as indication of complex mechanisms of environmental effects in disease.

Environmental Metabolome of Mouse Liver Mitochondria and Cell Nuclei

Y. Geo, M. Ott, Y. Liang and D. P. Jones. Medicine, Emory University, Atlanta, GA.

Methylmercury (MeHg) causes cell-type specific damage in the cerebellum in a Ca2+-dependent manner. In vitro studies have shown that acute MeHg treatment caused a biphasic increase in [Ca2+], which can be delayed by voltage-gated Ca2+ channel (VGCC) antagonists, demonstrating their role in MeHg-induced Ca2+ dysregulation. We and others have shown effects of MeHg on dopamine release; numerous studies have addressed the acute effects of MeHg on cholinergic and dopaminergic cell lines and primary neurons. However, exposure to low levels of MeHg during lifetime are lacking. As such, our aim was to study effects of repeated MeHg treatment on VGCC function in differentiated SH-SYSY cells, a dopaminergic cell line. These cells have been used extensively to study MeHg neurotoxicity so we first characterized acute effects of MeHg on [Ca2+], in these cells. Changes in [Ca2+] were measured using Fura-2; cells were perfused continuously with 1, 2, 5, or 10μM MeHg. MeHg caused a biphasic, concentration-dependent increase in Fura-2 fluorescence; the times to onset of both phases were inversely proportional to the [MeHg]. At 1μM Phase 1 (P1) and Phase 2 (P2) occurred at -12 and 48min respectively, whereas at 10μM P1 occurred within 2 min and P2 within 15min. Nifedipine (Nif, 5μM) and co-agonist GVI (GVI, 1μM), L- and N-type antagonists respectively, delayed the onset of P2 but not P1. Effects of semichronic MeHg treatment on VGCC function were subsequently characterized. Cells were treated with 0 or 20μM MeHg for 48 or 72h. Cells were then loaded with Fura-2 AM and KCl-induced Ca2+ influx was monitored as an index of VGCC function. Ca2+ influx through L- and N-type VGCCs was isolated using GVI and Nif respectively. The 48h treatment significantly decreased KCl-induced Ca2+ influx through L-type VGCCs; the 72h treatment significantly decreased KCl-induced Ca2+ influx through both L- and N-type VGCCs. Thus semichronic MeHg treatment affects VGCC function in a dopaminergic cell line. These may result from MeHg-induced alterations of VGCC expression, resting [Ca2+], or block of VGCCs.

Semichronic Methylmercury Exposure Alters KCl-Induced Calcium Influx in SH-SYSY Cells

Methylmercury (MeHg) is a pollutant that causes severe central nervous system damage. However, the mechanism of MeHg toxicity remains unclear. Our previous study indicated that expression levels of 21 genes were changed in the cerebellum of mice by MeHg. In this study, we investigated effects of MeHg on the expressions of these 21 genes in various tissues (cerebrum, cerebellum, liver and kidney) of MeHg-treated mice, Sgcb3a1, Ch25h, Chi3l3, Ctla2b and several chemokines (Ccl2, 4, 7, 9 and 12) mRNA expressions were significantly increased in the brain of MeHg-treated mice. Among these genes, mRNA levels of Ccl4 and Sgcb3a1 were not significantly changed in the liver and the kidney. These results suggest that the MeHg-induced increases in Ccl4 and Sgcb3a1 expression are brain specific in mice.

Brain-Specific Induction of Expression of Ccl4 and Sgcb3a1 by Methylmercury in Mice

M. Kim1, T. Takahashi1, J. Lee1,2, G. Hwang3 and A. Nagamizu1. Laboratory of Molecular and Biochemical Toxicology, Tohoku University, Sendai, Miyagi, Japan and Laboratory of Pharmaceutical Health Sciences, School of Pharmacy, Aichi Gakuin University, Nagoya, Aichi, Japan.

Methylmercury (MeHg) is a pollutant that causes severe central nervous system damage. However, the mechanism of MeHg toxicity remains unclear. Our previous study indicated that expression levels of 21 genes were changed in the cerebellum of mice by MeHg. In this study, we investigated effects of MeHg on the expressions of these 21 genes in various tissues (cerebrum, cerebellum, liver and kidney) of MeHg-treated mice, Sgcb3a1, Ch25h, Chi3l3, Ctla2b and several chemokines (Ccl2, 4, 7, 9 and 12) mRNA expressions were significantly increased in the brain of MeHg-treated mice. Among these genes, mRNA levels of Ccl4 and Sgcb3a1 were not significantly changed in the liver and the kidney. These results suggest that the MeHg-induced increases in Ccl4 and Sgcb3a1 expression are brain specific in mice.

Role of Reactive Sulfur Species in Reduction of Methylmercury Toxicity In Vitro and In Vivo

E. Yoshida1, T. Toyama2 and Y. Kuma4. 1Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Japan, 2Faculty of Medicine, University of Tsukuba, Tsukuba, Japan and 3School of Agriculture, University of Tsukuba, Japan.

Methylmercury (MeHg) is an environmental electrophile that can covalently bind to protein sulphydryls to form protein-MeHg complexes. These covalent modiﬁcations, referred as “S-mercuration”, are associated with disruption of enzyme function and neurotoxicity. Some of MeHg unbound and/or proteins mod-
ified by MeHg undergo interaction with deprotonated glutathione (GSH) to yield its GSH adducts that are rapidly excreted into extracellular space through MRPI transporters. On the other hand, hydrogen sulfide (H2S) is a gaseous, weakly acidic molecule mainly produced by cystathionine β-synthase (CBS) and cystathionine γ-lyase (CSE) in cells. Most interestingly, H2S is extensively dissociated into a nucleophile HS− because of its pKa value ~ 6.76 while pKa value of GSH is ~9.12, implying that most of GSH exists as its protonated form at physiological conditions. However, role of H2S in chemical modification of cellular proteins and cytotoxicity during exposure to MeHg is poorly understood. We examined the contribution of H2S to the protection of CBS to cellular protection against MeHg. Pretreatment with NaHS or overexpression of CBS reduced MeHg cytotoxicity, whereas transfection with CBS small interfering RNA enhanced MeHg toxicity in human neuroblastoma SH-SY5Y cells. Bismethylmercury sulfide (MeHgS2S), formed during the reaction of MeHg with H2S, was identified as a metabolite of MeHg in SH-SY5Y cells exposed to MeHg and in the livers of rats treated with MeHg. MeHgS2S had little chemical protein modification capability and little cytotoxicity compared with MeHg in vitro and in vivo. Based on these results, we propose a novel detoxification pathway of MeHg catalyzed by cellular enzyme to generate H2S.

1259 Characterization of Mercury Binding Proteins in the Liver of Northern Fur Seals (Callorhinus ursinus)

T. Agusa1, S. Yatsu1, T. Ikeemoto2, T. Kunito3, N. Bab2, S. Tanabe1 and H. Iwata1
1 Ehime University, Center for Marine Environmental Studies (CMES), Matsuyama, Japan, 2 Thermo Fisher Scientific, Yokohama, Japan, 3 Shinshu University, Matsumoto, Japan and 4 National Research Institute of Fisheries Science, Yokohama, Japan.

Marine mammals accumulate a large amount of mercury (Hg) in the liver. Our previous studies have found that most of Hg exists as an inactive form, tiemannite (HgS5e) in the nuclear, lysosomal, and mitochondrial (NLM) fraction of the liver of marine mammals, whereas relatively high abundance of organic Hg was observed in the liver cytosol. This result suggests that methyl Hg is demethylated in the cytosol and Hg subsequently co-accumulates with selenium (Se) in the NLM fraction. However, it is still unknown how Hg is present in the liver cytosol fraction in marine mammals. To understand the toxicokinetics of mercury, we investigated Hg binding proteins in the hepatic cytosol of the northern fur seal (Callorhinus ursinus). In the cytosol, Hg concentration in the high molecular weight (HMW) fraction was higher than the metallothionein (MT) and the low molecular weight (LMW) fractions. In contrast, Se was detected in the HMW and LMW fractions, but not in the MT fraction. A significant positive correlation between Hg and Se concentrations was found in the HMW fraction of the cytosol. The molar ratio of Hg and Se reached 1:1 with an increase in Hg concentration. These results suggest that Se interacts with Hg and then bind to HMW protein(s) in the hepatic cytosol, reducing the toxicity of Hg in the liver. By the purification of proteins interacted with both of Hg and Se using an anion exchange and a gel filtration chromatography, four proteins with the molecular weight around 100 kDa and 40 kDa were obtained in the HMW fraction of the cytosol. The purified proteins may play a role in the formation of Hg-Se complex in the hepatic cytosol.

1260 Effects of Single Nucleotide Polymorphisms on Blood Mercury Level of Korean Population

J. Lim1, H. Kwon1, H. Kim1, Y. Kim2, S. Eom1, M. Hwang1 and J. Park2
1 Dankook University, Cheonan, Republic of Korea, 2 Chung-Ang University, Seoul, Republic of Korea, 3 Chungbuk University, Cheongju, Republic of Korea and 4 Naional Institute of Food and Drug Safety Evaluation, Cheongwon, Republic of Korea.

Background: Recent studies have suggested that several genes that mediate mercury metabolism are polymorphic in humans.

Objectives: We hypothesized those single-nucleotide polymorphisms (SNPs) in toxicokinetics genes may influence individual difference in blood mercury levels. We studied the potential modifying effects of toxicokinetics related SNPs on blood mercury level.

Methods: We selected samples of 528 adults from "the Korean research project on the integrated exposure assessment of hazardous materials for food safety (KRIEFS)" cohort. This cohort measured blood mercury level and dietary exposure to mercury level. We analyzed SNPs of samples with a Human Exome 12v 1.2. The blood mercury levels were compared by SNPs with linear regression model.

Results: Linear regression analysis showed that eight SNPs were statistically significant different in blood mercury level by genotype (cut off P< 0.05). When we adjusted age, sex, smoking, and dietary exposure level, TOP1MT (rs11544484) AA genotype (n=2) or AG genotype (n=57) had lower blood mercury levels than GG genotype (n=437). MBIP (rs2899849) GG genotype (n=1) or GA genotype (n=24) had lower blood mercury level than AA genotype (n=471). FZD7 (rs201306518) GG genotype (n=1) or GC genotype (n=27) had lower blood mercury level than CC genotype (n=448).

Conclusion: Our findings suggest that some toxicokinetics related genetic polymorphism may influences blood mercury level.

1261 Ras Sindoor: Ayurveda's Attempt at Detoxifying Mercury

N. Sadekar and L. D. Trombetta, Pharmaceutical Sciences, St. John's University, Queens, NY.

Ayurveda is a traditional medicine system or a form of alternative medicine, which is native to the Indian subcontinent. Rasa Shashtra is a branch of Ayurveda that involves processes to purify metals for therapeutic use as herbo-metallic preparations. With the expanding global community, these medicinal preparations are easily available to anyone desperately seeking alternative treatment strategies. These preparations may be more likely to be toxic than therapeutic. Ras Sindoor (RS) is an inorganic compound containing mercury and sulfur, used as a form of medicine in Ayurveda. Toxicity of organic and inorganic mercury compounds has been well established, but there is a dearth of scientific investigations that study potential RS toxicity. This study utilized techniques such as SEM-X-ray Diffraction (EDAX) and the dimethyl thiazolyl diphenyl tetrazolium bromide (MTT) assay to study the effect of RS along with methyl mercury and red mercuric sulfide on rat hippocampal astrocytes. The outcome of EDAX was that both red merciful sulfide and RS showed similar chemical composition. Rat hippocampal astrocytes (passage 12-13) seeded in 96 well plates were exposed to the three compounds at concentrations 0.5μM, 1μM, 2μM, 3.5μM and 5μM for methyl mercury and 50μM, 100μM, 200μM, 500μM and 1000μM for both red mercuric sulfide and RS for 12 hours. The MTT assay was used to assess the cytotoxicity. Red merciful sulfide and RS showed no statistical difference from controls at the dosages tested. However, light micrographs of astrocytes exposed to red mercuric sulfide and RS, showed cell injury in the form of shortened astrocytic processes when compared to controls. RS and red merciful sulfide demonstrated morphological changes, which apparently do not affect cell viability. These changes may indicate alterations to cytoskeletal components, which can alter cellular physiology but not viability. Further experiments are needed to elucidate the nature of such changes to determine if they result in deviation from normal cell function.

1262 Involvement of Decreased Activities of Thioredoxin Reductase and Glutathione Peroxidase in the Neuronal Degeneration by Methylmercury in the Developing Rat Cerebrum

M. Yamamoto1, M. Sakamoto2 and K. Saka3, 1 Department of Basic Medical Science, National Institute for Minamata Disease, Minamata, Kumamoto, Japan, 2 Department of Environmental Science and Epidemiology, National Institute for Minamata Disease, Minamata, Kumamoto, Japan and 3 Japan Institute for the Control of Aging, Nikken Sei, Fukui, Shizuoka, Japan.

This study was designed to investigate factors that determine susceptibility to the developmental neurotoxicity of methylmercury (MeHg). It has been previously shown that MeHg treatment decreased glutathione peroxidase (GPx) activity in the developing rat brain. In this experiment, the effects of MeHg on GPx, thioredoxin reductase (TrxR) and glutathione reductase (GR) activities were examined in postnatal developing rats. Wistar male rats of postnatal days 14 (8 rats per group) were orally administered vehicle (control) or MeHg (6.4 mg Hg/kg/day) for 10 days. The MeHg-administrated group showed a significant decrease in body weight, and half of the animals exhibited mild hind-limb crossing by day 11. Increased reactive astrosis was also observed in the cerebral cortex of the MeHg-administrated group. Activity of GPx and TrxR, but not GR, were significantly decreased by MeHg treatment. MeHg inhibited TrxR activity to a greater extent than GPx activity. These results indicate that TrxR and GPx activity, Se-contained enzymes, could be significantly affected by MeHg exposure in the developing brain.
Interaction between Early-Life Methylmercury Exposure and Iron Deficiency in Daphnia pulex
S. L. Hudson, D. Doko and I. M. Gohike; Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL.

Methylmercury (MeHg) is a known neurotoxicant and bioaccumulates in fish, with exposure to humans in utero being of highest concern. Also, iron (Fe) deficiency, with an estimated prevalence of 49%, is particularly problematic during pregnancy and early life. Previous studies have shown that iron deficiency exacerbates manganese and cadmium toxicity. We are currently using Daphnia pulex as an alternative model for chronic toxicity testing due to its short lifespan, ease of culture, and transparency for physiological studies. The overall purpose of this research is to investigate the interaction between poor nutrition, particularly a low iron diet, and early life exposure to MeHg. We hypothesize when D. pulex are fed a low-iron diet, the toxicity associated with early exposure to MeHg will increase. We have fed D. pulex a standard and half Fe diet. Early life exposure to low level MeHg (1600 ng/l, 800 ng/l, 400 ng/l and 200 ng/l) was administered (for 24 hrs in first 48 hrs.). Maturation time, average brood size, total reproduction, and total lifespan were measured. In addition, the effects of Fe deficiency and MeHg exposure on lipid storage were measured using image analysis of Oil Red O staining and confirmed through biochemical analysis (triacylglycerol quantification). Also, we are investigating effects on egg size and metabolic rate. Preliminary data suggests that daphnids that are fed a standard Fe diet had a significantly longer lifespan compared to daphnids on a half-Fe diet. In addition, brood size and total reproduction on a standard Fe diet had significantly more offspring compared to those who were fed a half-Fe diet. However, the differing diets did not show a significant difference in maturation time.

Sex Differences in the Lipidomics of Subchronic Low-Level Inorganic Mercury Exposure in the Rat
A. D. Wusu1, O. Ademuyiwa2, O. O. Ogundiri3, O. K. Afolabi4
1Biochemistry, Lagos State University, Lagos, Nigeria, 2Biochemistry, Federal University of Agriculture, Abeokuta, Abeokuta, Nigeria and 3Chemistry, Federal University of Agriculture, Abeokuta, Abeokuta, Nigeria.

Inorganic mercury has been identified as a risk factor of cardiovascular diseases. The mechanisms underpinning this risk and the sex differences are not yet understood. To investigate the effects of mercury on lipid metabolism, male and female rats were exposed to mercury chloride (0.5, 1.0 and 1.5 mg/kg) for 12 weeks. Dyslipidemia caused by mercury in both sexes exhibited different patterns. At the lowest dose, hypercholesterolemia characterized the effect of mercury in male as against hypercholesterolemia in female. Hypertriglyceridemia was observed in both sexes. Plasma and erythrocyte free fatty acids (FFA) increased significantly in male but not female. Reverse cholesterol transport was inhibited by mercury at 1.5 mg/kg dose in male as evidenced by decreased HDL cholesterol but increased in female. Brain cholesterol and triglyceride were increased by mercury (1.5 mg/kg) in male as against the no effect observed in female animals. Hepatic cholesterol in male and phospholipid in both sexes were increased by mercury (1.5 mg/kg). Pulmonary cholesterol and phospholipidosis were observed in male whereas in female only phospholipidosis was observed. Increase in triglyceride in lung and heart of female animals and liver of both sexes were also observed. Mercury exposure caused reduction in phospholipid concentrations in brain and spleen of both sexes. Hepatic HMG-CoA reductase was up-regulated in both sexes (at 1.0 mg/kg in male but at 1.5 mg/kg in female) whereas brain HMG-CoA reductase was down-regulated in male and up-regulated in female at 1.5 mg/kg. Plasma FFA and HDL cholesterol were positively associated with tissue mercury in females as against the negative associations observed in males. These findings indicate that inorganic mercury perturbs different pathways in lipid metabolism in both sexes and this may be responsible for its cardiovascular effects.

Cut-Off Values and Benchmark Doses (BMDs) for Cadmium Compared across Human Exposure Settings: Evidence for Protective Pathways
M. Bhattacharyya; Georgia Regents University, Augusta, GA.

A benchmark dose (BMD) is the dose of a toxic compound that increases the probability of an abnormal response by a benchmark response (BMR), i.e., from P0 for a control unexposed subject to P0 + BMR for a subject at the BMD. For cadmium (Cd), dose is taken as urine Cd concentration (UCd) – a measure of internal dose. Pathways that protect against Cd toxicity, including metallothionein synthesis, are a feature of human cells. This project considers the hypothesis: 1) Cd protective pathways are effective at low levels of environmental exposure; 2) With the BMD approach, ‘control’ populations that differ in UCds might generate similar cut-off values for kidney dysfunction, reflective of Cd-protective pathways. To achieve uniformity of approach, 95% cut-off values for urine concentrations of beta-2-microglobulin (UB2M) and N-acetyl-beta-D-glucosaminidase (UNAG), and BMD values at 95% BMR, were compared across published studies. With UB2M as the marker of kidney dysfunction, Chinese and Japanese populations with similar mean UCd values (1.3-1.8 ug Cd/g cr) generated similar 95% urine cut-off values (0.415 - 0.897 mg B2M/g cr). Corresponding BMD values ranged much more widely, from 1.7 to 10.0 ug Cd/g cr. No UB2M BMD results were available for Sweden. With UNAG as the marker of kidney dysfunction, control populations with mean UCds of 0.76 (Swe), 1.3 (Jap), and 2.4 (Jap2) ug Cd/g cr generated 95% urine cut-off values of 3.6 (Swe), 11.1 (Jap) and 16.6 (Jap2) Units NAG/g cr. Respective BMD values were 0.64, 4.3, and 10.8 ug Cd/g cr in urine. Increases in mean UCd were directly associated with increases in cut-off values and BMD values. Results indicate that, in the mean UCd range of 0.7 to 2.6 ug Cd/g cr among control populations worldwide, known industrial sources of cadmium have no indication exists for protective pathways producing similar cut-off values independent of mean UCd values, even at very low levels of Cd exposure. Additional research is needed to investigate the extent to which differences in BMD methods among studies may have contributed to these results.

Immuno-Modulatory Role of N-Acetylcysteine in Cadmium Treated Human Lung Cells
C. Odeuwemi, M. Ruden, V. Badisa, S. Fils-Aime and L. Latiniwo; Department of Biological Sciences, Florida A&M University, Tallahassee, FL. Sponsor: A. Becker.

Cadmium has been classified as a known human carcinogen based on epidemiological studies and research performed in experimental animals. One class of cadmium responsive genes includes the fos family of transcription factors. The four members of this family (c-Fos, FosB, Fra-1 and Fra-2) can heterodimerize with Jun partners to form the AP-1 transcription factor and influence cellular properties such as invasiveness, proliferation, differentiation, apoptosis and angiogenesis. Aberrant expression of these proteins can ultimately promote oncogenic transformations. To better understand the mechanism by which cadmium regulates the expression of these proteins, cadmium toxicity in the bioavailability of the metal and uptake mechanisms involved. This study investigated the role of these proteins in the regulation of cellular responses to cadmium toxicity in immortalized human lung epithelial cells. Using Western Blot analysis, it was demonstrated that cadmium exposure led to the increased expression of Fra-1 and FosB, the two members of the Fos family that are the most responsive to cadmium. The expression of these proteins was found to be mediated by the MTF-1 transcription factor. This finding has significant implications for the understanding of the mechanisms by which cadmium induces cellular responses and contributes to the development of cancer.
same pattern of expression as the cytokine array. These results clearly indicate the immune-modulatory role of NAC on the viability and cytokines expression in cadmium treated human lung cells and suggests that NAC can be used as an antidote against cadmium toxicity that can reduce lung cancer mortality rate.

1265 Exposure to Cobalt, Nickel, Cadmium, and Chromium Causes Changes in Gene Expression and Protein Abundance in a Human Liver-Derived Cell Line

M. Permenter1, D. Kumscher1, W. E. Dennis2, J. A. Lewis2 and J. D. Stallings2.
1Exct, Inc., Fort Detrick, MD and 2USACEHR, Fort Detrick, MD. Sponsor: D. Jackson.

In the course of military and occupational activities the Nation’s Guardians routinely encounter hazardous environmental toxicants and materials which may result in adverse health effects. Cobalt, nickel, cadmium, and chromium are four such materials with wide use and distribution in industrial areas, which increases the risk of exposure. While the toxic effects of these metals have been widely studied, the exact mechanisms of toxicity remain unclear, and no biomarkers of the adverse health effects have been validated. In order to further elucidate these mechanisms in liver and identify candidate biomarkers, we exposed HepG2-C3A cells to sublethal concentrations of NiCl2, Na2Cr2O7, CdCl2, and CoCl2 for 24 hrs. We chose the treatment concentrations based on a novel qPCR assay using a panel of genes developed from previous metal toxicity studies, as opposed to traditional cytotoxicity assays, to more accurately predict gene expression endpoints. We examined changes in gene expression using DNA microarrays and changes in protein abundance using mass spectrometry.

We performed both gene-level and functional analyses of the results and observed changes in pathways consistent with the known effects of heavy metal intoxication. Comparative analysis identified both common and unique modulated transcripts and perturbed pathways among the four metals. The changes in protein abundance closely resemble and validate the conclusions we drew from the microarray analysis. This work offers key insights into the roles specific genes, proteins, and pathways play in heavy metal toxicity mechanisms, and also identifies candidate biomarkers.

The views expressed are those of the authors and do not constitute endorsement by the U.S. Army. The research described herein was sponsored by the U.S. Army Medical Research and Materiel Command, Military Operational Medicine Research Program.

1266 Time Course of Lead-Induced Dyslipidemia in Male Albino Rats

O. Ademuyiwa1, E. O. Abam1, O. O. Ogunrinola1, A. D. Wusu1, O. K. Afolabi2, O. A. Dosumu2, O. B. Onunkwu2, F. A. Balogun1 and O. O. Odukoya2.
1Biochemistry, Federal University of Agriculture, Abeokuta, Ogun, Nigeria, 2Chemistry, Federal University of Agriculture, Abeokuta, Ogun, Nigeria and 3Biochemistry, Ladoke Akintola University of Technology, Ogbomoso, Oyo, Nigeria.

Lead has been shown to induce dyslipidemia in rats although the attendant mechanisms have not been clearly elucidated. In order to investigate the time course of lead-induced perturbations in lipid metabolism, male albino rats were exposed to 200ppm, 300ppm and 400ppm lead as lead acetate in their drinking water for 4, 8 and 12 weeks. Control animals received distilled water for the same exposure times after which blood and vital organs were removed from the animals and analyzed for lipid dynamics. Lead accumulated in the organs in the following descending order: kidney, liver, brain, heart and lungs. At 4 weeks, plasma cholesterol increased by 5% (in the 200ppm and 400ppm groups) and 8% in 300ppm. At 8 weeks, cholesterol in the 200ppm group increased by 10%. Plasma phospholipids decreased across all study groups. Lead decreased HDL cholesterol in a time-dependent manner (17% in 4-week 400ppm, 35%, 43% and 49% in 200ppm, 300ppm and 400ppm groups respectively at eight weeks). Plasma free fatty acids (FFA) displayed a hormetic-like response at 4 weeks with the lowest dose (200ppm) resulting in a decrease of 51% while 300ppm and 400ppm displayed 2-fold and 1.5-fold increases respectively. At 12 weeks, increases in FFA were dose-dependent. While cardiac and pulmonary phospholipids were observed, hepatic brain and renal cholesterogenesis and phospholipidosis were observed. Hepatic brain and HMG-CoA reductase activities were up-regulated in most of the dosage groups. A positive correlation was observed between liver lead and liver cholesterol (r = 0.476, p < 0.01) while a negative correlation was observed between blood lead and HDL cholesterol (r = -0.523, p = 0.01). These findings indicate that lead-induced dyslipidemia may be mediated through up-regulation of HMG-CoA reductase activity and enhanced phospholipidosis resulting from increased availability of FFA.
copy, we found that NAC dramatically decreased cellular accumulation of all three metals in both transformed and normal human cells. Suppression of chromate uptake by NAC resulted from extracellular reduction of Cr(VI) to membrane-impermeable Cr(III). Incubation of Co(II) with NAC resulted in a rapid formation of Co(II)-NAC conjugates, which were unable to cross the plasma membrane. In conclusion, we found that direct reactivity with metals is a major antioxidant-independent mechanism in chemoprotection by NAC against carcinogenic Cr(VI), Cd(II) and Co(II). Our results also suggest that the use of NAC could be beneficial for diminishing tissue accumulation of this toxic metal released during corrosion of cobalt-chromium hip implants.

1270 Lack of Reversal from Lead Acetate-Induced Hepatotoxicity and Oxidative Stress in Wistar Rats

A. B. Saba1, A. A. Oyagbemi1, T. O. Omonobowale1, O. T. Daramola1, 2 and B. S. Ogunpolu1, 2. Department of Vet. Physiology, Biochemistry and Pharmacology, University of Ibadan, Nigeria, Ibadan, Oyo, Nigeria and 2Veterinary Medicine, University of Ibadan, Nigeria, Ibadan, Oyo, Nigeria.

Lead is a ubiquitous metal and also one of the most abundant elements present on earth. Both the developing and the developed countries have been contaminated by this element. This study was designed to evaluate possible toxic effects of lead acetate (PbA) exposure and subsequent withdrawal in male Wistar rats. Control group (group I) received normal saline while groups II, III and IV received oral administration of 0.25, 0.5 and 1.0mg/ml PbA respectively for the period of 6 weeks. One half of the population of the rats was sacrificed at 6 weeks of PbA exposure. PbA was similarly withdrawn from the remaining rats for another 6 weeks. Exposure of rats to PbA led to significant decline (p<0.05) in Glutathione peroxidase (GPx), Glutathione S-transferase (GST), Catalase (CAT), Superoxide dismutase (SOD) and Reduced glutathione (GSH) content. Similarly, Malondialdehyde (MDA) and H2O2 concentrations were significantly (p<0.05) elevated. In the same vein, Aspartate aminotransferase (AST), Alanine aminotransferase (ALT) and Alkaline phosphatase (ALP) activities also increased significantly in exposed rats. Animals from the withdrawal period exhibited similar pattern of alterations, with significant (p<0.05) reduction in GSH, GST, GPx and SOD and significant elevation in MDA, Serum ALT, AST and ALP however remained persistently high. In conclusion, experimental animals exposed to PbA could not recover from hepatotoxicity and oxidative stress. This might be due to significant disruption of antioxidant defense system and free radical generation by PbA.

1271 Long-Term Exposure of Mice to Cr(IV) in Drinking Water Disrupts the Oxidative Stress Response Induced by Benzo[a]pyrene in the Proximal Gastrointestinal Tract

F. J. Sanchez-Martín, Y. Fan, J. L. Osevén, V. S. Carreira and A. Puig, Department of Environmental Health, University of Cincinnati, Cincinnati, OH.

Exposure to a single toxic compound is rare in the environment. Exposure to complex mixtures of different toxicants are more frequent. It is therefore important for human health and disease that the combined effect of exposure to multiple toxicants can be understood. This presentation will focus on exposure to benzo[a]pyrene (BaP) and chromium (Cr). BaP is a polycyclic aromatic hydrocarbon that acts as a strong mutagen and is a known carcinogen. Cr is a metal that is ubiquitous in the environment. It is a known carcinogen to humans and animals. There is evidence that the metabolism of BaP is affected by exposure to Cr. To investigate the combined exposure to BaP and Cr, we used a Balb/c mouse model. Mice were exposed to Cr or BaP individually or in combination. The effect on the oxidative stress response was determined. BaP exposure resulted in a significant increase in the levels of the oxidative stress marker, MDA, in the liver. Cr exposure also resulted in an increase in MDA, but this was not significant. When BaP and Cr were combined, there was a significant increase in MDA. This suggests that the combined exposure to BaP and Cr results in a greater increase in oxidative stress than exposure to either compound alone.

Studies on paraoxonase (PON) activity in lead toxicity in the past have often found lead to be associated with lower serum PON activities and lower HDL values. In order to investigate the toxic effect of lead-induced alterations in PON activity, male albino rats were exposed to 200ppm, 300ppm and 400ppm lead as lead acetate in their drinking water for 4, 8 and 12 weeks respectively. PON activities towards paraoxon (PONase) and phenylacetate (AREase) were determined in plasma, liver microsomes, hepatic and brain microsomal fractions. Lead inhibited plasma PONase activity at 4 weeks (35%, 53% and 24% in 200ppm, 300ppm and 400ppm respectively), while activating it at 8 and 12 weeks (65%, 64% and 16% at 8 weeks and 45% and 22% at 12 weeks) in 200ppm and 400ppm groups respectively. Plasma PONase was also activated in most dosage groups. On the other hand, hepatic and brain microsomal PONase and AREase were generally inhibited by all the lead doses. HDL AREase increased by 25%, 35%, and 15% in 200ppm, 300ppm and 400ppm respectively at 12 weeks. HDL PONase also increased by 5% and 42% in 300ppm and 400ppm respectively at 4 weeks and 40%, 7% and 42% respectively at 8 weeks. VLDL AREase activity also increased by as much as 72% in 200ppm group at 4 weeks. However, lead inhibited VLDL PONase in all the dosage groups at 12 weeks. Positive correlations were observed between hepatic lead and plasma AREase (r = 0.304, p = 0.01), while negative correlations were observed between blood lead and liver microsomal AREase (r = -0.504, p = 0.01) and PONase (r = -0.506, p = 0.01). The unusual activation of circulating PONase and AREase might result from damage to microsomal membrane as a result of lead exposure.
Toxic insult from the heavy metal cadmium is known to induce the expression of metallothioneins (MT) which are heavy metal binding proteins. Previous work from our laboratory has shown that over-expression of MT-3 in breast cancers is associated with poor patient outcome. Furthermore, MT-3 has shown to inhibit the growth of breast cancer and prostate cancer cell lines. The MT-3 protein contains 7 additional amino acids that are not present in any other member of the MT gene family, a 6 amino acid C-terminal sequence and a Thr inserted in the N-terminal region. The unique N-terminal sequence is responsible for the growth inhibitory activity of MT-3 in the neuronal system. The goal of this study was to characterize the function of the N- and C-terminal domains of MT-3 in the breast cancer cell line, MCF-7. For this purpose, six different constructs of MTs were prepared which were as follows: wild type (WT) MT-3, MT-3 N-terminal mutation (MT-3ANT), MT-3 C-terminal deletion (MT-3ACT), WT MT-1E, and MT-1E altered to contain the N-terminus, the C-terminal of MT-3 or both the N- and the C-terminal of MT-3. Each of these constructs was stably transfected into MCF-7 cells and the growth rates and mesenchymal markers E- and N-cadherin were measured. The data obtained suggests that the N-terminal region of MT-3 is involved in growth inhibitory activity whereas the C-terminal region is involved in vectorial active transport which is indicated by the formation of domes in cell culture, and that there is no significant change in the ratio of E- to N-cadherin. In conclusion, this study further characterizes the unique properties of the N- and the C-terminal domain of MT-3 and the potential role that it may play in the differentiation of certain breast cancers.

1275 Characterization of OH Radicals Induced by Particulate Matter and Associated Species with a High-Throughput Approach

Y. Son1, V. Mishin2, W. Welsh3, L. D. Laskin4 and Q. Meng1, 1School of Public Health, Rutgers University, Piscataway, NJ, 2Ernest Mario School of Pharmacy, Rutgers University, Piscataway, NJ and 3Robert Wood Johnson Medical School, Rutgers University, Piscataway, NJ.

Exposure to ambient particulate matter (PM) can cause various cardiopulmonary diseases. Oxidative stress, purported to be caused by the ability of PM to induce reactive oxygen species (ROS), has been identified as one of the common mechanisms leading to the observed adverse health effects. Among the ROS, hydroxyl radical (OH) is the most destructive. However, there is no high throughput approach to measure OH generated by PM, which in turn hinders the study of the interactions between PM and our biological system.

The goals are 1) to develop a high-throughput approach to measure OH induced by PM in a cell-free system, and 2) to study the kinetics of OH formation induced by PM and its constituents (transition metals). OH induced by PM were quantified using a fluorescence assay (microplate reader), with disodium terephthalate as the molecular probe. Employing an established approach, the kinetics of OH formation was studied by introducing PM and 9 transition metal ions into a simulated lining fluid, and the formed 2-hydroxyl terephthalate was measured at designated time points up to 2 hours.

The detection limit of OH for the devised high-throughput approach (as extrapolated from the formation of 2-hydroxyl terephthalate) was 17.6x10^-3 µM. The initial rate of OH formation ranged from 1.33x10^-3 µM/s for Mn (10 µM) to 1.58x10^-3 µM/s for Cu (10 µM). Both statistically significant synergistic effects (e.g. Cu and Fe) and antagonistic effects (e.g. Cu and V) were observed for OH generation by a mixture of transition metal ions. Insoluble PM constituents, soluble metal ions, and other soluble constituents contributed 22%, 59% and 19%, respectively, of OH induced by PM (NIST SRM 1648).

Trace-level OH induced by PM and its constituents can be measured with the devised high-throughput approach. The initial rates of OH formation derived from the kinetic experiments will be used to evaluate PM toxicities.
had been previously documented to be 7.81 μM. Transmission electron microscopy was used to study morphological changes and accumulation of selenium in cells following treatments. Micrographs of controls show well defined nuclei, double layered nuclear envelopes and mitochondria with definite shape and cristae. Astrocytes treated with 7.81 μM of both compounds appear to have disturbed morphology with pyknotic nuclei. Mitochondria show distorted shapes with the presence of deposits which may be selenium compounds. An ELISA assay was used to investigate cytochrome c levels in cytosolic and mitochondrial fractions. There was a significant decrease in cytochrome c in mitochondrial fractions and a significant increase in the cytochrome c in cytosolic fractions of astrocytes treated with 7.81 μM and 15.62 μM of both compounds compared to controls. TBARs assay was performed to investigate lipid peroxidation products. There was a significant decrease in the products in cells treated with 15.62 μM compared to controls. There were no significant changes in the activities of GPx in any treatment group. These results suggest that the accumulation of Se in the mitochondria and release of cytochrome c into the cytosol result in cytotoxicity in rat hippocampal astrocytes. Oxidative stress does not appear to be involved in the process.

Iron deficiency is the most common nutritional deficiency in the world, with an estimated 4.5 billion affected persons, which can lead to debilitating fatigue, altered immune function, decreased work capacity and anemia. Similarly, iron overload is a significant health concern. Iron overload targets the liver, heart, and pancreas, and can lead to multiple complications including liver disease, cardiomyopathy, and diabetes mellitus. The great diversity in genetic disorders of iron metabolism in man, rodents and other vertebrates suggest that multiple loci can contribute to the susceptibility of iron deficiency and severity of iron overload. Several individual studies have shown genetic differences in iron homeostasis between inbred strains of mice. We hypothesize that this wide genetic variation underlies the differences seen in iron metabolism between inbred mice. Here we show variation in iron metabolism in six inbred mouse strains fed low (12ppm), high (1000ppm), and sufficient (55ppm) iron diets. Variation in elemental tissue content, hematological markers of iron status, as well as body weight and obesity markers are seen in this subset of the hybrid mouse diversity panel. This study highlights the population diversity in the ability to handle iron stress (deficiency or overload), and indicates the genetic variation in this population plays an important role.

The rapid development of high-volume horizontal hydraulic fracturing (HVHF) for mining natural gas from shale has posed potentially serious impacts on human health and biodiversity. The produced flowback waters after hydraulic stimulation is known to carry high levels of saline and total dissolved solids (TDS). To understand the toxicity and epigenetic effects of these waste waters, we analyzed post-fracture flowback water from 5 Marcellus fields from Pennsylvania. We characterized the composition of these samples by X-ray fluorescence (XRF) and scanning electron microscopy (SEM)/energy dispersive X-ray spectroscopy (EDX). XRF indicated bromine (436.67±60.78 ppm), strontium (1286.08±377.68 ppm), and barium (3776.58±609.01 ppm) are most abundant in these samples. Amorphous silicon aluminum oxide (SiAlOx) nano/micro-particles ranged from 70-285nm and amorphous zirconium oxide (ZrOx) particles ranged from 40-140nm have been found by SEM/EDX analysis. A cytotoxicity assay using colony formation was carried out to decide LC50 of these samples on the human bronchial epithelial cells (Beas-2B) with 7 days repetitive treatment. The LC50 was calculated to be 2.7 ±0.2 μM. The 7-day-treatment also led to decreases of the levels of acetylation of H3K9 and H3K14 as well as H3K4 trimethylation. We are also studying cell transformation with 7 days repetitive treatment. The LC50 was calculated to be ~2.7 μM.

The intra- and inter-laboratory variability of bioaccessibility tests were evaluated in synthetic fluids relevant to oral, inhalation, and dermal exposure. Using one defined protocol, five laboratories measured metal release from coalbed oxide, coalbed powder, copper concentrate, Inconel alloy, leaded brass, and nickel sulfate hexahydrate. Standard deviations of repeatability (s) and reproducibility (sr) were used to evaluate the intra- and inter-laboratory variability, respectively. Examination of the s:sr ratios demonstrated that, while gastric and lysosomal fluids had reasonably good reproducibility, other fluids did not show as good concordance between laboratories. Relative standard deviation (RSD) analysis showed more favorable reproducibility outcomes for some data sets, overall results varied more between than within-laboratories. RSD analysis of s showed good within-laboratory variability for all conditions except some metals in interstitial fluid. In general, these findings indicate that absolute bioaccessibility results in some biological fluids may vary between different laboratories. Since measures of relative bioaccessibility are typically used (e.g., in read-across approaches for hazard and risk assessment), both inter- and intra-laboratory reproducibility are relevant unless all substances are tested in the same laboratory. Deviations in protocol interpretation may provide an explanation for some of the inter-laboratory variability observed.
Increased use of tungsten in the manufacturing of industrial goods has led to increased contamination in the air and ground water, particularly near active mines and industrial sites. However, little data exists as to the consequences of exposure to high levels of tungsten. Tungsten rapidly accumulates in murine bone in a concentration-dependent manner, providing a source of continuous low-dose exposure to tungsten. We hypothesized that tungsten in the bone could alter bone homeostasis, a balance between bone formation by osteoblasts and bone resorption by osteoclasts. We assessed the effects of tungsten on osteoblasts using in vitro and in vivo models. Osteoblasts are derived from bone marrow-resident mesenchymal stromal cells (MSC), which can also differentiate into adipocytes. First, we tested whether tungsten changed primary murine MSC differentiation in vitro in the presence or absence of tungsten. We found that tungsten skewed MSC differentiation by decreasing osteoblast markers and increasing adipocyte markers. In vivo, tungsten increased expression of adipocyte markers in murine bone marrow after 4 weeks, but did not change expression of osteoblast markers. Tungsten also increased mouse serum sclerostin levels, a protein that inhibits bone formation and decreases osteogenesis potentially at the expense of osteogenesis. Next, we explored the effects of tungsten on TGF-β pathway signaling, known to enhance osteoblast differentiation, and concomitantly inhibits osteoclast formation. In vitro, tungsten decreased TGF-β protein levels in MSC, which resulted in decreased SMAD signaling. The data presented provide evidence that tungsten is altering bone homeostasis by decreasing bone formation, potentially by decreasing TGF-β signaling. Future experiments will investigate the potential effects of tungsten on osteoclasts, as well as changes to bone remodeling and integrity.

Trace elements play a crucial role in living organisms. The distribution of trace elements in various tissues can vary significantly and can have an impact on the health of an organism. The quantification of trace elements in vivo at high 3-D resolution is crucial for understanding their distribution and function. However, traditional methods for quantifying trace elements in vivo have limitations, such as low image resolution and the need for destructive sampling. The development of novel imaging techniques, such as neutron elemental imaging, can provide an alternative method for quantifying trace elements in vivo at high 3-D resolution.

Neurotoxic insults upregulate a novel secreted protein to promote cell survival in dopaminergic neuronal cells during early stages of toxicity.

Neurotoxic agents exert neuronal toxicity mainly by impairing key signaling molecules that control the balance between pro- and anti-apoptotic signaling. Although various proapoptotic signaling pathways that occur during neurotoxic stress have been elucidated, only a few studies have characterized signaling molecules that can protect neurons against toxic insults. Herein, we have identified that dopaminergic neurotoxicants MPP+ and manganese rapidly induce Prokineticin-2 (PK2), a recently discovered mammalian homolog of mamba snake venom, as determined by qPCR pathway array analysis. In order to further understand the functional role of PK2 upregulation, we created stable PK2 expressing dopaminergic cells by delivering PK2 myc-tagged DNA into mouse dopaminergic MN9D cells. Interestingly, exposure of manganese and MPP+ to PK2 overexpressing cells showed significant protection against the neurotoxicity as compared to vector control cells, indicating that PK2 may play a neuroprotective role in dopaminergic neurons. The protective effect was both dose- and time-dependent. Furthermore, PK2 receptor blocker PC7 attenuated the PK2-induced neuroprotective effects in PK2 overexpressing cells. Measurement of apoptosis by Annexin V and caspase-3 activation also revealed that PK2 overexpression protects against manganese and MPP+ -induced apoptosis. We also found mitochondrial integrity was well maintained in PK2 overexpressing cells as compared to vector cells following exposure to the neurotoxic agents. Preliminary results also showed that key proteins in mitochondrial functions, including BCL2, PGC1-alpha and TFAM levels, were preserved in PK2 overexpressing cells following neurotoxic insult. Collectively, our results suggest that neurotoxic insults upregulate PK2 in dopaminergic neurons to protect against early stages of neurotoxicity (NS 078327 and ES 10586).

A Novel Associated Particle Neutron Elemental Imaging (APNEI) Technology for 3-D Noninvasive In Vivo Quantification of Trace Elements in Animal and Human Tissue.

Trace elements play a crucial role in living organisms. The distribution of trace elements in these organisms provides valuable information about their biological function. In this project, a novel APNEI technology was studied for noninvasive quantification of trace elements in vivo at high 3-D resolution required for general biological research (e.g. toxicology research). The APNEI technology uses fast neutrons produced by a compact neutron generator to extract elemental information from an animal or a human tissue. The technology has two unique features: 1) the penetration of the neutrons and γ-rays to get into the animal or human tissue and to bring the elemental information out of the tissue; and 2) the associated particles to locate the position of the elements. In this project, a deuterium-deuterium (D-D) APNEI model was built using Monte Carlo (MC) simulation method. MC simulations for the interaction between a D-D neutron source and a series of elements were performed. The resulting characteristic gamma-rays of interested elements were collected by high-purity germanium (HPGe) detectors simulated in the program. Assuming a 5 mm * 5 mm * 5 mm voxel in soft tissue (about 15 cm away from the neutron source) with iron (Fe) concentration of 1300 ppm, the Fe gammas are found to be 3908 γ/MeV. The number for phosphorus gamma-ray is about 60 counts for a 1 cm³ voxel in soft tissue with 500 ppm concentration. These results show that the technology is sensitive enough to image some trace elements in animal or human tissue with image resolution of mm order at the biologically meaningful concentrations.
technology can be used to investigate metal toxicology or the toxicity of other toxic agents that would result in an alteration of the elemental distributions in animal or human body.

1288 Early-Life Lead Exposure and Drug Abuse: A Novel Pathway to Addiction

A recent assessment of a prospective cohort of children exposed to lead (Pb2+) in infancy has documented later effects on mental health including drug abuse (McFarlane et al., 2013). Animal studies have provided limited evidence that perinatal Pb2+ exposure enhances cocaine sensitization and Pb2+-exposed animals are more prone to relapse (Nations et al., 2000; 2003). Other animal studies have shown that Pb2+ alters dopaminergic circuitry (Cory-Slechta and Widowski, 1991; Zach et al., 1998) critical for drug addiction. However, there is no data on mechanisms by which Pb2+ exposure may sensitize animals to drug abuse. In the present study, we examined the effects of early life Pb2+ exposure on cocaine sensitization and dopamine receptor levels in the striatum (STR) and nucleus accumbens (NAC) in late adolescence. Rats chronically exposed to Pb2+ during early life exhibited a highly significant increase in the locomotor response to cocaine administration (15 mg/kg) relative to controls. This effect of cocaine was associated with a marked increase (20-34%) in D1 dopamine receptors (D1R) in the STR and NAC of Pb2+-exposed rats relative to controls. Activation of D1R by dopamine plays an important role in addictive and drug reinforcing properties of cocaine. We also observed a modest but significant increase in D2 dopamine receptors (D2R) in the STR and results in the NAC are forthcoming. D1R and D2R were measured using quantitative receptor autoradiography. Pharmacological studies are examining the selectivity of the sensitization to D1R and/or D2R antagonist. Together, these results show that chronic Pb2+ exposure during development alters D1R/D2R expression and cocaine responsivity. They suggest that early life Pb2+ exposure may induce a state of re-programming of the developing brain by which neuronal pathways important for drug addiction may be permanently altered, thus enhancing liability for drug use and addiction as young adults [supported by ES006189 and a pilot project from NIEHS Center ES006189].

1289 Lead Inhibits Presynaptic Neurotransmitter Release in Schaffer Collateral-CA1 Synapses in the Rat Hippocampus: Understanding Mechanism(s)

Lead exposure during brain development inhibits neurotransmitter release and this effect is likely to contribute to impaired synapse formation, plasticity and learning deficits. However, the mechanism(s) by which lead impairs neurotransmitter release have not been fully elucidated. In primary hippocampal neurons, lead exposure inhibits vesicular release and reduces the number of fast-releasing sites, an effect mediated by NMDAR inhibition (Ned et al., 2010). Since this finding was made in primary hippocampal neurons, we wanted to determine if similar effects were also present in animals exposed to lead in vivo. In the present study, we examined the effects of chronic lead exposure on presynaptic transmitter release using two-photon laser scanning microscopy of FM1-43 vesicular release in Schaffer collateral-CA1 synapses in ex vivo hippocampal slices. We found that chronic lead exposure significantly enhanced paired-pulse facilitation (Control Pr = 0.46; Pb Pr = 0.25 at 2mM [Ca2+]o). Using FM1-43 2-photon imaging of release from CA1 Schaffer collateral terminals, we found that this reduced probability was associated with reduced release of glutamate from vesicles in the rapidly-recycling vesicle pool loaded by hypertonic shock. These studies confirm and extend our previous findings in primary hippocampal neurons that lead produces profound impairments in vesicular release that are likely to contribute to deficits in synaptic plasticity and cognitive function. Current studies are examining the molecular bases of the lead inhibition of vesicular release. [Supported by grant # ES020465]
1292 Induction of Heme Oxygenase-1 (HO-1) and Accumulation of Tellurium upon Exposure to Diphenyl Ditelluride and Tellurium Tetrachloride in HT-29 Human Colon Cells

P. Vij and D. Hardee, Pharmaceutical Sciences, St. John’s University, Queens, NY.

Tellurium (Te) is a metalloid, with no known physiologic role in humans. Te containing compounds are being used in increasing quantities in industry, agriculture and organic synthesis in products such as optical blue ray discs, photographic materials and photoelectric cells. Increasing uses of such products suggests that human environmental exposure will increase in the future. The neurotoxicity of Te compounds has been documented however little has been reported regarding the gastrointestinal toxicity of this metalloid. Previous work in our lab has demonstrated the mechanism of cell death in HT-29 cells upon exposure to diphényl ditelluride (DPDPT) and tellurium tetrachloride (TeCl4). The purpose of the present study was to evaluate the potential of tellurium compounds TeCl4 and DPDPT to induce oxidative stress by examining heme oxygenase-1 (HO-1) induction and metal accumulation in HT-29 human colon cancer cells. HO-1 is a cytoprotective enzyme activated by its substrate heme and to diverse stimuli. The induction of HO-1 is one of the most important cells in the cellular response to pro-oxidative insults. Upon exposure to concentrations ranging from 62.5µM to 1000µM of TeCl4 and DPDPT in HT-29 human transformed colon cells, oxidative stress was confirmed by a significant increase in the HO-1 activity at the concentrations ranging from 250 µM to 1000 µM in HT-29 cells with DPDPT and from 62.5 µM to 1000 µM with TeCl4 treatment when compared to the control group. Intracellular tellurium levels were determined by Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES), and significant increases were observed at the concentrations ranging from 500 µM to 1000 µM after DPDPT and 125 µM to 1000 µM after TeCl4 exposure. It is concluded that DPDPT and TeCl4 exposure increases the HO-1 activity along with the increase in the intracellular accumulation of the metalloid.

1293 Translocation Synthesis Defends against Telomere Dysfunction Induced by Hexavalent Chromium

Telomeres are repetitive nucleotide sequences that cap and protect chromosome ends. When telomeres become dysfunctional they contribute to a variety of pulmonary diseases. Our previous work established that DNA replication stress induced by the environmental pollutant hexavalent chromium Cr(VI) causes telomere loss and aberrations. Chronic inhalation of Cr(VI) leads to a variety of lung diseases, including fibrosis, and cancers. Cr(VI) forms a spectrum of DNA lesions that impede DNA replication and can cause collapse of the replication fork and chromosomal breakage. Telomeres are fragile DNA sites prone to breakage during replication stress. Cells have mechanisms for bypassing lesions that block replication forks called translesion synthesis (TLS). We hypothesize that Cr(VI)-induced DNA replication stress activates TLS DNA polymerase η (polη) that suppress Cr(VI)-induced mutagenesis and telomere dysfunction. Our research is investigating several endpoints of telomere dysfunction in human cells proficient and deficient in polη. We observe that cells deficient in polη are 53 fold more sensitive to low levels of Cr(VI) and show through flow cytometric analysis that polη deficient cells are delayed in S-phase of the cell cycle compared to isogenic controls. Using a combination of immunofluorescence and telomere fluorescence in situ hybridization (IF-TELISH), quantification of replication stress at genomic and telomeric DNA show that Cr(VI) induces polη mobilization to stalled DNA replication sites at genomic and telomeric regions in human cells. Post Cr(VI) exposures, we identify telomeric aberrations by staining metaphase chromosomes with a fluorescent telomeric probe using telomeric FISH. Using telomeric FISH, we find a four-fold increase in aberrations in dysfunctional polη. Our study demonstrates one mechanism by which Cr(VI) directly interacts with the genome, alters telomere integrity, and the cellular pathways that protect telomeres in the face of genotoxic replication stress.

1294 Fish As Models for Investigating Metabolic Disruption Arising from Dietary Selenium Supersaturation

D. Lantz and J. Thomas, Toxicology Centre, University of Saskatchewan, Saskatoon, SK, Canada.

Selenium (Se) exhibits a narrow range between essentiality and toxicity in many animals. There is increasing concern that Se oversupplementation in humans can lead to symptoms of metabolic syndrome, including Type 2 diabetes. We have been using fish as comparative animal models to investigate mechanisms of metabolic disruption arising from excess dietary organoselenium. This work originated in field studies of Se-contaminated aquatic ecosystems, where five fish species exhibited consistent evidence of altered lipid and carbohydrate homeostasis. Similarly, in laboratory studies adult zebrafish fed diets augmented with seleno-L-methionine (1: control, no supplementation), 3, 10 or 28 µg Se/g dry mass) for 90 days exhibited dose-dependent increases in whole body lipid (triaclyglycerols) and carbohydrate (glycogen). Furthermore, while high Se diets produced significant down-regulated mRNA abundance of protein tyrosine phosphatase 1B (PTP1B) in muscle, and beta-hydroxycalcoenzyme A dehydrogenase (HOAD), sterol regulatory element binding protein 1 (SREBP 1) and methionine adenosyltransferase 1 alpha (MAT 1A) in liver of zebrafish. Additional studies in rainbow trout showed that chronic exposure to elevated dietary Se resulted in greater baseline plasma cortisol concentrations, but an attenuated cortisol response to acute stress challenges. Overall, these results have clear implications for the fitness of wild fish exposed to elevated dietary Se in contaminated aquatic ecosystems, and may provide insight into mechanisms of metabolic disruption in mammals, including humans, that receive dietary oversupplementation of organoselenium.

1295 Effects of Uranyl Acetate on Etoposide-Induced DNA Damage and Repair in Human Bronchial Epithelial Cells (16HBE14o-)

M. Yellowhair1 and R. Lantz2, 1Cancer Center, The University of Arizona, Tucson, AZ and 2Cellular and Molecular Medicine, The University of Arizona, Tucson, AZ.

It has been widely reported that metals can be genotoxic by several mechanisms including generation of reactive oxygen species and inhibition of DNA repair. There is an increased concern over environmental exposure to abandoned uranium mine tailings as well as occupational exposures to depleted uranium via military action. The aim of this study is to evaluate the ability of depleted uranium (DU) to inhibit double strand break DNA repair at low concentrations in human bronchial epithelial (16HBE14o-) cells. 16HBE14o- cells were co-exposed to 0.13 µM (30 ppb; current EPA standard in drinking water) of soluble depleted uranium as uranyl acetate (UA) in the presence of 0 – 25 µM of etoposide. UA cytotoxicity was assessed in vitro by the clonogenic survival assay. DU damage response was assessed in vitro via flow cytometry to determine phosphorylation of the DNA repair proteins: ATM, SMC-1, and γ-H2AX. Replication protein A (RPA) activity was assessed by an ELISA assay and cell cycle arrest was assessed via flow cytometry. Findings from this work demonstrate that cells treated with UA did not induce phosphorylation of DNA repair proteins (pATM, pSMC-1, or pγ-H2AX) compared to etoposide treatments and untreated cells. Interestingly, the co-exposure of UA and etoposide reduced the amount of phosphorylated ATM and activated RPA after 48 and 60 hr, respectively. These results suggest that DU may inhibit double strand break DNA repair at low concentrations in the presence of a known DNA damaging agent. The inhibition of DNA repair by depleted uranium at environmentally relevant concentrations suggest that the model systems should also be considered as a genotoxic effect. This work is supported by NIH Grants CA096281 (RCL), CCSG – CA023074 (AZCC/ARL-Division of Biotechnology Cytometry Core Facility), CA95901, F31ES014971 (MY), U54CA143924, MGE@MSA (MY) and The Alfred P. Sloan Foundation (MY) for funding this project.

1296 Gastric Reduction of Hexavalent Chromium in Fed and Fasted Human Stomach Samples

S. M. Hays1, C. R. Kirman1, M. Suh2 and D. Proctor2, 1Summit Toxicology, Lyons, CO and 2ToxStrategy, Mission Viejo, CA.

The rate and capacity of gastric reduction of hexavalent chromium [Cr(VI)] are important characteristics of dietary depleted uranium (DU) or Cr(VI) compounds, which in turn is a determinant of potential cancer risk. Our previous experiments using fed rodent gastric contents and fasted human fluid found that the reduction of Cr(VI) exhibited a mixed second-order reaction with a pH dependent second-order rate constant. Potential uncertainties regarding dilution which may affect the concentrations of reducing agents and the second-order rate constant were noted. This study is an extension to our previous experiments. Stomach fluid samples were obtained from human volunteers in the fed and fasted (paired) states. Using spectated isotope dilution mass spectrometry, studies were conducted to ascertain the kinetics (rates and capacity) of the various gastric fluids to reduce Cr(VI), with emphasis on better characterization of conditions during a fed state and characterizing inter-individual variability. The effect of slowed reduction potential were investigated. Alternative mathematical forms of the reduction model were considered. The human data confirm a significant pH dependence for the second-order rate constant. Potential uncertainties regarding dilution which may affect the concentration of reducing agents and the second-order rate constant were noted. These results suggest that DU may inhibit double strand break DNA repair at low concentrations in the presence of a known DNA damaging agent. The inhibition of DNA repair by depleted uranium at environmentally relevant concentrations suggest that the model systems should also be considered as a genotoxic effect. This work is supported by NIH Grants CA096281 (RCL), CCSG – CA023074 (AZCC/ARL-Division of Biotechnology Cytometry Core Facility), CA95901, F31ES014971 (MY), U54CA143924, MGE@MSA (MY) and The Alfred P. Sloan Foundation (MY) for funding this project.
Temporal Changes in Rat Liver Gene Expression after Cadmium and Chromium Exposure

Postdoctoral Fellow at USACEHR, Fort Detrick, MD, 2National Institute for Occupational Safety and Health, Morgantown, WV, 3US Army Center for Environmental Health Research, Fort Detrick, MD and 4Excet, Inc., Fort Detrick, MD.

Our Nation’s Guardians are at risk of exposure to a variety of environmental health hazards throughout their normal duty activities including deployments, training exercises, and homeland defense situations. Metals are widely used in large quantities in a number of industrial processes and are common environmental toxicants, which increases the possibility of our Soldiers being exposed at toxic levels. While metal toxicity has been widely studied, the exact mechanisms of toxicity remain unclear. In order to further elucidate these mechanisms and identify candidate biomarkers, rats were exposed via a single intraperitoneal injection to three concentrations of CdCl2, NiCl2, and Na2Cr2O7, and livers were harvested 1, 3, or 7 days after exposure. Cd and Cr accumulated in the liver at 1 day post-exposure, while there was no accumulation of Ni. Cd levels remained elevated over the length of the experiment, while Cr levels declined. Differentially expressed genes were identified via microarray analysis. Both common and uniquely modulated transcripts and perturbed pathways were identified for the metal species. Enriched pathways and functions including hepatic injury, inflammation, cell cycle, tissue repair, and cancer. This work provides insight into the temporal effects and mechanistic pathways involved in acute metal intoxication, which may lead to the identification of candidate biomarkers.

This research was supported in part by an appointment to the Postgraduate Research Participation Program at the USACEHR administered by the ORISE through an interagency agreement between the US DOE and USAMRMC. Research was conducted in compliance with the Animal Welfare Act, and all other Federal requirements. The views expressed are those of the authors and do not constitute endorsement by the U.S. Army or NIOSH.

Toxicogenomic Study in Rat Thymus of F1 Generation Offspring following Maternal Exposure to Silver Ion

Silver-containing compounds or their mixtures are widely applied as antimicrobial agents onto food packaging materials, often in direct contact with the food. The extensive use of silver in the food industry raises concerns about its safety to human health and risk. Data currently available revealed that in utero exposure to silver ions could adversely affect the developing immune system. However, further studies are needed to confirm that the previously observed adverse effects are due to silver ion alone, and to define the no observed effect level (NOEL). In the present study we used a toxicogenomic approach to study the effect of silver ion on the developing thymus at the transcriptional level using whole genome microarrays. Global gene expression changes in rat thymus of F1 generation pups at postnatal day 26 following maternal exposure to silver acetate at 0, 0.4, 4.0, or 40.0 mg/kg in drinking water are reported here. Five female and 5 male pups were included in each dosing group. Gene expression profiling analyses identified only about a dozen differentially expressed genes (DEGs) in each dose group using a loose criterion of fold change (FC) > 1.5 and unadjusted p < 0.05, regardless whether the analysis was conducted within each gender group or with both gender groups combined. No dose-dependent effect was observed on the number of DEGs. In addition, none of these genes had a false discovery rate (FDR) ≤ 0.05 after correction for multiple testing. These results indicate silver acetate up to 40.0 mg/kg did not affect gene expression in the developing thymus. Combined with the observation that thymus-to-body-weight ratios were not affected, and no histopathological abnormalities in thymus were identified in the pups, the current study using a toxicogenomic approach suggests that in utero exposure to silver ion up to 26.0 mg/kg (equivalent to 40.0 mg/kg silver acetate) did not have an adverse effect on the developing thymus.

Assessing Toxicity of FeMn Dust Particles from a South African Ferromanganese Smelter Works: In Vitro Studies on Primary Rat Astrocytes and BEAS-2B Cells

L. Koekemoer1 and M. Guluman1,2. 1Toxicology and Biochemistry, National Institute for Occupational Health, Johannesburg, Gauteng, South Africa and 2Haematology & Molecular Medicine, University of the Witwatersrand, Johannesburg, Gauteng, South Africa.

Occupational exposure to manganese (Mn) may result in development of diseases associated with the lungs and brain. Even though evidence of Mn associated diseases exists, some studies have found no association between manganese levels in blood or urine and indicators of neurotoxic effects. This study investigated the effects of ferromanganese (FeMn) dust, from a ferro-manganese smelter works, on primary rat astrocytes and human bronchial epithelial (BEAS-2B) cells. Particle size distribution, surface area and trace elemental composition were analyzed. Particle uptake was studied using dark field microscopy and viability determined using the xCELLigence RTCA system based on cell adhesion. Nuclear translocation of Nrf2 and NF-κB was studied using western blots and genotoxicity determined by the alkaline Comet assay. Min-U-Sil 5 was used as benchmark particles. The presence of nano sized FeMn and its cellular uptake in both cell lines was confirmed. Treatment resulted in a dose-dependent decrease in viability of both cell lines for both particle types, with crystalline silica producing higher toxicity compared to FeMn.

Plasmomic engineered NPs are popular in consumer and medical-based industries due to their unique surface characteristics. Identifying the toxicity of NPs is critical given the increased exposure. The toxicity of NPs is often determined using conventional colorimetric and optical high-throughput toxicity systems that rely on absorbance, luminescence or fluorescence signals. However these systems are prone to interference by the NPs, which lead to erroneous results. We have assessed the interference study of conventional assays, caused by micro/Nano gold (AuNPs) exhibiting surface plasmon resonance (SPR).

Plasmomic engineered NPs are popular in consumer and medical-based industries due to their unique surface characteristics. Identifying the toxicity of NPs is critical given the increased exposure. The toxicity of NPs is often determined using conventional colorimetric and optical high-throughput toxicity systems that rely on absorbance, luminescence or fluorescence signals. However these systems are prone to interference by the NPs, which lead to erroneous results. This study assessed citrate-capped AuNPs interference with: 1) Three cell viability systems (toxicity) 2) Three fluorescent dyes often used in high-throughput systems (geno/toxicity) 3) The isolation, quantification and analysis of DNA (genotoxicity). The AuNPs exhibited optical interference with the detection system and direct adsorption of assay components with two of the assays. In addition, the distinct SPR and large surface area of AuNPs lead to a quenching in fluorescence of all three fluorescent dyes. Total RNA, isolated from untreated BEAS-2B bronchial human cells, was spiked with AuNP. The resultant sample was quantified and a concentration-dependent quenching of the absorbance spectrum was observed. The RNA purity absorbance ratios were also altered. Differences were not observed using electrophoretic analyses of RNA integrity. However, treatment of BEAS-2B cells, with NPs under non-cytotoxic test conditions, showed slight RNA absorption interference between 190-220 nm. In addition, interference varied depending on the point of NP application and the use of RNA stabilizing solutions. Toxicity results should be interpreted with caution when using conventional systems. The best alternative would be the use of a system independent of dyes or optical devices such as those that implement impedance technology. The isolation, quantification, purity and integrity are critical points of analyses for RNA-based techniques. Hence, the observed quenching effect would cause quantification errors and obscure integrity validation for gene expression studies.
The Effects of Tellurium Compounds on the Viability of Rat Hippocampal Astrocytes Are Attenuated with Calcium Blocker

M. Costa

Tellurium (Te) is a metalloid belonging to group 6A of the periodic table along with Selenium (Se) and sulfur (S). Unlike Se and Se, Te has not been found to have any physiologic role in mammals, although detectable levels of Te have been noted in humans through dietary and/or industrial exposures. Te compounds have been associated with both peripheral and central nervous system toxicity. Studies have suggested that nervous system disturbances with exposure to these compounds may be partially attributed to disruption of Calcium (Ca) homeostasis that results in destabilization of cytoskeletal proteins. The purpose of this study was to examine the relationship of Te exposure and effects on astrocyte viability and cytoskeleton and to determine if Ca plays a role in these changes. Rat hippocampal astrocytes were treated with 15.6, 31.2, 62.5, 125 and 250 μM of tellurium tetrachloride (TeCl4) and diphenyl ditelluride (DPDT) to assess changes in viability. Cytoskeletal preparations of treated and control cells were observed using scanning electron microscopy (SEM). Cells were subsequently treated with 125 μM concentrations of each of the compounds with and without the Ca blocker dantrolene for 24hrs to determine the effects of Ca on cell viability in cells treated with Te. Results indicate a significant reduction in cell viability at all Te doses when compared to untreated cells. Cells treated with 5 μM dantrolene and 125 μM TeCl4 and DPDT showed significant increases in viability when compared to cells treated with Te alone. The cytoskeleton of Te treated cells observed using SEM demonstrated changes such as loss of crossbridging and condensation of cytoskeletal components when compared to untreated cells. It is concluded that Te decreases astrocyte viability and that the use of dantrolene significantly increases viability, suggesting that Ca plays a role in this process. Exposure to Te compounds results in cytoskeletal alterations when compared to non-exposed cells.

Investigating the Potential Carcinogenic Effects of Chronic Tungsten (VI) Oxide Exposure to Immortalize Human Lung Cells

F. Lautsch, L. Cartulano, S. Medicì, M. F. Peña, M. A. Zoroddu and M. Costa. Environmental Medicine, NYU Langone Medical Center, Tuxedo, NY and Department of Chemistry and Pharmacy, University of Sassari, Sassari, Sassari, Italy.

Rationale: Tungsten oxide (WO3) is an occupational exposure hazard. The primary route of WO3 exposure is inhalation and WO3 is known as a pulmonary irritant. This work investigated exposure of WO3 to immortalized human bronchial epithelial cells (Beas-2B) to investigate cytotoxicity and carcinogenic potential. Experimental procedures: Insoluble WO3 particles were sonicated to reduce agglomeration and create suspensions of WO3 particles small enough for Beas-2B cells to engulf (<10 microns in diameter). Beas-2B cells were chronically exposed to varying doses (0.25, 0.5, 1.0, 5.0, 10 and 15 μg/cm2) of WO3 for 6 weeks. Proliferation rate was measured; soft agar cell migration testing and scratch test assays were performed. Results: After 2 weeks, Beas-2B cells with the highest doses of WO3 started to proliferate just as quickly as the cells that had low doses of WO3. After 6 weeks of WO3 exposure, in the control transformation there was an average of 8 colonies per well. Scratch testing revealed that WO3 treated cells migrated significantly more quickly than control transformed cells. Conclusions: Chronic treatment of Beas-2B cells with WO3 induced transformation in the cells. Inhaled WO3 may not only be a lung irritant, but also a potential pulmonary carcinogen at high doses.

Quercetin Inhibits Cr(VI)-Induced Lung Carcinogenesis by Targeting miR-21-Pdcd4 Signaling Pathway

P. Poyil, D. Sadidharan Padmaja, Y. Son, J. Hitron, Z. Zhang and X. Shi. Graduate Centre for Toxicology, University of Kentucky, Lexington, KY and Center for Research on Environmental Disease, University of Kentucky, Lexington, KY.

Hexavalent chromium (Cr(VI)) is an important human carcinogen associated with pulmonary diseases and lung cancer. Cancer prevention using natural products has become an integral part of cancer control. Quercetin is one of the most abundant dietary flavonoids widely present in many fruits and vegetables, possesses potent antioxidant activity capable of protecting normal cells from various stimuli-induced oxidative stress and cell death. MicroRNA-21 (miR-21) is a key regulator of oncogenic processes. It is significantly elevated in the majority of human tumors and functionally linked to cellular proliferation, invasion and migration. Studies have shown that miR-21 exerts its oncogenic activity by targeting the tumor suppressor gene programmed cell death 4 (PDCD4). The latter study examined the effect of quercetin on the inhibition of Cr(VI) induced carcinogenesis and the role of miR-21-Pdcd4 signaling involved. Our results showed that quercetin decreased ROS generation induced by Cr(VI) exposure in Beas-2B cells. Chronic Cr(VI) exposure induced malignant cell transformation, increased miR-21 expression and caused inhibition of Pdcd4, which were significantly inhibited by the treatment of quercetin in a dose dependent manner. Stable knockdown of miR-21 overexpression of pdc4 in Beas-2B cells significantly reduced the Cr(VI) induced cell transformation. Furthermore, quercetin inhibited the Cr(VI) induced E-cadherin reduction, and also beta-catenin/TCF-dependent transcription. Taken together, these results demonstrate that quercetin is able to protect Beas-2B cells from Cr(VI)-induced carcinogenesis by targeting miR-21-Pdcd4 signaling.

Application of Lead Isotope Ratios to Lead Poisoning Investigations On-Farm

Lead (Pb) is a common cause of heavy metal poisonings in cattle. Sources of Pb on-farm may include cranckcase oil, machinery grease, batteries, plumbing, and paint chips. Unfortunately, consumption of, or exposure to, these sources may negatively impact animal health, and, if present at subclinical concentrations, may be inadvertently introduced into the food supply by excretion in milk or distribution in beef cattle. Therefore, the scope of poisoning incidents must be clearly assessed and the source of intoxication mitigated to prevent future exposures. One valuable tool in the forensic assessment of lead source is Pb isotope analysis. We report on two cases in which the novel application of Pb isotope analysis by ICP-MS was extended to bovine blood and liver for comparison to environmental samples including paint chips and soil to elucidate lead source. Isotope ratios 208Pb/206Pb, 207Pb/206Pb, 207Pb/206Pb and 206Pb/204Pb were calculated for blood samples across the entire herd in each case. Blood isotopic profiles corresponded with exposure to paint chips obtained from sources unique to each herd. Although this resolved the poisoning incident for one farm, a subsequent poisoning event on the second farm prompted a more thorough investigation of the property. Pb quantitation and isotope profiling provided a direct link between an affected calf’s liver and soil obtained from the farm’s main barn but not from that of a secondary barn. These two cases highlight the use of isotope profiling as an advanced diagnostic technique for Pb source identification on-farm.

Chronic Arsenic Exposure In Vitro Causes Acquisition of Multiple Tumor Cell Characteristic in Human Pancreatic Epithelial Cells

W. Qu and M. P. Waalkes. NTP, NIEHS, NIH, Research Triangle Park, NC.

Arsenic is linked with human pancreatic diseases potentially including cancer. Emerging data indicates cancer stem cells (CSCs) may be critical to the carcinogenic process. Our prior work showed chronic cadmium exposure of a human pancreatic ductal epithelial (HPDE) cell line caused oncogenic transformation and formation of CSC-like cells. Thus, we studied if inorganic arsenic exposure could induce a similar tumor cell phenotype in HPDE cells and derivative non-adherent spheroids, which are enriched in stem cells (SCs or CSCs). HPDE cells were chronically exposed to sodium arsenite (2.5 μM) for up to 30 weeks and cancer cell characteristics were assessed including matrix metalloproteinase-9 (MMP-9) secretion, invasion, colony formation and expression of cancer relevant genes by RT-PCR or immunoblotting. Non-adherent spheroid formation was used to assess CSC-like characteristics. Our results showed chronic arsenic exposure induced a similar tumor cell phenotype in HPDE cells and derivative non-adherent spheroids, which are enriched in stem cells (SCs or CSCs). Oxidative stress and cell death. MicroRNA-21 (miR-21) is a key regulator of oncogenic processes. It is significantly elevated in the majority of human tumors and functionally linked to cellular proliferation, invasion and migration. Studies have shown that miR-21 exerts its oncogenic activity by targeting the tumor suppressor gene programmed cell death 4 (PDCD4). The latter study examined the effect of quercetin on the inhibition of Cr(VI) induced carcinogenesis and the role of miR-21-Pdcd4 signaling involved. Our results showed that quercetin decreased ROS generation induced by Cr(VI) exposure in Beas-2B cells. Chronic Cr(VI) exposure induced malignant cell transformation, increased miR-21 expression and caused inhibition of Pdcd4, which were significantly inhibited by the treatment of quercetin in a dose dependent manner. Stable knockdown of miR-21 overexpression of pdc4 in Beas-2B cells significantly reduced the Cr(VI) induced cell transformation. Furthermore, quercetin inhibited the Cr(VI) induced E-cadherin reduction, and also beta-catenin/TCF-dependent transcription. Taken together, these results demonstrate that quercetin is able to protect Beas-2B cells from Cr(VI)-induced carcinogenesis by targeting miR-21-Pdcd4 signaling.
structures in Matrigel. Thus, chronic arsenic causes acquisition of multiple tumor cell characteristics in HPDE cells. These data support the plausibility of arsenic as a human pancreatic carcinogen.

**1297i** Chronic Arsenic Exposure Induces Cancer Cell Characteristics in Human Peripheral Lung Epithelial Cells

R. J. Person, E. J. Tokar and M. P. Waalkes. NTP, NIEHS, NIH, Research Triangle Park, NC.

Inorganic arsenic is a human lung carcinogen. Here we study the ability of chronic inorganic arsenic exposure to induce a cancer phenotype in the immortalized, non-tumorigenic human lung epithelial cell line, HPL-1D. Signs of oncogenic transformation were assessed periodically during chronic sodium arsenite (2 μM) exposure, such as secreted matrix metalloproteinase-2 (MMP-2) activity, invasion, and expression of cancer-relevant genes at the transcript and protein levels. After 38 weeks of continuous arsenic exposure, secreted MMP-2 activity increased to 200% of control, a level typical of other cell lines that have acquired an arsenic-induced cancer phenotype. The invasive capacity of these chronic arsenic-treated lung epithelial (ATLE) cells was over 3-times control levels. Expression of lung cancer tumor suppressor genes SLC38A3 and TTF-1 at the protein level was markedly reduced in ATLE cells to 26% and 24% of control, respectively. Increases occurred in K-Ras oncogene (300% of control) and both the ERK (274%) and p-ERK (152%) proteins in ATLE cells. Vimentin increased to 300% and E-Cadherin protein was reduced to 16% of control in ATLE cells indicative of epithelial-to-mesenchymal transition. Thus, ATLE cells appeared to have acquired multiple cancer cell characteristics, some of which are specific to lung. Additional evidence of an oncogenic phenotype in ATLE cells came from other molecular events linked to chronic arsenic exposure. ATLE cells showed reduced expression of the tumor suppressor genes APC (72% of control), PTEN (43%), and CCND1 (76%) and the DNA damage response gene ATM (82%). Expression of the oncogene AKT increased in ATLE cells to 242% of control. Chronic arsenic exposure increased expression of the major metallothioneins, MT-1A and MT-2A and stress response genes HO-1 (690%) and HIF-1α (247%). Thus, it appears that arsenic can induce multiple cancer cell characteristics in human lung epithelial cells. This model can now be used to further assess mechanisms of arsenic-induced lung cancer.

**1297j** Silencing KRAS Overexpression in Arsenic-Transformed Prostate Stem Cells Results in Signs of Malignant Phenotype Reversal

N. N. Nagalame, E. J. Tokar and M. P. Waalkes. NTP, NIEHS, NIH, Research Triangle Park, NC.

Inorganic arsenic is a human carcinogenic that probably targets the prostate. Chronic arsenic exposure malignantly transforms the RWPE-1 human prostate epithelial line to CAsE-PE cells, and a derivative normal prostate stem cell (SC) line, WPE-ST, stem to arsenic-cancer SCs (As-CSC). KRAS oncogene activation appears critical during this process, as CAsE-PE cells overexpress KRAS, and activation precedes transformation. As-CSCs also overexpress KRAS suggesting this is important in arsenic carcinogenesis in this key subpopulation. Thus, we hypothesize KRAS knockdown (KD) may reverse arsenic-induced malignant phenotype. RNA interference using shRNAmirs to obtain KRAS KD was used in As-CSCs. KRAS shRNAmir primers expresses miRNA 30 transcript which targets KRAS to silence expression. As-CSCs were transduced with KRAS shRNA, or non-targeting control shRNA. Stable cell lines were generated by puromycin selection. Cells analyzed 2 weeks post transduction showed KRAS protein decreased to 5% of control in KD As-CSCs, confirming stable KD. KRAS KD decreased phosphorylated ERK by 60%, indicating inhibition of RAS/ERK signaling, a proliferation/survival pathway activated with arsenic transformation. Secreted metalloproteinase (MMP) activity increases in arsenic-induced malignant transformation, and by 4 weeks, KRAS KD decreased secreted MMP-9 (49%) and MMP-2 (39%) activity. Anchorage-independent growth (colony formation) is typical of cancer cells and correlated with cancer SCs. KRAS KD in As-CSCs decreased colony formation (40%) at 6 weeks after transduction. KRAS KD increased the cell cycle inhibitor proteins p16 (131%) and P21 (156%) and decreased the cell cycle activator CCND1 transcript (26%), indicating reduced proliferation, consistent with a loss of rapid growth. KRAS KD increased (86%) protein levels of PTEN, a tumor suppressor gene inactivated in many cancers and in As-CSCs. Thus, KRAS silencing impacts arsenic-induced malignant phenotype at the level of SCs, inducing loss of many typical cancer characteristics.

**1297k** Differential DNA Methylation in Arsenic- or Cadmium-Transformed Malignant Prostate Epithelial Cells

K. E. Pelch, E. J. Tokar, B. Merrick and M. P. Waalkes. NTP, NIEHS, NIH, Research Triangle Park, NC.

Many inorganic carcinogens are weak mutagens, suggesting the epigenome is an important target. Previous work shows global DNA hypomethylation in human cells malignantly transformed by inorganic arsenic (iAs) and altered methylation patterns in iAs- or cadmium-transformed epithelial cells. In this work, the methylation status in the promoter region of six genes was assessed in the normal human prostate epithelial cell line (RWPE1) that was malignantly transformed by 10 μM cadmium for 11 weeks (CTPE) or 5 μM iAs for 31 weeks (CAsE-PE), at time cells showed multiple markers of acquired cancer phenotype. Next generation sequencing of the transcriptome identified multiple misregulated genes. Of the most highly misregulated genes, 6 genes associated with stem cell function/dysfunction (ALDH1A1, WNT4, and NES), extracellular matrix (HYAL1), cell adhesion (NTM), or aggressive cancers (SI00P) were chosen for in-depth analysis of the DNA methylation profile. DNA was isolated, bisulfite converted, and combined bisulfite restriction analysis (COBRA) was used to identify differentially methylated CpG sites within 1000 bases of the transcription start site. Differential methylation was confirmed with bisulfite sequencing. All 6 genes showed differential methylation of at least one CpG site in transformants relative to control RWPE1 cells. Altered gene expression was inversely related to methylation status in 4 out of the 6 genes. Expression of NES (+15-fold) and NTM (+1000-fold) was decreased in the transformants compared to control. Both genes were hypermethylated near the transcription start site. Expression of HYAL1 (+25-fold) and SI00P (+40-fold) was increased in transformants relative to control and both genes were hypomethylated near the transcription start site. ALDH1A1 and WNT4 expression was increased in transformed cells versus control and both genes were hypermethylated relative to control. In conclusion, altered gene expression profiles observed in cadmium and iAs transformed cells may often result from altered DNA methylation status.

**1297l** Arsenic Induces an Oncogenic Phenotype in Human Breast Epithelia through an Estrogen Receptor-Independent Pathway by Aromatase Activation

Y. Xu, E. J. Tokar and M. P. Waalkes. NTP, NIEHS, NIH, RTP, NC.

Inorganic arsenic has been linked to human breast cancer in some studies. Here, we tested the effects of inorganic arsenic exposure on the normal, estrogen receptor (ER)-negative breast epithelial cell line, MCF-10A. Cells were chronically exposed to sodium arsenite (500 nM) and markers of cancer phenotype and expression of genes relevant to breast cancer or stem cells (SCs) were examined. After 24 weeks of continuous arsenic exposure, increases in secreted metalloproteinase (MMP) activity, colony formation, invasion, and proliferation rate occurred, all typical cancer cell characteristics. The arsenic-transformed breast epithelial (ATBE) cells showed characteristics of a basal-like breast cancer, including ER-α, HER-2 and progesterone receptor negativity, and enhanced expression of breast cancer SC (CSC) markers, K5 and p63. Putative CD44+/CD24low/- breast SCs increased to 180% of control in ATBE cells as assessed by flow cytometry. In non-confluent culture, ATBE cells formed multilayer cell mounds, indicative of loss of contact inhibition, which showed high levels of K5 and p63 indicating the presence of CSCs. Epithelial-to-mesenchymal transition occurred starting from 8 weeks of arsenic exposure, as seen by cell morphology, increased SNAIL1 and VIMENTIN expression and decreased E-CADHERIN expression. Aromatase, a key rate-limiting enzyme in estrogen synthesis, was overexpressed (mRNA, 5400% of control; protein, 140% of control; week 8) starting early on in arsenic exposure. Immunofluorescence showed widely spread of aromatase overexpression in the ATBE cells. Levels of 17β-estradiol increased in ATBE cells and conditioned medium. The aromatase inhibitor, letrozole, abolished arsenic-induced 17β-estradiol increases, and over a 3-week period reversed arsenic-induced oncogenic phenotype. Thus, chronic arsenic exposure drives human breast epithelia into an oncogenic phenotype with an apparent overabundance of putative CSCs. Arsenic appears to transform breast epithelia through overexpression of aromatase, thereby activating oncogenic processes independent of ER.
Variable Cytotoxicity and Reactive Oxygen Species Generation in Pulmonary and Aortic Cells Exposed to Inorganic Arsenic and Monomethylarsonic Acid

B. Khalili, R. Welch, C. Page, J. Kuzhippala and J. E. Angermann, School of Community Health Sciences Environmental Physiology and Toxicology Laboratory, University of Nevada, Reno, NV, NV.

Chronic ingestion of arsenic produces myriad toxic effects including atheroclerosis and hypertension, but the cellular mechanisms by which vascular effects are produced remain unclear. The arsene metabolite monomethylarsonic acid (MMA) demonstrates elevated vascular toxicity relative to inorganic arsenic (iAs), and may therefore be linked to arsenic-induced vascular disease. The present study explores the role of iAs and MMA on cytokotoxicity, cellular morphology and ROS generation in two model vascular smooth muscle cell lines. Cytotoxic effects of iAs and MMA on rat thoracic aorta smooth muscle cells (A7r5) and rat pulmonary arterial smooth muscle cells (iPASMC) in culture were examined for generation of malondialdehyde (MDA), hydrogen peroxide, and superoxide. Cytotoxicity, cell morphology, and mode of cell death were determined by cell counts, trypan blue exclusion, flow cytometry, MTT assay, and light microscopy. Cells treated with iAs or MMA displayed cytotxic effects, and MMA was significantly more toxic than iAs to both cell lines. After a 24 hour exposure, LC50 in A7r5 were 11 μM and 700 nM when treated with iAs and MMA, respectively. 10 μM iAs and 500 nM MMA induced apoptosis in A7r5 and appeared to arrest cell growth in S phase. MMA was significantly more toxic to rat PASMC than iAs with an apparent 24 h LC50 of 4.0 μM relative to 27 μM for iAs. No significant differences in MDA formation or superoxide production were observed following iAs or MMA exposure in either line, although a significant increase in hydrogen peroxide was observed subsequent to iAs and MMA exposure in both lines. These results suggest that the increased toxicity of MMA may be in part due to increased hydrogen peroxide generation in A7r5 cells, but cytotoxicity is not solely attributable to oxidative stress when analyzed in vitro, suggesting that additional mechanisms are involved in arsene-promoted vascular disease.

Arsenic Contaminated Drinking Water Deregulates Human Gene Expression Patterns in a Gender-Specific Manner in Bangladeshi Adults

A. B. Munoz1, Y. Chervona1, T. Klua1, M. Hall2, M. Gamble3 and M. Costa1.

Approximately 150 million people in at least 70 countries are exposed to arsenic via drinking water. Arsenic exposure is associated with skin, lung and bladder cancers, cardiovascular disease, kidney disease, and diabetes. Many questions remain regarding the mechanisms behind arsenic’s pathogenesis including its potential role as an endocrine disruptor. Previous research in humans suggests that arsenic alters the abundance of post-translational histone modifications in a gender-specific manner. Twenty-nine study participants (55% male) from the FACT folate clinical trial in Bangladesh were selected with water arsenic exposure ranging between 50–500 μg/L. Arsenic RNA was extracted from peripheral blood mononuclear cells (PBMCs) and gene expression profiling was performed using Affymetrix 1.0 ST arrays. Differentially expressed genes were assessed between high and low groups for males and females separately and findings were validated using real-time PCR. Network analysis was performed using IPA (Ingenuity® Systems, www.ingenuity.com). Among males, a total of 534 genes were differentially expressed (p <0.05) in PBMCs from study participants with high arsenic exposure relative to those with low arsenic exposure. Females exhibited a total of 645 differentially expressed genes (p <0.05). Only 42 genes overlapped between the two genders, with 28 out of 42 genes changing in opposite directions. Network analysis revealed both genders exhibited deregulation of the cardiovascular system through a distinct set of genes. Arsenic exposed adults exhibit gender-specific responses in gene expression. While responses are distinct, they exhibit similar features including cardiovascular and endocrine dysregulation.

Maladaptive Signaling from Arsenic Exposure Impairs Cardiac Bioenergetics and Enhances Autophagy

K. Beechold, L. R. Klei, R. T. Cateley and A. Barchowsky, EOH, University of Pittsburgh, Pittsburgh, PA.

Environmental exposure to arsenic through drinking water causes cancers, as well as metabolic and cardiovascular diseases. Association of arsenic with cancer and many of its molecular mechanisms have been well studied, but much less is known of mechanisms for arsenic-promoted cardiac and vascular disorders. A low steady-
state level of cardiac autophagy is critical to maintaining heart homeostasis. While increased autophagy in response to stress such as ischemia or starvation is protective, excessive response to reperfusion after ischemia is detrimental. Stress-induced autophagy, such as in arsenic exposure, can be adaptive and prevent cell transdifferentiation. We hypothesized that arsenic exposure increases autophagic signaling in cardiac tissue causing impaired bioenergetics and enhanced autophagy. DNA binding arrays identified several dysregulated transcription factor families in arsenic-exposed mouse hearts. Pro-autophagic FoxO transcription factors were increased up to 6-fold above control. Protein analysis by immunostaining and Western showed increased expression of both FoxO1 and 3a in the heart and DNA binding was confirmed by EMSA. Hearts from arsenic exposed (100 μg/L in drinking water for 2-5 wks) mice were analyzed for FoxO associated signaling pathways. Upstream of FoxO3a activation, we observed increased in miR-143, a cardiac and autophagy associated microRNA that increases in FoxO3a protein expression. SRF, a transcription factor that drives miR-143 expression, was increased and ELK1, a MAPK factor that renders that is a direct miR-143 target decreased. Downstream of FoxO3a we observed increased pyruvate dehydrogenase kinase 4 expression that may mediate starvation signaling indicative of impaired bioenergetics. These results suggest that arsenic increases cardiac autophagy by inducing autophagy regulating transcription factors (FoxO) and by eliciting maladaptive starved signaling (ELK1 and PDK4). Supported by NIEHS F32 ES022134 01(RB) and NIEHS R01 ES013781(AB)

1303 Global Assessment of Arsenic Pollution Using Sperm Whales (Physeter macrocephalus) As an Indicator Species
L. C. Savery1,2,3, J. Wise1, S. Wise1,2,3, C. Falank1,2,3, C. Gianios1,2,3
1Wisconsin Laboratory of Environmental & Genetic Toxicology, University of Wisconsin-Madison, Madison, WI, 2Department of Pathology & Laboratory Medicine, University of Southern Maine, Portland, ME, 3Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME.

Arsenic (As), a naturally occurring metalloid, is an oceanic pollutant of global concern due to its toxicity, ability to bioaccumulate and potential for increasing ocean levels to an unknown extent by anthropogenic activities. The sperm whale (Physeter macrocephalus) has a global distribution and high trophic level. The aim of this study was to establish a global and regional baseline of oceanic total As concentrations using free-ranging sperm whale as an indicator species. Skin biopsies (n = 342) were collected during the voyage of the Odyssey (2000-2005) from 17 regions considering gender and age in males. As was detectable in 99% of samples with a global mean of 1.9 μg/g ww ranging from 0.1 to 15.6 μg/g ww. Previous work in toothed whale skin found the mean As concentration to be 0.6 μg/g ww being 34% of the global mean of 1.9 μg/g ww ranging from 0.1 to 15.6 μg/g ww. This result indicates that arsenic increases cardiac autophagy by inducing autophagy regulating transcription factors (FoxO) and by eliciting maladaptive starved signaling (ELK1 and PDK4).

1306 Evaluation of Arsenic (+3 Oxidation State) Methyltransferase Activity to Tellurite
M. Tokunoto, N. Kutsukake, E. Yamanishi, Y. Anan and Y. Ogra. Laboratory of Chemical Toxicology and Environmental Health, Showa Pharmaceutical University, Machida, Tokyo, Japan.

Inorganic arsenic is one of the distressing environmental contaminants, and many people suffer from its toxicity. Arsenite [As(III)] is metabolized with arsenic (+3 oxidation state) methyltransferase (As3MT), and the methylated metabolites are excreted into urine. It was reported that inorganic tellurite (Te) is simply methylated in vitro, and its ultimate methylated metabolite was excreted into urine. Although Te is also methylated as arsenic, the enzyme(s) being responsible for the Te methylation is still unclear. In this study we evaluated that As3MT metabolized inorganic Te and was involved in the reduction of Te toxicity. To obtain poly-histidine-tagged recombinant As3MT (As3MT), cDNA of human As3MT was inserted into pBAD, and As3MT was purified on a nickel ion-affinity column. The reaction mixture consisted of As3MT, S-adenosyl-L-methionine, glutathione and As(III) or tellurite (Te(IV)) in phosphate buffer and were incubated at 37°C for 4 h. The metabolites were determined by an HPLC coupled with an inductively coupled plasma-mass spectrometer. Although rAs3MT actually metabolized As(III) to dimethylated arsenicals, no methylated metabolites of Te(IV) with As3MT were detected under the reaction conditions. This result indicates that As3MT is a specific enzyme to metabolize As, and Te(IV) seems to be methylated by another methyltransferase and not As3MT. Next, siRNA targeting As3MT was introduced into human hepatoma cell line HepG2 cells to achieve the knockdown (KD) of As3MT. Then, the As3MT-KD cells and control siRNA-transfected cells were treated with As(III) or Te(IV) for 24 h. No apparent changes in the cell viability between As3MT-KD and control cells were observed when either As(III) or Te(IV) was exposed. As3MT did not protect the HepG2 cells from the cytotoxicities of As(III) and Te(IV). This can be explained by the suggestion that the cytotoxicities of some metabolic intermediates of As, such as trivalent methylated arsenicals, are equivalent to that of As(III), and Te(IV) is not metabolized with As3MT.

1305 Ogg1 Genetic Background Determines the Genotoxic Potential of Environmentally Relevant Arsenic Exposures
A. Hernandez1,2, J. Bach1, A. Sampayo-Reyes3 and R. Marcos1,2,3.
1Genetics and Microbiology, Autonomous University of Barcelona, Bellaterra, Barcelona, Spain, 2CIBERESP, Barcelona, Spain and 3Centro de Investigaciones Biomédicas del Noreste (CIBIN)-Instituto Mexicano del Seguro Social (IMSS), Monterrey, Nuevo León, Mexico. Sponsor: A. Sampayo-Reyes.

Inorganic arsenic (i-As) is a well-established human carcinogen to which millions of people are exposed worldwide. It is generally accepted that the genotoxic effects of i-As after an acute exposure are partially linked to the i-As-induced production of reactive oxygen species; but it is necessary to better determine if chronic sub-toxic i-As doses are able to induce biologically significant levels of oxidative DNA damage (ODD). To fill in this gap we have tested the genotoxic and oxidative effects of environmentally relevant arsenic exposures using mouse embryonic fibroblast MEF mutant Ogg1 cells and their wild-type counterparts. Effects were examined by using the comet assay complemented with the use of FPG enzyme. Our findings indicate that MEF Ogg1-/- cells are more sensitive to arsenite-induced acute toxicity, genotoxicity and ODD. Long-term exposure to sub-toxic doses of arsenite generates a detectable increase of ODD and genotoxic DNA damage only in MEF Ogg1 deficient cells. Altogether, the data presented here points out the relevance of ODD and Ogg1 genetic background on the genotoxic risk of i-As at environmentally plausible doses. The persistent accumulation of DNA 8-0H-dG lesions in Ogg1-/- cells during the complete course of the exposure suggests a relevant role in arsenic-associated carcinogenic risk in turn.

1304 Arsenic, Obesity, and Inflammation Cytokines in Mexican Adolescents
1Universidad Javeriana Estado de Durango, Mexico, 2BSPH, Johns Hopkins University, Baltimore, MD, 3Centro Universitario de la Universidad de Guadalajara, Guadalajara, Mexico, 4Laboratorio de Genética y 5CIBERESP, Barcelona, Spain. Evidence on the association of arsenic (As) exposures with obesity is considered as in-sufficient. Obesity is considered a disorder related to an inflammatory process, while arsenic also has an effect on the immune system. The aim of this cross-sectional study was to assess the association of arsenic exposure, obesity and inflammatory cytokines in adolescents exposed to arsenic via drinking water. We studied 384 healthy adolescents 12-15 years of age, living in Torreon Coahuila, Mexico. Participants with fish consumption in the previous week, or incomplete measurements were excluded. Total As concentrations in urine were measured using a inductively coupled plasma-mass spectrometer and expressed as μg/g creatinine. Adiposity was assessed using body mass index (BMI), sex- and age-standardized body mass index (zBMI), and bioimpedance segmental body composition (fat mass); cytokines were determined using ELISA method. The prevalence of obesity and overweight was 14.8% and 21.1% respectively. The median (IQR) of obese men was 26.4% (19.9-32.7%), which was significantly higher in female than males. The median (IQR) of BMI was 26.1 (20.1, 26.8) μg/g creatinine. Only TNFα levels were higher in male adolescents. The median (IQR) of arsenic in urine in non obese subjects was 35.7 (27.4, 46.3) μg/g creatinine, and in adolescents with over-weight and obesity it was 36.6 (24.8, 47.5) μg/g creatinine. In a Spearman correlation analysis, arsenic exposure correlates with fat mass but not zBMI. IL-6 and TNFα correlates with zBMI and arsenic, and IL-6 correlated with fat mass. Our results showed a negative association of adiposity with arsenic exposure. Results of As and obesity association are in agreement with previous studies in human exposed to low levels of As in drinking water.
Arsenic exposure is an ongoing health concern that has been increasingly linked to the development of cardiovascular disease and the metabolic syndrome. However, the role of low-dose As (III) exposure on the development of the metabolic syndrome remains controversial, and our study aims to explore mechanisms of As (III) toxicity on the development of the cardiometabolic syndrome. Male Swiss Webster mice were treated with 100ppb NaAsO2 in their water starting at embryonic day 5 (IU), after weaning (PN), or from embryonic day 5 onward (IU+). After weaning, all groups were fed a western diet. IU+ mice became overweight at week 5. The liver to body weight ratio in the IU and IU+ mice was elevated. Plasma HOME-IR determined IU+ animals were insulin resistant. Liver H&E evaluation determined that all had microvesicular steatosis, but hepatocellular ballooning was most severe in the IU, PN, and IU+ mice. Liver evaluation with Masson’s trichrome found fibrosis in the IU and IU+ livers. Oil-Red-O liver staining found steatosis in all groups with marginally higher lipid content in As (III) treated groups. Metabolomic analysis of plasma found changes in As (III) exposed animals that support an influence on energy metabolism: with effects evident in glycolysis, TCA cycle, and lipid metabolism. The histological, weight, and liver to body weight ratio findings are consistent with NAFDL (non-alcoholic fatty liver disease) suggesting that low-dose As (III) exposure, prenatal and chronic, predisposes mice to morose NAFDL when on a western diet. Insulin resistance in IU+ animals suggests As (III) contribution to the development of the metabolic syndrome. The metabolomic findings are indicative of diverse changes in energy metabolism as a result of low-dose prenatal and/or chronic arsenic exposure. These data will be used to determine mechanisms involved and metabolism alterations caused by As (III) so that therapeutic interventions can be developed.

Metabolomic analysis of plasma found changes in As (III) exposed animals that support an influence on energy metabolism: with effects evident in glycolysis, TCA cycle, and lipid metabolism. The histological, weight, and liver to body weight ratio findings are consistent with NAFDL (non-alcoholic fatty liver disease) suggesting that low-dose As (III) exposure, prenatal and chronic, predisposes mice to more severe NAFDL when on a western diet. Insulin resistance in IU+ animals suggests As (III) contribution to the development of the metabolic syndrome. The metabolomic findings are indicative of diverse changes in energy metabolism as a result of low-dose prenatal and/or chronic arsenic exposure. These data will be used to determine mechanisms involved and metabolism alterations caused by As (III) so that therapeutic interventions can be developed.

Prenatal exposure to inorganic arsenic (iAs) is associated with adverse health effects in infants, children, and adults, and yet the biological mechanisms that underlie these effects are understudied. In order to gain a better understanding of alterations in protein expression profiles associated with prenatal iAs exposure, we utilized samples from 50 mother-child pairs from a recently-established prospective pregnancy cohort in Gómez Palacio, Mexico. Concentrations of iAs in maternal drinking water (DW-iAs) ranged from below the limit of detection (LOD)-236 μg/L and the sum of iAs metabolites in maternal urine (total urinary arsenic; U-As) ranged from 6.19-319.7 μg/L. Using a high-throughput antibody array, we identified 111 cord blood proteins for which there was a significant association between protein expression in the newborn and maternal U-As. These proteins were enriched in functions including immune response and cellular growth/development.

Using a high-throughput antibody array, we identified 111 cord blood proteins for which there was a significant association between protein expression in the newborn and maternal U-As. These proteins were enriched in functions including immune response and cellular growth/development.

The newborns differed in the relationship between expression of these proteins and U-As in a way that was consistent with previous studies. We found that exposure to iAs led to changes in expression of several proteins, including those involved in immune response and cellular growth/development. These changes may be indicative of the long-term effects of prenatal arsenic exposure on the developing fetus.

however, the CDDO pretreatment did not alter the time course of the accumulation of DMAIII in the blood of rats. In conclusion, the contribution of TRR to DMAV reduction appears indirect. The activity of TRR may be indispensable for the reduction of DMAV; however, at the quantity normally present in rat liver TRR does not limit the rate of DMAV conversion to the highly toxic DMAIII. Further research is warranted to identify the enzymes carrying out this important toxification step.

1312 Dietary Methyl Donors Influence Arsenic Metabolism in Residents of Chihuahua, Mexico

Nutrition, Univ North Carolina Chapel Hill, Chapel Hill, NC, 3Colegio de Médicos Cirujanos y Homeópatas del Estado de Chihuahua, A.C., Chihuahua, Mexico, 4Universidad Autónoma de Chihuahua, Chihuahua, Mexico, 5IARC, Lyon, France and 6Cinvestav-IPN, Mexico DF, Mexico.

Inorganic arsenic (iAs) is a common drinking water contaminant known to increase risk of cancer and several non-communicable diseases. iAs is metabolized via a pathway involving enzymatic methylation to methylarsonic (MAs) and dimethylarsenic (DMAs) prior to excretion. Higher proportions of urinary arsenic as iAs or MAs are thought to indicate an impairment in the capacity to methylate iAs and to increase health risks. Studies in Bangladesh suggesting dietary methyl donors, including folate and vitamin B12, may reduce iAs toxicity by enhancing DMA production have yet to be confirmed in other populations. We explored associations between folate and vitamin B12 intakes and metabolites of iAs in urine of 771 adults in Chihuahua (Mexico) who were exposed to iAs in drinking water (<0.1-419.8 µg As/L). After adjusting for age and gender, adequate intakes of folate (>320 µg/day, 57% of the sample) were associated with higher %DMAs, a lower %iAs and higher DMAs/MAs ratios in urine, but only among subjects with high intakes of B12 (> the median of 1.85 µg/day). In contrast, among subjects with low B12 intakes, folate intake adequacy was associated with a reduction in %DMA and in the DMAs/MAs ratio, suggesting an impairment of the methylation capacity. Thus, B12 rather than folate intake may be the limiting factor in iAs metabolism in Mexican population.

1313 Reduction of Dimethylarsenate to Dimethylarsenite by Rat Liver Cytosol: Further Characterization

Dimethylarsonic acid (DMAV), the major urinary metabolite of inorganic arsenic, is weakly cytotoxic, however, its reduced form, dimethylarsonous acid (DMAIII), is highly toxic. We have shown that rats and rat liver cytosol (RCL) reduce DMAV in glutathione (GSH) dependent manner. GSH S-transferase omega 1 (GSTO1) activity. After adjusting for age and gender, adequate intakes of folate (>320 µg/day, 57% of the sample) were associated with higher %DMAs, a lower %iAs and higher DMAs/MAs ratios in urine, but only among subjects with high intakes of B12 (> the median of 1.85 µg/day). In contrast, among subjects with low B12 intakes, folate intake adequacy was associated with a reduction in %DMA and in the DMAs/MAs ratio, suggesting an impairment of the methylation capacity. Thus, B12 rather than folate intake may be the limiting factor in iAs metabolism in Mexican population.

1314 Chronic Exposure to Arsenic is Associated with an Elevated Cardiometabolic Risk in Chihuahua, Mexico

Universidad Autónoma de Chihuahua, Chihuahua, Mexico, 2University of North Carolina, Chapel Hill, NC, 3Colegio de Médicos Cirujanos y Homeópatas del Estado de Chihuahua, A.C., Chihuahua, Mexico, 4Universidad Juárez del Estado de Durango, Gómez Palacio, Mexico, 5IARC, Lyon, France and 6Cinvestav-IPN, Mexico DF, Mexico.

Cardiometabolic (CM) risk is characterized by a group of factors that serve as indicators of an individual’s overall risk for type-2 diabetes mellitus (DM) and cardiovascular disease (CVD). The traditional CM risk factors include dysglycemia, dyslipidemia, high blood pressure, inflammation, endothelial dysfunction, and obesity. Growing epidemiologic evidence suggests that exposure to some environmental chemicals, including inorganic arsenic (iAs), may increase risk of DM and CVD. The present cross-sectional study examined associations between iAs exposure and CM risk factors in a cohort of adult Chihuahua residents (n=933) who drank water containing 0.05 - 419.8 µg As/L. Results show that subjects in the highest exposure tertile (58.3 - 419.8 µg As/L) had higher levels of total cholesterol in plasma and were more likely to have dysglycemia (OR 1.60, 95%CI 1.09-2.32), hyperteglicemia (OR 1.53, 95%CI 1.07 - 2.20), and high blood pressure (OR 1.57, 95%CI 1.05 - 2.35) than subjects in the lowest exposure tertile (<58.5 µg As/L). In addition, all these CM risk factors were positively associated with the ratio of dimethylarsenic (DMAs) to methylarsonic (MAs) and with %DMAs in urine. Thus, an increased capacity to convert iAs to DMAs may be a risk factor for CM disease in individuals exposed to iAs. Prospective studies are needed to examine causality of the association of CM risk with iAs exposure and to determine if iAs metabolism can modify this risk.

1315 Inorganic Arsenic Suppresses Mast Cell Degranulation via a Pathway Target Upstream of Calcium Signaling

J. Shim1, R. Kendry1, L. Weatherly2, L. Hutchinson1, J. Pelleiter1, B. Evans1, H. Hashimi1, K. Blais1 and J. A. Goessl1. Molecular and Biomedical Sciences, University of Maine, Orono, ME and 2Graduate School of Biomedical Science and Engineering, Orono, ME.

Exposure to Arsenic (As) is a global concern and is linked to many diseases. Many millions of people worldwide are exposed to elevated levels of arsenic through drinking water, food, and other sources. Using a well-characterized mast cell model (RBL-2H3 cells), we previously demonstrated that inorganic Arsenic inhibits antigen-mediated mast cell degranulation. Found in the vast majority of human tissues, mast cells are critical players in numerous diseases, including allergy, asthma, infectious disease, cancer, and even many central nervous system disorders such as autism and anxiety. Mast cells secrete myriad effectors from cytoplasmic granules such as histamine and β-hexosaminidase. The present studies have been performed in order to investigate arsenic’s molecular target in the degranulation pathway. We have found that Arsenic does not affect F-actin membrane ruffling of RBL-2H3 cells stimulated with antigen, suggesting that arsenic’s target is not common to both the ruffling and degranulation pathways. We found that Arsenic dampsens calcium influx, as measured by Fura-2 fluorescence. When stimulating degranulation while bypassing early signaling events, via the use of thapsigargin or calcium ionophore, we found no Arsenic effect on the degranulation response. Using an alternative, non-IEG-mediated mast cell stimulant, G-protein activator compound 48/80, we observed no Arsenic effect degranulation. Taken together with our earlier data showing an inhibition of IEG-mediated degranulation, this result suggests that arsenic’s target in the degranulation pathway is upstream of calcium influx, protein kinase C, phospholipase D, and actin ruffling. Recently, we investigated arsenic’s effect on phosphorylation using a sandwich ELISA and the data suggests that arsenic may be interfering with the phosphorylation of the early kinase Syk.

1316 Arsenic-Induced ROS/RNS Generation Causes Zinc Loss and Inhibits the Activity of Poly(ADP-Ribose) Polymerase-1

X. Zhou1, F. Wang2, W. Liu1, X. Sun1, C. Chen1, L. G. Hudson1 and K. Liu1. College of Pharmacy, University of New Mexico, Albuquerque, NM and 2Department of Nutrition and Food Hygiene, Fourth Military Medical University, Xi’an, Shaanxi, China.

Arsenic enhances the genotoxicity of other carcinogenic agents such as ultraviolet radiation and benzo[a]pyrene. Recent reports suggest that inhibition of DNA repair is an important aspect of arsenic cocarcinogenesis, and DNA repair proteins...
such as poly(ADP ribose) polymerase (PARP)-1 are direct molecular targets of arsenic. Although arsenic has been shown to generate reactive oxygen/nitrogen species (ROS/RNS), little is known about the role of arsenic-induced ROS/RNS in the mechanism underlying arsenic inhibition of DNA repair. We report herein that arsenic-generated ROS/RNS inhibits PARP-1 activity in cells. Cellular exposure to arsenic, as well as hydrogen peroxide and NONOate (nitric oxide donor), decreased PARP-1 zinc content, enzymatic activity, and PARP-1 DNA binding. Furthermore, the effects of arsenite on PARP-1 activity, DNA binding, and zinc content were partially reversed by the antioxidant ascorbic acid, catalase, and the NOS inhibitor, aminoguanidine. Most importantly, arsenite incubation with purified PARP-1 protein in vitro did not alter PARP-1 activity or DNA-binding ability, whereas hydrogen peroxide or NONOate retained PARP-1 inhibitory activity. These results strongly suggest that cellular generation of ROS/RNS plays an important role in arsenite inhibition of PARP-1 activity, leading to the loss of PARP-1 DNA-binding ability and enzymatic activity.

1317 Protective Role of Vitamin E Succinate and Selenite in Arsenic-Itoxicated Hamster: Arsenic-Induced Oxidative Stress and Its Reversible Damage

A. Sampayo-Reyes1, R. Dauder2 and A. Hernandez2. 1Toxicology and Pharmacology, Centro de Investigaciones Biomedicas, Monterrey, Nuevo Leon, Nuevo Leon, Mexico and 2Genetic, Universitat Autonomas de Barcelona, Barcelona, Bellatera, Spain.

We studied the effects of combined exposure to arsenic, selenite and vitamin E succinate. (i) oxidative stress and its correlation with glutathione and linked enzymes; (ii) alterations in the structural integrity of DNA with assay comet; and (iii) biochemical parameters. Efficacy of selenium and alpha-tocoopherol succinate in reducing these changes was also determined. Hamsters were exposed to sodium arsenite, 100 ppm of arsenite via drinking water. Co-treatment with 8.5 mg/Kg/day of selenite or 6 mg/Kg/day of vit E was also carried out to assess whether those compounds exert any protective role, individually and in combination for twenty weeks. The samples of whole blood were collected at 24hrs and 20 week post-treatment and the assay was carried out to determine DNA damage as represented by comet tail-length and biochemical parameters assay. Arsenic species were measured in the urine by HPLC-ICP/MS. Exposure to arsenic altered the levels of oxidative stress enzymes. These changes were accompanied by increased reactive oxygen species (ROS) levels. Arsenic exposure led to a significant depletion of super oxide dismutate (SOD) activity with no effect on catalase and glutathione peroxidase (GPs) activities. The distribution of DNA migration revealed that the hamster exposed to arsenic showed more DNA damage than samples obtained from control. The results demonstrate a As toxic effect, and a noticeable preventive effect of both vit E and selenite, coexposure had additional beneficial effects in restoring altered bio-chemical variables, maintaining pro-oxidant/antioxidant balance. Our experiments indicate the significant protective action of vitamin e succinate and sodium selenite on arsenic-induced toxicity in the hamster.

1318 Prenatal Arsenic Exposure and the Epigencode: Altered microRNAs Associated with Innate and Adaptive Immune Signaling in Newborn Cord Blood

J. E. Rager1, K. Bailey1, L. Smeester1, S. K. Miller1, J. E. Laine2, Z. Drobna3, J. Currie4, C. Douillet1, A. F. Oldham1, M. Rubio-Andrade5, M. Styblo6, G. G. Garcia-Vargas3 and R. Fry7,8. 1Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC, 2Department of Epidemiology, University of North Carolina, Chapel Hill, NC, 3Department of Nutrition, University of North Carolina, Chapel Hill, NC, 4Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and 5Facultad de Medicina, Universidad Juárez del Estado de Durango, Gómez Palacio, Durango, Mexico.

The Biomarkers of Exposure to ARsenic (BEAR) pregnancy cohort in Gómez Palacio, Nuevo León, Mexico and 2Genetics, Universitat Autonomas de Barcelona, Barcelona, Bellatera, Spain.

This work is supported by NIEHS grants R15ES021587 (H.X.) and ES016893 (K.K.M.).

Arsenic is a toxic metal that is widely used in the semiconductor industry, and is naturally present in the environment, including water, soil, and food. Prenatal exposure to arsenic has been shown to be associated with increased risk of cancer and other health outcomes in children. The epigenome, which includes DNA methylation and non-coding RNA molecules, is thought to play a role in the health effects of arsenic exposure. In this study, we focused on microRNAs (miRNAs), a class of non-coding RNA molecules that regulate gene expression. We measured miRNA expression in newborn cord blood samples from the BEAR cohort, to identify miRNAs that are altered by prenatal arsenic exposure.

We found that prenatal arsenic exposure was associated with changes in the expression of several miRNAs. These miRNAs are involved in various biological processes, including immune response, cell cycle regulation, and DNA damage repair. For example, miR-15a and miR-16, which are involved in DNA repair, were upregulated in newborns of arsenic-exposed mothers. This suggests that these miRNAs may play a role in increasing the risk of cancer and other health outcomes associated with prenatal arsenic exposure.

1319 Arsenic Exposure Increases Monocytes Adhesion to the Vascular Endothelium, a Pro-Atherosclerotic Mechanism

M. Lemaire1, R. M. Krohn2, L. Negro Silva3, C. A. Lemarié4, M. Flores Molina1, S. Lehoux4, J. E. Smits2 and K. K. Mann1. 1Oncology, McGill University, Montreal, QC, Canada, 2Ecosystem and Public Health, University of Calgary, Calgary, AB, Canada, 3Experimental Medicine, McGill University, Montreal, QC, Canada and 4Medicine, McGill University, Montreal, QC, Canada.

Arsenic exposure is linked epidemiologically to increased atherosclerosis, but the mechanisms by which arsenic enhances atherosclerosis are unknown. Monocytes, macrophages and platelets are key players in the early stage of an atherosclerotic lesion. Circulating monocytes and macrophages bind to the activated endothelium of vessels and migrate into the sub-endothelium where they become lipid-laden foam cells. This process can be facilitated by platelets, which favour monocyte recruitment to the lesion. Thus, we assessed the effects of arsenic exposure on platelet activation, platelet-monocyte aggregation and monocyte adhesion to endothelial cells. We observed no effect of arsenic on platelet activation or platelet-monocyte aggregation. Then, we assessed the monocyte adhesion to VCAM-1, an adhesion molecule normally found on activated endothelial cells. We found that 1) monocyte and macrophage adhesion to VCAM-1 is increased by arsenic; 2) the surface expression of the β1 integrin (CD29) that binds to VCAM-1 is increased on macrophages by arsenic; and 3) these effects can be inhibited by antioxidants. We extended these results using a co-cultured model of human endothelial and mononuclear cells and an ex vivo organ culture system. We found that both cell types need to be exposed to arsenic to maximize monocyte adhesion in a dose-dependent manner, at concentrations as low as 10 ppb. Finally, we assessed the CD29 level on circulating monocytes in mice exposed to arsenic. Arsenic increased mononuclear CD29 levels as compared to control animals, and addition of high selenium diet decreased CD29. Together, these data suggest that arsenic enhances atherosclerosis by increasing monocyte adhesion to endothelial cells, a process that is inhibited by antioxidants.

1320 Synergistic Effect of Arsenic on Hexavalent Chromium Cytotoxicity and Genotoxicity in Human Lung Cells

Hexavalent chromium (Cr(VI)) and inorganic arsenic are well known environmental and occupational hazards and are often found as mixed contaminants and wastes. Both of them are known human lung carcinogens. Despite that people are exposed to these metals simultaneously under most conditions, little is known about the potential co-exposure impact. Arsenic is known to inhibit DNA damage repair and our previous studies show that Cr(VI) induces DNA double strand breaks and neoplastic transformation in human lung cells. Thus, it is likely that co-exposure to Cr(VI) and arsenic could cause greater toxic effect. The objective of this study is to determine the ability of arsenic to increase Cr(VI) genotoxicity and carcinogenicity in human lung cells. We found that arsenic has a synergistic effect on Cr(VI) cytotoxicity. 0.5 μM arsenic alone induces 14 percent of relative cell death. Cr(VI)-induced cell death is increased from 32. 50 and 62 to 47, 65 and 80 percent of relative cell death, respectively after co-exposure to 0.5 μM arsenic and 0.1, 0.5 and 1 μg/cm² lead chromate. Arsenic has a similar effect on soluble Cr(VI) compound, sodium chromate. Arsenic also causes an increase in Cr(VI)-induced chromosome aberration. 0.5 μM arsenic alone induces 9 metaphases with chromosome damage. When co-treated with 0.01, 0.05 and 0.1 μg/cm² lead chromate, the number of metaphase with damage increased from 5, 6 and 19 to 16, 16, and 31, respectively. These data suggest that co-exposure to Cr(VI) and arsenic induces a synergistic toxic effect in human lung cells. Further work will include assessing the effect of arsenic on Cr(VI)-induced DNA double strand break and repair. This work is supported by NIEHS grants R15ES021587 (H.X.) and ES016893 (J.F.W.).
1321 Tissue Distribution and Excretion of Arsenic and Selenium following Co-Administration of Diphenylarsinic Acid and Selenite in Rats

Diphenylarsinic acid (DPAA) is a chemical precursor as well as a degradation product of arsenic-containing chemical weapons such as diphenylarsine chloride. Toxicological findings on DPAA are limited as compared to inorganic arsenicals (iAs). Selenium (Se) is an essential element, and is known to interact with arsenic. We investigated metabolic interactions between Se and As in rats co-administered with DPAA and selenite in this study. Male Sprague-Dawley (SD) rats were injected intravenously with DPAA, selenite or co-administered with As and Se, at a dose of 1.0 mg As or 1.0 mg Se/kg body weight, and urine and feces were collected separately for 24 h using metabolic cages. In a separate experiment SD rats were anesthetized with sodium pentobarbital, the bile duct was cannulated, and DPAA or/and selenite were administered intravenously at a dose of 1.0 mg As or 1.0 mg Se/kg body weight to study biliary excretion of Se and As. The bile fluid was collected on ice for 30 min up to 3 h after the injection. The animals were sacrificed by withdrawing blood from the abdominal aorta under anesthesia at 24 or 3 h after the injection, and heparinized blood and tissue samples were collected. Selenium significantly reduced concentration of As in plasma 24 h after the administration. DPAA significantly reduced distribution of Se in kidney, and yet significantly increased excretion of Se into urine 24 h after the administration. On the other hands, selenium significantly reduced the biliary excretion of DPAA, and DPAA significantly increased the biliary excretion of selenium in 30 min after the administration and then significantly reduced the biliary excretion when DPAA and selenite were co-administered. DPAA significantly increased distribution of Se in whole blood, and significantly reduced distribution of Se in liver; however, distribution of As to blood and liver was not influenced by selenite 3 h after the administration. These results suggest that DPAA interacted with Se, and changed distribution and excretion of these metalloids each other in rats.

1322 Increased Expression of the Proto-Oncogene Anterior Gradient 2 in the MCF-10A Cell Line by Arsenite Exposure

J. Van Giesen, S. H. Garrett, D. A. Sens and S. Somji. Pathology, University of North Dakota, Grand Forks, ND.

Arsenite and cadmium are environmental carcinogens that have been implicated in various cancers. Previously, our laboratory has shown that arsenite and cadmium can cause malignant transformation of the immortal human epithelial cell line MCF-10A. Microarray analysis of the transformed cells revealed an over-expression of the gene Anterior Gradient 2 (AGR2). These findings are significant since AGR2 is known to be overexpressed in estrogen receptor positive breast cancers. AGR2 is a proto-oncogene protein that is highly expressed in a variety of human cancers. It is known to play a role in promoting cellular transformation, tumor growth as well as metastasis. In this study, we validated the expression level of AGR2 in the parent MCF-10A cell line and in the arsenite and cadmium transformed MCF-10A cells using PCR and Western analysis. The data obtained indicated that the expression of AGR2 was significantly increased in the arsenite transformed cells compared to the cadmium transformed cells. We were also interested in determining if exposure to arsenite or cadmium could increase the expression of AGR2 in the parent MCF-10A cells. For this purpose MCF-10A cells were exposed to 4, 8 or 16 μM arsenite or 2, 4, or 6 μM cadmium for 48 hrs and the expression levels of AGR2 were determined. The data obtained showed that exposure to arsenite resulted in a significant increase in the expression of AGR2, whereas exposure to cadmium had no effect on the expression level of AGR2. These results suggest that arsenite has the potential to induce the proto-oncogenic protein AGR2, the expression of which may increase the metastatic potential of the cancer cells.

1323 The Prebiotic Oligofructose Protects against Enhanced Liver Injury Caused by Arsenic in a Model of NASH

Arsenic, a ubiquitous drinking water contaminant, tops the ATSDR list of hazardous environmental chemicals and is a known hepatotoxin. This group showed that subhepatotoxic doses of arsenic sensitizes the liver to experimental non-alcoholic fatty liver disease (NAFLD) caused by a high fat diet (HFD). It is now strongly suspected that an altered gut flora plays an important role in NAFLD. Indeed, prebiotics (oligofructose; OFC), protect against experimental NAFLD, and correlate with repletion of commensal bacteria (e.g., Bifidobacteria spp.) in the GI tract. The purpose of the current study was to test the hypothesis that OFC protects against enhanced liver injury caused by arsenic in experimental NAFLD. Accordingly, male C57Bl/6j mice were fed low fat diet (LFD), HFD or HFD containing OFC during concomitant exposure to either tap or arsenic-containing water for 10 wks. Abundance of bacteria in cecal contents was determined by qPCR. Histological changes were determined by hematoxylin and eosin staining. Macrophage activation and fibrin deposition were determined by immunostaining. HFD caused fatty liver injury, as characterized by an increase in liver/body weight ratio, steatosis and transaminases. Arsenic synergistically enhanced HFD-induced liver damage, inflammation, and fibrin deposition. HFD and arsenic alone both altered content of cecal bacteria, and both decreased the abundance of Bifidobacterium spp; OFC supplementation protected against this effect. OFC supplementation also protected against the enhanced liver damage, inflammation, and fibrin accumulation caused by the combination of HFD and arsenic. These results indicate that enhanced HFD-induced liver damage caused by arsenic may be mediated, at least in part, by GI tract dysbiosis and that prebiotic supplementation may confer significant protective effects. Together, these data support our hypothesis that arsenic-mediated changes in the GI tract flora play an important factor in sensitizing the liver to injury.

1324 Metabolomics Signature of Inorganic Arsenic-Associated Diabetes: Links to Amino Acid Metabolism

E. M. Sebastian1, K. Bailey1, C. González-Horta2, B. E. Sánchez Ramírez2, L. Ballinas-Casarrubias2, M. Ishida3, D. Gutiérrez Torres2, R. Hernández Cerón3, D. Viniegra Morales2, F. Baeza Terrazas2, L. M. Del Razo4, G. G. García-Yargas5, R. Saunders6, W. Jia7, B. B. John7, D. Loomis8, Z. Drobna9, M. Styblo1 and R. Fry1. School of Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, 1Universidad Autónoma de Chiuhuahua, Chihuahua, Mexico, 2Colegio de Medicina, Universidad Autónoma de Chihuahua, Chihuahua, Mexico, 3Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional, Chihuahua, Mexico, 4Universidad Juárez del Estado de Durango, Gómez Palacio, Mexico, 5University of Hawaii Cancer Center, Honolulu, HI, 6School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC and 7International Agency for Research of Cancer, Monographs Section, Lyon Cedex, France.

The Chihuahua Cohort was established to study chronic disease associated with exposure to inorganic Arsenic (iAs) in drinking water, specifically diabetes mellitus (DM). The present study profiled the metabolic shifts in a group of individuals selected from this cohort (91 diabetics and 86 non-diabetics) using both LC-MS and GC-MS platforms. Exposure to iAs was characterized by iAs levels in drinking water (DW), and by the sum of iAs metabolites in urine (U-iAs). Fasting plasma glucose (FPG) and 2-hour plasma glucose (2HBG) were recorded by a glucose tolerance test and were used to determine an individual’s DM status. Levels of DW-iAs ranged from 0 to 419.7 μg/L, and U-iAs level ranged from 4.69 to 445.2 μg/L. Both urine and plasma metabolite levels were analyzed as they related to DM, iAs exposure or iAs-associated DM. Metabolites that were identified that specific to iAs exposure, as well as to DM. Notably, a metabolomic signature of 23 metabolites was identified that distinguish iAs-associated DM. These metabolites reflect changes not only in glucose, but also in amino acid metabolism, providing additional evidence that iAs-associated DM may differ from the common type-2 DM.

1325 Inorganic Arsenic Exposure and Bone Loss in Normal and Hypertensive Rats

C. Wu1, B. Chen1, H. Wui1, C. Chiu1, R. Yang2, Y. Chen1, C. Huang3 and S. Liu1. 1Institute of Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan, 2Department of Orthopedics, College of Medicine and Hospital, National Taiwan University, Taipei, Taiwan, 3Department of Physiology and Graduate Institute of Basic Medical Science, College of Medicine, China Medical University, Taichung, Taiwan and 4Graduate Institute of Chinese Medical Science, School of Chinese Medicine, College of Chinese Medicine, China Medical University, Taichung, Taiwan.

Exposure to inorganic arsenic through drinking water is a major international public health issue. It can be absorbed via digestive tract or skin and then accumulated in the variant target organs to disturb tissues functions. Previously epidemiological studies showed that arsenic exposure from drinking water could increase vascular disorders to elevate blood pressure or decrease bone mineralization. However, whether arsenic exposure from drinking water enhances the loss of bone mineralization during hypertension disease remains unclear. Here, we examined the changes of bone morphology and bone mineral density in normal (WKY) and spontaneously hypertensive rats (SHR) after exposure to inorganic arsenic from drinking water using micro-computed tomography (micro-CT) analysis. Rats were exposed with arsenic trioxide (As2O3) from drinking water for three months. The results showed that arsenic exposure obviously increased blood pressure in WKY.
rats and significantly enhanced blood pressure in SHR rats in a dose dependent manner. The results of micro-CT-derived bone morphology and density measurements showed that connectivity density, trabecular thickness, bone volume, trabecular bone number, trabecular separation, and bone mineral density were significantly changed in both WKY and SHR rats. However, no significant differences were observed in these bone parameters between SHR and WKY rats. Taken together, these results suggest that inorganic arsenic is capable of inducing bone loss in normal and hypertensive rats, but hypertension condition seems not to enhance the arsenic-induced bone loss.

1326 In Vivo Mutagenicity Assay of Arsenite Using Gpt Delta Transgenic Mice

S. Takumi1, 2, Y. Aoki1, T. Sano1, T. Suzuki, T. Nohmi1 and K. Nohara1.
1National Institute for Environmental Studies, Tsukuba, Japan; 2The Jichi University School of Medicine, Tokyo, Japan and 3National Institute of Health Sciences, Tokyo, Japan.

While arsenic has been classified as a Group 1 human carcinogen by the International Agency for Research on Cancer (IARC), the mutagenicity in animal model has not been fully characterized. The aim of this study was to assess the in vivo mutagenicity of arsenite in C57BL/6J gpt delta mice. Male gpt delta mice were given drinking water containing 85 ppm sodium arsenite for 3 weeks, and the hepatic genome was assayed for mutations 2 weeks later. The result of gpt mutation assays showed a significant increase in mutation frequency in the liver following arsenite exposure. Analysis of the mutation spectra revealed that 67% of mutations detected were G:C to A:T transitions and 6% were G:C to T:A transversions in both control and treated groups. In contrast, arsenite exposure resulted in a markedly higher rate of G:C to T:A transversions (46% of mutations detected). G:C to T:A transversions have been reported to be induced following formation of 8-hydroxy-2'-deoxyguanosine (8-OHdG), one of the major forms of oxidative DNA damage. We also detected a significant increase in 8-OHdG in the livers of the mice exposed to arsenite. These results demonstrate that arsenite induces G:C to T:A transversions through oxidative-stress-induced 8-OHdG formation in vivo. We also discuss the results of the DNA methylation analysis of gpt gene and the expression analysis of DNA repair genes.

1327 N-Cadherin Up-Regulation in Arsenite and Cadmium-Transformed Urothelial Cells

E. Sandquist, X. Zhou, S. Somji, D. A. Sens and S. H. Garrett. Pathology, University of North Dakota, Grand Forks, ND.

The switch from E- to N-cadherin is a well-known indicator of the epithelial-to-mesenchymal transition occurring in bladder cancer. N-cadherin upregulation is correlated with tumor stage, increased recurrence, and decreased survival in patients. While the factors mediating the decrease in E-cadherin expression are well-established, little is known of the factors regulating the increase in N-cadherin expression. Environmental agents are the common cause of bladder cancer. Specifically, arsenic and cadmium are known carcinogens and implicated in the development of bladder cancer. Previous studies from our laboratory have shown that arsenic and cadmium can cause malignant transformation of normal immortalized bladder urothelial cells. These transformed cells can form tumors when injected subcutaneously or intraperitoneally into nude mice. The goal of the present study was to determine if there was a difference in expression levels of E- and N-cadherin in the transformed cell lines and the tumor heterotransplants. For this purpose real-time PCR was performed on RNA samples isolated from the transformed cell lines and the tumor heterotransplants. Western analysis was performed to determine the protein levels whereas immunohistochemical analysis was performed to determine the localization of the proteins within the tumor heterotransplants. The results obtained show that E-cadherin is expressed in the transformed cell lines as well the tumor heterotransplants. The expression of N-cadherin was very low in the parent UROtsa cells whereas the levels increased in the transformed cell lines. The expression level of N-cadherin decreased in the tumor heterotransplants compared to the cell lines. An interesting finding was the focal expression of N-cadherin in the intraperitoneal tumors suggesting that heavy metal exposure promotes the epithelial-to-mesenchymal phenotype and bladder cancer progression.
6 until birth. Mice were maintained on normal chow and water for 36 weeks. Weight and metabolic end-points were evaluated throughout the study. Blood plasma analysis demonstrated that in-utero (IU) arsenic-exposed mice exhibited a significant increase in blood glucose levels between weaning age and 4 months of age, relative to those elevated after 8 months. On the other hand, glucose levels in control mice did not change over time. Similarly, IU arsenic-exposed mice showed a consistent elevation in total cholesterol, as well as LDL cholesterol at weaning age, 4 months and 8 months of age, when compared to control mice. Further analysis demonstrated the development of nonalcoholic fatty liver disease in IU arsenic-exposed mice, as evidenced by major morphological changes and an increase in steatosis concomitant with hepatocellular ballooning. Growth rates were not statistically different; however, IU arsenic-exposed mice showed a trend of heavier weights when compared to control mice. Taken together, these results suggest that IU arsenic exposure is a possible contributor to metabolic syndrome onset in mice.

**354 SOT 2014 Annual Meeting**

**1327d Biological and Behavioral Modifiers of Urinary Arsenic Metabolic Profiles in a US Population**

Relations between intensity of arsenic exposure from home tap water and levels of inorganic As (iAs) and its mono- (MAs) and di-methylated (DMAs) metabolites were examined in urine from 903 individuals ≥ 45 years of age who resided in Churchill County, Nevada, continuously for 5 or more years. Over a wide range of exposures (home tap water supplies contained <3 to 1200 μg of As per liter), concentrations of iAs, MAs, and DMAs strongly correlated with concentrations of As in home tap water. However, percentages of the summed iAs, MAs, and DMAs concentrations in urine accounted for by each species were unaffected by home tap water As concentration, suggesting that capacity for formation and excretion of methylated metabolites was not exceeded. Mean urinary iAs, MAs, and DMAs concentrations were significantly lower (P<0.001) in urine of women than in men; women had significantly lower iAs and MAs (P<0.005) and significantly higher DMAs percentages (P<0.0001) in urine than men. Age did not affect concentration of any arsenic in urine, although there were significant age-related trends for decreased iAs percentage (P<0.0002) and increased DMAs percentage (P<0.01). Body mass index (BMI) did not affect iAs, MAs, or DMAs levels in urine but BMI was significantly associated (P<0.01) with lower MAs percentage and increased DMAs percentage. Smoking status (assessed by urinary cotinine levels) was associated with significant trends for urinary iAs, MAs, or DMAs concentrations and for iAs, MAs, or DMAs percentages (P<0.05). These results indicate that among older Americans with a wide range of exposure to iAs from home tap water, both biological factors (gender, age, BMI) and behavioral factors (smoking) can affect profiles of arsenicals found in urine. These modifiers may contribute to interindividual and interpopulation variation in response to chronic exposure to As from water and other media. (This abstract does not reflect U.S. Environmental Protection Agency policy.)
Manganese (Mn) is an essential element, however exposure to high Mn levels may affect structures of the basal ganglia, leading to motor impairment similar to Parkinson’s disease. The molecular mechanisms underlying Mn neurotoxicity, particularly in the developing central nervous system (CNS), need further investigation. Our goal was to investigate whether early-life exposure to Mn affects motor coordination and cognitive function in adulthood. Male Wistar rats were exposed to saline (control) or intraperitoneal MnCl₂ (5, 10 or 20 mg/kg) injections from post-natal day (PND) 8 up to 12. Behavioral tests were performed on PND 60-63. Motor coordination was assessed in the rotarod. Object recognition task was used to evaluate short-term memory. Biochemical analysis of the striatum was performed on PND 70. Rats exposed to the highest Mn dose failed to recognize a familiar object when replaced by a novel object (p<0.05), attesting memory impairment. These effects were accompanied by decreased levels of non-protein thiols, e.g. glutathione (p<0.05), and increased levels of glial fibrillary acidic protein (GFAP) (p<0.05) in the striatum. This study documents that acute low-level exposure to Mn during critical neurodevelopmental period induces cognitive and motor dysfunctions that last into adulthood.

nucleus accumbens, striatum, hypothalamus, olfactory bulb) were evaluated in one pup/ gender/litter to preclude litter effects. Blood and brain Hg increased with increasing MeHg exposure; corticosterone levels were not influenced by MeHg or PS. Instances of non-linear monamine concentration-effect curves with MeHg occurred in virtually every brain region, particularly in females. Hg altered mEPSCs at 0.5 ppm, but not at 2.5 ppm. Further, multiple monamine changes were seen only in the presence of MeHg + PS, particularly in striatum and frontal cortex in males, and hippocampus and nucleus accumbens in females. In females, MeHg+PS reduced hippocampal monoamines, and increased nucleus accumbens and olfactory bulb monoamines, whereas MeHg-PS decreased frontal cortex and striatum monoamines males. These results demonstrate that PS can enhance the neurotoxicity of MeHg. Consequently assessment of neurotoxic risk in the absence of PS may underestimate its hazardousness. These findings underscore the need to develop animal models more reflective of the multiplicity of risk factors in the human environment. Further, the non-linearity of MeHg effects raises concerns in relation to human health risk assessment. EPA RD 83457001

1334 Preliminary Characterization of Neuroantibody (NAb) Associations with Hg and PCB in 7-Year-Old Faroese Children with Prenatal Exposure to Seafood Neurotoxins C. Osuna1, P. Weihe2, P. Grandjean1,3 and H. A. El-Fawal4.

Preclinical studies of neurotoxicity and human studies of neurodegeneration suggest that NAb may be useful biomarkers of insult. In a proof-of-concept study, archived sera from 38 children at the age of 7 (16 males; 22 female) were randomly selected from a birth cohort established in 1986-1987 as part of the Children’s Health and the Environment in the Faroes. Maternal hair-Hg [Mg7: geometric mean (IQR)]; 5.8 (2.6-10.9) μg/g, cord blood-Hg [Cord-Hg7; IQR: 4 (1.1-6.4) μg/L] and cord blood-PCB [Cord-PCB7; IQR: 0.3-3.2 (9) μg/L] indicated no prenatal exposure. Blood-Hg [Hg7; IQR: 3.5-5.2 (2.8) μg/L] and serum-PCB [PCB7; IQR: 6 (0.97-2.9) μg/L] at the age of 7, current exposure indicators, were used. Titters of IgM and IgG against neurolamine (NF-L), NF-M, NF-H, cholineacetyltransferase (ChAT), GFAP, MBP, desmin (D) and actin (A) were measured. Positive associations (r=0.3-0.5; p<0.01) were observed for IgM titters against NF-L, NF-H, GFAP, MBP (and IgG), ChAT and A with Hg7. Higher titters of anti-NF-H and MBP, IgG, and anti-A and D, IgM, in girls were not significant (p=0.06-0.9). Stratification by Hg7 (or >10 μg/g) or Cord-Hg7 (or >60 μg/g) indicated higher anti-NF-M and GFAP, IgM, while stratification by Hg7 (or >10 μg/g) indicated higher anti-NF-L, NF-M, GFAP, MBP, ChAT and D, IgM, and anti-NF-M and GFAP, IgG (p<0.05) at higher exposure. Differences in anti-NF-M, GFAP, ChAT, D and IgM, and GFAP, IgG, occurred at higher levels of PCB7 (or >10 μg/L). Multivariate regression indicated that Hg7 is the major determinant of NAb. After controlling for Cord-Hg, Cord-PCB, and PCB7, 8 of 16 NAb were significantly positively associated with Hg7. Taken together, this study suggests that NAb may be useful biomarkers of NS insult resulting from Hg exposure. This warrants further testing in a larger cohort with the incorporation of neurobehavioral assessment.

1335 Ontogeny of Fc-Gamma Receptors in the Developing Rat Brain P. Lein and M. Stamos. Molecular Biosciences, School of Veterinary Medicine, UC Davis, Davis, CA.

Immunoglobulin G (IgG) antibodies that cross-react with intracellular antigens in the developing brain have recently been identified in an experimental animal model of developmental mercury toxicity and in mothers at risk for having a child with autism. But whether these autoantibodies interfere with neuronal development remains controversial, in part because it is not clear how IgG would access an intracellular neuronal target. Fc receptors (FcR) bind the constant (Fc) region of immunoglobulin G (IgG), and mediate uptake of IgG and cellular responses triggered by IgG binding in immune cells. This raises the question of whether neurons in different brain regions also express functional FcR. Investigation of FcR expression by RT-PCR indicated that transcripts of FcRI, FcRIIa, FcRIIb, FcRIII and the neonatal FcRn are expressed in the cortex, hippocampus and cerebellum of naïve male and female rat pups on postnatal days (PND) 2 and 7, but at lower levels than in the liver and spleen. Transcript levels did not vary significantly as a function of sex or age, with the following exceptions: (i) FcRIIa and FcRIII were downregulated by PND7 in the spleen but not in brain or liver; (ii) FcRn was upregulated in the cerebellum but downregulated in the spleen at PND7 compared to PND2. To determine cell-specific expression, we also performed RT-PCR of these five FcR isoforms in primary cultured cortical and hippocampal cells. All five transcripts were detected in both cell culture models at days in vitro ranging from 2 to 21. Immunocytochemical analysis indicates that FcRI and FcRII are predominately expressed in neurons; whereas FcRII FcRIII and FcRn are predominantly expressed in astrocytes. We are currently designing assays to assess whether these receptors are functional in neurons. In summary, our data confirm that FcR are expressed at the transcript and protein level in neurons and glial cells in different regions of the rat brain during neurodevelopment. This work supported by NIH grants R01 ES014901 and P4Z ES04699.

1336 Developmental Lead Exposure and the Exacerbation of Alzheimer’s Pathology: An Immunological Analysis A. vanderEmde, D. Johnson, J. N. Franklin, Q. Hu and J. DeWitt. Physiology and Toxicology, Brody School of Medicine, East Carolina University, Greenville, NC.

Although Alzheimer’s disease (AD) is typically a late-onset neurodegenerative disorder, there may be a period of susceptibility early in brain development which, if disrupted, may exacerbate the disease pathology. We hypothesize that early exposure to a known neurotoxic and immunotoxic chemical, such as lead acetate, may alter microglia function and/or phenotype during this critical window of development, which then promotes amyloidosis or decreases microglia phagocytosis of amyloid-β, the protein associated with AD neuropathology. The exact mechanism by which microglia are involved with amyloid-β deposition or removal is currently contested in the scientific literature, although there is significant evidence for the colonization of microglia and amyloid-β plaques. We investigated this “double-hit” model of the concurrent effects of environmental toxicant exposure and critical windows of development susceptibility through the use of a genetically predisposed triple transgenic mouse model (3XTgAD). Pups were orally gavaged with 100 parts per million of lead acetate and vehicle from postnatal day (PND) 5-15, a known postnatal period of vulnerability for microglia. At PND50, 90, and 180, hippocampus was isolated from brains of treated and control animals and stored for further analysis of microglia colonization with amyloid-β. The remaining brain tissue was processed to measure microglial activity by flow cytometry. Activity of microglia from treated animals was increased relative to control animals. These initial data suggest that early-life exposure to an environmental agent, when given during a critical window of microglia maturation, changes microglial activity. We believe that these changes in activity alter the course of AD neuropathologies.

Lead exposure has been implicated in the impairment of synaptic transmission and plasticity in the developing hippocampus. However, the mechanism remains unclear. Here we investigated whether chronic lead exposure during development affected hippocampal dendritic spine formation and synapse strength and if the Wnt signaling pathway was involved. Sprague–Dawley rats were exposed to lead only during lactation. The lead-exposed pups acquired lead via milk of dams whose drinking water contained 0.2% (1090 ppm) lead acetate from parturition to weaning, while the control dams remained on distilled water throughout the lactation period. Hippocampal lead accumulated significantly in lead-exposed rats (0.471 ± 0.11 μg/g) compared with the controls (0.021 ± 0.002 μg/g). Golgi-Cox staining method was used to examine the spine density of hippocampal CA1 pyramidal neurons in postnatal (PND) 14 and PND21 rats. Lead significantly down-regulated the spine density in both age groups. This was accompanied by a significant age-dependent decline of Wnt7a expression and stability of its downstream protein following chronic lead exposure. Furthermore, in cultured hippocampal neurons lead (0.1 and 1 μM lead acetate) significantly decreased the spine density in a dose-dependent manner. Exogenous Wnt7a application restored the frequency of miniature excitatory postsynaptic currents (mEPSCs) in the Pb2+-treated cultures back to control levels. Additionally, the lead-induced decrease in the spine density was attenuated by Wnt7a, which also increased the stability of the downstream molecules in the Wnt signaling pathway. Our results suggest that lead negatively impacted spine growth and synaptic transmission of the developing hippocampus through alteration of the presynaptic Wnt7a signaling. [Supported by the National Key Basic Research Program of China (973 Program, No. 2012CB525003).]
Lead (Pb) is a non-essential toxic heavy metal; its use in industrial applications is widespread and has resulted in an increased risk of human environmental exposure. Multiple organs are targets of Pb toxicity; however, the central nervous system (CNS) is most sensitive during early development due to rapid cell proliferation and migration, axonal growth, and synaptogenesis. One of the primary components of CNS development is the GABAergic system. Gamma-aminobutyric acid (GABA) is the primary inhibitory neurotransmitter in the adult brain. However, during early development GABA functions as an excitatory neurotransmitter which contributes to cell proliferation, neuronal differentiation and migration, and synaptogenesis. Studies report the effects of Pb on GABA in the mature brain, but little is known regarding the adverse effects of Pb exposure on the GABAergic system during embryonic development. To characterize the effects of developmental Pb exposure on the GABAergic system, zebrafish embryos were exposed to 10, 50, or 100 ppb (ug/l) Pb or a control treatment shortly after fertilization through 24, 48, 60, or 72 hours post fertilization (hpf). A dose-response was observed between Pb exposure and tissue uptake in zebrafish larvae. Genetic analysis showed that developmental Pb exposure caused either an increase or a decrease in mRNA expression of seven genes (gad2, gad1b, gaba2a, gaba2b, gat-1, gat-3, vgat) throughout the GABAergic pathway that was developmental time point and dose specific. GABA levels were analyzed and also revealed dose and time point specific alterations. These data provide evidence indicating that changes in gene expression throughout the GABAergic pathway do not cause similar immediate alterations in GABA levels and that the compensatory response of the GABAergic system is highly dependent upon dose and developmental time point. These data provide a framework for further analysis of the effects of Pb on the GABAergic system during the excitatory phase and transition to an inhibitory neurotransmitter during development.
Links between autism, schizophrenia, and cognitive decline and exposure to ambient air pollution have been reported. Ultraviolet (<100nm) particles are considered the most toxic of ambient particulates. To determine potential neurotoxicity of concentrated ambient ultraviolet particles (CAPS) to developing brain, mice were exposed to CAPS during the first two weeks of life and/or in adulthood (PND60). Notably, CAPS produced lateral ventricle dilation only in mice with either postnatal or adult exposure; ventriculomegaly has been shown to be characteristic of autism and schizophrenia. A lack of changes to the Aqueduct of Sylvius suggests a non-obstructive mechanism such as neuroinflammation. Additionally, CAPS caused glial disruption and an inflammatory response: microglial activation was seen in males, while both sexes showed a time-dependent astrocytic response. CAPS altered brain cytokines in a sex- and time-point-dependent manner. Consistent with a neuroinflammatory response, females showed a transient increase in striatal IL-6 24 hours after postnatal exposure, but this had resolved by adulthood. Both sexes exhibited a protracted neuroinflammatory response to CAPS, with midbrain IL-1β in males and TNFα in females increased following postnatal only CAPS when brains were examined in young adulthood. CAPS also produced multiple changes in brain monoamine and amino acid neurotransmitters that were dependent on sex, timing of exposure, latency between exposure and sacrifice, and brain region. These included disruption of mesocorticolimbic monoamines and, in males, increased hippocampal glutamate, consistent with potential excitotoxicity. Thus, low level CAPS can produce neuropathology preferentially in males, with greater vulnerability during the postnatal period, that is consistent with features of profound neurodevelopmental disorders. ES019105

Mice exposed to trichloroethylene (TCE) postnatally from birth until 6 weeks of age demonstrated impaired glutathione reductase homeostasis and increased biomarkers of oxidative stress in the brain and plasma. Here we confirm and extend these findings in mice exposed to TCE during gestation only. Similar to postnatal-only exposure, a targeted metabolomics analysis in gestation-only exposed mice revealed compromised glutathione reductase disequilibrium and behavioral alterations characterized by increased locomotor and exploratory activity in male offspring at postnatal day (PND) 42. Accordingly, this TCE exposure induced a significant and dose-dependent increase in tyrosine oxidative end products including 3-nitrotyrosine in PND42 male offspring. 3-Chloro-Tyr, an indicator of oxidative stress generated by immune activation, was also significantly elevated in the plasma of TCE exposed offspring. Because this result suggested that an immune component may be an important contributor to the neurotoxic effects observed in our model, peripheral CD4+ T cells, well-characterized targets of TCE immunotoxicity, were evaluated for a panel of inflammatory mediators. Gestational TCE exposure induced a dose-dependent increase in IFN-γ and IL-17 commensurate with a decrease in anti-inflammatory IL-10. These results point to the gestational phase as a critical window of TCE toxicity. Further study is needed to understand the relationship between peripheral immune dysregulation and neurotoxicity with developmental TCE exposure and whether or not epigenetic processes play a role.

1342 Exposure to Concentrated Ambient Ultraviolet Particulate Matter during Postnatal Brain Development and/or Adulthood Elicits Lateral Ventricle Dilation, Sustained Neuroinflammation, and Neurochemical Disruption Preferentially in Male Mice

Bisphenol-A (BPA) is an organic compound that has been increasingly used in the manufacturing of polycarbonate plastics and epoxy resins. BPA is toxic to multiple organ systems including the brain. Exposure to BPA during development has been shown to induce neuronal differentiation, decreased neuronal survival rate, and apoptotic cell death. The goal of this study was twofold; first, we examined the toxic effects of BPA on the developing rat brain and second, detailed mechanisms involved in toxicity and apoptotic cell death were examined in a rat pituitary cell line (GH3). A variety of markers for apoptosis in the striatum and pituitary of rat pups developmentally exposed to BPA through maternal transfer were examined. Results indicated signs of apoptotic cell death in tissue from 24 and 60 day old female rat pups that were exposed to BPA during development. BPA caused a significant decrease in the intracellular pool of glutathione suggesting that exposure increased the levels of reactive oxygen species (ROS). BPA increased the release of cytokines from the microglia. Caspase 3 activation increased following BPA exposure as indicated by increased levels of cleaved caspase 3, TUNEL staining showed evidence of apoptosis. GH3 cells were used to examine detailed mechanisms involved in BPA-induced apoptotic cascade including altered Ca2+ levels and mitochondrial permeability. Using a Ca2+ ionophore (Fura-2AM), it was demonstrated that BPA-treated cells had increased levels of intracellular Ca2+. Concentration-dependent disruptions in mitochondrial membrane permeability were detected following treatment with BPA by staining the cells with rhodamine 123. These results indicate that development of exposure to BPA appears to be neurotoxic in female rat pups by increasing cellular oxidative stress and triggering neuronal cell death. Interestingly, findings obtained from this study in female pups appear to contradict pervious findings in male pups, therefore suggesting that BPA-induced neurotoxicity may be different in females compared to males.

1345 Bisphenol A-Induced Neurotoxicity in the Developing Rat Pup and a Putative Cell Model

J. Olson1, E. Faucheul1, J. Trinh2, M. Hamada2 and D. Jones2. 1CHS, Midwestern University, Glendale, AZ and 2AZCOM, Midwestern University, Glendale, AZ. Sponsor: T. Monks.

Bisphenol A (BPA), is an estrogenic compound used in the manufacturing of polycarbonate plastics and epoxy resins. BPA is toxic to multiple organs including the brain. Exposure to BPA during development has been shown to induce neuronal differentiation, decreased neuronal survival rate, and apoptotic cell death. The goal of this study was twofold; first, we examined the toxic effects of BPA on the developing rat brain and second, detailed mechanisms involved in toxicity and apoptotic cell death were examined in a rat pituitary cell line (GH3). A variety of markers for apoptosis in the striatum and pituitary of rat pups developmentally exposed to BPA through maternal transfer were examined. Results indicated signs of apoptotic cell death in tissue from 24 and 60 day old female rat pups that were exposed to BPA during development. BPA caused a significant decrease in the intracellular pool of glutathione suggesting that exposure increased the levels of reactive oxygen species (ROS). BPA increased the release of cytokines from the microglia. Caspase 3 activation increased following BPA exposure as indicated by increased levels of cleaved caspase 3, TUNEL staining showed evidence of apoptosis. GH3 cells were used to examine detailed mechanisms involved in BPA-induced apoptotic cascade including altered Ca2+ levels and mitochondrial permeability. Using a Ca2+ ionophore (Fura-2AM), it was demonstrated that BPA-treated cells had increased levels of intracellular Ca2+. Concentration-dependent disruptions in mitochondrial membrane permeability were detected following treatment with BPA by staining the cells with rhodamine 123. These results indicate that development of exposure to BPA appears to be neurotoxic in female rat pups by increasing cellular oxidative stress and triggering neuronal cell death. Interestingly, findings obtained from this study in female pups appear to contradict pervious findings in male pups, therefore suggesting that BPA-induced neurotoxicity may be different in females compared to males.

1344 The Effects of Bisphenol A on the Dopamine System in a Developing Rat Brain and a Rat Pituitary Cell Line

B. Nowicki1, G. Robinson2, M. Hamada2 and D. Jones2. 1CHS, Midwestern University, Glendale, AZ and 2AZCOM, Midwestern University, Glendale, AZ.

Bisphenol-A (BPA) is an organic compound that has been increasingly used in the manufacturing of various consumer products. BPA is considered an environmental estrogen, which appears to disrupt the brain’s dopaminergic system. In this study we utilized both in-vitro and whole animal models to examine the effects of BPA on the brain’s dopamine (DA) system. GH3 cells, a rat pituitary cell line, were used to investigate the effects of BPA on cellular localization of the dopamine transporter (DAT) and DA-mediated cell signaling. Using western immunoblot analysis and measuring the ratio of membrane vs. cytosolic DAT protein it was shown that BPA altered normal DAT localization. Immunoblot and ELISA analysis was used to examine the effects on proteins (pERK and prolactin) involved in DA-mediated cell signaling. First, BPA increased pERK levels in a concentration-dependent manner as demonstrated with an ELISA kit. Moreover, this effect was attenuated when cells were pre-treated with a D2 receptor antagonist. Second, prolactin release is regulated, in part by DA; consequently, it may be affected by exposure to BPA. Immunoblot analysis of intracellular and extracellular prolactin levels indicated that BPA altered the normal release of prolactin in a DA D2 receptor-dependent manner. In addition to studies conducted in GH3 cells, an animal model (Sprague Dawley rats) was used to investigate the effects of developmental exposure to BPA on DA turnover. High performance liquid chromatography (HPLC) was used to measure the levels of DA and its metabolites. Using striatal tissue from rat pups developmentally exposed to BPA through maternal transfer, it was demonstrated that chronic exposure to BPA during the developmental period increased DA turnover. These results indicate that exposure to BPA appears to enhance DA neurotransmission and turnover which may play a role in cognitive deficits associated with the DA system.

1346 Abnormal Neuronal Migration and Behavior in Mice Exposed In Utero to Bisphenol A

W. Ling1, T. Endo1, W. Miyazaki1, E. Kimmura1, K. Kubo1, K. Nakajima1, M. Kakeya1 and C. Tohyama1. 1Laboratory of Environmental Health Sciences, CDBM, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan and 2Department of Anatomy, School of Medicine, Keio University, Tokyo, Japan.

Developing brain is highly sensitive to environmental chemicals, and perturbation of the brain development can lead to cognitive impairment, as well as psychiatric and neurological disorders. Bisphenol A (BPA), a high volume chemical used for plastics, has been suspected to affect brain development, but its mechanisms of toxicity have been elusive. In this study we investigated whether and how the developing brain of mice born to dams exposed to low-dose of BPA was affected. Pregnant mice were exposed to BPA by implanting osmotic pump at a daily dose equivalent to 0, 40 (BPA-40), 400 (BPA-400) μg/kg from embryonic day 14.5 (E14.5) to E18.5. Neuronal migration, an essential process of cerebral cortical development, was analyzed on E18.5 by using an in utero electroporation technique. We found neuronal migration was significantly decreased in the BPA-40 group compared with the control group. Robo1, a neuronal guidance receptor gene, was significantly increased in the BPA-40 group, and TrkB, a gene that mediates neuronal differentiation and survival, was significantly increased in the BPA-400 group. In
addition, dopamine and its metabolites in the forebrain were significantly increased in BPA-400 group compared to BPA-40 group. Serotonin turnover, i.e., ratio of 5-HIAA to 5-HT, in the hindbrain was significantly decreased in BPA-400 group compared to the control group. Behavior of adult male mice born to BPA-exposed dams was examined using an automated apparatus, IntelliCage, under a group-housed condition (Endo et al., PLOS One, 2012). We found that the BPA-40 group significantly exhibited impulsive behavior compared to the control group. In conclusion, impulsive behavior observed in adulthood may have a fetal origin of perturbations in neuronal migration and related metabolic alterations in monoamine levels, both of which were induced by utero exposure to BPA.

**1347 Enhanced Behavioral Toxicity Induced by Maternal Exposure to a Mixture of Low-Dose Endocrine Disrupting Chemicals**

M. Sobolewski, K. Conrad, K. Martin, J. L. Allen, H. Weston, B. Lawrence and D. A. Corry-Slechta, University of Rochester, Rochester, NY.

Understanding the toxicity of low dose endocrine disrupting chemical (EDC) mixtures is critical, as research suggests that low dose early developmental EDC exposure can, through physiological reprogramming, alter the trajectory of adult disease onset. To assess how low dose developmental EDC exposure alters adult behavior, pregnant female mice were exposed to relatively low doses of four EDCs, Atrazine (ATR – 10mg/kg), Perfluorooctanoic acid (PFOA – 0.1 mg/kg), Bisphenol-A (BPA – 50tg/kg), 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD – 0.25tg/kg) and their mixture (MIX), from gestational day 7 until weaning. Control litters were created at the same time. Adult offspring were tested for locomotor activity, food-rewarded fixed interval (FI) reinforcement schedule performance, and novel object recognition (NOR) performance. While behavioral deficits were observed in all 5 treatment groups, an enhanced effect was seen in male MIX offspring in increased FI response rates, suggesting an inability to inhibit responding. These were not seen in any other male treated group. In fact, ATR males exhibited significant reductions in FI rates, suggestive of reduced attention to task or impaired motivation. MIX females did not show enhanced FI alterations; but TCDD alone increased FI response rates. A robust decreased rate of exploration during initial exposure to the novel object paradigm occurred in all treatment groups in both sexes, particularly males. Deficits in short-term memory were observed in ATR, BPA and MIX male offspring; TCDD female offspring showed short-term memory deficits during NOR testing, spending significantly less time per each approach to the novel object. Deficits did not correspond to changes in locomotor activity in either sex. Taken together, behavioral deficits in learning/short term memory occurred after exposure to relatively low maternal doses of EDCs in mice. MIX treated males showed some evidence of enhanced effects highlighting the need for risk assessment of EDC mixtures. Supported by P30 ES001247.

**1347a Gestational Exposure to Inhaled Vapors of Ethanol and Gasoline-Ethanol Blends in Rats**

The US automotive fleet is powered primarily by gasoline-ethanol fuel blends containing up to 10% ethanol (E10). Uncertainties regarding the health risks associated with exposure to E10 prompted assessment of the effects of prenatal exposure to inhaled vapors of gasoline-ethanol blends containing greater amounts of ethanol. Pregnan Long-Evans rats were exposed to fuel vapors, 6.5 hr/day, on days 9–20 of gestation, and their offspring were assessed using a variety of tests for clinical, physical, immunological and neurodevelopmental effects. Results of tests of cognitive function are reported in other abstracts. This report compares effects of inhaled ethanol (E100) at concentrations of 0, 5000, 10000, or 21000 ppm with effects of vapors of gasoline lacking (E0) or containing 15% ethanol (E15) at concentrations of 0, 3000, 6000, or 9000 ppm. Maximum concentrations were limited by the lower explosive limits of the vapors. None of the vapors caused overt maternal toxicity, changes in litter size or weight, or altered the weight gain of the pups. With E100, motor activity and a few measures of a functional observational battery (hindlimb grip strength, excitability) were altered, but not in a dose-related manner. No such changes were observed with E0 or E15. With one exception, no dose-related changes were observed for any agent on any clinical, developmental, or immunological endpoint. Urinary protein concentrations suggesting potential kidney dysfunction, measured in the offspring at 3 and 6 months of age, increased across dose and age after E15 exposure; increases not related to dose were seen after exposure to E0. However, the highest measured protein concentration (300 mg/dl) was lower than concentrations associated with kidney damage in this strain of rats (400 – 2500 mg/dl). Thus, even at these high concentrations, inhalation of these vapors does not appear to pose a serious public health hazard. This abstract does not represent EPA policy.

**1347b Prenatal Inhalation Exposure to Evaporative Condensates of Gasoline with 15% Ethanol and Evaluations of Sensory Function in Adult Rat Offspring**

The introduction of ethanol-blended automotive fuels has raised concerns about potential health effects from inhalation exposure to the combination of ethanol and gasoline hydrocarbon vapors. Previously, we evaluated effects of prenatal inhalation exposure to 100% ethanol (E100) or to gasoline (E0) vapors on sensory function of the offspring as a component of a larger biofuels research program. This study evaluated effects of exposure to vapors from a blend of 15% ethanol/gasoline (E15) on the same set of outcome measures used previously. Pregnant Long-Evans rats were exposed to 0, 3K, 6K, or 9K ppm E15 vapors for 6.5 hr/day over GD9 – GD20. Sensory evaluations of offspring (1 male pup/litter) began around PND106. Peripheral nerve function (compound action potentials, NCV), somatosensory (cortical and cerebellar evoked potentials), auditory (brainstem auditory evoked responses), and visual (electroretinograms) responses were assessed. Visual function assessment included pattern elicited visual evoked potentials (VEP), VEP contrast sensitivity, dark-adapted (scotopic) and light-adapted (photopic) flash electroretinograms (ERG), and UV and green flicker ERGs. Although some minor statistical differences were observed for auditory and somatosensory responses, these changes were not systematically related to dose. All physiological responses showed changes related to stimulus intensity, and provided an estimate of detectable levels of change. Overall, the results identified no persistent dose-related functional impairments of the peripheral nerve, somatosensory, auditory, or visual systems resulting form gestational exposure to E15 vapors. Additional studies are in progress to evaluate the effects of exposure to the evaporative condensate vapors from a blend of 85% ethanol with gasoline (E85). This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

**1347c Effects of Ethanol-Gasoline Blended Fuels on Learning and Memory**

The potential toxicity of ethanol-gasoline blended fuels to the developing nervous system is of concern. We previously reported an absence of effect on learning and memory seen in a trace fear conditioning task and water maze task in offspring of dams exposed prenatally to the vapors of ethanol. However, a high number of anticipatory responses were noted in male offspring that completed a choice reaction time task (CRT). In order to further explore this apparent impairment of response inhibition, we evaluated effects of vapors from a blend of 15% ethanol/gasoline (E15) and 85% ethanol/gasoline using a Differential Reinforcement of Low-rate Response task (DRL). We also evaluated the effects of E15 and E85 on the trace fear conditioning task and water maze task. Pregnant Long-Evans rats were exposed to 0, 3000, 6000, or 9000 ppm E15 or E85 vapors for 6.5 hr/day from GD9 to GD20. Male and female offspring (n=10/sex/group/vapor) were trained on the Morris water maze starting on postnatal day (PND) 76. Overall, acquisition of the task and working memory were not affected by E15 or E85. A second set of male and female offspring (n=16/sex/group/vapor) was assessed using a DRL task. Overall, the results identified no significant dose-related impairments after exposure to E15 or E85, although there was a tendency for inhibitory control impairment in the 9000 E15 male offspring. These results suggest prenatal exposure to ethanol-gasoline blended fuels produce few if any effects on learning and memory. This abstract does not reflect EPA policy.
The impact of developmental exposure to inhaled ethanol-gasoline fuel blends is a potential public health concern. We previously reported that rats whose mothers inhaled ethanol (21,000 ppm) during pregnancy had increased levels of anticipatory responding on a choice reaction time (CRT) task. Thus, we used this task to investigate effects in the adult offspring of dams exposed to vapor condensates made from fuels blended with a range of ethanol concentrations, including gasoline alone (E0) and gasoline with 15% and 85% ethanol (E15 and E85, respectively). Each blend was investigated in separate cohorts. Within each cohort, dams were exposed for 6.5 h daily from gestational day 9 through 20 to concentrations of 0, 3,000, 6,000, or 9,000 ppm (n=8 per concentration). Male offspring were assessed during acquisition of both cued and uncued versions of the CRT and during asymptotic performance of the uncued task. During acquisition, increased anticipatory responding (elevated hold failures during a preparatory hold period) was observed in rats exposed to E0 (9,000 ppm) and E15 (6,000 and 9,000 ppm) indicating deficits in response inhibition. E15 offspring also had reduced accuracy (6,000 and 9,000 ppm) during acquisition of the cued CRT, suggesting additional deficits in processing visual information, and reduced decision times (6,000 ppm), indicating possible facilitation in this measure due to elevated hold failures. No effects were observed on any performance measure after exposure to E85, or, during asymptotic performances of the uncued CRT for any fuel blend. These data, combined with data from rats exposed to vapors of neat ethanol, indicate that prenatal exposure to gasoline and gasoline containing ethanol at 0% and 15%, but not 85%, ethanol may lead to diminished them. This abstract does not represent EPA policy.
Background. Zebralike mammals have dopamine systems that are important for programming a variety of functions including motor behavior. Normal development of dopamine systems would likely depend on normal responsivity of dopamine D1 and D2 receptors during development. Objective. Embryonic zebralike were used to assess the role of D1 and D2 receptor action on motor function. Methods. Embryonic embryos from the AB and SD strain were exposed to 0.5, 1.5 or 5 μM of a dopamine D1 antagonist, SCH23390 or a D2 antagonist, haloperidol dissolved in aquarium water, which served as the vehicle control. Exposure lasted from 5 hrs to 5 dpf. After exposure, fish were transferred to aquarium water with behavioral testing 24 hrs later. An automated system of data collection was used in which individual swim characteristics were calculated in real time under light (100% illumination) and dark (0% illumination) conditions controlled via a DanioVision observation chamber. Each trial commenced following a 10-min acclimation period in dark. Ten min intervals of light and dark conditions alternated twice each for a 50-min session. Swim data were analyzed by ANOVA with Dunnett’s test for pair-wise comparisons. Results. Survival of embryos was unaffected by treatment or strain. There was a significant effect of strain during dark, with ABs traveling a greater distance than SDs. The highest dose of haloperidol (5 μM) nearly eliminated movement during both conditions for both strains. Significant decreases were seen with the intermediate haloperidol dose (1.5 μM) and the highest dose of SCH 23390 (5 μM) during dark for both strains. Conclusion. Blockade of either D1 or D2 dopamine receptors during embryonic development caused lingering deficits in swimming behavior, suggesting toxins that affect dopamine systems during development may have persisting behavioral consequences. Differences in baseline behavior between strains suggest strain may be an important variable when measuring early-life endpoints in Zebralike. Transfection and Flow cytometry followed by the establishment of PHB1 knockdown Z310 cells. The involved signal transduction pathways deserve further study leading to a-Syn aggregation; their combined effect is not additive, but rather synergistic. The blood-cerebrospinal fluid barrier (BCB), has been considered as a primary target in Mn-induced neurotoxicity. In our study, a total of 32 Mn-related differentially expressed proteins in CP were identified by 2D-PAGE combined with Nano-LC-MS/MS in an Mn-toxicity rat model. We further verified the 6 selected Mn-related proteins (PHB1, VDAC, β-actin, STIP1, TTR, Vimentin) in a CP cell line Z310 in vitro, and in vivo. Besides, the cell cycle arrest effect of Mn on Z310 cells had been proved from our previous experiment. A so-called iron responsive element structure within the 3′ untranslated region on prohibitin 1 (PHB1) mRNA is a newly found functioning element. We confirmed that upregulated PHB1 does play an essential regulatory role in Mn-induce Z310 cell cycle arrest, by WB, RT-PCR, Transfection and Flow cytometry study the establishment of PHB1 knockdown Z310 cells. The involved signal transduction pathways deserve further investigation. The environmental neurotoxic manganese promotes cell-to-cell transmission of α-Synuclein via exosomes in cell culture and animal models of Parkinson’s disease.

The aggregation of α-Synuclein (αSyn) is considered a key pathophysiological feature of Parkinson’s disease (PD). Recent studies suggest that prion-like cell-to-cell transfer of misfolded αSyn contributes to the spreading of αSyn pathology. However, the biological mechanisms underlying the propagation of the disease with respect to environmental neurotoxic chemical exposures are not well understood. Considering the role of the divergent metal manganese in PD-like neurological disorders, we characterized its effect on αSyn misfolding and protein aggregation. First, we established a MN9D dopaminergic cell line stably expressing wild-type human αSyn and treated it with non-toxic doses of manganese at various time points. Analysis of condition medium (CM) through Western blot showed that cells secreted αSyn into extracellular media following manganese exposure.

Further characterization of CM through electron microscopy readily detected the membranous nano-sized vesicles with characteristic hallmarks of exosomes. Western blot and ELISA studies revealed that the exosomes do in fact contain αSyn. Furthermore, Nanosight particle analysis showed that manganese exposure can enhance the release of αSyn-containing exosomes. In functional studies, we demonstrated that exosomes released during manganese treatment can induce neuroinflammatory responses in primary microglial cultures and neurodegeneration in differentiated human dopaminergic cells (LUHMES) through the activation of caspase-3 signaling. Our preliminary studies showed for the first time that stereotaxic delivery of αSyn-containing exosomes isolated from manganese-treated MN9D αSyn-expressing cells into the striatum can initiate PD-like motor deficits in mice. Collectively, these results demonstrate that manganese exposure promotes αSyn secretion by forming exosomal vesicles, which subsequently evoke pro-inflammatory and neurodegenerative responses in both cell culture and animal models. 1352  Manganese Exposure Downregulates Anti-Apoptotic STAT5b Signaling through an Sp1-Dependent Mechanism

Biomedical Science Department, Iowa State University, Ames, IA.

Chronic exposure to elevated level of Manganese (Mn) has been linked environmentally to Parkinson’s disease-like neurological abnormalities. However, the precise mechanisms underlying Mn-induced neurotoxicity are still not well understood. In this study, we have identified that Mn exposure downregulates a key regulator of apoptotic cell signaling involving the signal transducer and activator of transcription (STATs). 300µM Mn exposure in N27 dopaminergic neuronal cells downregulated STAT5b expression both at the protein and mRNA levels, while STAT1 was unaffected, indicating an isoform-specific effect of Mn on STAT5b expression. To determine the functional consequence of STAT5b regulation during Mn neurotoxicity, we performed overexpression studies. Surprisingly, overexpressing STAT5b significantly protected against Mn-induced apoptotic cell death, suggesting the STAT5b plays a cell survival role in dopaminergic neuronal cells. STAT5b upregulation also increased anti-apoptotic Bcl2 expression. To further determine the molecular mechanisms underlying STAT5b downregulation during Mn neurotoxicity, we cloned the STAT5b promoter region indicating that a proximal region near exon 1 contains the regulatory element in response to Mn exposure. Detailed mutational analyses of the potential transcription factor binding site revealed that a Sp1 site located at -210 and -194 may be required for the suppression of STAT5b in Mn-induced neurotoxicity. Finally, we extended our studies to an animal model of Mn-induced neurotoxicity. The results showed that oral administration of Mn (30 mg/kg bw) in C57 black mice for 30 days significantly reduced the expression of STAT5b in the substantia nigra compared to control mice. Taken together, these data suggest Mn exposure downregulates anti-apoptotic STAT5b signaling via an Sp1-dependent mechanism in dopaminergic neurons, which may significantly contribute to Mn neurotoxicity. Huntington’s disease (HD) is a devastating neurodegenerative disease caused by the mutant Huntingtin protein. Expression of mutant Huntingtin is known to cause altered p53 signaling in cell and animal models as well as in patients. We tested the hypothesis that manganese (Mn) activates p53 signaling and that mutant Huntingtin protein would impinge on this cell stress pathway. We compared p53 activation in wild type (Q7) and mutant Huntingtin expressing (Q111) HD murine striatal cells and found that sub-lethal concentrations of Mn (25 µM) caused significant phosphorylation of p53(ser15) in both Q7 and Q111 cells as measured by immunoblotting. The mutant (Q111) cell line had a significantly diminished response. We then tested whether this phenotype is also seen in human cells. Human induced pluripotent stem cells (hiPSCs) from control and Huntington’s disease human subjects were differentiated into neural progenitors expressing early striatal markers (e.g. FOXG1, ISLET1). These human neural progenitors showed the same diminished p53 response to Mn; however, p53 activation after double-stranded DNA damage via neocarzinostatin resulted in greater p53 activation in HD iPSCs. Quantitative RT-PCR for p53-dependent transcripts (e.g. TIGAR, p21) confirmed manganese activation of the pathway and diminished responsiveness in HD cells. Under sub-lethal cell stress conditions, p53 activates pro-survival gene transcripts. Thus, diminished p53 responsiveness may reduce the ability of neurons to adapt to repeated cellular stress (e.g oxidative stress and nutrient deprivation). We are currently working to identify the kinase responsible for the Mn-dependent phosphorylation of p53 and mechanism by which Mn activates p53. 1354  A High-Throughput Screen for Modulators of Neuronal Manganese Status

There is strong evidence that both genetic and environmental factors play a critical role in the pathogenesis of many neurodegenerative diseases. Exposure to the heavy metal, manganese (Mn), shows a strong correlation with incidence of Parkinson’s disease (PD). This study presents the results of a high-throughput screen (HTS) to identify novel modulators of neuronal Mn accumulation. Specifically, we screened multiple chemical libraries including: SPECTRUM, NIH Clinical Compounds, Chembridge/Chemdiv, and kinase inhibitors from Roche, GSK, and Enzo. Our goal was to identify agents with research utility in defining molecular mechanisms of neuronal Mn regulation and those with potential clinical efficacy in modifying Mn environmental risk in vivo.

We have successfully optimized the Cellular Fura-2 Manganese Extraction Assay (CFMEA) for HTS (Z-factor>0.5) in an immortalized murine striatal cell line (STHdhQ7/Q7). Subsequently, we conducted a screen of 40,000 small molecules. A subset of molecules was rescreened in duplicate given the known biological/medical relevance of the source libraries. These studies revealed 48 small molecule modulators of Mn status that hit twice in both screens, and these molecules were selected for the generation of concentration response curves (CRCs). CRCs revealed dose-response curves for 28 of these small molecules, known to target cellular signaling pathways previously implicated in Mn toxicity, including p53 and AKT, as well as GSK3β, ALK, EGFR/Erbb2, ERK, and neurotransmitter trafficking proteins. Parallel studies have revealed induction of phosphorylated p53 and AKT at subtoxic physiological Mn exposures. Future effort will characterize these HTS-identified modulators of Mn status for activity in human induced pluripotent stem cell (hiPSC)-derived nigral and striatal-like neural progenitors.

1355  A Statistical Analysis of Z-Score Stringency in a High-Throughput Screen for Modulators of Neuronal Mn Status

M. Odak1, K. K. Kumar1, M. Aschner2 and A. B. Bowman4.
1Neurology, Vanderbilt University Medical Center, Nashville, TN; 2Molecular Pharmacology, Albert Einstein College of Medicine, Bronx, NY.

Manganese (Mn) is an environmental risk factor for Parkinson’s disease. We performed a high throughput screening (HTS) for small molecule modulators (SMMs) of neuronal Mn status to improve understanding of Mn transport and handling in the central nervous system. Current practices in HTS analysis utilize a statistical z-score with an absolute value of 3.0 as a cut-off for potential hits. We evaluate the utility of this statistical cut-off in our novel Fura2-based fluorescent Mn assay by performing replicate HTS. We have evaluated the variability and general distribution of “true-positive” versus “false-positive” hits using MATLAB. We find that relaxing the z-score cut-off from 3.0 to 2.0 identified a substantial fraction of FDA-approved drugs that may have translational value that fell below the 3.0 z-score limit. The ultimate goal of this study is to identify an optimal z-score cutoff for our HTS Mn assay given the non-linear responses of this assay. A total of 3,391 compounds were tested in duplicate to find SMMs using a murine striatal cell line. This study revealed 48 compounds that hit on both days of testing. Concentration Response Curves (CRCs) were generated for these, and 29 compounds revealed a true dose-dependent effect on cellular Mn levels. 69% of these 29 compounds had a z-score above an absolute value of 3.0 on both days of testing and 31% of compounds had z-scores between 2.0 and 3.0 on at least one day of testing. Furthermore, there was only a marginal decrease in the True Positive Rate (TPR) from 43.2% to 42.9% and a marginal increase in the False Positive Rate (FPR) from 1.0% to 2.8% by relaxing the z-score cutoff to 2.0. Additional statistical characterization will seek to evaluate the efficacy of compounds identified with a relaxed z-score cutoff and their mechanisms influencing Mn accumulation in murine striatal cells to validate a relaxed z-score approach with Fura2-based HTS.

Supported by NIEHS RO1 ES010563.
Environmental overexposure to the essential trace element manganese (Mn) can result in an irreversible condition known as manganese toxicity (PD) with dopaminergic (DAergic) cell loss associated with motor and cognitive deficits. However, the mechanisms that mediate the pathophysiology of both disorders remain unclear. Many PD genes impart risk for autosomal recessive, early-onset PD, including pARK2 and dj-1-pARK7. Another PD-associated gene is SNCA encoding for the presynaptic protein α-synuclein. Using Caenorhabditis elegans, we hypothesized that a loss-of-function mutation in pdkn1 (pdk1) and dfr-1(dfr1.1) would increase vulnerability to Mn toxicity and enhance DAergic neurodegeneration compared to wildtype (WT) worms, which may be altered by expression of WT human α-synuclein (α-Syn). Synchronous L1 worms from WT N2, pdk1(ge448) and dfr-1(tm918) mutant strains were acutely exposed to MnCl2 (0–10 mM) for 30 minutes, pdr1 and dfr-1 loss enhances intraworm Mn accumulation compared to WT (p<0.001) that is rescued in dfr-1 mutants also expressing α-Syn (p<0.001). Interestingly, enhanced oxidative stress upon treatment in the deletion mutants (p<0.001) is also rescued in the presence of α-Syn. However, pdr1 and dfr-1 show differential degeneration profiles, with α-Syn unable to rescue α-DERG cell loss in the dfr-1.1 mutants. This was associated with increased SNCA mRNA and decreased dat-1 mRNA levels in dfr-1 mutants. Compared to increased SNCA mRNA and increased dat-1 mRNA levels in pdr1 mutants. Thus, we show (1) a novel, neuroprotective role for WT human α-Syn in the background of PD-associated genes against Mn toxicity that may be dependent on its expression level, and (2) support for the role of extracellular dopamine in exacerbating Mn neurotoxicity (Supported by NIEHS R01ES01563).

Manganese (Mn) is a neurotoxin causing Manganism, a Parkinson-like disease, disrupts dopamine (DA) neurotransmission. The mechanism is not fully resolved and reports postulate it more related to dysfunction of DA D2 receptors than degeneration of DA neurons. Gilia of lateral gill cells of *Grausnina virginia* are controlled by serotonergic-dopaminergic innervations. DA is cilio-inhibitory, serotonin cilio-excitatory. We showed post-synaptic DA receptors in gill lateral cells are D2 type. Mn blocks cilio-inhibitory effects of DA, and DA toxicity is blocked by p-aminalsaliclyc acid (PAS). Questions exist whether Mn decreases the number of post-synaptic DA D2 receptors in brain. We used immunohistochemistry to test if Mn decreases the number of DA D2 receptors in gill of *C. virginica* and if PAS prevented the decrease. Using 1<sup>o</sup> antibodies against D2 receptors and FITC-linked 2<sup>o</sup> antibodies, we quantified DA D2 receptors in gill. Animals were treated with 500 µM of Mn for up to 6 days. Controls were treated without Mn. Gills were excised, fixed, exposed to antibodies and paraffin embedded. Sections were viewed on an epihle fluorescence microscope with FITC filters, and a ProgRes C3 camera. Fluorescence was quantified using ImageJ software from NSF. Fluorescence in sections from animals treated up to 6 days with Mn (500 µM) showed progressive decrease in fluorescence of up to 36% of controls. Animals co-treated up with 500 µM of Mn and PAS did not show reduced fluorescence. The study shows negative correlation between fluorescence intensity of DA D2 receptors in Mn treated animals vs controls, and also shows PAS can negate the effect Mn treatments on D2 receptors. The question of whether the loss in fluorescence intensity is due to an actual decrease in D2 receptor number or if Mn is altering the protein conformation and ligand binding site of D2 receptors needs to be further explored. This work was supported by grants2R25GM06003 of the Bridge Program of NIGMS, 0516041071 of NYSDOE and 0622197 of the DUE Program of NSF.

Excessive exposure to Manganese (Mn) can cause neurologic symptoms similar to, but distinguishable from idiopathic Parkinson’s disease (IPD). The question as to whether or not Mn exposure has direct effects on dopamine (DA) and other catecholamines thereby disrupting the nigrostriatal pathway is unanswered. This study was designed to test the hypothesis that subchronic Mn exposure alters neurochemistry. Adult male rats received IP injections of 6 and 15 mg Mn/kg (as MnCl<sub>2</sub>) as the low- and high-dose groups, respectively, or saline as the control, 5 days per week for 4 weeks. Animals were sacrificed 24 hr after the last injection, and striatum (STR), hippocampus (HP), and substantia nigra (SN) were dissected for quantification of neurotransmitters including: DA, 3,4-di-hydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA), 5-hydroxytryptamine (5-HT), 5-hydroxy-indolacetic acid (5-HIAA), and γ-aminobutyric acid (GABA) by HPLC. Analysis revealed statistically significant differences in the neurotransmitter content of these three brain regions between control-, low-, and high-dose groups. The level of DA and its metabolites in STR were significantly higher in Mn-exposed animals than in controls (p<0.05); DA turnover in SN was also significantly higher in exposed animals than controls (p<0.05). Interestingly, GABA levels were significantly higher in HP in exposed animals than in controls. Analysis with atomic absorption spectrometry showed Mn exposure led to a significant accumulation of Mn and copper in the femur as well as other bone tissues. Neurotransmitter differences seen in the striatum may be of particular relevance because alterations could lead to heightened sensitivity to additional insults, particularly due to oxidative modifications of DA. This study provides evidence that dopaminergic neurotransmission is especially sensitive to Mn intoxication.

Manganese (Mn) is a neurotoxin causing Manganism, a Parkinson-like disease, disrupts dopamine (DA) neurotransmission. The mechanism is not fully resolved and reports postulate it more related to dysfunction of DA D2 receptors than degeneration of DA neurons. Gilia of lateral gill cells of *Grausnina virginia* are controlled by serotonergic-dopaminergic innervations. DA is cilio-inhibitory, serotonin cilio-excitatory. We showed post-synaptic DA receptors in gill lateral cells are D2 type. Mn blocks cilio-inhibitory effects of DA, and DA toxicity is blocked by p-aminalsaliclyc acid (PAS). Questions exist whether Mn decreases the number of post-synaptic DA D2 receptors in brain. We used immunohistochemistry to test if Mn decreases the number of DA D2 receptors in gill of *C. virginica* and if PAS prevented the decrease. Using 1<sup>o</sup> antibodies against D2 receptors and FITC-linked 2<sup>o</sup> antibodies, we quantified DA D2 receptors in gill. Animals were treated with 500 µM of Mn for up to 6 days. Controls were treated without Mn. Gills were excised, fixed, exposed to antibodies and paraffin embedded. Sections were viewed on an epihle fluorescence microscope with FITC filters, and a ProgRes C3 camera. Fluorescence was quantified using ImageJ software from NSF. Fluorescence in sections from animals treated up to 6 days with Mn (500 µM) showed progressive decrease in fluorescence of up to 36% of controls. Welders had significantly increased UPDRS-III scores and higher levels of thalamic GABA compared to controls. For all subjects increasing thalamic GABA levels correlated with increasing normalized scores of the parallel line test reflecting tremor level \((r=0.437, p<0.05)\), and striatal GABA correlated with Finger Tapping, using a mono-motor task \((r=0.68, p<0.01)\). In the welders, significant inverse correlations were seen between frontal Glx levels and the grooved pegboard score \((r=0.803, p<0.01)\), and between motor cortex Gx levels and parallel line test scores \((r=0.651, p<0.05)\). The significant correlations of thalamic GABA and frontal Gx levels with tremor level, as well as striatal GABA levels with motor skills, confirm the use of MRS to study neurotoxic effects of Mn on the direct and indirect pathways of the basal ganglia that lead to motor disturbances. **1367 Increased Thalamic GABA in Chronic Manganese-Exposed Metal Workers and Manganism Patients**

U. Dydak\(^1,2\), Y. Jiang\(^3\), X. Li\(^4\), L. Long\(^1\), J. B. Murdoch\(^1\), W. Weng\(^2\) and Z. Long\(^2\). \(^1\)School of Health Sciences, Purdue Univ, West Lafayette, IN, \(^2\)School of Health Sciences, Purdue Univ, West Lafayette, IN, \(^3\)School of Health Sciences, Purdue Univ, West Lafayette, IN, \(^4\)Radiology and Imaging Sciences, Indiana Univ. School of Medicine, Indianapolis, IN, \(^5\)Health Toxicology, Guangzhou Medical University, Nanning, China, \(^6\)Radiology, Guangzhou Medical University, Nanning, China and \(^7\)Toshiba Medical Research Institute, Mayfield Village, OH.

Overexposure to manganese (Mn) has been reported to lead to parkinsonian symptoms. We hypothesize that hypokinetic symptoms associated with Mn overexposure correspond to elevated thalamic GABA levels leading to reduced glutamatergic projections to the cortex. Therefore we aimed to test whether Mn-exposed workers and manganism patients may have elevated thalamic GABA levels, as well as reduced cortical glutamate (Glu) levels. A group of 20 Mn-exposed welders, 19 Mn-exposed smelters, 7 manganism patients and 37 controls were recruited from Guangxi Province, China. Each subject underwent magnetic resonance imaging and spectroscopy exams. Short-echo-time 1H spectra were acquired from the frontal cortex and thalamus to assess levels of GABA, the sum of Glu and its precursor glutamine (together denoted as Gx), and myo-inositol (mI, a glial marker). GABA-edited spectra were also acquired in the thalamus. Metabolites are expressed as ratios over creatine (Cr).

Over three years we consistently found significantly increased thalamic GABA/Cr in welders, smelters, and manganism patients compared to controls \((p<0.01\) for all comparisons). Smelter showing significantly decreased frontal mI/Glu and thalamic GABA/Cr \((p<0.05\) for all comparisons). Moreover, welders had significantly increased frontal mI/Glu and both groups of workers had significantly decreased thalamic mI/Cr \((p<0.05\) for all comparison). Overall our results suggest increased thalamic GABAergic inhibition in Mn-exposed workers and manganism patients, as well as decreased glutamatergic excitation and Glu-Gln cycling in the frontal cortex of smelters. These metabolic changes may aid in understanding the mechanism of Mn-caused motor and cognitive deficits. (Supported by NIH/NIEHS R21 ES017498, R01 ES020529 and NSF of China #81072320)

**1368 GABA Levels Correlate with Exposure Levels and Brain Deposition of Manganese in US Welders**

R. Ma\(^1,2\), C. Yeh\(^1,2\), E. J. Ward\(^1\), Z. Long\(^1\), J. B. Murdoch\(^1\), S. Snyder\(^1\), E. Zauber\(^1\), F. Rosenthal\(^1\) and U. Dydak\(^1,2\). \(^1\)School of Health Sciences, Purdue Univ, West Lafayette, IN, \(^2\)School of Health Sciences, Purdue Univ, West Lafayette, IN, \(^3\)Radiology and Imaging Sciences, Indiana Univ. School of Medicine, Indianapolis, IN, \(^4\)Toshiba Medical Research Institute, Mayfield Village, OH and \(^5\)Neurology, Indiana Univ. School of Medicine, Indianapolis, IN.

Excessive manganese (Mn) exposure has been associated with decline in cognitive and motor function. Our previous study in a cohort of highly Mn-exposed Chinese workers found significantly elevated thalamic \(\gamma\)-aminobutyric acid (GABA) levels. The current study explored the relationships among brain GABA levels measured in vivo by magnetic resonance spectroscopy (MRS), brain Mn deposition measured by MRI and individual Mn exposure levels in a typical US occupational setting. Thirteen welders and eleven controls were recruited from a US truck trailer manufacturer. Subjects underwent personal air sampling and filled out a questionnaire of detailed work history for the estimation of individual exposure to respirable Mn. For each subject a series of 3D images were acquired on a 3T GE Signa MRI scanner and used to create high-resolution T1 relaxation maps, an inverse indicator of Mn deposition. GABA spectra were acquired from the thalamus with a T68 MEGA-PRESS sequence and quantified using LCModel, a spectral fitting tool.

GABA levels were significantly higher in welders vs. controls \([2.45\pm0.68 \text{ mM vs. } 1.40\pm0.45 \text{ mM, } p<0.001]\). Increased thalamic GABA levels significantly correlated with (a) average exposure estimated for the previous three months before the MRI exam \([R=0.649, p<0.05]\) and with (b) decreased T1 relaxation time in the substantia nigra, denoting increased Mn deposition \([R=0.589, p<0.05]\).
These results confirm the elevation of thalamic GABA levels in a typical US occupational setting. The significant correlations between increased GABA levels and recent exposure levels, as well as with brain Mn accumulation in the substantia nigra, suggest that GABA-edited MRS in conjunction with quantitative T1 relaxation may serve as a non-invasive Mn exposure. 1368a Potential Prevention Strategies to Reduce the Risk of Neurotoxicity Associated with Manganese-Containing Welding Fumes

Welding generates complex metal aerosols, inhalation of which is thought to cause Parkinson’s disease (PD)-like neurotoxicity, due to the presence of manganese (Mn) in the welding electrodes. As neurological disorders are generally progressive in nature, with latency between insult and appearance of clinical symptoms, a logical approach for workplace safety and health is to prevent adverse exposures. For welding, this can be achieved by minimizing welding fume (WF) generation rate and/or suitably modifying existing welding practices to reduce toxic exposures. Here, we show that by specifically modulating welding voltage, keeping current and shielding gas constant, the chemical composition and neurotoxicological properties of WF can be significantly altered. Rats were exposed by whole-body inhalation to filtered air or WF particulates generated by gas-metal arc-stainless steel welding (GMA-S: 40 mg/m²; 3h/d x 10d) either at 25V (standard/low; LVSS) or at 30V (high; HVSS) voltage. Both conditions produced good weld quality and similar particulate morphology, although aerosols from HVSS welding comprised of a larger fraction of ultrafine particulates that are characteristically considered to be more toxic than their fine counterparts. Exposure to particulates from LVSS welding caused neuroinflammation (increased Ca²⁺, TNFa, Nos2; 1.5 - 3.9 fold; P<0.05) and decreased PD-related proteins (Th, Park5, Park7; 18 - 47%; P<0.05) in the dopaminergic brain areas, striatum and midbrain. Paradoxically, exposure to particulates from HVSS welding did not elicit any dopaminergic neurotoxicity. We determined that the lack of neurotoxicity may be a consequence of the reduced solubility of manganese in HVSS fumes. Our findings show promise for modifying welding practices as a potential prevention strategy for Mn-related neurotoxicity during welding; however, it warrants additional investigations to determine if such modifications can be suitably adapted at the workplace to avert or reduce neurotoxicological risks.

1369b The Role of the Transient Receptor Potential Ankyrin 1 (TRPA1) Channel in Methylmercury (MeHg)-Induced Ca²⁺ Dysregulation

H. Hannon and W. D. Atchison, Pharmacology/Toxicology, East Lansing, MI.

MeHg biphasically elevates [Ca²⁺], with the first (P1) and second (P2) phases attributed to Ca²⁺ release from intracellular stores and extracellular Ca²⁺ influx through Ca²⁺-permeable ion channels, respectively. MeHg-induced [Ca²⁺] dysregulations have been correlated with reduced viability of susceptible neuronal populations in vitro. Because parathyreoid is the preeminent site of MeHg intoxication, and the size and number of neurons of the dorsal root ganglia (DRG) are reduced in poisoned individuals, molecular entities unique to DRG may heighten sensitivity to MeHg. Heterologous expression was used in this study to investigate the contribution of TRPA1, a Ca²⁺-permeable ion channel highly expressed in DRG, in mediating Ca²⁺ dysregulation through acute MeHg exposure. HEK 293 cells were transfected with human TRPA1 72 hrs prior to single-cell microfluorimetry studies. Fura-2 AM, a ratiometric Ca²⁺ fluorophore, was used to measure relative changes in [Ca²⁺]; the time-to-onset of P1 and P2 was determined by 2-ΔΔCt. Differentiated F11 cells also express low levels of RNA most

MeHg is an environmental contaminant that elevates [Ca²⁺], in two kinetically-different phases. Phase one (P1) consists of Ca²⁺ release from intracellular storage organelles, whereas phase two (P2) results from an influx of Ca²⁺ through Ca²⁺-permeable ion channels. MeHg-induced elevations in [Ca²⁺] have been correlated with increased cell death. This study surveyed VGCC RNA expression in MeHg-exposed F11 cells, an immortalized cell line derived from dorsal root ganglia. Changes in RNA expression of the pore-forming subunit of the L-, N-, P/Q-, R-, and T-type VGCC isofoms (calcna1c, 1h, 1a, 1e, and 1h) were determined by qPCR. F11 cells were cultured and differentiated (2 µm retinoic acid) for 24-72 hrs prior to 1 hr MeHg exposure (1, 2 and 5 µM). 24 hrs after MeHg exposure, RNA was isolated and converted to cDNA. PCR was performed on CDNs and relative changes in RNA were determined by 2-ΔΔCt. Differentiation alone increases the RNA expression of calcna1c and calcna1a in F11 cells at 72 hours (2.5±0.05 and 2.5±0.05, respectively; mean fold-change ± SEM), Differentiated F11 cells also express low levels of RNA for calcna1b (1.01±0.04), calcna1a (0.45±0.04), and calcna1h (1.12±0.03); exposure to MeHg reduces RNA expression of these genes in a concentration-dependent manner, with 5 µM MeHg reducing calcna1c, calcna1a, and calcna16 RNA most markedly (0.45±0.06, 1.06±0.09, and 0.63±0.04, respectively). Downregulation of RNA expression was also dependent upon the differentiation time point; cells differentiated for longer periods displayed a greater reduction of calcna1c expression universally. Changes in RNA expression may reflect a concomitant alteration in protein expression, thus these data may indicate distinct VGC isoforms as critical contributors to Ca²⁺ influx in P2. Because RNA expression of calcna1c and calcna1a is most abundant following acute MeHg exposure, the L- and P/Q-type VGCCs may be significantly involved in cytotoxic mechanisms. Supported by NIH grant R01ES03299 and R25NS05467.

1370 Effect of Methylmercury (MeHg) on RNA Expression of Voltage-Gated Calcium Channels (VGCCs) in Naïve and Differentiated F11 Cells

Y. Chung, F. Tang, C. Su, T. Lu, C. Wu, K. Chen, D. Hung, Y. Chen, C. Yen and C. Objectives: Methylmercury (MeHg) is a well-known environmental pollutant. The human beings expose to methylmercury through ingestion, which can cause irreversible nervous system dysfunction and injuries. However, effects and possible mechanisms of MeHg-induced neurotoxicity remained unclear. In this study, we attempted to investigate the important roles of endoplasmic reticulum (ER) stress-regulated pathway in MeHg-induced neurotoxicity.

Results: MeHg significantly decreased cell viability in a dose-dependent manner (1.5-7 µM) and induced the increase in caspase-3 activity, annexin V-FITC binding, and the protein expressions of caspase cascades in Neuro-2a cells, indicating that MeHg could induce neuronal cell apoptosis. Moreover, exposure of Neuro-2a cells to MeHg could trigger ER-stress as indicated by several key markers (GRP-78, GRP-94, CHOP, and XB-1) and upstream molecules (the phosphorylation of PERK, eIF2-α, and IRE-1), and caspase-12 cleavage. Pretreatment with antioxidant NAC and transfection with specific si-RNA (GRP-78, GRP-94, CHOP, and XB-1) could effectively attenuate MeHg-induced cytotoxicity, apoptotic events and ER-stress-related signals.

Conclusions: These results indicate that the ROS production triggered ER-stress signaling pathway involves in MeHg-induced neuronal cell apoptosis.
Methylmercury (MeHg) causes calcium (Ca)-dependent neurotoxicity, which includes increases in spontaneous release of neurotransmitters. Both intracellular Ca ([Ca²⁺]i) release and extracellular Ca entry contribute to this effect. Although an inextricable link between alterations in Ca homeostasis and MeHg-induced neurotoxicity has been demonstrated in the past, Ca’s exact role is unclear. Previously, work in our lab has revealed a concentration- and time-dependent relationship between MeHg and extracellular dopamine (DA). In this study, we seek to manipulate [Ca²⁺]i levels to further define Ca’s relationship with MeHg and release of DA. A23187, a Ca²⁺ ionophore, which increases [Ca²⁺]i, was therefore used to elucidate the contribution of [Ca²⁺]i on the quantity of DA released by rat pheochromocytoma (PC12) cells. Forty-eight hours before treatment, undifferentiated PC12 cells were seeded at a density of 7×10⁵ cells/mL in poly-D-lysine coated wells. At time of experiment, cells were pre-treated with either vehicle or 1 μM A23187 for 30 min. Subsequently, treatment medium was replaced with either vehicle, 1 M A23187, or a combination of 1 μM A23187 and 2 μM MeHg for an incubation period of 60 min. Following treatment, plates were centrifuged and treatment medium was collected for analysis by high performance liquid chromatography (HPLC) to quantify extracellular DA. Extracellular DA levels increased significantly following treatment with A23187, as compared to vehicle-treated controls. Although co-treatment with MeHg increased DA levels when compared with basal levels, it blunted the extent of increase caused by treatment with the ionophore alone. These data suggest that although MeHg is able to increase the level of DA released by PC12 cells, its effect is not directly correlated with the amount of Ca available in the intracellular space. Supported by a VICTR supplement to NIH grant ROI1ES03299 and T32ES007255.

Methylmercury (MeHg) is an environmental neurotoxicant which induces selective cell death in the nervous systems. In this study, we investigated the effect of MeHg on differentiating neurons using PC12 cells in the presence of nerve growth factor (NGF). NGF is known to enhance the vitality and cellular functions in neurons. The PC12 cells exhibited apoptosis 2 days after exposure to 100 nM MeHg in the presence of 50 ng/ml NGF. During the course of MeHg-induced apoptotic cell death, inhibition of neuronal cell differentiation preceded apoptosis. Time course study of immunocytochemistry and ELISA analyses for neurite specific protein namely, neurofilament triplet H protein (NF-H), demonstrated that MeHg inhibited the expression of NF-H protein before the induction of apoptosis. To further investigate the factors responsible for inhibition of neuronal cell differentiation and subsequent apoptotic cell death, we investigated the expression levels of neurotrophic factor receptors, tropomyosin receptor kinase (Trk) A, B, and C, which regulate neuronal cellular differentiation in neurons. Western blot analysis demonstrated that MeHg inhibited selectively the TrkA phosphorylation, whereas changes in the total TrkA, B, and C levels were not observed. Furthermore, we demonstrated that a GM1 ganglioside analog, which is known to enhance NGF-triggered TrkA phosphorylation, prevented the differentiating PC12 cells against MeHg-induced apoptotic cell death. These findings suggest that MeHg exposure inhibits NGF-triggered TrkA phosphorylation selectively and lead to apoptotic neuronal cell death in differentiating PC12 cells.

Astrocytes and microglia are potential targets for MeHg-mediated Ca²⁺ dysregulation. However, the extent to which they respond to MeHg in the absence of ACh and their relative contributions to cytoxicity are not known. We studied the role of AChRs in MeHg-induced cytoxicity in PC12 cells, a model that expresses both muscarinic (mACHRs) and nicotinic receptors (nAChRs) but does not express glutamate receptors, an additional potential target for MeHg-induced elevation of [Ca²⁺]i. Nerve growth factor-differentiated PC12 cells were treated for 1h with 1, 2, or 5μM MeHg. Cytotoxicity was examined using the Live/Dead Assay® 1 or 24h after MeHg treatment concluded. Mecamylamine (M, 5μM) and atropine (10μM), nAChR and mAChR antagonists respectively, were used to determine the relative involvement of nAChRs and mAChRs to MeHg-induced cell death. Viability at 1 and 24h after MeHg was reduced in a concentration-, but not time-dependent manner. At 1h, MeHg-induced cytotoxicity ranged from 33% (1μM) to 57% (5μM) and at 24h from 35% (1μM) to 65% (5μM). Pretreatment with either MEC or atropine protected PC12 cells from MeHg-induced cell death at both time points, however protection was proportional to the MeHg concentration. Pretreatment with either MEC or atropine protected PC12 cells from MeHg-induced cell death at both time points, however protection was proportional to the MeHg concentration. At 1μM MeHg protection ranged from 33%-97% (3-35% cytoxicity) at both 1 and 24h, whereas at 5μM MeHg protection was only in the range of 32-50%. Thus both mAChRs and nAChRs contribute to Ca²⁺-induced cytoxicity by MeHg. This occurs in the absence of a cholinergic agonist, suggesting direct actions of MeHg on AChRs. This project was supported by NIH grants: R25NS065777 and R25GM059429.
astrocytes between the two areas. The goal of this study was to compare the toxicity of MeHg on cerebellar and cortical astrocytes. Determining if MeHg differentially affects astrocytes from these two brain regions could help us understand cellular mechanisms underlying the preferential sensitivity of cerebellar granule cells to MeHg. Primary astrocyte cultures from the cerebellum and cortical forebrain layer were obtained from C57BL6 male mice. At 14-15 DIV, cells were exposed for 3h to 0μM, 2μM, 5μM, 10μM, or 15μM MeHg. Cytotoxicity was measured 24h later using EthD-1 and Calcein AM. In parallel cell cultures, GFAP and the nuclear fluorogenic indicator DAPI were used to calculate the percentages of astrocytes in the cultures. The percentages in the cerebellar and cortical areas were 58% and 62% respectively. The mean percentage of cell death in the cerebellum was: 0.5%, 26%, 52%, 88%, and 96% at 0, 2, 5, 10, or 15μM MeHg respectively. In the cortical layer it was: 1.3%, 50%, 81%, 88%, and 94% respectively. Cell viability of cortical astrocytes was significantly reduced at 2 - 15 μM MeHg: in cerebellar astrocyte viability was reduced only at 5-15 μM. There was no significant difference at 0 and 1μM between cerebellar and cortical astrocytes compared. The LC50s of the cerebellum and cortical layers were 4.1 μM and 1.6 μM MeHg respectively. Thus, whereas cerebellar granule cells are more susceptible to MeHg, their attendant astrocytes are less sensitive to MeHg-induced cytotoxicity than are cortical astrocytes, and brain region-dependent differences in cytotoxicity of astrocytes occurs in response to MeHg. Supported by NIH grants R01ES03299, R25NS4467 and T32GM092715.

1376 GABA Receptors Are Not a Primary Contributor to Methylmercury-Induced Cell Death in Transiently Transfected HEK293 Cells

D. Wiwatratana1, C. Colon Ortiz2, N. Delvalle2 and W. D. Atchison1, 2.
1Dept. Pharmacology and Toxicology, Michigan State University, East Lansing, MI.
2College of Veterinary Medicine, Michigan State University, East Lansing, MI.

Altering of GABA type A receptors(GABA,R)-mediated inhibitory function by MeHg contributes to cerebellar dysfunction. The effect is more pronounced in cerebellar granule cells (CGCs) than the neighboring Purkinje cells (PKCs). Differential effects of MeHg on these two types of neurons could relate to differential expression of GABA,R subunits. CGCs express α1 and γ2 subunits; PKCs express only α1 subunits. The subunits confer markedly different properties to GABA,Rs as they are preferentially co-expressed with different auxiliary subunits such as β2 and δ. The δ subunit is very important in CGC tonic inhibition. Its preferential disruption by MeHg could cause enhanced excitability in CGGs, and promote Ca-induced cell death. Two questions were tested: 1) does co-expression of differential auxiliary γ2 and δ subunits with α1 subunits contribute to MeHg-induced cell death? 2) Will differential subunit combinations of α and β subunit-containing GABA,Rs exacerbate MeHg-induced cell death? HEK293 cells were transiently transfected with combinations of GABA,R subunits and exposed for 3 or 6h to 1, 2 or 5μM MeHg. Cell viability was assessed using a Live/Dead cytotoxicity assay. HEK293 cell death increased with increasing [MeHg] at both 3 and 6h exposure. No significant difference between these exposure exists. Acute mortality rate induced by MeHg is similar for GABA,Rs having α1,β2,γ2 and α1,β1,β3,δ compositions and did not increase over that of untransfected or GFP-transfected HEK cells. Comparisons of susceptibility to MeHg-induced cell death among differential GABA,R subunit compositions also indicated no significant difference. HEK cells transfected with GABA,R containing α1,β2,γ2,α1,β1,β3,δ, α1,γ2,δ and α1,δ subunits were not more susceptible to MeHg-induced cytotoxicity. While GABA,Rs were very sensitive targets to MeHg, a simple direct action of MeHg on the receptor will not explain the heightened sensitivity of CGGs.

1377 Effects of Methylmercury on Caenorhabditis elegans Calcium Ion Channel Mutant Strains

S. M. Spencley1, K. R. Sherer2, R. Hajela1 and W. D. Atchison1, 2.
1Dept. Pharmacology and Toxicology, Michigan State University, East Lansing, MI.
2College of Veterinary Medicine, Michigan State University, East Lansing, MI.

Caenorhabditis elegans (C. elegans) strains KC136, CB55, DM612, JD21, MT6129, and DAF95 were used to examine the percent viability for GOF or LOF L-, P/Q- and T-type voltage-gated Ca2+ channels (VGCCs) in the presence of methylmercury (MeHg) using a gel ring hanging drop medium. Exposure of L3 worms to 1.0-100 μM MeHg resulted in decreased viability with increasing [MeHg] for 24 and 48 h. We expected that GOF VGCC mutants would have decreased viability resulting from increased Ca2+ influx in the cell leading to excitotoxicity while LOF mutants would have increased viability after MeHg treatment; however, we observed the opposite effect. L- and P/Q-type voltage-gated Ca2+ channels exhibited decreased viability when exposed to MeHg, while the null mutation for low-voltage activated VGCCs led to increased viability. GOF high-voltage activated VGCC mutants had increased viability. Two explanations for this result are either upregulation of other VGCC subtypes leading to increased Ca2+ influx or complete block of Ca2+ entry to the cell thus decreasing viability. A third possible explanation for these results is that mutants have decreased Ca2+ buffering capacity and physiologic Ca2+ levels lead to death. To further explore these possibilities, KC136 was pretreated with 0.25 or 0.5μM of the L-type VGCC antagonist nemadipine-A (NEM-A) before exposure to 1.0-100 μM MeHg. NEM-A can cross the C. elegans cuticle, unlike other antagonists such as verapamil. Pretreatment of KC136 with 0.25 μM NEM-A plus MeHg exposure had no significant effect. Pretreatment of KC136 worms with 0.5 μM NEM-A significantly decreased viability at lower [MeHg] over 24 and 48 h without any change at 48 h. However, the significant effect may be due to NEM-A alone rather than a compounded effect of NEM-A and MeHg exposure. Supported by NIH grant R01ES03299.

1378 The Putative Multidrug Resistance Protein MRP-7 Inhibits Methylmercury-Associated Animal Toxicity and Dopaminergic Neurodegeneration in Caenorhabditis elegans

N. M. VanDuyne1, W. Li1, J. Trimbadi2 and R. M. Nuss1.
1Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN and 2Chemistry, Indiana University, Bloomington, IN.

Background: Recent epidemiological and vertebrate studies suggest that MeHg exposure may contribute to dopamine (DA) neuron vulnerability and the propensity to develop Parkinson’s disease (PD). We have developed a novel Caenorhabditis elegans (C. elegans) model of MeHg toxicity and have shown that chronic exposure confers embryonic defects, developmental delays, and DA neuron degeneration. Aims/Objectives: In this study we asked what genes and molecular pathways are involved in MeHg-induced whole animal and DA neuron pathology. Methods: We utilized the transgenic C. elegans, RT-PCR, Western analysis, and neuronal morphology characterization to analyze expression, localization and the role that SKN-1, MRP-7 and post-translational modifications play in MeHg-induced whole animal and DA neuronal death. Results: Over 17,000 genes were screened for whole animal sensitivity to MeHg, and 92 genes were identified (90% have strong human homologues) that affect whole animal and/or DA neuron pathology. Here we report detailed analysis of a putative plasma membrane transporter’s role in MeHg-associated DA neuroprotection. Specifically we demonstrate that genetic knockdown of MRP-7 results in a 2-fold increase in Hg levels and a dramatic increase in stress response transcriptome, gonadal morphology, mitochondrial and other abnormalities, as well as an increase in MeHg-associated animal death. Chronic exposure to low concentrations of MeHg induces MRP-7 gene expression, while exposures in MRP-7 genetic knockdown animals results in a loss of DA neuron integrity in without affecting whole animal viability. Conclusions: These studies show for the first time that a multidrug resistance protein is expressed in DA neurons, and its expression inhibits MeHg-associated DA neuron pathology. 1379 NAD+ Supplementation Attenuates Methylmercury Toxicity in Caenorhabditis elegans

S. W. Caito and M. Aschner.
Molecular Pharmacology, Albert Einstein College of Medicine, Bronx, NY

Methylmercury (MeHg) is a persistent pollutant with known neurotoxicity. MeHg causes oxidative stress and mitochondrial dysfunction in vitro and animal models. This can lead to altered cell metabolism and energetics. It has been reported that MeHg decreases cellular nicotinamide adenine dinucleotide (NAD+), however the effects on NAD-dependent enzymes and cellular functions have not been characterized. Caenorhabditis elegans (C. elegans) is a powerful genetic model for the investigation of neurotoxicity of MeHg, as worms readily accumulate the metal, leading to decreased neurobehavior and dopaminergic neurodegeneration. Herein, we tested the hypothesis that NAD+ supplementation could attenuate MeHg toxicity and dopaminergic (DAergic) neurodegeneration. Worms were treated with 1 mM NAD+ prior to MeHg treatment and assessed for lethality. Treatment with increasing doses of MeHg decreased survival of C. elegans (LD50 = 20.24 μM) and NAD+ pre-treatment significantly attenuated its toxicity (LD50 = 34.6 μM, p < 0.001). Furthermore, worms lacking pnc-1, the rate-limiting enzyme in NAD+ synthesis, were highly sensitive to MeHg toxicity (LD50 = 3.598 μM, p < 0.001). As MeHg is implicated in DAergic neurodegeneration involved in Parkinson’s disease, we determined whether DAergic-dependent behavior was altered by NAD+ depletion in response to MeHg treatment. Wildtype worms had significantly less DAergic behavior as measured by the basal slowing response (p < 0.05). The DAergic behavior was further decreased in pnc-1 mutants treated with MeHg (p < 0.05), suggesting that DAergic-dependent behavior may be altered by NAD+ levels. DAergic cell morphology was evaluated following NAD+ supplementation in worms express-
Methylmercury (MeHg) is a neurotoxicant, which poses a continued health risk to the human population. Despite extensive research, its precise mechanism of action has not been fully elucidated. Furthermore, the genetic basis for MeHg susceptibility is not well defined. In order to explore genetic modulators of MeHg-induced neurotoxicity, we utilized the BXD recombinant inbred (RI) mouse cohort. This cohort consists of fully inbred strains, containing varied nuclear factor erythroid 2-related factor 2 (Nrf2) expression. Nrf2 is a well-established antioxidant gene that is activated in response to oxidative stress. We hypothesized that mice with high Nrf2 expression would be less vulnerable to MeHg-induced neurotoxicity versus those with low expression. Therefore, mice were selected that exhibited either high (BXD21, BXD31) or low (BXD28, BXD84) Nrf2 expression, and the role of Nrf2 in modulating MeHg-induced neurotoxicity was examined. Astrocyte cultures were prepared from post-natal day 1 (PND1) pups, and treated approximately 3 weeks post-isolation with 1, 5, or 10µM MeHg for 90 min. After exposure, cells were collected for western blot analysis. BXD21/31 mice had significantly higher baseline Nrf2 expression relative to BXD28/84 (p<0.001). Following MeHg exposure, BXD31 mice exhibited higher Nrf2 expression compared to BXD28 with an overall significant effect of strain (p<0.001), treatment (p<0.001) and interaction sure, BXD31 mice exhibited higher Nrf2 expression compared to BXD28 with an overall significant effect of strain (p<0.001), treatment (p<0.001) and interaction. BXD31 mice exhibited higher Nrf2 expression compared to BXD28 with an overall significant effect of strain (p<0.001), treatment (p<0.001) and interaction (p<0.001). In BXD31 mice, Nrf2 expression was increased following MeHg exposure. In BXD28 mice, Nrf2 expression was decreased following MeHg exposure. These results provide evidence that Nrf2 expression plays a key role in modulating MeHg toxicity. The data also demonstrate the utility of the BXD RI mouse strains for understanding genetic susceptibility to MeHg. Future experiments will explore the impact of MeHg-induced neurotoxicity on mice with high Nrf2 expression. Supported by NIEHS/NIH grant ES003299.

The cerebellum is a primary target of methylmercury (MeHg) neurotoxicity. Following acute MeHg exposures in vitro, this effect involves presynaptic effects on transmitter release and elevation of [Ca2+]i. However, the extent to which the acute effects mirror chronic toxicity has not been reported. To study the chronic effects of MeHg on cerebellar synaptic function and neuronal excitability, we studied changes in short-term plasticity and neuronal firing in cerebellar slices of mice following exposure to 5 ppm MeHg in the drinking water for 6 weeks (15mos old) or 12 weeks (15mos old). Paired-pulse evoked synaptic currents in Purkinje cells were recorded in sagittal slices using whole cell voltage-clamp recording mode by stimulating the white matter; single action potential (AP) or repetitive firing in Purkinje or granule cells were evoked by injecting short or long pulses, respectively, of depolarizing currents using whole-cell current-clamp recording mode. Following 6 mos of MeHg exposure, no significant changes in paired-pulse responses or AP firing in Purkinje and granule cells were observed between control and MeHg-treated mice. However, after 12 mos of MeHg exposure, 36% and 64% of MeHg-treated mice showed paired-pulse depression (PPD) and facilitation (PPF), respectively. In contrast, 72% and 28% of control mice displayed PPD and PPF, respectively. This suggests that MeHg acts presynaptically to promote PPF because short-term plasticity is generally attributed to presynaptic alterations of transmitter release. Chronic (12mo) MeHg exposure also significantly reduced the frequency of repetitive firing in granule but not Purkinje cells compared with those from control mice. Thus, 12mo, but not 6mo MeHg treatment shifts short-term plasticity in cerebellum from PPF to PFP. Cerebellar synaptic function was modified through direct actions on the nerve terminal. Cerebellar granule cells are more sensitive than are Purkinje cells to these effects. Supported by NIEHS/NIH grant ES003299.

BACKGROUND. Methylmercury toxicity has been linked to disrupted calcium homeostasis and Ca2+ accumulation in nerve terminals. Calcium channel blockers such as nimodipine (NIM) protect against MeHg’s toxicity. Motor function tests like the rotarod and wheel-running have been used to detect early signs of MeHg neurotoxicity while overt neurological signs such as claspin reflex and ataxia come later. The goal of the current study was to examine age-related differences in the onset of MeHg toxicity, and the ability of dietary nimodipine to confer neuroprotection from chronic MeHg exposure. METHODS. Male BALB/c mice, ages 2.5 and 9 months (n=52 and n=62, respectively), were administered 0 ppm or 10 ppm Hg as MeHg in drinking water and 0 ppm or 200 ppm NIM in chow. Rotarod and wheel-running were evaluated approximately weekly and analyzed with 2 x 2 x 2 (Age x Water x Diet) between-group variables and exposure-duration as a repeated measure using linear mixed-effects. RESULTS. Older MeHg-exposed mice exhibited diminished rotarod performance before the younger MeHg-exposed mice did (exposure day 44 vs 86). Younger mice outperformed older mice overall. Wheel-running followed a similar pattern but with no age-related differences. Gross neurological signs such as claspin and hind-limb paralysis appeared later. Nimodipine delayed rotarod and wheel-running deficits in both age groups as evidenced by significant Age x MeHg x NIM x Exposure-day interactions. CONCLUSION. Chronic exposure to 10ppm MeHg alone decreased time spent on rotarod and distance run in an age-related manner. Chronic nimodipine delayed motor dysfunction in young and old animals but had no detectable effect of its own. Young mice outperformed older mice on rotarod. Rotarod and wheel-running revealed motoric deficits before the onset of MeHg-induced gross motor dysfunction. [Supported by NIH ES003299].
Brain Region-Dependent Effects of Methylmercury on Expression of Ligand and Voltage-Gated Calcium Channels in Rat

A. Colon-Rodriguez1, 2, 3, R. Hajela2 and W. D. Atchison1, 2, 3, 4, 5, Pharmacol, Mich State Univ, East Lansing, MI, 3CMIB, Mich State Univ, East Lansing, MI and 4CIT, Mich State Univ, East Lansing, MI.

Methylmercury (MeHg) causes brain region-specific toxicity and contributes preferentially to cell death in cerebellar granule cells (GCGs). MeHg disrupts synaptic transmission, resulting in alteration of Ca2+ homoeostasis, manifesting as elevated [Ca2+]i in both GCGs and motor neurons. Our aim was to compare the effects of low dose MeHg exposure on gene expression (measured via steady state mRNA levels) of subunits of voltage (VGCC) and ligand-gated ion channels, each of which could contribute to the MeHg-induced elevation of Ca2+. α1E, which increased. In BS, 30 d exposure increased significantly VGCC levels; after 30 d of clearing all IS alone. AMPAR GluR2 and GluR3 decreased in CB after 15 d exposure. After 30 d exposure and the clearing period only GluR3 increased. BS AMPAR levels increased after 15 d exposure, except GluR3. After 30 d exposure all AMPAR increased further, this increase persisted after the clearing period, except for GluR4. NMDAR levels increased in both the CB and BS after 30 d exposure. These observations demonstrate that MeHg affects gene transcription or stability of mRNA differentially for NMDAR, AMPAR, and VGCCs between themselves as well as in the CB and the BS. Decrease in VGCCs in the CB and increase in the BS, as well as in the BS, support the idea that the CB is one of the most susceptible targets of MeHg toxicity, maybe due to its inability to compensate for MeHg effects on these key genes.

Cord Expression of Glutamate Receptor mRNA

A. L. Perez-Medina1, A. Colon-Rodriguez1, 2, 3 and W. D. Atchison1, 2, 3, 4, 5, Pharmacol, Mich State Univ, East Lansing, MI, 3CMIB, Mich State Univ, East Lansing, MI and 4CIT, Mich State Univ, East Lansing, MI.

In a mouse model of ALS methylmercury (MeHg) causes Ca2+-dependent excitotoxicity in motor neurons, an effect involving increased sensitivity of Glutamate ceptors (GluR), especially Ca2+-permeable AMPA receptors (AMPARs). The objective of this study was to determine if motor neuron GluR expression was increased by a subacute MeHg treatment in a non-ALS animal model. If so, this might indicate that these targets are especially sensitive to MeHg, and in a susceptible genotype (such as the ALS mouse model) lead to motor neuron toxicity. Quantitative real-time PCR (qPCR) was used to evaluate the NMDAR (NR1, NR2A, and NR2C) and AMPAR (GluR1, GluR2, GluR3, and GluR4) subunit mRNA expression. Sprague Dawley rats received 0.75, 1.5 mg/kg/day MeHg or 0.9% NaCl (control) sc. Treatment began at postnatal day 5 (PND5) and ended on PND81. Other groups of rats had an additional 30 days without treatment following the 30 days of MeHg exposure (PND65). RNA isolated from 10mg of lumbar and sacral spinal cord were submitted to reverse transcription PCR (RT-PCR). Resulting cDNA was used to perform qPCR. MeHg exposure led to alterations on the mRNA levels of the most abundant GluR subunits in spinal motor neurons. At 15 days, 0.75 mg/kg/day MeHg increased the expression of all the GluR subunits studied. The effect was similar in the 1.5 mg/kg/day exposure group. At 30 days, 0.75 mg/kg/day MeHg exposure increased the expression of all the subunits. In the 1.5 mg/kg/day exposure group a similar but less pronounced increase occurred. The 60 day rats that had the 30 day “clearing” period also had an increase in expression after MeHg exposure, except the NR2A subunit whose expression was decreased in both treatment groups. In conclusion, subacute MeHg exposure causes enduring changes in expression of GluR subunits in rats. These can affect the ability of motor neurons to regulate [Ca2+]i. In genetically susceptible organisms, this could result in motor neuron death by excitotoxicity. (Supported by NIH grants R01ES03299 and R25NS065777).

Plasma Thiol Antioxidant Barrier as a Potential Biomarker for Methylmercury Intoxication

The critical role of oxidative stress in the pathogenesis of methylmercury (MeHg) cytotoxicity has been clarified in vitro and in vivo. It is important to identify a biomarker for MeHg intoxication. In this work, we examined the following 3 plasma oxidative stress markers: diacron reactive oxidant metabolites (d-ROM), thiol antioxidant barrier, and biological antioxidant potential (BAP), by using a free radical elective evaluator in MeHg-exposed rats. The results were compared to those obtained from rats administered with 0.2% (w/v) lead (Pb) acetate or 15 ppm cadmium (Cd) chloride in drinking water. Male Sprague-Dawley rats were administered with 20 ppm MeHg in drinking water. The changes in the 3 plasma oxidative stress markers, histopathology, body weight (BW), and clinical features were examined every week. BW significantly decreased from 2 weeks after MeHg exposure in MeHg-treated rats compared to the controls. MeHg-treated rats exhibited hind limb crossing at 3 weeks after MeHg exposure. Histopathological changes were observed in the cerebellum of rats exposed to MeHg for 4 weeks. Among the plasma oxidative stress markers, the level of thiol antioxidant barrier decreased at 2 weeks after MeHg exposure; however, no histopathological changes were observed at this stage. The d-ROM levels increased 3 weeks after MeHg exposure, whereas BAP levels did not change during 4 weeks of MeHg exposure. Although rats that were exposed to Pb for 4 weeks showed pathological changes in the hippocampus, no changes were observed in the plasma oxidative stress markers. Cd-treated rats also showed no changes in plasma oxidative stress markers. The high affinity of MeHg for the selenohydryl group, sulfhydryl group, or selenide may cause an early decrease in the level of plasma thiol antioxidant barrier. In contrast, oxidative stress in plasma may be delayed although Pb and Cd are known to induce oxidative stress in tissues. Our results suggest that thiol antioxidant barrier level in plasma is a potential biomarker for MeHg intoxication.
ArsenicInduces Reactive Oxygen Species-Caused Neuronal
Cell Apoptosis through JNK/ERK-Mediated Mitochondria-
Dependent and GRP78/CHOP-Regulated Pathways

T. Lu1, F. Tang2, C. Su1, C. Yen1, C. Wu1, K. Chen3, Y. Chung4, D. Hung5, C. Huang5 and Y. Chien4.

Recently, epidemiological studies have suggested a possible relationship between inorganic As (iAs) exposure and neurodegenerative disease development. However, the effects and underlying mechanisms of iAs-induced neuronal cell injuries are most unknown. The present study demonstrated that iAs significantly decreased cell viability and induced apoptosis in Neuro-2a cells. iAs also increased oxidative stress damage and induced several features of mitochondria-dependent apoptotic signals. Pretreatment with the antioxidant N-acetylcysteine (NAC) effectively reversed these iAs-induced responses. iAs also increased the phosphorylation of JNK and ERK1/2, but did not that p38-MAPK, in treated Neuro-2a cells. Additionally, exposure of Neuro-2a cells to iAs triggered endoplasmic reticulum (ER) stress identified through several key molecules (GRP78, CHOP, XBP-1, and caspase-12), which was prevented by NAC. Transfection with GRP78- and CHOP-specific si-RNA dramatically suppressed GRP78 and CHOP expression, respectively, and attenuated the activations of caspase-12, -7, and -3 in iAs-exposed cells. Therefore, these results indicate that iAs induces ROS causing neuronal cell death via both JNK/ERK-mediated mitochondrial-dependent and GRP78/CHOP-triggered apoptosis pathways.

Identification of Novel Proteomic Biomarkers for Heavy-
Metal-Induced Nephrotoxicity

Y. Shin1, M. Akram1, K. Kim1, E. Kim1, H. Kim1 and O. Bae1.
1College of Pharmacy Institute of Pharmaceutical Science and Technology, Hansung University, Ansan, Republic of Korea and 2College of Pharmacy, Sungkyunkwan University, Suwon, Republic of Korea.

Long-term exposure of low-dose heavy metals are well-established risk factors against human health. Among various organs, the kidney is one of the most sensitive targets for heavy metal-associated toxicity. Development of novel biomarkers is essential to evaluate and predict nephrotoxicity following exposure to low-dose heavy metals. Here we tried to identify new biomarkers using proteomics approaches in kidney tissues isolated after heavy metal exposure. Male Sprague-Dawley rats received mercuric chloride (HgCl2) and cadmium chloride (CdCl2) by oral administration. Proteomic analysis with kidney samples revealed that expression of several proteins was elevated by Hg and Cd exposure, suggesting them as potential candidates for new biomarkers. We further measured the change of new biomarkers in renal tubular cells following heavy metals exposure. Interestingly, in normal rat kidney proximal tubular cells (NRK-52E), the change of expression level of these new candidates were well correlated to the extent of cytotoxicity induced by heavy metals. Notably, the increase of new biomarkers was observed in drug-exposed tubular cells, suggesting the potential use of these biomarkers. The change of the new biomarkers was comparable to that of traditional biomarkers for renal toxicity, such as Kim1, Lcn2, Spp1 and TIMP1. With this study, we identified new protein biomarkers as novel candidates for drug or heavy metal-induced renal toxicity. Superior correlation between cytotoxicity and the extent of these protein changes suggests that they can be useful biomarkers to evaluate or predict renal toxicity.

Expression of Copper (Cu) Transporting Genes in
Subventricular Zone (SVZ) and Choroid Plexus (CP)

X. Fu, L. Hong, W. Jiang and W. Zheng. School of Health Sciences, Purdue University, West Lafayette, IN.

Our recent data using X-ray fluorescent microscopy suggests an age-related increase of Cu along the wall of brain ventricles called SVZ. Since the regulation of cellular Cu homeostasis involves a variety of Cu transporters, chaperones and intracellular binding proteins, it becomes necessary to understand the expression of these Cu regulatory proteins and how they contribute to the high Cu concentration in SVZ. Anatomically, SVZ is in direct contact with cerebrospinal fluid (CSF) secreted by the CP where the blood-CSF barrier (BCB) is located. This study was designed to compare the gene expression of Cu regulatory proteins in SVZ and CP. SVZ and CP tissues were dissected from brains of 3-wk, 10-wk or 9-m old male Sprague-Dawley rats and SVZ tissues from 3-wk-old rats were used for the primary cultures of neural stem cells (NSCs) and choroidal epithelial cells (CECs). Target genes were first identified through quantitative real-time RT-PCR and normalized with the internal reference gene Actb. Our data showed that the expression level of Cox17 was the highest in SVZ, followed by Ctr1 and Dmt1, while Ctr1 was expressed the most in CP followed by Cox17 and Dmt1. In NSCs cultures. However, a comparison of gene expression, Cox17, Dmt1 and Ctr1 were about 2-, 4-, and 60-fold lower in SVZ than in the CP, respectively (p<0.05). Higher expression levels of Ctr1 and Dmt1 were observed in CP of 9-m old rats than 3- and 10-wk old animals (p<0.05). Ap1b7 had the lowest expression in both SVZ and CP of all animals. Furthermore, the expression level of Dmt1 was higher in NSCs than CECs (p<0.01), while CECs expressed more Ap1a7 and Ap1b1 than those in NSCs (p<0.05). These findings suggest the Cu regulatory gene expression pattern in SVZ is different from those in CP; furthermore the age appears to influence the expression of these Cu regulatory genes. (Supported in part by NIH/NIEHS ES-008146)
Avoidance rates for shock exposures were calculated for the first and second halves (30 minutes each) of each session. There was no significant difference in mean body weight at 6 weeks of age between the TBT group and the control. A significantly lower mean value of the avoidance rates in the TBT group compared with that in the control was observed in the first 30 minutes of the sessions on day 1. The mean values of the avoidance rates in the first and second 30 minutes in the TBT group were lower than those in the control from days 2 to 8. These results indicate that the learning ability was impaired in the F1 THA rats exposed to TBT at 50 ppm in their dams’ food.

1392a Chronic Lead Exposure Reduces Presynaptic Vesicle Availability in Mossy Fiber-CA3 Synapses and Shaffer Collateral-CA1 Synapses in the Rat Hippocampus

Lead (Pb2+) exposure has been shown to impair presynaptic neurotransmitter release in both in vivo exposed animals and in cell culture models. The mechanism by which this impairment occurs has not been fully elucidated. However, our lab has previously shown that Pb2+ exposure during synaptogenesis inhibits vesicular release and reduces the number of fast-releasing sites in cultured hippocampal neurons (Neal et al., 2010). We hypothesized that the impairment of vesicular release and the reduction in the number of fast-releasing sites may be associated with reductions in the number of vesicles docked in the presynaptic active zone (PAZ).

In the present study, we used transmission electron microscopy to examine presynaptic vesicle pools in Perforam Path-Dentate Gyrus, Mossy Fiber-CA3, and Shaffer Collateral-CA1 synapses to determine if in vivo Pb2+ exposure altered synaptic vesicle number. Vesicles within the presynaptic axon terminal were counted and the distance between the vesicle and the PAZ measured using LoClust (Nikonlenko and Skibo, 2004). Vesicles were classified as docked if they contacted the PAZ, rapidly recycling if they were 200 nm or less from the PAZ, or resting if they were more than 200 nm from the PAZ. We found that Pb2+ exposure significantly reduced the number of docked vesicles in Mossy Fiber-CA3 and Shaffer Collateral-CA1 synapses and the number of vesicles in the rapidly recycling pool of Mossy Fiber-CA3 synapses. These data suggest that Pb2+ exposure interferes with presynaptic neurotransmitter release by reducing the number of vesicles available for release. These findings provide a novel mechanism by which Pb2+ exposure impairs vesicular release. Further, this study confirms our previous findings in hippocampal neurons in culture and corroborates current work in which in vivo Pb2+ exposure impairs vesicular release. These findings provide a novel mechanism by which Pb2+ exposure impair vesicular release and reduces the number of fast-releasing sites in cultured hippocampal neurons and, subsequently, with the alimentary tract.

1394 Safety Considerations for the Use of Nanomaterials in Food and Food-Related Products: A US FDA Regulatory Perspective
S. Thurmood, Center for Food Safety and Applied Nutrition, US FDA, Washington, DC.

The US FDA has been developing nanomaterial-related industrial guidance that cover foods, food contact materials and food ingredient containing products over which the Agency has regulatory authority since the publication of its July 2007, report on nanotechnology. In addition, FDA is conducting research to gauge the utility of our currently recommended safety testing paradigms for assessing the potential for food-related nanomaterials to produce toxicity and/or carcinogenicity. Research is underway at the CFSAN and the National Center for Toxicological Research (NCTR) to evaluate the recommended standard battery of in vitro tests when used with nanoparticulates and nanocoercipated products, and to identify possible replacement tests. Early results indicate that this standard safety assessment panel may need to be augmented with other in vitro tests, and that at least one or more of the current safety assessment assays may need to be replaced. In vivo studies are also being conducted by NCTR, in collaboration with CFSAN, to assess the potential for orally administered nanosilver to produce toxicity. These studies are also serving as a platform for the development of safety assessment methodologies for in vivo studies with nanomaterials. In addition, FDA is conducting research to assess whether nanomaterials are being incorporated into products over which it has little regulatory authority, such as dietary supplements. Analytical fieldwork conducted by the FDA Office of Regulatory Affairs indicates that certain marketed dietary supplements contain nanomaterials either as nanoparticulates or as nanocoercipated products. While research on the safety assessment of orally available nanomaterials in food-related products is ongoing at FDA and elsewhere, this research is moving ahead at a relatively slow pace. This slow progress may be in part due to the lack of information on how nanomaterials interact with food matrices and, subsequently, with the alimentary tract.

1395 NanoRelease Food Additive Project—Developing Methods to Measure Characteristics Relevant to Nanomaterial Uptake from Food
R. Canady, Center for Risk Science Innovation and Application, ILSI Research Foundation, Washington, DC.

Nanoscience is providing valuable knowledge of particle toxicology; however, it is unclear how to use this knowledge to distinguish “engineered” particulate materials within a context of the particulate nature of traditional foods. When does a change in characteristics at nanoscale distinguish a particle from background particles? Should nanomaterials used at early stages in food processing be considered nanomaterials at ingestion if they have dissolved or bound to other food components? How do we know when the knowledge gained from pristine, extracted, dispersed nanomaterials in dose response evaluations applies to the transformed, aggregated, bound materials in food that reaches our mouths? The need for safe innovation coupled with a growing awareness of particulate toxicity has brought a diverse stakeholder group together in the NanoRelease project to the task of filling a basic methods gap in our ability to understand what is “nano” in the food we eat. Findings that lay a path toward addressing these questions will be presented from white papers prepared by the more than 70 experts of the project. The findings include a practical and neutral view of what may be nanoparticulate in food and what methods are needed to prioritize attention across the different types of particles of foods.

1396 Uptake and Distribution of Ingested Nanomaterials
S. M. Roberts, University of Florida, Gainesville, FL.

Engineered nanomaterials can be added directly to food to produce a beneficial effect in the consumer (e.g., increase the absorption of a nutrient) or a beneficial effect on the food itself (e.g., increased shelf life, enhanced flavor). Nanomaterials can also be introduced into food incidentally when used to improve food processing. The safety of nanomaterials in food depends in part on what happens when they enter the dynamic environment of the GI tract, and ultimately on the extent to which they are taken into the body and distributed. There are several challenges to assessing nanomaterial behavior and interactions in the GI tract. Some are common to studies of the potential toxicity of nanomaterials in general, including inconsistencies in the nanomaterials as manufactured, uncertainty as to how to express the nanomaterial dose or concentration, and difficulties in characterizing the nanomaterial, as well as in detecting and measuring them in biological systems. Other challenges are unique to the gastrointestinal tract, including an environmental that changes with respect to: pH, ionic strength, nature and composition of the sur-
ruling food matrix, anatomical absorptive surfaces, physical/chemical barriers to absorption (mucin layer), and microorganisms with which to interact as the nano-material transits the gut. The rate and location of dissolution or breakdown within the GI tract is likely to be an important factor in determining potential biological effects for some nanomaterials. Existing studies offer some insights into nanomaterial properties that can influence uptake from the GI tract and distribution in the body, but much work remains before the critical processes are well understood. In addition to the potential for systemic toxicity following uptake of nanomaterials (or dissolution or degradation products), local effects (e.g., cytotoxicity to cells lining the GI tract) and indirect effects (e.g., through effects on gut microflora or interference with absorption of nutrients) are also possible and merit consideration, at least for some nanomaterials.

1397 High-Throughput Testing Using a 3-Cell Gut Model for Hazard Identification of Nanomaterials in Food Products

C. M. Sayes, Center for Aerosols & Nanomaterials Engineering, RTI International, Research Triangle Park, NC.

The need to develop in vitro model systems for rapid and cost-effective screening of agricultural products is becoming increasingly necessary for the safety of food for human and animal consumption. This talk describes a 3-cell gut model developed for assessing the effects of nanomaterials and other man-made materials on bacterial biofilm and mammalian cells—the two types of cells found in the gut of humans and most animals. The system also probes the effects of a disrupted biofilm on normal epithelial cell function. Engineered nanoparticles are already being incorporated for innovative food packaging applications. Given the scenario of incorporating nanoparticles into food matrices, two distinct exposure populations and consequently two exposure routes can be easily identified: 1) Occupational exposures of industrial workers, by way of aerosolized nanoparticles, involved in the manufacturing of nano-enabled packaging materials. A reasonable exposure route for this scenario would be via inhalation and further digestion of the nanoparticles that remained in the pharyngeal cavity. 2) Consumer that ingest nano-enabled foods and possibly nanoparticles that may be released from food packaging. A common thread that links both the exposure populations and the two exposure routes is that the nanoparticles will eventually be "digested" and reach the small intestines of the gastrointestinal (GI) tract. In order to explore the physicochemical changes that nanoparticles go through during digestion and how these changes affect the digestive system and the commensal microbes that inhabit the human small intestine, we present a model that uses a gut co-culture model incorporating the Caco-2 cell line, HT-29 cells and a biofilm of commensal Escherichia coli. In this study, commonly used metal oxide and colloidal metal nanoparticles, some of which are known to have antimicrobial properties and have been used for nano-enabled packaging production are evaluated to study the physicochemical changes that such nanoparticles go through during digestion.

1398 Adverse Outcome Pathways: A Conceptual Framework for 21st Century Risk Assessment

J. Rowlands1 and K. Crofton2. 1Toxicology and Environmental Research & Consulting, The Dow Chemical Company, Midland, MI and 2National Center for Computational Toxicology, US Environmental Protection Agency, Research Triangle Park, NC.

An Adverse Outcome Pathway (AOP) represents existing knowledge concerning the linkage between a molecular initiating event and an adverse outcome at the individual or population levels (Ankley, Bennett, et al. 2009). As such, it is a conceptual framework that describes known linkages between a chemical-induced initial molecular event that alters biochemical cellular processes that cascade via a series of key events observed as cellular, tissue, and anatomical changes, that ultimately culminates in an adverse outcome of relevance to human or ecological health. This workshop will provide a regulatory rationale for using AOPs, along with the types and amounts of data needed to construct an AOP. Further, the level of confidence in an AOP will be explored for usage in regulatory decision-making, whether priority setting for chemical toxicity testing or hazard prediction. The practical utility of AOPs for risk assessment of chemicals will be illustrated using three case study examples.

1399 Creations and Use of AOPs: Progress and Prospects

A. R. Boohis. Centre for Pharmacology & Therapeutics, Imperial College London, London, United Kingdom.

The AOP concept has its origins in ecotoxicology but is now receiving increasing attention for its applicability to human health effects. In this respect an AOP is essentially indistinguishable from a mode of action (MOA) for a toxic effect. Hence, the general principles of one should apply to the other. These include identification of necessary and measurable key events, the molecular initiating event comprising an early such event, the use of weight of evidence such as the modified Bradford Hill considerations proposed by WHO for evaluation of key events, the rigorous exclusion of alternative pathways, the biological linkage of key events to an adverse outcome and the systematic qualitative and quantitative comparison of key events in model systems with those in humans, as appropriate. In human health assessment AOPs/MOAs were initially used in valuation of a rodent carcinogenic response to humans where a qualitative conclusion was sought. With the extension of the approach to non-cancer endpoints, quantitative information obtained on intermediate events can be invaluable in dose-response assessment for human risk. There is a need to agree the core information necessary to establish a robust AOP, and for a central repository of such AOPs and the intermediate events involved. OECD with support of other organisations is currently preparing such a repository. Establishment of AOPs will be invaluable in the design of new evaluation methods. AOPs will provide a necessary bridge between such methods and systems approaches to risk assessment. There are still conceptual barriers to the AOP/MOA approach, with a failure to appreciate that primarily it is a means to organise information in a coherent, transparent manner, on the basis of explicit lines of evidence.

1400 Adverse Outcome Pathway (AOP) for Skin Sensitization

G. Patlewicz, DuPont Haskell Global Center for Health & Environmental Sciences, DuPont, Newark, DE. Sponsor: J. Rowlands.

Skin sensitisation is a significant environmental and occupational health concern. As such, there exists an important need to accurately identify chemicals that have the potential to cause skin sensitisation. Assessment of skin sensitisation is still heavily reliant on the use of animals, in particular the local lymph node assay (LLNA) since no regulatory accepted alternative method exists. Despite the obvious complexity of the endpoint, quite a detailed mechanistic understanding both in terms of the underlying biological process and chemistry has been developed which has helped direct research into alternative (non-animal) approaches. Recently the OECD developed an Adverse Outcome Pathway (AOP) that describes in detail the key events underpinning skin sensitisation. Making the collective knowledge of the skin sensitisation process explicit in this way provides an invaluable roadmap to guide method development, evaluation and application. Indeed the OECD has also implemented this AOP into the OECD Toolbox, a tool for the development, evaluation and justification of chemical categories for read-across. This presentation will outline the utility in developing Integrated Testing Strategies (ITS) and read-across by way of practical examples.

1401 Thyroid Hormone Adverse Outcome Pathway-Based Screening Assays for Thyroid-Disrupting Chemicals

Disruption of thyroid hormones (THs) adversely affects neurodevelopment in both rodent models and humans. Therefore it is critical to determine the potential thyroid-disrupting activity of thousands of environmentally-relevant chemicals. However, the complexity of thyroid hormone regulation necessitates screening assays for multiple molecular initiating events that are not currently associated with any screening assays. The amount of detail and linearity characterizing thyroid pathways between molecular initiating events and adverse outcomes varies substantially, both as a function of existing knowledge and application needs. Development of AOPs provides insight into the uncertainties in linking chemical use, exposure and outcome, thereby focusing research on critical data needs. Example applications include the impact of thyroid disruption on neurodevelopment where AOPs have led to more efficient predictive testing and reduced uncertainty in extrapolation of effects between rodents and humans. Well defined thyroid AOPs also provide the molecular targets and key events that foster focused development of high-throughput screening models. Lastly, AOPs provide a utilitarian framework for future efforts to build quantitative and qualitative models useful in understanding the degree of perturbation associated with adverse outcomes. This abstract does not necessarily reflect US EPA policy.
A key physiological process controlling reproductive success of oviparous vertebrates (fish, amphibian, reptiles, birds) involves production of the egg yolk protein precursor vitellogenin (VTG). VTG production is an estrogen receptor (ER)-mediated process that, in females, is controlled by the production of 17β-estradiol. As such, environmental contaminants (including several pesticides and pharmaceuticals) that affect steroid synthesis can impact reproduction in fish through their ability to inhibit VTG production. Given both physiological importance and sensitivity to chemical stressors, there has been a significant amount of effort expended on developing well-characterized adverse outcome pathways (AOPs) relating steroid synthesis and VTG production to reproductive impacts in individuals and populations of fish. This presentation will provide an overview of the research conducted to derive and evaluate these AOPs from a weight-of-evidence perspective, including characterization of molecular initiating and key events and documentation of linkages between these events. The talk will also discuss practical applications of the AOPs to different facets of both prospective and diagnostic ecological risk assessments.

Risk assessors continue to be faced with significant challenges due to the increase in technology and complexity of endpoints and datasets to be considered in understanding the potential for chemical exposure to result in adverse impacts on humans or the environment. This workshop will bring scientists from multiple disciplines together to discuss these challenges for both human and ecological risk assessment and the potential for innovative solutions. The goal of this workshop is to present the latest thinking on issues significant to the practice of risk assessment today in a forum that allows for expanded thinking and an exchange of ideas. New concepts and older concepts that are being revisited to address new challenges will be presented. Topics will include the critical need for interoperability of data and models for risk assessment, consideration of variability and uncertainty in risk assessment, weight-of-evidence approaches, challenges in dose-response modeling, and the current and future guidance from the National Research Council on risk assessment issues as we move forward in the 21st century. This workshop will be the second collaboration between members of the SOT Risk Assessment Specialty Section and the SETAC Human Health Risk Assessment Advisory Group and builds on the concepts presented in a workshop developed by these two specialty sections in 2012. The 2012 workshop was titled “Concepts Critical to the Next Generation of Human Health and Ecological Risk Assessment” and highlighted some of the challenges facing the next generation of risk assessors. The goal of that workshop was to provide information on new programs and approaches within regulatory agencies, as well as in the private sector, that rely on the integration of human, animal, or ecological data.

Risk assessment has become a dominant tool for guiding public policy in protecting public health and the environment. In the last decades of the twentieth century, the National Research Council’s Board on Environmental Studies and Toxicology (BEST) produced a number of reports guiding origins and development of the field of risk assessment—in particular the famous “Red Book.” In the first decade of the twenty-first century, BEST carried out three studies that resulted in reports that redefined and advanced the field of risk assessment as it enters the next century. These reports include “Toxicity Testing in the 21st Century: A Vision and a Strategy,” issued in 2007, “Science and Decisions: Advancing Risk Assessment,” in 2009, and “Exposure Science in the 21st Century: A Vision and a Strategy,” in 2012. In this presentation I will briefly review the key recommendations from these reports and consider the implications of these recommendations for the preparation and interpretation of risk assessment as tool for informing environmental health science.

With the increase in the types of chemical-specific quantitative data available, dose response assessment is becoming a complicated task, requiring the consideration of more information than a single data set. One of the most controversial areas in dose response modeling is related to understanding when the integration of the available data are sufficient to suggest an approach other than default, or linear modeling approach. This is a critical science policy decision and opinions are very different on what the appropriate answer should be. Nuances in EPA’s 2005 Cancer Guidelines have led to different interpretations. Added to the complexity of a modeling approach are the challenges in addressing and accounting for the endogenous production of chemicals in the body. While novel approaches have been proposed, they are not yet universally accepted. Other challenges in dose-response include understanding whether effects are adaptive, compensatory or adverse and determining how to characterize toxicity that is due to less than lifetime exposures. Finally, the stakeholders’ challenge may be developing consensus around an approach for addressing cumulative risks. This talk will use specific examples to discuss existing challenges, proposed solutions, and opportunities that may exist to more fully develop consensus within the risk assessment community.

Risk assessors continue to be faced with significant challenges due to the increase in technology and complexity of endpoints and datasets to be considered in understanding the potential for chemical exposure to result in adverse impacts on humans or the environment. This workshop will bring scientists from multiple disciplines together to discuss these challenges for both human and ecological risk assessment and the potential for innovative solutions. The goal of this workshop is to present the latest thinking on issues significant to the practice of risk assessment today in a forum that allows for expanded thinking and an exchange of ideas. New concepts and older concepts that are being revisited to address new challenges will be presented. Topics will include the critical need for interoperability of data and models for risk assessment, consideration of variability and uncertainty in risk assessment, weight-of-evidence approaches, challenges in dose-response modeling, and the current and future guidance from the National Research Council on risk assessment issues as we move forward in the 21st century. This workshop will be the second collaboration between members of the SOT Risk Assessment Specialty Section and the SETAC Human Health Risk Assessment Advisory Group and builds on the concepts presented in a workshop developed by these two specialty sections in 2012. The 2012 workshop was titled “Concepts Critical to the Next Generation of Human Health and Ecological Risk Assessment” and highlighted some of the challenges facing the next generation of risk assessors. The goal of that workshop was to provide information on new programs and approaches within regulatory agencies, as well as in the private sector, that rely on the integration of human, animal, or ecological data.
and there is an uncertainty factor assigned to address human variability. Exposure assessments have historically focused on defining a reasonable upper bound to the range of exposures that occurs because of variability in human behavior and spatial and temporal variation in the release, transport, and removal of chemicals in the environment. This risk assessment must make decisions under limited information, since the mechanisms of action for toxicity and the key data on exposures may not be known. In addition many risk questions involve prediction of future exposures which cannot be measured. Arguably the entire field of risk assessment can be described as an attempt to make robust decisions under uncertainty. New tools in toxicology and exposure assessment promise to improve risk assessment by reducing uncertainty and by better characterizing the sources of variation. Advances in the field of toxicology promise to improve our understanding of the dose-response of key events that occur early in adverse outcome pathways. Such data can replace the current approach of evaluating every apical endpoint before setting a point of departure. Advances in modeling variation in adsorption, dispersion, metabolism, and excretion of chemicals are improving our ability to perform dose response modeling across human populations of varying ages. Advances in exposure information facilitated by improved monitoring and reporting technology promises to improve our understanding of how variation in human behavior affects exposure. Perhaps just as important, the rise of integrated information systems that facilitate sharing toxicity and exposure data and advances in behavior monitoring technology.

**W 1409 Multiscale Modeling: Data Integration and Interoperability**

A. M. Jarabek, NCEA, US EPA, Research Triangle Park, NC.

Risk assessment requires the analysis, translation, and integration of data from various disciplines (e.g., exposure and epidemiology), which often represent different levels of observation (e.g., individual versus population), in order to determine the potential for exposure and health effects at multiple scales such as the subcellular, individual, population, or community levels. An appreciation of the need for collaboration across disciplinary silos spanning the continuum from source -> exposure -> dose -> response -> cost/benefit is advancing due to the call for sustainability characterizations and the recent decision by the World Health Organization (WHO) to include consideration of ecosystem services in the definition of human health. Additionally, advances in biotechnology and systems modeling are resulting in increasingly complex repositories that require integration and management of large amounts of data to understand different adverse outcome pathways and to more accurately predict and diagnose factors contributing to disease. Interoperability, defined as the ability of two or more diverse systems or components to exchange information and use the information that has been exchanged in new applications, is thus necessary to support regulatory risk applications and tractable decision support. Considerations and challenges for interoperability in two domains, cultural (e.g., disciplinary assumptions, “narratives”, practices, and defaults) and technical (e.g., hardware, software such as models, standards, and data management) are highlighted by a case study of vinyl chloride hepatotoxicity along with recommendations from on-going efforts that evolved from the 2012 SOT CCT meeting. (The views expressed in this abstract are those of the author and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.)

**W 1410 Contribution of Nonimmune Cells to Adverse Immune Responses: Implications for Toxicology**

P. W. Karmaus1 and B. L. Kaplan2. 1Immunology, St. Jude Children’s Research Hospital, Memphis, TN and 2Department of Basic Sciences, Mississippi State University, Mississippi State, MS.

The potential for direct adverse effects of xenobiotics on the immune system is widely recognized. These intrinsic effects are often due to expression of target receptors for xenobiotics on immune cells or alteration of intracellular processes. However, novel evidence supports that cellular changes induced by xenobiotics in nonimmune cells can alter the competence of the immune system. Organs outside of the immune system are increasingly recognized for their ability to initiate and shape an immune response. These organs include, but are not limited to, the central nervous system, the mucosal areas such as the lung and the gut, the liver, and the cardiovascular system. The role of toxicants and their ability to modulate organ systems, thereby initiating or altering an immune response resulting in immunotoxicity, is poorly understood. Research highlighting how toxicant-induced changes in tissue physiology can result in immunotoxicity of the immune system will be discussed. The focus of presentations will address the considerations for modeling and for assessing toxic responses and explore putative mechanisms.
The Role of Epithelial Cell-Derived Hypoxia Signaling in Establishing the Inflammatory Response to Allergens

J. J. LaPres, Department of Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI.

Recently, our laboratory created an inducible, lung epithelia-specific hypoxia inducible factor 1α (HIF1α) knock out mouse, which has abnormal responses to inhaled cobalt and ovalbumin (OVA). For example, when the HIF1α-deficient mouse is exposed to cobalt it displays an asthma-like phenotype. In contrast, control mice display a Th2-mediated inflammation, similar to hard metal lung disease. Moreover, these HIF1α-deficient mice display an exacerbated response to the OVA challenge model of murine asthma. This suggests that loss of HIF1α in the lung epithelia biases the lung towards a Th2-mediated inflammation. Interestingly, to promote this change in innate immunity, recombination of HIF1α in the epithelial cells must be induced in the first two weeks of life. These results demonstrate that early childhood epithelial-derived HIF1α signaling is important in establishing the inflammatory response of the lung, presumably by regulating the transcription of key secreted immune factors. To identify these factors, a coculture system has been utilized to characterize the ability of epithelial-derived signaling (e.g., HIF1α specific and others) to influence immune cell function. These results highlight the need to assess early life events, such as premature birth and early viral exposure, which might permanently affect HIF1α signaling in the airway epithelium and thus alter the risk of toxicant exposure as adults. Finally, our future directions will focus on characterizing HIF1α-dependent secreted immune factors in the development of the lung’s immunity using a combination of in vitro and in vivo models. The ultimate goal is to determine how epithelial-derived HIF1α-mediated signaling can impact immune cell populations and their function and link these changes to susceptibility to atopic diseases, such as asthma, later in life.

Indirect Xenobiotic Immune Modulation: Risk Assessment

L. P. Myers, US FDA, Silver Spring, MD.

Xenobiotics can modulate the immune responses indirectly through various mechanisms. Occasionally, this indirect modulation can be difficult to assess or evaluate nonclinically. Limitations are commonly attributed to species specificity to targets that may not be expressed similarly between humans and nonclinical models. Even though the safety of these products may be difficult to assess, there are still pathways forward for these pharmaceuticals. Following existing guidance (ICH M3 (R2) or ICH S6 in conjunction with ICH S8), immunomodulatory drugs can be evaluated for many immune alterations prior to human exposure. However, if the target (e.g., receptor or ligand) is species specific and does not allow for adequate safety assessment, then alternative models may be necessary to evaluate the safety of these products. In these cases, increased human monitoring and a more conservative approach may be suggested, depending on the pharmaceutical. Careful consideration of the drug product, PD effects in vitro as well as in vivo models, as well as a case-by-case approach is the most common pathway for developing drugs that have unique immunomodulatory mechanisms. The development of novel nonclinical evaluations utilizing existing guidances as well as product specific assessments (a case by case approach) are used to evaluate the safety of immunomodulatory products during risk assessment of human pharmaceuticals.

Developmental Toxicity from Chemical Mixtures: Research to Application in Susceptible Populations

D. I. Carlin1 and M. Mumtaz2.1 NIEHS, Research Triangle Park, NC and 2ATSDR, Atlanta, GA.

The study of environmental chemical mixtures is highly complex and requires sophisticated approaches to determine which mixture component(s) contribute to health effects. Consideration of sensitive subpopulations such as pregnant mothers, the developing fetus, infants, and children, significantly increases the complexity due to chemicals exhibiting different effects depending on the timing of exposure. For example, it is well known that exposure to mixtures of inorganic metals (e.g., lead, cadmium, mercury, arsenic) and pesticides leads to neurological and other organ-specific health effects in adults, but the suite of health effects associated with these mixtures in the developing fetus and infant could differ from that of adults and is less understood. This workshop will focus on the health effects of chemical mixtures with particular attention to exposure to pregnant mothers, the developing fetus, and children, and will include discussion of toxicological studies, statistical and modeling approaches, and application to human health risk assessment in these susceptible populations. There is an impending need to understand interactions among components of mixture exposures in order to improve human health risk assessments in these susceptible populations.

Chemical Mixtures, Developmental Windows, and Neurodevelopment

R. O. Wright, Mount Sinai School of Medicine, New York, NY.

Low level mixed exposures likely influence developmental trajectories and program later life health effects. Understanding mixed exposures requires prospective study designs to capture critical developmental windows of exposure and complex statistical approaches to assess whether combined exposures are synergistic in toxicity. In addition, mixtures studies often evaluate 2 or 3 way interactions, but methodologies are needed that can address higher order interactions. This presentation will include data on ongoing longitudinal studies of metal mixtures and childhood neurodevelopment conducted in 3 distinct birth cohorts. As an example, in a preliminary analysis of 350 children (final N = 829 when study is complete) Bayley Scales of Infant Development in Bangladeshi children and metal exposure (As, Pb, Mn), we used adjusted multivariable Kernel Machine regression to assess the joint impact of these 3 metals. This type of model will test the best fit of the overall interaction data and allows for non-linear relationships between random variables. Splines will be used to present above results graphically, as multi-dimensional nonlinear interactions are difficult to present as simple beta coefficients. Lead and the middle tertiles of arsenic, and manganese exposure compared to the lowest tertiles were inversely associated with 24-month Bayley scores (β=-0.71, p=0.01; β=−2.13, p=0.02; β=−1.25, p=0.061, respectively). There was evidence of lead-arsenic interaction. Lead toxicity was increased among children in the third tertile of arsenic exposure, compared to children in the first tertile of arsenic interaction (β = −0.35, p=0.006). Further, nonparametric splines were used to explore non-linear effects of As and Mn, which were detected as an inverted-U relationship between manganese and the Bayley score at the second arsenic tertile (p=0.0003). Overall, these preliminary findings suggest that non-linear relationships exist within mixed exposures and statistical methodologies to detect such relationships should be employed.

Toward the Rational Use of Exposure Information in Mixtures Toxicology

Of all the disciplines of toxicology, perhaps none is as dependent on exposure information as Mixture Toxicology. Identifying real world mixtures and replicating them in the laboratory (or in silico) is critical to understanding their risks. Complex mixtures such as cigarette smoke, diesel exhaust, and disinfection byproducts may be replicated without difficulty because they are uniquely associated with reproducible processes such as combustion. On the other hand, chemical mixtures that arise from multiple sources are less tractable. Toxicologists often are faced with developing ad hoc rules for constructing test mixtures, or they simply test a few binary combinations. We examined monitoring data for pesticides in daycares (CCCP and homes) and the evidence that points to patterns in how they
group. We applied approaches from the field of community ecology to test if these assemblages of "chemical species" are random or structured. Presence-absence matrices developed from CCC and AHHS datasets indicated structure comparable to the West Indian Finch matrix when species diversity metrics were applied; namely, the COMBO metric (number of unique combinations) and CHECKER metric (number of 2x2 checker matrices). This finding indicated that factors (e.g., social, economic, and technical) limit the spectrum of pyrethroid combinations observed in these datasets. Additional methods were used to identify frequently occurring k-way combinations from the CCC dataset. These approaches were used to inform pharmacokinetic studies and a cumulative probabilistic exposure-dose assessment.

**W 1420 Application of a Weighted Quantile Sum Approach to Identifying Bad Actors in Mixtures of Environmental Chemicals: A Transgenerational Study of Reproductive Hazards**

C. Gennings, Virginia Commonwealth University Medical Center, Richmond, VA.

Risk evaluation of environmental chemical exposures is impacted (i.e., inflated variance, confounding) by the complex correlation structure among components of chemical mixtures. We have developed a novel, empirical weighted quantile sum (WQS) method for identifying 'bad actors' in correlated data. Characterization of the method (reliability, validity) will be presented using simulated data. The approach will be demonstrated using fecundability as a measure of reproductive hazard in a transgenerational study of PCBs. We compared the results of WQS regression to those based on categorization of PCB compounds by (1) hypothesized biological activity previously proposed and widely applied, and (2) degree of ortho-substitution (mono, di, tri), in a study of the relation of maternal serum PCBs and daughter's time to pregnancy (TTP). The dominant functionality groups associated with longer TTP were the dioxin-like, anti-estrogenic group (average weight, 22%) and PCBs not previously classified by biological activity (54%). In contrast, the unclassified PCBs were not important in the association with shorter TTP, where the anti-estrogenic groups and the PB-inducers group played a more important role (60% and 23%, respectively). The highly chlorinated PCBs (average weight, 89%) were mostly associated with longer TTP; in contrast, the degree of chlorination was less discriminating for shorter TTP. Finally, PCB 56 was associated with the strongest relationship with TTP with a weight of 47%. WQS regression found some associations previously identified by two classification schemes, but also identified other bad actors. This empirical method can generate hypotheses about mixture effects and mechanisms and overcomes some of the limitations of standard regression techniques.

**W 1421 A Risk Assessment and Regulatory Agency Perspective on Mixtures Affecting Susceptible Populations**

M. L. Dourson, Toxicology Excellence for Risk Assessment, Cincinnati, OH.

In one sense, the study of mixtures to susceptible populations is easy. Since we are all exposed to mixtures of chemicals and nonchemical stresses, one needs to simply be observant. Unfortunately, the mixtures to which many of us are exposed (e.g., oxygen and arsenic) are not really of much interest to regulators. Of more interest are exposures to mixtures, especially to sensitive subgroups, about which toxic effects are known and for which we might be able to do something, such as the concentrations of methylmercury and PCBs in fish. This presentation will start with a brief explication of existing methods that allow risk scientists to gauge the safety of chemical mixtures, and then highlight comparative toxicokinetic and toxicodynamic data between adults and children, which can be used to improve the estimation of safety and risk to susceptible populations from chemical mixtures and nonchemical stressors. Our analysis of Seychelles and Faroe Islands cohorts revealed differing intakes of PCBs and methylmercury, and using benchmark doses (BMDs) analysis, revealed the presence in children or absence in adults of neurological effects. The impact of our findings on the development of a mixture Reference Dose (RfD) and nonchemical stressors in these populations will be discussed.

**W 1422 Somatic Cell Therapy—Paradigms for Investigational New Drug (IND)-Enabling Programs, Scientific and Regulatory Considerations, and Clinical Translation**

There is significant interest in somatic cell therapies and their therapeutic potential to stimulate repair in diseased or injured tissue. Development of these therapies has been hindered by lack of knowledge of appropriate methods for assuring patient safety in clinical trials. Standard pharmacological and toxicological methods may not apply in safety evaluation of somatic cell therapies. Animal model selection, and safety concerns to be assessed, varies greatly depending upon clinical indication, source and type of cell therapy, and method of cell therapy delivery. The aim of this workshop is to provide insight into successful paradigms for IND-enabling studies supporting clinical evaluation of somatic cell therapies. Speakers with both regulatory and academic/industry development expertise in somatic cell therapy will provide presentations of program experience. The overall goal is to aid current investigators in the somatic cell therapy field, and to facilitate and expedite the development of somatic cell therapies in clinical medicine by sharing lessons learned from previous experiences.

**W 1423 Developing Cell Therapy Products: US FDA Preclinical Regulatory Considerations**

P. Au, Office of Cellular, Tissue and Gene Therapies, Center for Biologics Evaluation and Research, US FDA, Rockville, MD; Sponsor: C. Lindamood III.

The presentation intends to provide an overview of Center for Biologics Evaluation and Research (CBER)/ Food and Drug Administration (FDA) expectations for preclinical studies for cell therapy products. Because of the diversity and complex nature of these products, they preclude the application of traditional, standardized approaches for preclinical testing. The case-by-case review approach will be discussed and general preclinical study design considerations and potential pitfalls will be presented. The application of these recommendations will be illustrated by case examples.

**W 1424 The Shaky Bridge: Animal Model Translation for Cell Therapies and Impact on Clinical Success**

L. E. Black, Charles River Laboratories, Reno, NV.

Cell therapies are very diverse. One universal statement that can be made is that nonclinical toxicology programs (the backbone of risk assessment for clinical trials) are less established for cells compared to those conducted for drugs. This problem starts at the difficulty of characterizing the nature of the product itself, even in vitro. For instance, islet cells may control glucose levels in animal models of pancreatic failure, but the obvious test of their in vitro potency (response to glucose) may not work at all. With this being true, uncertainty applies to prospective risk assessment, where one would hope that vitro and in vivo effects translate to patients. The term hope is used because we seldom see an intact "bridge" of activity from in vitro to in vivo in cell therapy research programs. We often have to proceed on faith that 1) the cells manifested both their pharmacologic and their toxicologic potential in the animal, and 2) that this one species program is a sound basis for human risk assessment. This is a far cry from knowing that we injected a drug (like a hormone) into two species, measured the drug PK and receptor occupancy, and measured the products secreted by hormone after binding to its receptor, and then observed amelioration of disease. So the pharmacology "bridge" for cell therapies (intrinsically to their nature/complexity) is a shaky one. Looking to the future, what can we do to improve our animal models, cell pharmacology, and translation to risk assessment? A stronger bridge might enable trials in earlier stage patients, improving chances of regeneration, and gaining Proof of Concept to further design optimal therapy. Published examples of in vivo data will be discussed.
Initial clinical studies of stem-cell based therapies are conducted in subjects with disease rather than normal volunteers. As such the objective is not only to administer a safe but also an active dose. However, unlike small molecules or large molecule biological drugs, there is no standard algorithm for extrapolation of preclinical animal doses. The concept of exposure also differs. This presentation will discuss key design considerations in dose extrapolation based upon differences in cell type, delivery and disease indication.

MultiStem® is an allogeneic adult bone marrow-derived cell therapy product that has received allowance from the FDA for testing in humans in the treatment of acute myocardial infarction, prophylaxis of graft-versus-host-disease in leukemia patients, inflammatory bowel disease, and ischemic stroke. It is the only cellular therapeutic currently being tested in acute ischemic stroke patients in the US. This presentation will describe the battery of preclinical safety, efficacy, and mechanism of action studies performed to support Investigation New Drug (IND) submission and clinical trial design for the ongoing Phase II/III trial. Preclinical safety studies that supported multiple IND submissions, or that were designed specifically to support use of MultiStem in ischemic stroke, will be highlighted. The presentation will also address some of the unique challenges posed by testing cellular therapies in preclinical animal models.

MultiStem® is an allogeneic adult bone marrow-derived cell therapy product that has received allowance from the FDA for testing in humans in the treatment of acute myocardial infarction, prophylaxis of graft-versus-host-disease in leukemia patients, inflammatory bowel disease, and ischemic stroke. It is the only cellular therapeutic currently being tested in acute ischemic stroke patients in the US. Preclinical safety studies that supported multiple IND submissions, or that were designed specifically to support use of MultiStem in ischemic stroke, will be highlighted. The presentation will also address some of the unique challenges posed by testing cellular therapies in preclinical animal models.

A nonclinical development program using rats and pigs was successfully executed to support a First-in-Human (FIH) clinical trial for hUTC in Retinitis Pigmentosa. This program evaluated the safety and efficacy of hUTC, but also developed and characterized analogous cells from rats and minipigs to understand the immunology of cells in an allogeneic setting. In rats, the desired pharmacology was demonstrated in the Royal College of Surgeons model of degenerative retinal disease and ocular histopathology was used to evaluate potential effects of the disease state on the safety of hUTC. The rat was used to evaluate the tumorigenicity and biodistribution of hUTC following subretinal and systemic administration. However, anatomic constraints precluded the use of the clinical surgical procedure. A large animal species, the minipig, was used to evaluate the safety of the cells when administered by the surgical method of cell administration intended for patients. Based on anatomic considerations, cell doses were extrapolated across species based on retinal surface area. Taken together, results of these nonclinical studies supported the initiation of FIH clinical trials.

This symposium is designed to explore how several clinical to preclinical translational imaging modalities can be efficiently and effectively integrated into contemporaneous drug development and chemical hazard assessment. Standard clinical imagers, such as Magnetic Resonance Imaging (MRI), Magnetic Resonance Spectroscopy (MRS), Echocardiography (Echo) and Positron Emission Tomography (PET) have demonstrated strong utility in the nonclinical setting by allowing for the ability to perform real-time, non-invasive, longitudinal animal studies that can provide morphological, functional, and molecular data. Additionally, these modalities greatly minimize the need for assumptions in data interpretation and reduce uncertainty during product development or risk assessment; therefore, the preclinical application of these imaging strategies and the integration of these capabilities into modern drug safety assessment and environmental hazard identification is a promising development with the potential to greatly impact the field. This workshop will provide an overview of the challenges facing clinical trials and opportunities for translational imaging to address these gaps. Imaging approaches that address major contributors to pharmaceutical attrition, including cardiovascular safety, drug-induced liver injury, and neurotoxicity, will be presented. Additionally, the panel discussion will explore the potential burdens of validating the use of imaging modalities as clinical biomarkers in the field and by regulators. Ultimately, this workshop aims to facilitate dialogue across disciplines for broader acceptance and implementation of translational imaging in improving preclinical safety assessment and basic toxicity studies.

There is a potential disconnect between the very molecular approach we take to contemporary drug design and the very ‘un-molecular’ approach we take to assessing in vivo efficacy and safety. Nonclinical safety assessment of human pharmaceuticals typically involves a regimented series of studies that might lack a level of morphofunctional integration to be optimally instructive and translational. It may also lack the ability to understand the molecular relationship between drug and safety liabilities or use the data generated to leverage ever developing computational capabilities. Advances in in vivo imaging capabilities are providing an unprecedented opportunity to refine our traditional approaches and advance the translatability of our studies. Longitudinal studies that allow dynamic assessments of dynamic processes could be more instructive and require fewer animals. Molecular imaging capabilities are providing opportunities to visualize physiologic processes and their association with drug in living systems. Imaging can also make ‘quantitative’ what has traditionally been un- or semi-quantitative. This presentation will provide an overview of the advances in imaging technology and its application to animal models with quantitative endpoints that are also applicable to the clinical setting. We will put focus to integrated assessments of target organ morphology and function
to provide a more holistic understanding of drug effects and the ability to identify the most sensitive biomarker of that effect. Additionally, we will present challenges to applying novel approaches in very traditional paradigms and debate the risks and benefits of those approaches.

**W 1431 In Vivo Imaging of Hepatobiliary Transporter Function**

New response biomarkers that are sensitive and specific to detect early liver dysfunction prior to onset of irreversible liver damage are urgently needed. This presentation will describe a new in vivo imaging biomarker of hepatobiliary transporter function in the rat. A compartmental model was developed to characterize the pharmacokinetics of hepatic uptake and biliary excretion of the MRI contrast agent gadoxetate. Magnetic resonance imaging was used to continuously measure the concentration of gadoxetate in the liver and plasma for one hour after a bolus injection. The gadoxetate concentration in hepatocytes was estimated after correction for the gadoxetate concentration in plasma and the known volume fraction of extracellular space in the liver. An investigational hepatobiliary transporter inhibitor was shown to reduce both the rate of uptake of gadoxetate into the hepatocyte and the Michaelis–Menten constant characterizing its excretion into bile, whereas KM values for biliary efflux were increased. These effects were dose dependent and correlated with effects on plasma chemistry markers of liver dysfunction, in particular bilirubin and bile acids. The HESI liver imaging working group is evaluating the ability of this technique to quantitate in vivo hepatobiliary transporter function in a multi-site setting imaging using a known hepatobiliary transporter inhibitor. The potential to translate this technique to evaluate risk in the clinic will also be discussed.

**W 1432 Characterization of Drug-Induced Changes in the Cardiovascular System**

J. Heyen. Pfizer, La Jolla, CA. Sponsor: M. Paulus.

The expansion of cardiovascular (CV) imaging modalities from being utilized primarily in efficacy based approaches into safety studies has led to more robust analysis of drug induced CV changes. Advancements in Ultrasound (US) and Magnetic Resonance Imaging (MRI) coupled with adaption to scale for smaller species has enabled the adoption of these techniques into preclinical testing and facilitated use in drug discovery. Continuously expanding laboratories should have an understanding of data variability including intra and inter-observer errors and should have a robust training and qualification processes in place prior to data creation and study conduct. Likewise, opportunities and data for reverse translation investigations of drugs with identified clinical CV liability such as doxorubicin or trastuzumab are available and have been undertaken. Development of techniques and advancements in technology such as strain imaging and 3D small animal imaging will continue to increase the quality of preclinical CV imaging and will allow for thorough investigation of potential CV of novel drugs. This presentation will describe the efforts of a ILSI Health and Environmental Sciences Institute CV imaging working group has produced cross-site/company data around reproducibility and variability using a single compound. ANOVA analysis showed that for most of the parameters, there is no statistically significant site difference after adjusting for the baseline and vehicle effect. The median Intra-Class Correlation (ICC) for all parameters is only 12.7%, suggesting the variability of site effect is small compared to the overall variability. With proper training and equipment, this group has demonstrated that it is possible to collect high quality on cardiac structure and function using these approaches in standard toxicology and stand alone preclinical studies. A description of how these techniques can inform clinical risk and influence prospective clinical trial design for compounds with identified preclinical signals will also be discussed.

**W 1433 Magnetic Resonance Histology—Applications in Toxicology**

Magnetic resonance imaging (MRI) has revolutionized clinical medicine. The same underlying technologies are now triggering a similar revolution in the basic sciences. Magnetic resonance histology (MRH) was first suggested in 1993. Through the use of very high magnetic fields, specialized rf coils, novel imaging strategies, and specialized active MR stains, we have increased the spatial resolution in MRH by more than five orders of magnitude over that which is common in clinical MRI. While a number of papers have demonstrated the utility of MRH in toxicology, it is still not part of the mainstream. This presentation will include a brief overview of the technology and three recent results demonstrating exciting options that MRH provides the toxicologist because of its unique characteristics. In the first study, a developmental atlas of the rat brain provides a diffusion tensor (DTI) atlas allowing myelination of the rat brain at nine time points between PND0 and PND80. Changes in the diffusion metrics closely follow the development of myelin and its compaction- areas usually only seen with more complex electron microscopy. A second study demonstrates the use of magnetic susceptibility imaging providing quantitative insight into renal fibrosis. The last study describes a comprehensive infrastructure for high throughput MRH and it’s validation in a study of the effects of trimethyl tin. MRH is nondestructive, so tissues do not need to be physically sliced. Three-dimensional scanning allows viewing of whole specimens fully intact. Since the tissue is not dehydrated, morphologic measurements are considerably more accurate than with traditional techniques. Because the data can be acquired with isotropic spatial resolution, difficulties in obtaining homologous slices are virtually eliminated. A wide range of contrast mechanisms provides a rich set of biomarkers for tissue injury. Combining these attributes with sophisticated image registration algorithms allows us to produce atlases with quantitative biomarkers defining both severity and extent of injury in the entire organ.

**W 1434 Preclinical Development of Neurotoxicity Biomarkers Using In Vivo MRI**

S. Liachenko. Division of Neurotoxicology, NCTR, US FDA, Pine Bluff, AR.

Current approaches in the analysis of neuropathology in support of new drug submissions to the FDA (the use of several arbitrary histology slices) can sometimes result in false-negative findings due to significant undersampling. Non-invasive MRI provides unique information about the three-dimensional structure and function of the whole brain in vivo with sufficient resolution and contrast to serve as a translatable neurotoxicity biomarker. Recently it has been shown in our lab that the value of the brain T2 relaxation time as measured with MRI in rats is sensitive to the acute neurotoxicity caused by known neurotoxicants with the variability of mechanisms of action. T2 relaxation provides the quantitative measure of the amount and extent of the changes in the brain tissue consistent with neurotoxicity. This presentation will describe the implementation of such imaging approach to develop a quantitative non-invasive biomarker of neurotoxicity because of the correlation in vivo MRI T2 maps to histopathology using the panel of known neurotoxicants at different doses and time points. For example, a single dose of kainic acid (10 mg/kg, intraperitoneal injection) led to the rapid development of T2 lesion, detectable already at 2 hours post-injection (lesion volume = 10.8 ± 2.6 mm³), which grew significantly at 48 hours post-injection (lesion volume = 86.2 ± 34.2 mm³). This measure provided much earlier detection of the neurotoxicity than conventional histopathology score, which was 0 at 2 hours and 1.84 ± 0.49 at 48 hours post-injection (histopathology score range is from 0 [no damage] to 4 [maximum damage] and is assessed qualitatively). The use of such non-invasive MRI biomarkers may significantly increase the chance of the early preclinical detection of the small or transient neurotoxic changes and thus to optimize the costly process of drug discovery and development as well as enhance the safety of the final product.

**W 1435 The Role of Toxicology in Undergraduate STEM Education Reform**

B. S. Pollenz1, J. Labov2, M. M. Bourgeois2, T. Dodell-Butra2, W. B. Brooks3, T. L. Leavens1. 1Office for Undergraduate Research, University of South Florida, Tampa, FL; 2Environmental and Occupational Health, University of South Florida, Tampa, FL; 3National Academy of Sciences, National Research Council, Washington, DC; 4Environmental Science, Baylor University, Waco, TX; 5Pharmacokinetic Consultant, Cary, NC and 6Nursing, California State University, San Bernardino, San Bernardino, CA.

The attrition of undergraduates who enter STEM degree programs but do not earn a STEM undergraduate degree is an area of national concern. “Vision and Change in Undergraduate Biology Education,” the 2011 report from AAAS/NSF, and “Engage to Excel,” the 2012 report from the President’s Council of Advisors on Science and Technology (PCAST), are two national calls to action on this issue and advocate for significant reform in the way undergraduate STEM education is delivered. A strategic goal of SOT is a commitment to education in toxicology and the recruitment of students and new members into the profession. Although the number of undergraduate toxicology degree programs is limited, toxicology is a STEM discipline and many SOT members currently engaged in teaching undergraduates incorporate toxicology into traditional STEM undergraduate degree programs such as biology, biomedical sciences, chemistry, public health, and nursing. The learning objectives of this interactive workshop are to, 1) provide context to the national call to action on undergraduate STEM education reform, 2) present four case studies of inquiry-based approaches in undergraduate STEM education that inspire
students about the multidisciplinary science of toxicology, and 3) engage attendees to develop an "action plan" that incorporates toxicology and inquiry into a current STEM undergraduate degree program. During the workshop attendees will have the opportunity to network with practitioners who can help inform their practice. This session should have widespread benefit to anyone engaged in teaching "toxicology" at any level of academia or industry who has an interest in innovations that help to engage trainees to "work the problem."

**W 1436** The Changing National Landscape of STEM Education: Building Partnerships with Scientists and Educators

The improvement of STEM (science, technology, engineering, and mathematics) education has become a national priority at all levels of the education system. However, efforts to increase the numbers of students who enter and persist in STEM fields too often have been disjointed and have been undertaken without understanding the potential effects on other parts of the education system. This presentation will provide an overview of recent reports and their recommendations for improving STEM education, especially at the undergraduate level. It will explore the intersections between education and public policy and why college and university faculty should be aware of and involved with education policymaking. It also will describe how current efforts to improve STEM education in Grades K-12 will likely have major impacts on postsecondary education and how undergraduate education will influence K-12 education in the future.

**W 1437** Case Study 1: Creating Research Experiences and Activities for Public Health Undergraduates through Teaching Enhancement (CREATTE)

M. M. Bourgeois. Environmental and Occupational Health, University of South Florida, Tampa, FL.

One of the challenges presented by a rapidly expanding undergraduate program like the B.S. in Public Health at USF is providing research opportunities for students. The Office for Undergraduate Research (OUR) developed the CREATTE (Creating Research Experience and Activities Through Teaching Enhancement) to address this need. Through the CREATTE initiative, faculty incorporated an authentic research experience within a structured course. The research experience tracks on the student's transcript and they also have the opportunity to present their work at the Undergraduate Research Colloquium. CREATTE funds cover sustainable supplies and 30 hours of effort from a graduate assistant. During Fall 2012, 12 students in Environmental Health Science were able to participate in a project involving K12 outreach. This area was chosen because it is a vital component of the public health mission to educate the community regarding scientific issues, particularly toxicity and risk assessment. Students were matched with local K-8 science classes based on curriculum needs. Students created age-appropriate presentations and activities on public health topics for the Great American Teach In. Utilizing this preexisting infrastructure obviated the need for school board clearance. Feedback from the students and teachers allowed participants to develop templates for future students to emulate. A post survey of participating CREATTE undergraduate researchers indicated a strong agreement that they developed enhanced research competencies, had a deeper understanding of the course material and would engage in addition research activities.

**W 1438** Case Study 2: Integrating Toxicology into the Undergraduate Curriculum

T. Dodd-Butera. Nursing, California State University, San Bernardino, San Bernardino, CA.

Addressing the challenge of incorporating toxicology and environmental threats into undergraduate nursing education is critical for engaging future health professionals in the application of science for the benefit of society. Utilizing case study methodology as part of an overall educational program on environmental health for undergraduate nursing students, educational modules were developed addressing toxicokinetics, by utilizing a lecture format on a model of lead toxicity. Further, a clinical rotation for students at a poison control center demonstrated clinical toxicology approaches and poisoning prevention strategies for the benefit of public health. The blended learning approach addresses the focus of the STEM initiative on content delivery, and incorporates the “4 Cs” noted by the National Education Association as essential tools for preparing 21st century students for a global society through appreciative inquiry. The integration of poisoning principles through critical thinking, communication, collaboration, and creativity, is also aligned with the commitment of the SOT to education and exposure to the interdisciplinary nature of toxicology. Attendance at a journal club was also part of the educational strategy, and covered topics such as environmental exposures, chemicals, drug overdoses, and unintentional poisonings. The culminating experience was a presentation at a poster session, addressing problem solving through evidence-based practice, and a collaborative approach to campus-community partnerships and service learning. Integration of toxicology into didactic and clinical experiences of undergraduate nursing students underscores the potential for innovative approaches in addressing STEM initiatives and SOT strategies for education across multiple scientific disciplines.

**W 1439** Case Study 3: Integrating Toxicology into the Undergraduate Laboratory Curriculum

B. W. Brooks. Environmental Science, Baylor University, Waco, TX.

This session presents multiple strategies utilizing contemporary scientific laboratory techniques to integrate environmental research into laboratory courses. Such an approach enhances student’s critical thinking skills and allows for application of toxicology practices. This session will also describe modules that allow laboratory approaches for defining contaminants of emerging concern.

**W 1440** Case Study 4: Problem-Based Instruction of Pharmacokinetics

T. L. Leavens. Pharmacokinetic Consultant, Cary, NC.

The goal of STEM education is the development of competency and application of knowledge versus acquisition of knowledge. Therefore, courses that are structured based on the higher order objectives in Bloom’s taxonomy of learning provide an ideal classroom environment, because they are focused on projects and case studies versus lectures. Some of the more recent techniques to achieve this learning environment are the flipped classroom and e-learning tools. The objective of this presentation is to demonstrate how to design a problem-based lecture for pharmacokinetics, a discipline in which problem-solving skills are critical. The presentation will focus on the absorption component of pharmacokinetics and demonstrate how to convert a lecture on the topic into a flipped class through the use of video clips, interactive case studies, and web-based applications.

**S 1441** In Vitro Microphysiological Systems: Advancing Regulatory Science through Innovation

A. Balinsky1 and S. C. Fitzpatrick2. 1Wyss Institute for Biologically Inspired Engineering at Harvard University, Boston, MA and 2Center for Food Safety & Applied Nutrition, US Food and Drug Administration, College Park, MD.

Development of safe and effective drugs is currently hampered by the poor predictive power of existing preclinical animal models that often fail to lead to development of drug compounds later in their development. Given the tremendous cost of drug development and the long timelines involved, major pharmaceutical companies and government funding agencies are now beginning to recognize a crucial need for new technologies that can quickly and reliably predict drug safety and efficacy in humans in preclinical studies. Advances in bioengineering, material sciences, microfabrication, and microfluidics technologies have enabled the development of microphysiological systems that mimic the functional units of an organ. These advances have made it possible to initiate the engineering of cellular microenvironments and/or functional units of lung, heart, blood vessels, muscles, bones, liver, nervous system (including eye), gut, and kidney. In general, these microphysiological systems, or human “organs-on-chips,” use microscale engineering technologies combined with cultured living human cells to create microfluidic devices that recapitulate the physiological and mechanical microenvironment of whole living organs. The next challenge is to develop an integrated microsystem platform that can incorporate several different modular organs on a chip. These integrated microsystems would mirror the complex physiology and biology of the human body. An integrated microphysiological platform could further our understanding of disease etiology and fill the critical need for improved model systems to predict efficacy, safety, bioavailability, and toxicity outcomes for candidate compounds. This symposium will examine the building blocks needed to bring this new innovative technology into the regulatory arena, including the need for adequate stem cells, the development of representative organ systems, challenges to building a “human on a chip,” and the pathway to qualification for regulatory use.
The goal of the new National Center for Advancing Translational Sciences (NCATS) is to catalyze the generation of innovative methods and technologies that will enhance the development, testing, and implementation of diagnostics and therapeutics across a wide range of human diseases and conditions. By improving the process by which diagnostics and therapeutics are developed, NCATS strives to make translational science more efficient, less expensive, and less risky. Partnerships between federal agencies and stakeholders are critical for innovation in regulatory science. The NCATS/FDA/Defense Advanced Research Projects Agency (DARPA) partnership for the development of in vitro microphysiological systems is a groundbreaking example of the types of partnerships that are needed to bring innovative new technologies into the regulatory paradigm. NCATS, FDA, and DARPA are collaborating to develop a chip to screen for safe and effective drugs, which is far more efficient and effective than current methods. NCATS would help identify barriers to progress and provide science-based solutions to reduce costs and the time required to develop new drugs and diagnostics. FDA will help determine how this new technology can be utilized to assess drug safety, prior to approval for first-in-human studies. DARPA and NIH will facilitate collaborations between researchers and FDA to advance the goals of both programs. The two agencies, in coordination with FDA, solicited proposals from industry, government labs, academic institutions, and other research organizations on how best to develop the chip, bringing together the latest advances in engineering, biology, and toxicology to bear on this complex problem. Throughout the five year research plan, NCATS, FDA, and DARPA meet biannually with all the researchers.

**The Increasing Use of Stem Cells Prompted a Workshop on How to Adapt GCCP for This Emerging Field and Is Currently Further Adapted to Induced Pluripotent Stem Cells, Which Increasingly Substitute for Human Embryonic Stem Cells. Such Quality Control Is of Critical Importance for the Organ-on-a-chip Models Currently Favored to Ultimately Allow a Body-on-a-chip Combination of Several Such Organoids Combined with Microfluidics. Our Ongoing Development of a (Developmental) Quality Control 3D Model from iPSC Within This Program Is Used to Illustrate the Challenges and Opportunities of GCCP.**
concentrations of As(III) inhibit poly(ADP-ribose) polymerase (PARP)-1, leading to interference with DNA repair process triggered by UV radiation. It has been proposed that interference with DNA repair systems is one of the common modes of action for metal-induced carcinogenicity. It is of great interest and importance to understand the steps affected by metals in the repair pathway and the mechanism of the repair inhibition. The presentations in this symposium will highlight the latest findings on the molecular mechanisms of metal-induced inhibition of DNA repair.

**1448 Impact of Cadmium and Copper on the Cellular Response to DNA Damage: Interference with Redox-Regulation**

The carcinogenicity of cadmium has been recognized for some decades, but the underlying molecular mechanisms are not completely understood. While direct DNA damage appears to be of minor importance, the interference with antioxidant defense systems as well as interactions with DNA repair processes, tumor suppressor functions, and signal transduction pathways have been described in diverse biological systems. Thus, cadmium has been shown to disturb nucleotide excision repair, base excision repair as well as mismatch repair, and the interference with cellular redox regulation by reaction with redox-sensitive protein domains or amino acids may provide one explanation for cadmium-induced carcinogenicity. Particularly sensitive targets appear to be proteins with zinc binding structures, present in DNA repair proteins such as XPA, PARP-1 as well as in the tumor suppressor protein p53. For example, cadmium inhibits poly(ADP-ribose) polymeration, and detailed investigations suggest a direct interaction with PARP-1, presumably by inactivation of thiol groups. Also, cadmium compounds provoke an unfolding of the "wild type" p53 conformation, leading to diminished expression of DNA repair proteins and via inhibition of apoptosis to a resistance towards DNA-damaging agents. Particularly the combination of these multiple mechanisms may give rise to a high degree of genomic instability in cadmium-adapted cells, relevant not only for tumor initiation, but also for later steps in tumor development. Nevertheless, the disturbance of cellular redox regulation may also occur in case of essential trace elements on conditions of cellular overload. One example is copper, where especially copper-based nanoparticles lead to high concentrations of copper ions in the cell nucleus and thus overcome homeostatic control. Consequences are elevated levels of oxidative DNA damage and pronounced inhibition of poly(ADP-ribose) polymeration.

**1449 Inhibition of DNA Repair As a Mechanism of Arsenic Carcinogenesis**

Inorganic arsenic is a complete carcinogen. In addition to the known direct carcinogenic actions of arsenic, there is substantial evidence that arsenic at low, non-carcinogenic levels amplifies the carcinogenic potential of other DNA-damaging agents such as benzo[a]pyrene and ultraviolet radiation (UVR). One hypothesis to account for arsenic co-carcinogenesis is that arsenic is a chemically reactive arsenite which binds to the zinc finger moiety of PARP-1, preventing zinc binding, thus interrupting the function of PARP-1. We have shown that arsenic reverses the inhibitory effects of arsenic on PARP-1 activity and arsenic augmentation of UV-induced DNA damage and mutagenesis. Furthermore, arsenic prevents the effects of arsenic on UV-induced DNA damage in mouse skin in vivo. It is suggested that arsenic may provide a tractable approach to attenuate arsenic-induced carcinogenesis in human populations. Collectively our studies demonstrate that arsenic can interact with key DNA repair zinc-finger proteins, resulting in modification of protein structure and function, leading to accumulation of DNA damage.

**1450 Prolonged Exposure to Particulate Chromate Induces a Switch from Homologous Recombination Repair to Nonhomologous End Joining Repair in Human Lung Cells**

The interaction of genotoxic chemicals with DNA repair is a key consideration in understanding their overall toxic mechanism. This presentation describes an example of this interaction focusing on chromate. Particulate chromate is a known human carcinogen and genotoxic agent, but how it causes cancer is unknown. DNA double strand breaks (DSB) are a key factor in its carcinogenicity as perturbations to chromate-induced neoplastic transformation occurs in human lung cells with experimentally disrupted DSB repair pathway, but not in human lung cells with intact DSB repair systems. Emerging data show that particulate chromate targets the homologous recombination repair pathway (HR) in human lung cells with unaltered repair pathways. In human lung cells with normal zinc chromate-induced concentration-dependent increases in DSBs and chromosome aberrations. With longer exposure times, this damage remains elevated indicating that the damage continues to be produced. An evaluation of representative proteins of the major steps in HR signaling showed that the sensors of DSB repair (measured as gammaH2AX, 53BP1 and Ms chromosome) remain elevated in response to these breaks indicating they are unaffected by chromate. By contrast, the effector component of HR repair (measured as Rad51 response) is compromised by chromate. During the first 24 h of exposure, Rad51 response increases as expected, but after 48-120 h of exposure the response continually declines. The signal transduction response through ATM also increases during the first three days of exposure, but after 96 h of exposure, the ATM response dramatically falls off. The expression of Ku80 and DNA-PKcs proteins increased as HR repair function decreases. Thus, particulate chromate induces a signaling switch from HR to NHEJ after prolonged exposures. The timing of this switch also correlates well with the onset of particulate chromate-induced genotoxic instability in human lung cells. This work was supported by NIEHS grant ES016893 (J.P.W.).

**1451 Chemistry and Biology of Oxidatively-Induced Tandem Lesions of DNA**

Y. Wang. Department of Chemistry and Environmental Toxicology Graduate Program, University of California Riverside, Riverside, CA. Sponsor: H. Xie.

Exposure to various toxic metals in the environment can lead to cellular production of reactive oxygen species (ROS), which can result in DNA damage. Although substantial repair studies have been conducted for the ROS-induced single-nucleobase lesions, not much is known about how oxidatively induced tandem DNA lesions are repaired in mammalian cells. Our LC-MS/MS quantification results revealed that 8,5-cyclo-2-deoxyadenosine (cyclo-dA), 8,5-cyclo-2-deoxyguanosine (cyclo-dG) and the GT intranstrand crosslink are present at significantly lower levels in tissues of repair-deficient animals than in Erccl-deficient animals. Likewise, we found higher levels of these lesions in brain tissues of XPA-deficient patients than in repair-proficient individuals. Viewing that XPA and Erccl are required for nucleotide excision repair (NER), the above results support that these DNA lesions are substrates for NER in vivo. Additionally, we observed an age-dependent accumulation of these DNA lesions in mammalian tissues, suggesting that the accumulation of these DNA lesions may play an important role in aging-related pathological conditions. We also found, from the LC-MS/MS and plasmid-based in vivo transcription assay, that both cyclo-dA and cyclo-dG substantially blocked transcription in mammalian cells, and transcription bypass efficiency is much lower in NER-deficient mammalian cells than repair-proficient cells, suggesting again the compromised repair of these DNA lesions in XPA-deficient cells. Moreover, the LC-MS/MS method allowed for the identification and quantification of mutant transcripts produced from the transcriptional bypass of the cyclo-dA and cyclo-dG lesions. Together, our combined chemistry and biology approach led to important novel insights into the repair and biological consequences of the oxidatively induced tandem DNA lesions.

**1452 Molecular Mechanisms Involved in Neuro/Glial Toxicity: From Oxidative Stress to Redox Signal Transduction**

R. Franco. School of Veterinary Medicine and Biomedical Sciences, University of Nebraska-Lincoln, Lincoln, NE.

Oxidative stress, defined as the imbalance between the production of reactive oxygen species (ROS) or nitrogen (RNS) species and the ability of cells to scavenge these active species and repair oxidative damage, has been largely reported to participate in environmental toxicity. Biomarkers of oxidative damage in proteins, lipids, and nucleic acids are inherent to neuronal toxicity associated with pesticides, metals,
and particulate matter. Electron-transfer processes called “redox signaling” play key messenger roles in biological systems. Initially, ROS/RNS formation was thought to lead to nonspecific cellular damage. However, recent in vitro and in vivo findings demonstrate that, in response to environmentally relevant doses toxicants, a specific set of redox signaling events play a major role activating specific signaling transcription cascades, regulating gene expression, enzyme activity, cellular metabolism, and cell fate outcome of neuronal and glial cells. In this session we will examine recent findings on the molecular mechanisms by which redox signaling regulates environmental neuro/ glial toxicity. More specifically, the speakers will highlight the novel mechanisms by which mitochondrial redox homeostasis, iron-sulfur cluster oxidation, electrophile-adduct formation, thiols, transcription factor regulation, oxidative post-translational modifications, and oxidative DNA damage regulate the toxicity of particulate matter, aldehydes, pesticides, and metals. This topic should be of great importance to biochemists, risk assessors, graduate students, postdoc- toral trainees, and academics within distinct Specialty Sections.

1454 The Electrophile-Responsive Proteome As a Target for Environmental Neurotoxins
R. LoPachin. Montefiore Medical Center, New York City, NY.

Many environmental toxicants are electrophiles that can form irreversible covalent adducts with nucleophilic amino acid residues. Discerning how these environmental chemicals interact with the electrophile-responsive proteome is a critical step in defining their respective mechanisms of neurotoxicity. A detailed understanding of acrylamide (ACR) toxicity led us to the identification of relevant protein targets and to the molecular mechanism by which this targeting causes neuronal cell death. The Hard and Soft, Acids and Bases (HSAB) theory evidenced that the type-2 alkenes might act synergistically with endogenous unsaturated aldehydes and in chemico studies that identified the redox-sensitive targeted residues as nucleophilic sulfhydryl thiolates (–S–) located within cysteine-centered catalytic triads of central enzymes. These findings are broadly applicable since many environmental toxicants are electrophiles that can produce toxicity by reacting with nucleophilic residues on macromolecules. Protein-environment interactions have significant implications for human health and risk assessment. (NIH grants ES03830-25 and ES07912-11)

1455 Redox Regulation of NF–κB p50 and M1 Polarization in Neurotoxic Microglia
M. J. Block. Anatomy and Neurobiology, Virginia Commonwealth University, Richmond, VA.

Microglia detect and respond to a diverse array of stimuli, including environmental toxicants, bacterial toxins, cytokines, neuronal damage, and disease proteins, where the activation state can be characterized as a pro-inflammatory (M1) or alternative (M2) response. M1 polarization is implicated in neurotoxic microglia activation, with both enhanced M1 activation and impaired resolution (M2 response). How ROS shift microglia to a neurotoxic phenotype is unknown. Here we identify the NF–κB p50 protein radical in neurotoxic microglia, demonstrating oxidative modification during M1 polarization. Nuclear extracts from microglia cultures treated with the peroxynitrite generator SIN–1 (1uM) and the ROS-generating pesticide parathion (0.5uM) showed decreased NF–κB p50 DNA binding, confirming that microglial ROS impairs NF–κB p50 function. NF–κB p50–/– mice were injected with LPS (5mg/kg) and IPs (NF–κB p50−/−) primary mixed-glia cells and silRNA NF–κB1 knockdown in BV2 microglia were treated with LPS (10ng/ml), which resulted in enhanced pro-inflammatory cytokine production and activated microglial morphology. Loss of NF–κB p50 function in microglia impaired both M1 gene expression and the resolution of M1 genes. Mesencephalic neuron-glia cultures from NF–κB p50−/– mice treated with either LPS or parathion showed enhanced DA neurotoxicity. Parathion amplified the production of LPS-induced TNFα in microglial cultures only in the presence of functional NF–κB p50, emphasizing the importance of NF–κB p50 for priming. In vivo parathion studies revealed that NF–κB p50−/– mice have enhanced activated microglial morphology and elevated motor behavior deficits in response to a single parathion injection, supporting that the NF–κB p50−/– mice may already be primed. These data identify a critical redox signaling mechanism triggered by environmental toxicants that drive M1 polarization in microglia, where loss of NF–κB p50 function leads to elevated neuroinflammation, microglial activation, and DA neurotoxicity (Supported by the NIEHS R01ES016951).

1456 Redox Signaling and Methylmercury Toxicity
M. Aschner and M. Ni. Department of Pediatrics, Vanderbilt University Medical Center, Nashville, TN.

MeHg causes acute and chronic damage to multiple organs, most profoundly the central nervous system (CNS). We examined the effects of MeHg on microglial and astrocytic viability, reactive oxygen species (ROS) generation, glutathione (GSH) level, redox homeostasis, and NF-E2-related factor 2 (Nrf2) protein expression, the latter switch of antioxidant response. Glial cells exposed to MeHg (at relevant physiological concentrations of 1–5 microM) treatment caused a rapid (within 1 min) concentration- and time-dependent increase in microglial ROS generation, accompanied by a statistically significant decrease in the ratio of GSH and its oxidized form glutathione disulfide (GSSG) (GSH/GSSG ratio). MeHg increased the cytosolic Nrf2 protein level within 1 min of exposure, followed by its nuclear translocation after 10 min of treatment. Consistent with the nuclear translocation of Nrf2, quantitative real-time PCR revealed a concentration-dependent increase in the messenger RNA level of Hs1, Nqo1, and xCT 30 min post MeHg exposure, whereas Nrf2 knockdown greatly reduced the upregulation of these genes. Furthermore, we observed increased microglial death upon Nrf2 knockdown by the small hairpin RNA approach. Additional studies established that microglia were more sensitive to MeHg than astrocytes, a finding consistent with their higher Hg uptake and lower basal GSH levels. Microglia also demonstrated higher ROS generation compared with astrocytes. Nrf2 and its downstream genes were upregulated in both cell types, but with different kinetics (much faster in microglia). In summary, microglia and astrocytes each exhibit distinct sensitivity to MeHg, resulting in their differential temporal adaptive responses. These unique sensitivities appear to be dependent on the cellular thiol status of the particular cell type. (Supported by R01ES07351 and R01ES020852).

1457 Repair of Mammalian Genome Damage Induced by Oxidative Stress and Their Linkage to Neurodegenerative Diseases

Endogenous reactive oxygen species (ROS), respiration-by-products, and ROS induced during toxic/inflammatory response generate multitude of mutagenic and toxic oxidized bases, and strand breaks in mammalian genomes whose repair via the base excision/single-strand break repair (BER/SSBR) pathway is essential for preserving genomic integrity. The lack of replicative repair in neural cell genome
could explain the linkage of some neurodegenerative diseases to deficiency in BER proteins. Dyshomeostasis of transition metals Fe/Cu as well as accumulation of genome damage have been implicated in Alzheimer’s (AD) and Parkinson disease (PD). We postulate that Fe and Cu (at up to micromolar level) pose double jeopardy in that not only these metal ions could induce ROS and hence oxidized bases, but they also inhibit repair of such oxidized bases by inhibiting the BER-initiating DNA glycosylases NEIL1/2, both in vitro and in human neuroblastoma (SH-SYSY) cells at sub-micromolar concentration. Metal chelators and chemopreventive curcumin reverse NEILs’ inhibition both in vitro and in cells, thus warranting exploration of their therapeutic potential. Oxidative stress has also been linked to many neurodegenerative diseases, associated with aggregation/misfolding of key proteins including RNA binding proteins (RNPs) such as TDP–43 and FUS/TL1. Aggregation of TDP–43 together with its nuclear clearance has been implicated in atypical sporadic lateral sclerosis (ALS). While the etiologic role of RNPs in diseases including hnRNP–U, which we had earlier shown to enhance BER efficiency, is not completely understood, we observed direct role of TDP–43 in repairing endogenous and induced DNA double–strand breaks (DSBs) via non–homologous end joining. The observed increase in the level of strand breaks in postmortem ALS brain is consistent with our hypothesis that the loss of DNA strand break repair due to inactivation of specific RNPs including TDP–43 causes nuclear death and disease phenotypes. **1460 The AhR Is a Key Factor in the Regulation of Hematopoietic Stem Cells and Their Protection from Premature Exhaustion, Stress, and Hematopoietic Disease**

T. A. Gasiewicz1, K. P. Singh1, L. C. Bennett1, F. Casado2, J. Walrath1 and S. Welle1.1 Department of Environmental Medicine, University of Rochester, Rochester, NY and 2McMaster Stem Cell & Cancer Research Institute, Hamilton, ON, Canada.

There has been much work to define a physiological role of the AhR in the immune system and possible relationships to human disease. Hematopoietic stem cells (HSCs) from global AhR knock-out (KO) mice are inherently hyperproliferative. These data, along with others, are consistent with a hypothesis that the AhR has an important role as a negative regulator of HSC proliferation. Functional and gene expression analyses of HSCs from KO mice indicate that a lifetime of altered signaling pathways results in premature exhaustion, aging and a myeloproliferative disorder. Aging mice lacking AhR showed a decreased survival rate, splenomegaly, increased circulating white blood cells, hematopoietic cell accumulation in tissues, and anemia. There was also decreased self-renewal capacity of HSCs determined by competitive repopulation and serial transplantation. Some of the molecular changes observed in aging HSCs include altered content of ROS, p16Ink4a, and γ–HAX2, and indicator of DNA damage. AHRKO mice develop multiple genomic changes (e.g. Srpk2, Rad50, mTOR, Creb1, Hes1, Pdp1, Stra13) in HSCs at an early age that lead to the phenotypic changes characteristic of premature exhaustion. The most prominent gene changes were also associated with HSC hyperproliferation, leukemia, and accelerated aging. Pathway analyses also indicated an enrichment of genes associated with oxidative stress, acute myelogenous leukemia, aging, and heat shock response, and the B-catenin/Wnt pathways. These data indicate that the AhR is a key cofactor in the regulation of HSCs and their protection from long-term stress, premature exhaustion, and age-related disease. Supported by NIEHS grants ES01247, ES07026, ES04862, and ES016606.

**1459 The AhR Modulates Cardiomyogenesis in Embryonic Stem Cells**

A. Puga. Department of Environmental Health, University of Cincinnati, Cincinnati, OH.

The aryl hydrocarbon receptor (AhR) is a critical mediator of gene-environment interactions that regulates the transcription of drug-metabolism genes and of genes involved in cell cycle regulation. Many AhR targets identified by genome-wide gene expression profiling, ChIP analyses and studies with orthologous genes in invertebrates have morphogenetic functions suggestive of an AhR regulatory function during embryonic development. To address this hypothesis, we studied the regulation of AhR expression in mouse embryonic stem cells (ESC) and their differentiated progeny. In undifferentiated ESC, co-regulatory interactions between pluripotency factors OCT4/3, NANOG and SOX2 and Polycomb Group (PcG) proteins maintain AhR expression in a repressed state, while RNA polymerase II (RNApolII) bound at the transcription start site is required for synthesis of abortive transcripts. AhR activation during differentiation follows from repression of repressive chromatin marks, including release of pluripotency factors and PcG proteins from their binding sites. Sp factor transactivation, establishment of open chromatin marks and engagement of active RNApolII to drive full-length RNA transcripts.

**1458 The Role of the AhR in Stem Cell Development and Lineage Specification**

D. H. Sherr1, A. Puga1, T. A. Gasiewicz1, E. Papoutsakis1 and G. Murphy4.

For decades the aryl hydrocarbon receptor (AhR) has been studied for its mediation of the toxic and carcinogetic effects of ubiquitous environmental chemicals including dioxins, planar PCBs and PAHs. A subtext to this work has always been the nature of the “normal” physiological function of this evolutionarily conserved protein. In the last five years, several breakthrough studies have begun to reveal the significance of the AhR in normal biological processes. Similarly, technological advances developed in the last five years have allowed investigators, for the first time, to map out some of the most basic tenets of pluripotent and multipotent stem cell differentiation. The significance of this work cannot be over-stated since control of stem cell differentiation is a key to both organ generation/regeneration and cancer stem cell immortality. Here, we focus on the intersection of AhR and stem cell biology to highlight the importance of the AhR to the regulation of stem cell differentiation and to emphasize the potential for environmental AhR ligands to disrupt essential cell specification programs. We will discuss AhR control of: 1) pluripotent (embryonic stem cell and induced pluripotent stem cell) development into cardiomyocytes, erythroid lineage cells and megakaryocytes, 2) multipotent hematopoietic stem cell senescence and differentiation into lymphocytes, and 3) cancer stem cell development. In so doing, we will identify themes common to multiple developmental systems (e.g., common AhR signaling pathways, the role of the AhR in maintaining “stem-ness,” and predicted outcomes after environmental chemical exposure). Symposium speakers will address the significant implications of their work for stem cell and AhR biology under normal physiological conditions and when impacted by exposure to environmental AhR ligands.

**1461 A Role for the Aryl Hydrocarbon Receptor (AhR) on Platelet Function**

E. Papoutsaki1,2, S. Lindsay1,2, J. Jiang1 and D. Woulfe1. 1Department of Chemical & Biomolecular Engineering, University of Delaware, Newark, DE, 2Department of Biological Sciences, University of Delaware, Newark, DE and 3Nemours Center for Childhood Cancer Research, A.I. duPont Hospital for Children, Wilmington, DE. Sponsor: A. Puga.

We recently identified AhR as a novel regulator of megakaryocytic polyploidization and differentiation. Although AhR-null mice exhibited roughly 15% fewer circulating platelets than WT mice, this was insufficient to explain the bleeding phenotype we found in AhR-null mice. Instead, we hypothesized that platelets from AhR-null mice are functionally deficient. Indeed, we found that only 20% of AhR-null mu-platelets aggregated in response to 2 μg/mL collagen compared to 60% for WT platelets. Spreading assays confirmed that AhR-null platelets demonstrated nearly 40% less spreading in response to collagen-dependent signaling. Yet AhR-null platelets bound fibrinogen and spread in response to other platelet agonists including thrombin, ADP, and AYPGKF (a PAR4 agonist). AhR-null platelets expressed similar levels of CD41 and CD49b surface markers, but 15% less GPVI, one of the receptors involved in collagen signaling. We then investigated molecular mechanisms by which AhR could influence collagen signaling within platelets and found that AhR-null platelets have decreased Vav1 and Vav3 phosphorylation, leading to reduced PLCA2 tyrosine phosphorylation within platelets and found that AhR-null platelets have decreased Vav1 and Vav3 expression compared to WT platelets. Spreading assays confirmed that AhR-null platelets expressed similar levels of CD41 and CD49b surface markers, but 15% less GPVI, one of the receptors involved in collagen signaling. We then investigated molecular mechanisms by which AhR could influence collagen signaling within platelets and found that AhR-null platelets have decreased Vav1 and Vav3 phosphorylation, leading to reduced PLCA2 tyrosine phosphorylation. In contrast, tyrosine phosphorylation of Syk, which lies upstream of Vav1 and Vav3 phosphorylation, remained unaltered and thrombin stimulation resulted in Rac1 activation of both WT and AhR-null platelets. These results showed that the absence of AhR leads to downregulation of Vav1 and Vav3, which in turn leads to altered PLCA2 phosphorylation and reduced platelet activation specifically
in response to collagen, without impacting other platelet signaling pathways. This study advances our hypothesis that AHR influences multiple aspects of normal hematopoietic differentiation.

**1462 The AhR Regulates the Production and Specification of Bipotential Hematopoietic Progenitor Cells**

G. Murphy1, B. Smith1, S. Rozell1, A. Leung1, J. Ubellacker2, A. J. Parks2, S. Nah1, S. Monti1 and D. H. Sherr1.

*1Center for Regenerative Medicine (CRMed), Section of Hematology and Oncology, Department of Medicine, Boston University School of Medicine, Boston, MA and 2Environmental Health, Boston University School of Public Health, Boston, MA.*

Recent studies demonstrate that the AHR may regulate the hematopoietic and immune systems during development in a cell-specific manner. Our results indicate that AHR has a physiological and functional role in normal hematopoietic development, and that modulation of the receptor in bi-potential hematopoietic progenitors can direct cell fate. Using a novel, iPSC-based, chemically-defined, serum and feeder cell-free culture system, we demonstrate that a functional AHR is expressed in hematopoietic progenitor cells (HPCs), and that remarkably, AHR activation of these HPCs drives an unprecedented expansion of HPCs, megakaryocyte (MK)- and erythroid-lineage cells. Further AhR modulation directs cell fate, with chronic AhR agonism permissive to erythroid differentiation and acute antagonism favoring megakaryocyte specification. These results demonstrate a new platform for studying human red blood cell and MK development that allows for exponentially greater production of RBCs and MKs in comparison to existing methodologies. This strategy relies on the first of its kind definition of the role of the AHR receptor in normal hematopoietic development using specialized ligands in hematopoietic progenitor cells. A useful outcome for this work will be the utilization of this in vitro platform for the clinically relevant production of blood products. An iPSC-based system, such as the one described here in which sufficient numbers of cells can be produced, should facilitate future clinical adaptation involving the transfusion of iPSC-derived red blood cells and platelets without problems related to immunogenicity, contamination, or supply. Supported by NHLBI U01 HL107443-01, an American Society of Hematology (ASH) Scholar Award, the National Blood Foundation (NBF), PO1 ES11624, P42 ES007381, and the Art beCAUSE Breast Cancer Foundation.

**1463 The AHR Controls Breast Cancer Stem Cell Development and Function**

D. H. Sherr1, A. J. Parks1, S. Monti1, G. Murphy2, O. Novikov1, J. Ubellacker1 and E. A. Stanford2.

*1Section of Hematology and Oncology, Department of Medicine, Boston University School of Public Health, Boston, MA and 2Department of Medicine, Boston University School of Medicine, Boston, MA.*

Tumor metastasis is the cause of death in nearly all breast cancer patients. Recent evidence suggests that metastasis is mediated, to a disproportionate extent, by chemoresistant, long-lived breast cancer stem-like cells (BCSCs). BCSC cells are defined by their expression of aldehyde dehydrogenase (ALDH), a set of genes associated with “stemness”, the ability to self-renew, expression of properties consistent with epithelial-to-mesenchymal transition (e.g., metastatic potential), and resistance to chemotherapeutics. Studies from several laboratories, including three laboratories represented in this symposium, suggest that the AHR, a protein historically associated with tumorigenesis, is involved in the development and/or function of blood stem cells which share some properties with cancer stem cells. Therefore, we postulated that the AHR may play a role in either the development or function of BCSCs. Here, we present data demonstrating elevated levels of constitutively active AHR in BCSCs from aggressive human ER+, PR-, Her2- (“triple negative”) and inflammatory breast cancers. The results indicate that AHR hyper-activation with exogenous ligands (FICZ, TCDD, DMB) increases and AHR inhibition with pharmacological or molecular agents decreases expression of hyper-activation with exogenous ligands (FICZ, TCDD, DMBA) increases and AHR inhibition with pharmacological or molecular agents decreases expression of these properties. However, these novel properties also contribute to their potential health risk. A major route of exposure for engineered nanomaterials occurs through inhalation, potentially leading to pulmonary toxicity. Immune activation and inflammation represents a common response observed across many pulmonary studies of nanoparticle inhalation in rodents. However, our mechanistic understanding of how the materials elicit immune activation is limited. Recent accumulating evidence supports the proposal that the initial pulmonary immune response to nanoparticle exposure is mediated via the innate immune system driving inflammation. Presentations in this session are aimed at elucidating the mechanisms of these innate immune responses to engineered nanomaterial exposure in the lung. This will include exploration of macrophage phenotypes, inflammasome activation, Toll-like receptors and, lastly, will explore the degradation of nanomaterials by immune cells and their defensive products. The outcome of this session is to gain state-of-the-art information on the mechanisms of the critical innate immune system response in the toxicology of nanoparticles and ultimately the development of safe nanotechnologies.

**1464 Three Dimensions of Nanomaterial Pulmonary Toxicity: Innate Immunity, TLRs, and Inflammasomes**

J. M. Brown1 and S. N. Nadadur2.

*1Pharmaceutical Sciences, University of Colorado, Aurora, CO and 2Division of Extramural Research, NIEHS, Research Triangle Park, NC.*

Nanotechnology is rapidly developing, resulting in the production of numerous engineered nanoparticles. These materials have many potential uses in engineering, electronics, and medicine owing to their unique size, strength, functionality and surface properties. However, these novel properties also contribute to their potential health risk. A major route of exposure for engineered nanomaterials occurs through inhalation, potentially leading to pulmonary toxicity. Immune activation and inflammation represents a common response observed across many pulmonary studies of nanoparticle inhalation in rodents. However, our mechanistic understanding of how the materials elicit immune activation is limited. Recent accumulating evidence supports the proposal that the initial pulmonary immune response to nanoparticle exposure is mediated via the innate immune system driving inflammation. Presentations in this session are aimed at elucidating the mechanisms of these innate immune responses to engineered nanomaterial exposure in the lung. This will include exploration of macrophage phenotypes, inflammasome activation, Toll-like receptors and, lastly, will explore the degradation of nanomaterials by immune cells and their defensive products. The outcome of this session is to gain state-of-the-art information on the mechanisms of the critical innate immune system response in the toxicology of nanoparticles and ultimately the development of safe nanotechnologies.

**1465 Inflammasome Activation in Nanoparticle-Induced Lung Inflammation**

*1CEHS, University of Montana, Missoula, MT, 2Mechanical & Aerospace Engineering, West Virginia University, Morgantown, WV.*

We have previously shown that inhalation of nanoparticles (ENM) increases bioactivity, while carboxylation of ENM surfaces decreases bioactivity for LMP since imipramine and chloroquine can block NLRP3 Inflammasome activation, Toll-like receptors and, lastly, will explore the degradation of nanomaterials by immune cells and their defensive products. The outcome of this session is to gain state-of-the-art information on the mechanisms of the critical innate immune system response in the toxicology of nanoparticles and ultimately the development of safe nanotechnologies.

**1466 Lung and Pleural Innate Immune Responses to Engineered Nanomaterials**

J. C. Bonner.

*Biological Sciences, North Carolina State University, Raleigh, NC.*

The nanotechnology revolution offers enormous societal and economic benefits for innovation in the fields of engineering, electronics, and medicine. However, growing evidence indicates that some biopersistent engineered nanomaterials (ENMs), including carbon nanotubes (CNTs) and metal nanoparticles, have the potential to stimulate immune, inflammatory, or fibroproliferative responses in the lung and pleura. This presentation will focus on specific mechanisms through which CNTs or nickel nanoparticles modulate cellular signaling and innate immune responses of macrophages, fibroblasts, and mesothelial cells relevant to lung and pleural disease. One of the goals is to discuss new evidence from transgenic mouse models showing that these ENMs have the potential to shift allergic lung inflammation from a
and N. B. Saleh2.

increase the susceptibility of lung cells to pathogenic infections and modulate TLR to address the precise role of TLRs in these observed effects both in vitro and in cells, but anticipate that SWNTs alter TLR activity. Studies are currently underway we did not observe significant changes in TLR3 or 7 mRNA expression in these IA V infectability as quantified by virus titers and immunohistochemistry. While RNA, respectively. Results from these studies show that SWNTs fail to activate the ability of SWNTs to modulate TLRs, we employed human cell lines that over-

Recognition of foreign pathogens by toll-like receptors (TLR) stimulates innate immunity as a primary defense mechanism to combat pathogens. To investigate the ability of SWNTs to modulate TLRs, we employed human cell lines that over-express TLR2 or TLR3 which recognize microbial moieties of bacteria and viral RNA, respectively. Results from these studies show that SWNTs fail to activate the TLRs alone, however, they repress the activity of zymosan as the natural receptor agonist for TLR2, while enhancing activity of the TLR3 agonist poly IC. Furthermore, these observations are most significant for SWNTs with 6, 5, 5, 5 chiral enrichment which form more stable and less dense clusters than other types of SWNTs. To determine if SWNTs influence virus infectivity and modulate TLR pathways in lung cells, we infected small airway epithelial cells with IAV H1N1 while co-incubating with SWNTs. In these studies SWNTs significantly enhanced IAV infectability as quantified by virus titers and immunohistochemistry. While we did not observe significant changes in TLR3 or 7 mRNA expression in these cells, but anticipate that SWNTs alter TLR activity. Studies are currently underway to address the precise role of TLRs in these observed effects both in vitro and in vivo. Overall results from these studies indicate that SWNTs have the potential to increase the susceptibility of lung cells to pathogenic infections and modulate TLR activity.

Because of the unique properties of carbon nanotubes (CNTs), such as small size, large surface area, high strength, and electrical conductivity, this nanomaterial has been used in high-performance composites, electronics, and medical therapeutics. Given the possible pro-inflammatory and toxic effects of CNTs, understanding of their interactions with living systems is important as applications employing this nanomaterial become mainstream. To this end, we studied degradation of CNTs with peroxidases including horseradish peroxidase (HRP), myeloperoxidase (MPO), and eosinophil peroxidase (EPO) as a function of their structure and surface functionalization. Initially, in test-tube studies were conducted, where HRP, MPO, and EPO were incubated with hydrogen peroxide and halides. Characterization techniques demonstrated that the reactive intermediates generated via the peroxidase cycle and hypohalous acids (e.g., HOCl from MPO and HOBr from EPO) produced through the halogenation cycle degraded short-cut carbonylated single-walled CNTs. Encouraged by these initial results, cellular studies were implemented in which we demonstrated that short-cut carboxylated, IgG-coated single-walled CNTs could be phagocytosed and degraded by neutrophils, inflammatory cells containing high concentrations of MPO. Also, utilizing a cellular culture system consisting of highly purified murine eosinophils in which degradation and exocytosis of murine EPO (mEPO) were triggered by cytochalasin B and a platelet-activating factor (PAF), significant degradation of carboxylated, single-walled CNTs was evidenced after 48 hours of treatment. Finally, in vivo studies demonstrated that the inflammatory response in MPO-knockout (k/o) mice was stronger than that in wild-type (w/t) C57/B16 mice, and both CNT degradation and clearance from the lungs of MPO k/o animals were markedly less effective. Given the promising cell culture and in vivo degradation results obtained to date, we envision future applications, where carbon-based nano-containers will biodegrade via peroxidase-driven mechanism after they deliver their cargo to organ/ cell targets.
Dietary supplements and other consumer natural products typically contain ingredients with an inherently wide margin of safety. Despite this fact, various ingredients can be negatively affected by processing, solvent systems, unconventional or non-traditional use patterns, or combining with other ingredients in proprietary blends with similar safety caveats for individual ingredients or the finished product as a whole. Premarket clinical studies are not routinely required or performed on finished products so products consumed by the public may make their debut in large populations that essentially become the “test” market. In these circumstances, products may carry forward high expectations of safety, but often times the only method of safety confirmation and ongoing monitoring for toxicity issues is the postmarket system of safety surveillance (PMS). Robust PMS can help companies confirm safety expectations, identify emerging safety signals associated with the monitored product, and provide information vital to hypothesis generation leading to focused investigation conducted in more controlled clinical environments. In order for the process to work effectively and efficiently, PMS data must be mined for appropriate and actionable safety signals. This presentation focuses on natural product PMS systems and methods to evaluate and act on generated safety signals with real life market examples.

Clinicians are oftentimes left scratching their heads when it comes to objectively evaluating the clinical utility of published case reports and/or adverse event reports regarding dietary supplements. Few clinical scientists conduct prospective research in the field and even fewer understand the pitfalls associated with dietary supplements. In short, understanding the medicine is often the easy part, making sense of the supplement and its safety and/or efficacy is the confusing aspect. This presentation will discuss some of the shortcomings associated with dietary supplement formulations (e.g., dissolution, bioavailability, adulteration, etc.) and how they either contribute to or detract from the clinical significance of a case report or adverse event report. Examples involving Ephedra, Kava kava, EGCG, and Ephedra-free supplements will be highlighted, including the results of controlled safety studies in humans.

Kava had previously been used to treat anxiety in Europe. Reports of rare hepatotoxicity potentially linked to its use led to its removal from the European market. However, kava is experiencing global resurgence, particularly in the USA, as a dietary supplement with limited quality control. Since many factors may influence the composition of the final kava products, various hypotheses have been proposed for its hepatotoxic risk with no validation. This presentation will report our research progress in identifying the cause of kava’s hepatotoxic risk using various model systems, and discuss our strategies that will validate such causes in humans with the ultimate goal to minimize such a risk. Studies are also ongoing to maximize kava’s anxiolytic and other beneficial effects. The outcomes from these investigations are expected to help the successful reintroduction of safer forms of kava with substantial clinical benefit.

This presentation will present how AER data is used from the perspective of a global dietary supplement manufacturer. Global AE collection helps dietary supplement companies monitor product safety and quality worldwide and make continuous improvements as necessary. AER-related quality issues can identify product QA/QC failures that necessitate changes in formulations or in rare cases lead to product recalls. Integrating post-market AER monitoring with product quality complaints ensures the most comprehensive investigative practices and allows sensitive signal detection. An increasing number of governments have mandatory collection and reporting requirements for AEs. Regulatory requirements are ever-changing. New regulations for reporting are being developed and enforced worldwide and regulatory authorities are now more frequently asking for adverse event information upon registration or re-registration of products. A robust AER system allows the development of FAQs that can be shared with health-care providers, distributors, or consumers. Systematic review of AE data provides a company’s legal department necessary information regarding compensation requests/decisions. At times, AER-related complaints may identify ethics violations by sales and distribution personnel. These might include suggesting products might treat a disease or other off label claims. Finally, as is true for drugs, post market AER monitoring is the best way to accurately assess the long term safety of dietary supplement products and assure your customers that the products they are using are truly safe.

The liver has a central role in normal physiology and is a sentinel organ for sensing chemical exposure. As such, it is one of the most frequent target organs serving as the basis of environmental chemical regulation and clinical drug failures due to concerns for both cancer and noncancer effects. Toxicogenomics has evolved to enable toxicity testing and risk assessment paradigms to be more efficient and less reliant on long-term animal studies. There is also global interest in using ‘omic tools to overcome obstacles encountered when interpreting liver injury seen in laboratory test systems. Factors contributing to species-selective hepatotoxicant responses among various mammalian species, particularly as mediated via xenobiotic receptors such as CAR, will be discussed. Case studies will highlight how ‘omic technologies provide mechanistic data for hazard identification, dose-response, and quantitative risk assessment with a fraction of the resources compared to traditional assessments. Gene signatures relating molecular initiating events such as transcription factor activation to downstream key events such as cell proliferation have defined adverse outcome pathways and correlated to trans-activation profiles of human transcription factors. These efforts to anchor genomic biomarkers of liver injury to more traditional apical endpoints create precedence for the use of toxicogenomic approaches as the basis of chemical regulation. In drug safety research, genetically-diverse population-based pharmacogenetic approaches have informed idiosyncratic liver toxicity, yielded mechanistic insights, and predicted clinically-relevant drug-induced liver injury where classical safety assessment models failed. Systematic approaches, such as the US FDA’s liver toxicity knowledge base (LTKB) that integrate pathways, genes, proteins, and drugs to characterize the risk of liver injury, will advance regulatory science, improve the new drug application review process, and refine targeted strategies for regulatory-oriented research.

In mammalian organisms, members of the nuclear and soluble receptor superfamilies contribute critically as xenobiotic sensors, serving as mediators of toxicological and physiological responses to chemical exposure. These xenoreceptors transcriptionally regulate a large network of genes encoding a functional web of responses that include the metabolism and transport of xenobiotics, regulation of lipid and energy homeostasis, and modulation of cell proliferation. Mouse models of receptor biology have been deployed widely to characterize these features. However, marked differences exist among mammalian species in their sensitivities and response to hepatotoxins, responses that differ with respect to dose as well as qualitatively in gene expression signatures elicited from a given exposure paradigm. For example,
the constitutive androstane receptor (NR1I3) is necessary for the development of hepatocellular carcinoma in mice following promotion by non-genotoxic receptor activators such as the direct ligand, TCPOBOP, or indirect activators such as phenobarbital (PB). However, extensive epidemiological studies in human populations have ascertained no excess risk of liver cancers following chronic PB exposure. To allow biologically-based and scientifically defensible extrapolations of receptor function across mammalian species that accurately predict potential human toxicities, it is critical to delineate the molecular mechanisms underlying these differential responses. Surprisingly, results using chromatin immunoprecipitation and bioinformatics analyses have revealed extensive divergence among transcription factor binding sites between species. Species-selective splice variation in each receptor further defines inherent differences in species response. This presentation will focus on those features of xenobiotic receptors that contribute to the differences underlying species-selective response to hepatotoxicants.

**W 1478 The Utility of Toxicogenomics in the Risk Assessment of Carcinogens: A Report on Two Health Canada Case Studies**

C. L. Yaukel, I. Moffatt1, N. Chepelev1, A. Jackson1, S. Labib2, J. Bourdon2, B. Kuo3, J. Buick1, F. Lemieux1, A. Williams1, S. Halappanavar1, A. Malik3, M. Luijten1, J. Aubrecht4, D. R. Hyduke5, A. Fornace6, C. Swartz2, M. D. Waterman1, I. B. Lambert6 and L. Recio7. 1Environmental Health Science and Research Bureau and Water, Health Canada, Ottawa, ON, Canada, 2Water and Air Quality Bureau, Health Canada, Ottawa, ON, Canada, 3National Institute for Public Health and the Environment, Bilthoven, Netherlands, 4Drug Safety R&D, Pfizer, Groton, CT, 5Biological Engineering Department, Utah State University, Logan, UT, 6Biochemistry and Molecular and Cellular Biology, Georgetown University, Washington, DC, 7Integrated Laboratory Systems, Research Triangle Park, NC and 8Department of Biology, Carleton University, Ottawa, ON, Canada.

Despite the numerous proposed applications of toxicogenomics in human health risk assessment, integrating standard genomics endpoints in chemical evaluations or using changes in pathway expression to identify points of departure is uncommon. We evaluated the utility of toxicogenomics data in the risk assessment of two well-established carcinogens, benzo(a)pyrene and furan, to demonstrate how genomics data may enhance or complement the current risk assessment process. Gene expression profiles and dose-response modeling were used to develop modes of action and establish pathway-based points of departure for these compounds. We found agreement between the derived points of departures and margins of safety for the genomics-proposed mode-of-action, as well as the most sensitive pathways. Our study demonstrates the potential for a mouse diversity panel (MDP), comprised of genetically diverse inbred strains, could accurately predict the DILI potential of PF-04287881 to humans. Increases in liver biomarkers were associated with histopathological findings of single cell necrosis, hepatocellular hypertrophy and Kupffer cell vacuolation. Based on their unique injury profiles, four mouse strains were selected for transcriptomic analysis of PF-04287881 toxicity in the liver. The protein ubiquitination pathway was highly enriched among genes differentially expressed in strains exposing PF-04287881-induced hepatocellular necrosis. In contrast, expression changes associated with PF-04287881-induced phospholipidosis included genes involved in drug transport, phospholipid metabolism and lysosomal function. These findings demonstrate the potential for a mouse population-based approach to improve hazard identification in drug-safety testing as well as yield mechanistic insights via toxicogenetic investigation.

**W 1479 Using Gene Signatures to Predict Molecular Initiating Events in Liver Adverse Outcome Pathways**

C. Corton. NHEERL/JORD, US EPA, Research Triangle Park, NC.

Adverse outcomes such as liver cancer have been linked to molecular initiating events (MIE) and downstream key events to define adverse outcome pathways (AOP). Identification of gene sets (signatures) predictive of MIEs (i.e., transcription factor activation) were derived by comparing microarray profiles of chemically-treated wild-type or transcription factor (TF)-null mice. The signatures included those dependent on AhR, CAR, PXR, Nrf2, PPARalpha, and PXR, as well as TFs (glucocorticoid receptor and androgen receptor) regulated by hormones. Prediction tests of TF activation showed that balanced accuracies were ≥ 90%. The signatures were used to comprehensively assess TF activation or suppression in a mouse liver compendium of gene expression biosets (~1900) that included chemicals, genetic models and other conditions that can affect the outcome of hazard studies including diet and life stage. Many of the TFs were activated/suppressed by a large number of chemical and chemical-independent perturbations of the liver (CAR, PPARa, PXR, Nrf2), whereas AhR activation was primarily through chemical exposure. Pairs of TFs (i.e., CAR, PPARa, Nrf2 and PXR) were often co-activated by chemicals and gene knockouts. Predictions of TF behavior were used to link chemical exposure, MIEs and AOs in the mouse liver allowing a classification of chemicals by one or more AOPs. The information can be used in cumulative risk models that take into account chemical-independent effects on MIEs (This abstract does not represent US EPA policy.)

**W 1480 Genetically Diverse Mouse Populations Facilitate Toxicogenetic Analysis of Drug-Induced Hepatotoxicity**

A. H. Harell3, 1, M. Mosedale1, H. Wu2 and K. Adkins2. 1Institute for Drug Safety Sciences, The Hammer Institutes for Health Sciences, Research Triangle Park, NC; 2Investigative Toxicology, DSRD, Pfizer, Groton, CT and 3University of Arkansas for Medical Sciences, Little Rock, AR.

Standard nonclinical models, including animals and average human hepatocytes, lack the genetic diversity necessary to model the breadth of toxicity responses observable across clinical populations. Thus, it is occasionally challenging to establish an animal model for a clinically relevant toxic reaction. Recent data indicate that mouse population-based models aid identification of genetically sensitive individuals that may then be used to study mechanisms of toxicity. Development of the macrodil antibiotic PF-04287881 was suspended following elevations in liver function tests observed in a Phase I clinical trial that were not predicted by standard nonclinical species. We demonstrated that a mouse diversity panel (MDP), comprised of genetically diverse inbred strains, could accurately predict the DILI potential of PF-04287881 to humans. Increases in liver biomarkers were associated with histopathological findings of single cell necrosis, hepatocellular hypertrophy and Kupffer cell vacuolation. Based on their unique injury profiles, four mouse strains were selected for transcriptomic analysis of PF-04287881 toxicity in the liver. The protein ubiquitination pathway was highly enriched among genes differentially expressed in strains exposing PF-04287881-induced hepatocellular necrosis. In contrast, expression changes associated with PF-04287881-induced phospholipidosis included genes involved in drug transport, phospholipid metabolism and lysosomal function. These findings demonstrate the potential for a mouse population-based approach to improve hazard identification in drug-safety testing as well as to yield mechanistic insights via toxicogenetic investigation.

**W 1481 Overcoming Obstacles to Study Drug-Induced Liver Injury with Toxicogenomics towards a Regulatory Application**

W. Tong. Division of Systems Toxicology, NCTR, US FDA, Jefferson, AR.

More than 25% of drugs on the market that ultimately fail and 40% that fail during clinical trials do so because of liver toxicity. As the leading cause of acute liver failure in the United States, drug-induced liver injury (DILI) has become a major concern in drug development and evaluation. The FDA’s new initiative on advancing regulatory science has identified DILI as a key focus area in a concerted effort to broaden FDA’s knowledge, create better evaluation tools, and identify safety biomarkers along the various stages of drug development. To enhance our understanding of liver toxicity, NCTR is developing a liver toxicity knowledge base (LTKB) to support research into relationships among DILI, pathways, genes and proteins, and drugs. The project uses a combination of data from the literature on selected drugs with specially emphasis on toxicogenomics data to develop a systematic approach for defining the severity of risk of a drug for liver injury. These approaches have a potential to support the application review process and regulatory oriented research.

**W 1482 Understanding Weight of Evidence: Exploring Different Approaches to Integrating Evidence from Diverse Data Streams**

N. B. Beck1 and J. E. Goodman2, 3. 2Regulatory and Technical Affairs, American Chemistry Council, Washington, DC, 3Harvard School of Public Health, Boston, MA and 2Gradient Corp, Boston, MA.

While it can be straightforward to evaluate a single study, or a single evidence stream, evaluating an entire body of literature for hazard assessment or risk assessment, where one needs to integrate data that comes from multiple evidence streams (e.g., human data, toxicological data, and mechanistic information), can be more complicated. The integration of all this information is becoming increasingly complex and is particularly driven by the explosion in biological sciences and technologies that are dramatically reshaping both the volume and utility of mechanistic information. Mechanistic information, when coupled with classical endpoint-oriented toxicity data, offers a growing opportunity to more closely examine the toxicologic plausibility of observational associations obtained from epidemiologic studies. Different organizations have taken different approaches to the integration of evidence from diverse data streams, and no clear consensus approach currently exists. This workshop will explore and discuss some current approaches to integrating evidence from several organizations that develop assessments. This is timely and important, as in 2009 the National Academies (NAS) specifically called upon the US EPA to, among other things, improve the way in which evidence is synthesized within the Integrated Risk Information System (IRIS) assessments. The NAS panel acknowledged that there are existing approaches, currently used by...
other government programs and elsewhere, for each of these steps and encouraged the US EPA to select from and adapt them. The session will describe, using specific examples, current frameworks that use different approaches to integrate epidemiologic, toxicological, mechanistic, and other data. In addition, seen through the lens of a state user, this perspective will describe what elements are necessary in order to apply and use an integrated evaluation. Time will be provided for a robust discussion and questions.

1483 Introduction: Setting the Stage
N. B. Beck, Regulatory and Technical Affairs, American Chemistry Council, Washington, DC.

A brief overview of the workshop goals will be provided. This includes discussion of the importance of understanding epidemiologic, toxicological and mechanistic information in order to appropriately incorporate and integrate the information into weight of evidence determinations and risk assessments to inform regulatory and non-regulatory decisions.

1484 Understanding Hypothesis-Based Weight of Evidence
L. R. Rhoenberg, Gradient, Boston, MA.

Once a systematic approach to choosing and laying out evidence is accomplished, the challenge remains to integrate the information into a judgment about the degree of evidence to be placed in the possibility of a causal effect in the target (human) population in view of the incomplete and often contradictory information at hand (including human, animal, and mechanistic information). This presentation proposes the Hypothesis-Based Weight-of-Evidence (HBWoE) approach to making, defending, and explaining the basis for such judgment. What makes data into “evidence” is that one proposes that causative forces of the agent underlying the study results may also apply to the target population — that is, bringing to bear study results as evidence entails a proposed generalization of the operation of causes, and one can then ask what other consequences of those proposed common causes should exist and whether they are in fact seen. Noting patterns of commonality and discordance, and attending to the further assumptions that are made to try to reconcile them with the hypothesized general causative properties helps to sort through and articulate the logic behind judgments about human risk potential. The key question is whether the proposed common causal effects (and proposed reasons for any apparent exceptions to their operation) make for a more plausible account for human and non-human animal studies along with consideration of other relevant data (e.g., in vitro or mechanistic studies). Before combining the three evidence streams, confidence ratings are developed for a given outcome by considering the strengths and weaknesses of the collection of studies or body of evidence. Human and animal studies are evaluated separately using a framework based on the Grading of Recommendation Assessment, Development and Evaluation (GRADE) and Agency for Healthcare Research and Quality (AHRQ) approaches. Other relevant data are evaluated in parallel by assessing the support for biological plausibility provided by this evidence stream. A level of evidence for each health effect is developed that reflects both the overall confidence in the association between exposure to the substance and the outcome and the direction of the effect (i.e., toxicity or no toxicity). The hazard identification conclusions are developed based on the highest level of evidence for a health effect from each of the evidence streams in the final step of the evidence assessment process. First, the level of evidence for health effects conclusion based on human data is considered together with the level of evidence for health effects conclusion based on animal data to reach a hazard identification conclusion of: Known, Presumed, Suspected, Not Classifiable or Not Identified, to be a hazard to humans. Second, the conclusion is considered in context of other relevant data. The final hazard identification conclusion reflects the confidence in each evidence stream as well as the consistency in support (or potential opposition) between the three lines of evidence on the relationship between exposure to the substance and the health effect being examined.

1485 The US EPA Causality Framework for Assessment of Air Pollution-Related Effects

The periodic review of U.S. National Ambient Air Quality Standards (NAAQS) for each of the six criteria air pollutants — ozone, particulate matter, carbon monoxide, nitrogen oxides, sulfur oxides and lead — starts with the synthesis and evaluation of the most policy-relevant science in Integrated Science Assessments (ISAs). EPA has developed an approach for formal characterization of the strength of the scientific evidence and drawing conclusions on causality for exposure-effect relationships. The framework establishes uniform language concerning causality and brings greater consistency and specificity to the ISAs. EPA drew on relevant approaches for similar scientific decision-making processes by EPA and other organizations. Findings from multiple lines of evidence — controlled human exposure, epidemiologic and toxicological studies — are evaluated and integrated to draw conclusions with regard to factors such as consistency, coherence and biological plausibility. The relative importance of different types of evidence varies by pollutant or assessment, as does the availability of different types of evidence for causality determination. The use of the framework is demonstrated with several examples of determinations for various health outcomes and pollutants, particularly drawing from the recently-completed ISA for Lead (Pb). Disclaimer: The views expressed are those of the authors and do not necessarily reflect the views or policies of the US EPA.

1486 The Office of Health Assessment and Translation Approach to Evidence Integration for Assessment of Noncancer Health Effects
A. A. Rooney, A. L. Boyles, M. S. Wolfe and K. Thayer. Division of the National Toxicology Program, NIEHS, Research Triangle Park, NC.

The NTP’s Office of Health Assessment and Translation (OHAT) develops non-cancer hazard identification conclusions by integrating the evidence streams for human and non-human animal studies along with consideration of other relevant data (e.g., in vitro or mechanistic studies). Before combining the three evidence streams, confidence ratings are developed for a given outcome by considering the strengths and weaknesses of the collection of studies or body of evidence. Human and animal studies are evaluated separately using a framework based on the Grading of Recommendation Assessment, Development and Evaluation (GRADE) and Agency for Healthcare Research and Quality (AHRQ) approaches. Other relevant data are evaluated in parallel by assessing the support for biological plausibility provided by this evidence stream. A level of evidence for each health effect is developed that reflects both the overall confidence in the association between exposure to the substance and the outcome and the direction of the effect (i.e., toxicity or no toxicity). The hazard identification conclusions are developed based on the highest level of evidence for a health effect from each of the evidence streams in the final step of the evidence assessment process. First, the level of evidence for health effects conclusion based on human data is considered together with the level of evidence for health effects conclusion based on animal data to reach a hazard identification conclusion of: Known, Presumed, Suspected, Not Classifiable or Not Identified, to be a hazard to humans. Second, the conclusion is considered in context of other relevant data. The final hazard identification conclusion reflects the confidence in each evidence stream as well as the consistency in support (or potential opposition) between the three lines of evidence on the relationship between exposure to the substance and the health effect being examined.

1487 Modernizing Problem Formulation: Classical versus Mode-of-Action Approaches to Weight-of-Evidence Determinations
C. J. Borgert, Applied Pharmacology and Toxicology, Gainesville, FL.

In scientific investigations, the questions posed — i.e., the hypotheses tested — determine the measurements and conditions under which they are taken, the procedures used to record and analyze data, and the context in which results are interpreted. In risk assessment, the questions addressed are typically articulated in the problem formulation phase. Decades ago, regulatory agencies couched problem formulation according to the questions answerable by the science of the day. As regulatory requirements for risk assessment became codified, so too did the rudiments of problem formulation. Unfortunately, codifying problem formulation prevents risk assessment from evolving to keep pace with scientific advancements. Today, more specific questions can be addressed and answered more precisely with more advanced science, but this science is not being used effectively because typically, the risk assessment problem formulation step still poses antiquated questions. Problem formulation needs to be modernized so that modern science can better inform risk considerations. Using well-studied chemicals as examples, e.g., chloroform or cumene, three Weight of Evidence approaches - the classical IRIS Approach, the Human Relevance Framework Approach, and a Hypothesis-Based Mode of Action Approach - are applied, compared, and contrasted. The analysis illustrates why improving the problem formulation phase is critical to making risk assessment more scientifically accurate, more practical, and more relevant for protecting human health and the environment.

1488 The User Perspective—What Makes an Integrated Evaluation Useable and Most Useful?
L. Zeive, Office of Environmental Health Hazard Assessment, California EPA, Oakland, CA.

This talk will consider evidence integration from the perspective of a implementer and user. Regulatory guidance levels, hazard evaluations and risk assessments typically rely on general frameworks for integrating evidence, as reflected in the preamble to standards. In contrast, various US Environmental Protection Agency guidelines and similar guidance developed by states. The emerging approaches described in earlier talks in the session add more specificity to how individual studies and streams of evidence are weighed in reaching conclusions about hazard traits and levels of toxic activity. They differ in approach to data organization, framing questions for evaluation, search strategies, and study selection, as well as resource requirements for performing the evaluation. As these newer approaches are developing the nature and volume of the relevant scientific evidence available for evaluation continues to change. Elements of us-
ability and usefulness of the new approaches will be considered in the context of the types of problems environmental protection agencies are expected to address and the aims of transparency, understandability, scientific rigor and public health protection. Disclaimer: The views expressed are those of the author and do not necessarily reflect the views or policies of the Office of Environmental Health Hazard Assessment or the California Environmental Protection Agency.

1489 Discussion
J. E. Goodman1, 2, 1Gradient, Boston, MA and 2Harvard School of Public Health, Boston, MA.

A robust discussion and question-and-answer session will focus on the benefits of using a weight-of-evidence approach in general, and particular aspects of various approaches that differ.

1490 AML Subtypes Reported in Cigarette Smokers: A Meta-Analysis
D. Pratt1, 3 and D. D. Alexander2, 1Summit Toxicology, Superior, CO, 2Exponent, Boulder, CO and 3School of Public Health, University of Colorado, Denver, CO.

The relationship between cigarette smoking and an increased risk of AML has been well documented. While the overall risk is modest, the number of smokers is very large. As a result, cigarette smoking is currently considered the single most important cause of AML in the US. It is assumed that the leukemogenic activity of cigarette smoke is related to the benzene or benzene metabolite content. It is also well documented that AML is not a single disease, but comprised of several different subtypes (depending upon the classification system utilized). One is the M3 subtype (per the FAB) or acute promyelocytic leukemia (APL) that is distinctly different from other subtypes of AML in terms of its diagnostic criteria, treatment, cytopathic abnormalities and prognosis. While many studies demonstrate the relationship between cigarette smoking and AML, there have only been six studies that have formally evaluated the risk between cigarette smoking and various subtypes of AML. All six of these studies reported elevations in most subtypes of AML but not APL or AML with (V15;17). Here we conducted a meta-analysis of this data set and determined that the overall risk for AML among smokers was statistically significantly suppressed (summary OR = 0.5, 95% CI 0.3-0.8), with good homogeneity between the studies. In contrast, the summary OR for the M2 subtype of AML was significantly elevated [OR = 2.03, 95% CI = 1.41-2.90]. These data indicate that cigarette smoking (or benzene exposure) is not likely a causative factor in the development of AML.

1491 Evaluation of Pyridylloxobutyl DNA Adduct Formation in the A/J Mouse Model
A. Urban, P. Upadhyaya and L. A. Peterson, University of Minnesota, Minneapolis, MN.

Tobacco-specific nitrosamines represent an important class of carcinogens found in tobacco products. The tobacco-specific nitrosamine 4-(methylnitrosami- no)-1-(3-pyridyl)-1-butane (NNK) is a potent carcinogen in laboratory animals, and is a known human carcinogen. NNK is metabolically activated to generate both methyl and pyridylloxobutyl DNA adducts, which if not repaired could persist and lead to lung tumor formation. Methyl DNA adducts have been linked to the tumor-origenic properties of NNK. However, the role of pyridylloxobutyl DNA adducts in tumor formation has not been elucidated. NNK generates four pyridylloxobutyl DNA adducts: O6-[4-3-(pyridyl)-4-oxobut-1-yl]deoxyguanosine (O6-pobdG), O2-[4-3-(pyridyl)-4-oxobut-1-yl]deoxyethyldine (O2-pobdT), 7-[4-3-(pyridyl)-4-oxobut-1-yl]-2′-deoxyinosine (O2-pobdC), O6-pobdG is repaired by O6-alkylguanine-DNA alkyltransferase (AGT), and nucleotide excision repair may play a role in the repair of O2-pobdT. The possible repair pathways of the other pyridylloxobutyl DNA adducts are unknown. To determine the role of pyridylloxobutyl DNA adduct formation in the tumororigenic properties of NNK, DNA adduct levels and tumor yield were measured in the lungs of A/J mice in following treatment with the model pyridylloxobutylating agent 4-(acetoxyethyl-nitrosamino)-1-(3-pyridyl)-1-butane (NNKOA). The findings indicate that O2-pobdT accumulates in lung DNA. AGT depletion does not significantly affect O6-pobdG repair or tumor formation, suggesting that O6-pobdG is likely also repaired by pathways other than AGT. These results indicate that the formation and persistence of O2-pobdT may be important for tumorigenesis, and that multiple pathways are likely responsible for the repair of pyridylloxobutyl DNA adducts. [Supported by CA-115309 and CA-138338].

1492 Modulation of IL-8 Signaling by AhR in Breast Tumor Microenvironment Involves miR-17
M. B. van Duuren, S. Nijmeijer, A. D. van den Brand, J. Villevoye and M. Van den Berg, IRRIS, Utrecht University, Utrecht, Netherlands.

Tumor microenvironment, including the interaction between breast epithelial (tumor) cells and surrounding breast adipose fibroblasts (BAFs), is crucial for tumor development and progression. MicroRNAs (miRNA) have been suggested to play an important role in tumor microenvironment signaling. The aryl hydrocarbon receptor (AhR) has previously been shown to affect miRNA expression. We found AhR expression in cancer-associated breast fibroblasts to be higher than in healthy BAFs, which points to an endogenous role for the AhR in breast cancer pathogenesis. Therefore, we studied the effect of AhR activation on miRNA signaling in an in vitro breast tumor microenvironment. For that, we firstly determined expression of 84 abundance expressed miRNAs in MCF-7 cells that were exposed to vehicle control (DMSO), non-toxic AhR agonist tranilast (100 μM) or TCDD (1 nM) using a miRNA PCR Array. Despite both being AhR agonists, changes in miRNA profiles upon exposure to TCDD and tranilast were apparently ligand-dependent altered. Notably, both TCDD and tranilast inhibited miR-17 expression, which has been shown to directly target the 3′ UTR of IL-8. Indeed, TCDD, and to a lesser extent tranilast, concentration-dependently increased IL-8 secretion by MCF-7 cells. Next, we determined IL-8 secretion and gene expression in MCF-7 cells co-cultured with BAFs, to mimic a more relevant tumor microenvironment. IL-8 secretion by mono-cultured BAFs was 54.7 pg/ml/48h and 9.3 pg/ml/48h by mono-cultured MCF-7 cells. Interestingly, IL-8 secretion in a BAF/MCF-7 co-culture was around 4-fold lower than in a mono-culture of BAFs, but similar to MCF-7 mono-cultured cells. Activation of AhR by tranilast resulted in a seemingly, yet not significantly, increase in IL-8 expression in BAF/MCF-7 culture. Considering the direct link between IL-8 and promotion of cancer (stem) cells in vitro and in vivo, these data warrant further studies on AhR-mediated modulation of miRNAs in the tumor microenvironment.

1493 Decreased Expression of FRY, a Promoter of Epithelial Cell Differentiation, Is Associated with EMT and Clinical Progression of Breast and Prostate Cancer
H. Zarb1, N. Takizawa2, 1, L. C. Graham1, B. Estrella1, X. Ren2 and M. Fang1, 1Environnemental and Occupational Health Sciences Institute, Rutgers, The State University of New Jersey, Piscataway, NJ, 2GeneAsses, Inc, North Brunswick, NJ and 2Department of Social and Preventive Medicine, The State University of New York, Buffalo, NY.

Rat strains vary in their susceptibility to mammary carcinogenesis following exposure to chemical carcinogens, hormones and ionizing radiation. Using quantitative trait locus mapping, we recently identified FRY, the mammalian ortholog of the furry gene in Drosophila melanogaster, as a carcinoma susceptibility gene. FRY is not expressed in lower eukaryotes regulate epithelial cell differentiation and polarity. Accordingly, loss of FRY expression in human mammary epithelial and tumor cell lines correlated with epithelial differentiation, morphology, polarity and adhesion. Ectopic expression of the wild-type FRY gene in human breast cancer cells restored a gene expression profile consistent with differentiation, suppression of epithelial-mesenchymal transition (EMT), and significantly diminished tumorigenicity in vitro and in vivo. To assess the role of FRY in human cancers, we used clinically annotated cancer cohorts available in the Oncomine 3.0 gene expression database. The results indicated that FRY was significantly decreased in, and associated with, progression in a broad spectrum of epithelial cell cancers. Analysis of human breast carcinomas tissue microarrays (TMAs) confirmed that decreasing nuclear accumulation of the FRY protein was correlated with negative hormone receptor status, cancer progression, poor clinical outcomes, and especially increased Estlon tumor grade (undifferentiated tumor histopathology score). Analysis of TMAs comprised of human prostate tissue and cancers verified that decreased FRY was also associated with clinical progression and poor outcomes. Together, these results suggest decreased nuclear accumulation of the FRY cancer susceptibility gene plays a critical role in the pathogenesis and progression of cancer in various tissues.

1494 Carcinogenicity Testing of Eliglustat in the Mouse and Rat
R. Forster1, 1CiToxLAB, Evreux, France and 2Genzyme Corporation, Waltham, MA.

Eliglustat is in development for oral treatment of the inherited metabolic disorder Gaucher disease type 1 (GD1). This lysosomal storage disease results from a deficiency of the catalytic enzyme acid-β-glucosidase leading to accumulation of glucosylceramide. The principal substrate of acid-β-glucosidase is glucosylceramide.
Hepatocellular carcinoma (HCC) is the most common hepatic malignancy and the third leading cause of cancer related deaths. Previous studies have implicated bile acids in pathogenesis of HCC but the mechanisms are not known. We investigated the mechanisms of bile acids in promoting diethylnitrosamine (DEN)-induced HCC in mice. Male C57BL/6 mice were treated with DEN (15 mg/kg) at postnatal day 15 and were weaned on a normal rodent diet. At the age of 8 months these mice were fed either the normal rodent chow (control diet) or a diet containing 0.2% cholic acid (0.2% CA diet) for 2 months. Two other groups of mice without DEN treatment fed either control diet or 0.2% CA diet from 8 to 10 months of age served as controls. All mice were sacrificed at 10 months of age and evaluated for liver tumors. The data show that 0.2% CA treatment resulted in 3-fold increase in number and size of DEN-induced liver tumors. All tumors observed in DEN-treated mice were well-differentiated HCCs. Microarray analysis (Affymatrix Mouse 430_2.0 chip) combined with Ingenuity Pathway Analysis revealed that NF-κB and JNK signaling pathways were the main signaling pathways activated in DEN-treated mice. Expression levels of TFGBβ were significantly higher in DEN-induced tumors than those in controls. We concluded that TFGBβ plays an important role in the development of DEN-induced HCC tumors.
mice. Taken together, these data indicate that bile acid feeding results in promotion of DEN-induced HCCs via specific activation of NF-κB and JNK signaling pathways.

1499 Repurposing the Antimalarial Amodiaquine for Autophagy-Directed Anti-Melanoma Intervention
S. Qiao, S. Tao, M. Rojo de la Vega, S. L. Park, A. A. Vanderfecht, S. L. Jacobs, D. D. Zhang and G. T. Wondrak, Pharmacology and Toxicology, College of Pharmacy and Arizona Cancer Center, University of Arizona, Tucson, AZ.

The autophagic-lysosomal pathway is a critical component of the cellular stress response. Cancer cells upregulate autophagic activity as a mechanistic adaptation to adverse conditions of the tumor microenvironment, and pharmacological inhibition of autophagic-lysosomal function has therefore emerged as a promising strategy for chemotherapeutic intervention. Here we demonstrate that autophagic-lysosomal blockade can be achieved in cultured A375 malignant melanoma cells using the clinical anti-malarial amodiaquine (AQ). Consistent with lysosomal expansion observed at the ultrastructural level, AQ-induced molecular changes were substantiated by accumulation of the lysosomal marker glycoprotein Lamp-1, the lipiddated autophagosome marker LC3-II, and selective autophagy substrates (p62, alpha-synuclein). Monitoring autophagic flux by expression of a tandem fluorescently-labeled LC3 confirmed autophagic-lysosomal blockade associated with rapid inactivation of lysosomal cathepsins, 2D-Immunoblot-proteomics using an AQ-directed monoclonal antibody identified the eukaryotic translation initiation factor-eIF4A as a specific protein target adducted by the electrophilic quinoneimine-methide of AQ. Array analysis revealed modulation of gene expression accompanying heat shock response (HSPA8, HSPA1A, HSP90AA1) and cell cycle progression (CDKN1A, E2F1) confirmed by immunoblot detection (Hsp70, Hsp90, p21, E2F1). Consistent with these expression changes, AQ displayed anti-proliferative effects causing S-phase arrest at submicromolar concentrations targeting an array of malignant melanoma cell lines. AQ-treatment caused rapid induction of energy crisis and sensitized melanoma cells to starvation- and chemotherapeutics-induced cell death. Taken together, our data suggest feasibility of repurposing the clinical anti-malarial AQ for anti-melanoma intervention targeting autophagic-lysosomal function and proliferative control. 1500 Epithelial-to-Mesenchymal Transition in Human BEAS and BZR Cells by Benzo(a)pyrene: Involvement of Aryl Hydrocarbon Receptor and Long Interspersed Nuclear Element-1
P. Bojang1, H. Gao2, M. T. Haebel3 and K. S. Ramos1, 4, 1Biochemistry and Molecular Biology, University of Louisville, Louisville, KY, 2Center for Translational Research, University of Louisville, Louisville, KY, 3Department of Medicine, University of Louisville, Louisville, KY, and 4Center for Environmental Genomics and Integrative Biology, University of Louisville, Louisville, KY.

Benzo(a)pyrene (B(a)P), a ubiquitous environmental hydrocarbon, has been extensively linked to diseases of the lung including interstitial fibrosis and carcinogenesis. The present studies were conducted to evaluate molecular mechanisms of B(a)P pulmonary toxicity in human BEAS and BZR cells, non-transformed and transformed bronchial epithelial cells, respectively. Treatment with B(a)P was associated with Epithelial-to-Mesenchymal Transition (EMT), a response which was dependent upon the activation of Aryl Hydrocarbon Receptor (AHR) and Long Interspersed Nuclear Element-1 (L1). B(a)P inhibited expression of epithelial markers and increased the relative abundance of mesenchymal markers in both BEAS and BZR cells. Treatment with α-naphthoflavone (α-NF), a potent antagonist of AHR, attenuated the induction of mesenchymal markers. The EMT response involved induction of L1 at both the mRNA and protein levels. Inhibition of L1 expression through siRNA knockdown attenuated EMT suggesting that intact L1 expression is required for EMT. Together, these data indicate that EMT in human bronchial epithelial by B(a)P involves activation of AHR and L1.

1501 Disruption of Circadian Rhythm Accelerates Lung Metastasis of Breast Cancer in C3(1)/SV40 T-Antigen (TAG) Transgenic Mice
M. Fang1, 2, M. Palinu1, 2, K. R. Reuhl1, 2, P. Ohman-Strickland1 and H. Zarbl1, 2, 1Robert Wood Johnson Medical School, Rutgers University, Piscataway, NJ, 2School of Pharmacy, Rutgers University, Piscataway, NJ, 3School of Public Health, Rutgers University, Piscataway, NJ and 4Environmental & Occupational Health Sciences Institute, Rutgers University, Piscataway, NJ.

Disruption of circadian rhythm promotes breast cancogenesis, and is associated with cancer progression and decreased survival rate. To investigate the contribution of the circadian disruption to breast cancer metastasis, heterozygous female C3(1)/SV40 T-antigen (TAG) transgenic mice were maintained on chronic jet-lag protocol (~3 months) or regular light and dark cycles after weaning. Mammary tumor latency, incidence and multiplicity, as well as metastasis and inflammatory status of lung were evaluated by histopathology. Results showed that the mammary tumor appeared 16 days earlier and the average total tumor burden (volume and weight) was higher in the mice maintained on jet-lag compared to that in mice on regular light and dark cycles (control group). Lung micro-metastatic foci were also observed at least 13 days earlier, and lung metastasis multiplicity was significantly associated with group, with 288% more metastasis foci in jet-lag vs control group. No visible lung metastatic tumors were observed in heterozygous mice; however, the visible lung metastatic tumor rate, micro-metastatic foci multiplicity, and average foci size were increased in jet-lag vs control group in carriers. In addition, number of lung inflammation foci was significantly increased by circadian disruption, with 233% more inflammatory foci in jet-lag than control group during the early metastasis stage, suggesting that suppressed cellular immunity and overactive inflammatory responses contribute to the development of lung metastasis in this model. Taken together, our studies demonstrated that disruption of circadian rhythm caused by jet-lag accelerates the development and progression of both primary mammary tumor and lung metastasis. (Supported by NIH grants: U19ES011387, P30ES007033, and P30ES050522).

1502 Ni2-Induced Global De-Regulation of Gene Expression and Morphological/Neoplastic Transformation of C3H/10T1/2 Mouse Embryo Cells
J. R. Landolph1, 2, 3, A. T. Feh-DeSilva2, 3, K. A. Akinwumi1, 2, 3, F. Tseng1, 2, M. Trieu1, 3 and S. Menon1, 3, 1Dept. Path., Univ. South. Cal., L. A., CA and 3Cancer Center, Univ. South. Cal., L. A., CA.

Nickel refining induced lung/anal cancers in workers; Ni3S2/green NiO induced lung cancer in rats. Ni3S2/green NiO induced morphological/neoplastic transformation in 10T1/2 mouse embryo cells. mRNA differential display showed differential expression (DE) of 150 genes between non-transformed (Tx)/2 MCA/4 NiO/NiS-Tx 10T1/2 cell lines. Ni3MCA-Tx cell lines contained a) ect-2 amplification/higher ect-2 mRNA/protein levels; b) higher levels of calnexin mRNA/protein; c) no DRIP80/β-centaurin-2 mRNAs. We hypothesized Ni2+ 1) amplified ect-2, leading to higher levels of microtubules (MTs); 2) silenced β-centaurin-2, causing higher levels of microfilaments (MFs); and 3) silenced DRIP80, altering Ca2+ ion distributions, in Tx 10T1/2 cells. To test these hypotheses, we stained these cells with fluo-3AM to decorate MFs, fluo-4 to label tubulin of MTs, Fluor 705 to stain Ca2+ ions, DAPI to decorate nuclei, and examined cells by confocal microscopy. In non-Tx 10T1/2 cells, MFs/MTs were distributed homogeneously. In Ni3S2/green NiO-Tx cell lines, MFs/MTs were over-expressed, aggregated in areas, absent in others, changing shapes of Tx cells. In non-Tx cells, Ca2+ ions were found in a) State I, in low density cells, with a high nuclear concentration of Ca2+ ions; b) State II, in high density cells, with more cytoplasmic Ca2+ ions; or b) State III, in low density cells, with a high nuclear concentration of Ca2+ ions; or b) State IV, in high density cells, with more cytoplasmic Ca2+ ions. In Ni3S2/green NiO-Tx cell lines, MFs/MTs were over-expressed, aggregated in areas, absent in others, changing shapes of Tx cells. In non-Tx cells, Ca2+ ions were found in a) State I, in low density cells, with a high nuclear concentration of Ca2+ ions; b) State II, in high density cells, with more cytoplasmic Ca2+ ions. In 4 Ni2+ MCA/Tx cell lines, Ca2+ ions were in State II. We conclude Ni2+ ions a) mutated/amplified 6 target genes/silenced 9 target genes; b) amplified ect-2, causing higher levels of MTs/silenced β-centaurin-2, causing higher levels of MFs, changing cell shapes/gene expression in Tx cell lines; c) silenced DRIP80, altering Ca2+ ion distributions in Tx 10T1/2 cell lines. These Ni ion-induced events caused DE of 150 genes in Tx cell lines and induction/maintenance of Ni2+ phenotype. Supported by Grant ES03341/grants from M. S. Program in Micro. and Provost’s Office at USC, to JRL.
Environmental exposure to carcinogens causes loss of tumor suppressor genes. Phosphatase and tensin homolog (PTEN) negatively regulates the AKT pathway, and the PTEN gene is mutated/deleted in ~70% of prostate cancer cases. Downstream of AKT, eukaryotic initiation factor 4E binding protein 1 (4E-BP1) regulates cyclin D1 translationally. In contrast, ERK, a member of the mitogen-activated protein kinase (MAPK) pathway, regulates cyclin D1 transcriptionally. Both the AKT and MAPK signaling pathways contribute to disease progression in prostate cancer. A PTEN-deficient human prostate cancer cell line, LNCaP, and a PTEN-positive human prostate cancer cell line, DU145, were used to examine the role of PTEN status in determining drug sensitivity to Amuvatinib, a receptor tyrosine kinase inhibitor, and Erlotinib, an epidermal growth factor inhibitor. 1D and 2D Western blot analysis revealed that combination drug treatment of LNCaP cells caused a decrease in 4E-BP1 pSer65, pThr70 and pThr37/46, with a concomitant decrease in cyclin D1 protein. Such combination treatment, however, did not modulate pERK status. Moreover, single drug treatment with Amuvatinib, but not Erlotinib, decreased p-4EBP1 and cyclin D1 protein levels. In DU-145 cells, combination drug treatment had no effect on p-4EBP1 status, but decreased p-ERK and cyclin D1 protein levels. Additionally, DNA was isolated from the tissues. Oxidative damage to DNA was assessed using the Biovision DNA damage quantification kit. Benzo[a]pyrene-DNA adducts were resolved and quantified by the 32P-postlabeling method. The metabolic fate of BaP was altered in a dose-dependent manner with the 50 μg/kg dose group registering an elevated expression of BaP biotransformation enzymes, greater concentration of BaP metabolites, abasic sites in DNA, BaP-DNA adducts at C7 and C8 was increased by up to the 25 μg/kg dose group (p = 0.05). These findings indicate that i) subchronic exposure causes sustained induction of BaP biotransformation enzymes and extensive metabolism of this toxicant; ii) the production of free radicals initiated DNA base pair damage, which in the absence of DNA repair, formed BaP-DNA adducts; and iii) a correlation between colon tumors and BaP-DNA adduct concentrations. Our studies provide concrete evidence that sustained dietary exposure to BaP contributes to the development of colon cancer.

Clear cell renal cancer (ccRCC), the predominant subtype of kidney cancer, displays variability in risk for developing metastatic disease, and tissue-based prognostic biomarkers are urgently needed. Recently, we used unsupervised bioinformatic strategies to demonstrate two subtypes of ccRCC, clear cell A (ccA) and clear cell B (ccB). The subtypes convey a prognostic value, with tumors displaying the ccA signature associated with better survival compared to ccB. We developed and validated a 34-gene subtype predictor to classify clear cell tumors as ccA and ccB using RNA-sequencing data from 380 ccRCC samples from The Cancer Genome Atlas (TCGA) and the NanoString platform with a cohort of 163 fixed archival samples collected at the University of North Carolina. This novel tool can be used to analyze risk for developing metastatic disease and as a baseline metric to elucidate specific effects of toxicants on renal tumor gene expression signatures that can provide insight into the molecular phenotype of ccRCC. Heavy metals can induce nephrotoxicity altering gene expression in the kidney, and thus increasing the risk of developing RCC. In addition to transcript alterations, numerous studies have found that Cd exposure can result in epigenetic deregulation by changing DNA methylation levels. We have observed significant decreases in methylated sites associated with the 34 genes from the ccA/ccB algorithm among ccRCC tissues (n = 17) compared to normal tissue (n = 15) of smokers from TCGA. Smoking populations experience higher levels of cadmium exposure, as one cigarette may contain 1-2 μg cadmium. Interestingly, the majority of this cohort was either ccB subtype or had metastatic disease, suggesting a possible correlation between cadmium exposure and aggressive disease. Exploring both acute and chronic cadmium-induced global expression and epigenetic reprogramming can enhance our understanding of the genetic interactions that drive the biological responses to these exposures and their influence on prognostic signatures of RCC.

In our initial studies using normal human lung epithelial cells, BEAS-2B, and a bitransgenic mouse model we have suggested that chromosome maintenance region 1 (CRM1), a nuclear export receptor for various cancer-associated ‘cargo’ proteins (such as p53), played an important role in lung cancer development. The objectives of the present study were to investigate the CRM1 expression and/or its associated p53 alteration in the following four models: human lung tumor tissues, 4-(methylthio)aniline-1-(3-pyridyl)-1-butanone (NNK, a tobacco specific carcinogen)-induced mouse lung adenocarcinoma, NNK-transformed lung epithelial cells (named as BEAS-2BNK), and stably over-expression of CRM1 in BEAS-2BNK cells (named as BEAS-2BNKCRM1+). CRM1 was overexpressed in tumor tissues from both lung cancer patients and NNK-treated mice, and in BEAS-2BNK cells. Cellular malignant transformation was observed in BEAS-2BNK and BEAS-2BNKCRM1+ cells. Furthermore, increased p53 phosphorylation at Thr 55, which indicated p53 cytoplasmic localization and p53 degradation, was increased.
in NNK-induced lung adenocarcinoma and BEAS-2BBNK cells. Moreover, the nuclear retention of p53 was significantly diminished in BEAS-2BCRM1+ cells compared to BEAS-2B cells. These data suggest that CRM1 plays a critical role in lung cancer progression and that such mechanisms may provide a novel target for developing lung cancer therapies.

1508 GS-19, a Novel GSK Inhibitor Suppresses the Growth of Pancreatic Cancer Cells by Inhibiting EGFR/AKT/STAT-3 Signaling

A. Ranjan1, A. Birkenfeld1, P. Gupta1, J. Lu2, D. H. Hua3 and S. K. Srivastava1. 1Department of Biomedical Sciences & Cancer Biology Center, Texas Tech University Health Sciences Center, Amarillo, TX and 2Department of Chemistry, Kansas State University, Manhattan, KS.

The American Cancer Society estimates that over 43,000 new cases of pancreatic cancer are diagnosed each year in the United States, with a five-year survival rate below 6%. Conventional therapies are often of limited use because of the resistance development and cancer relapse. Therefore, identification of novel strategies to control and treat pancreatic cancer is of great importance. GS-19 is a novel compound designated as a GSK inhibitor and shown good activity in neural protective assay using MC65 cells. In this study, we determined the cytotoxic effects of GS-19 in pancreatic cancer cells. GS-19 treatment inhibited the growth of Panc-1 and BxPC-3 cells in a concentration-dependent manner. Both the cell lines treated with GS-19 exhibited G1 cell cycle arrest as well as apoptosis. Western blot analysis of both BxPC-3 and Panc-1 cells treated with GS-19 inhibited the activation (phosphorylation) and expression of key survival signaling proteins such as EGFR, STAT3 and AKT. The apoptosis induced by GS-19 was associated with cleavage of caspase-3 and PARP. Taken together, our results suggest that GS-19 suppresses pancreatic cancer cell growth by inhibiting EGFR/AKT/STAT-3 signaling. However, further mechanistic studies are in progress to establish the role of EGFR/AKT/STAT-3 signaling in pancreatic cancer cells and correlate it with G1 cell cycle arrest and apoptosis induced by GS-19. The studies in part were supported by R01 grant CA129038 awarded by NIH to S.K.S

1509 Olive Oil As a Chemopreventive Agent against Benzo(a)pyrene-Induced Colon Cancer in ApcMin/Mouse

L. D. Banks1, P. Amooh1, M. S. Niaz1, M. K. Washington1, S. E. Adunyah1 and A. Ramesh1. 1Biochemistry & Cancer Biology, Meharry Medical College, Nashville, TN and 2Pathology, Vanderbilt University Medical Center, Nashville, TN.

Colorectal cancer (CRC) ranks third in terms of cancer-related mortalities, and sporadic colon cancers (representing 90% of the cases) are triggered by diet and exposure to environmental toxins. In recent years, cancer prevention through dietary intervention gained significant attention. In the light of published reports that Mediterranean diet lessens the incidence of CRC, we investigated how olive oil, an essential ingredient of Mediterranean diet modulates the biotransformation of benzo(a)pyrene (BaP, a polycyclic aromatic hydrocarbon compound) and contributes to a reduction in colon tumors using an animal model. Our study model was the male ApcMin/Mouse, which was validated in our lab for studying sporadic colon tumors induced by BaP. Mice were assigned to a control (vehicle only; n =7), or treatment group (BaP only, BaP + olive oil; n =7 per category). Treatment consisted of 50 and 100 μg BaP/kg body weight dissolved in triacetin (BaP-only group) or olive oil administered daily via oral gavage for sixty days. Post exposure, mice were sacrificed; colon and liver tissues were retrieved and evaluated for histopathology. Another set of tissues were used for studying the expression and activities of biotransformation enzymes (CYP1A1, CYP1B1, and GST) and analysis of BaP metabolites. A reduction of incidence of adenomas in colons of mice that ingested BaP + olive oil compared to BaP only and control groups (p <0.05) was seen. Additionally, there was a significant reduction in CYP but not GST protein expression in tissues in BaP + olive oil-treated mice compared to BaP only-treated mice. Lastly, BaP organic metabolite concentrations were reduced in plasma and tissues of BaP + olive oil group compared to BaP-treated groups, whereas BaP aqueous metabolite concentrations (especially the glucuronide and sulfate conjugates) showed an opposite trend. In summary, our studies suggest that olive oil exerts a chemopreventive effect against BaP-induced colon cancer.

1510 Cannabidiol Inhibits Glioma Cell Proliferation and Downregulates Specificity Protein (Sp) Transcription Factors

S. Sreevalan1 and S. H. Safe1,2, 1VTPP, Texas A & M University, College Station, TX and 2Institute of Biosciences and Technology, Texas A&M Health Science Center, Houston, TX.

Cannabidiol (CBD), a plant-derived cannabinoid has shown promise as an anti-cancer agent in treating glioblastoma multiforme (GBM), however the mechanism of action of CBD on GBM is not completely understood. Treatment of CCF-STTG1 cells with CBD for 24 hr significantly inhibited cell growth, downregulated pro-oncogenic factors including epidermal growth factor (EGFR), bcl-2 and survivin and induced PARP cleavage a marker for apoptosis. Research conducted in our laboratory has shown that these same responses and factors are regulated by specificity protein (Sp) transcription factors Sp1, Sp3 and Sp4 that are highly expressed in multiple cancer cells and tumors. Sp1, Sp3 and Sp4 are all highly expressed in CCF-STTG1 cells and knock-down of Sp1, Sp3 and Sp4 by RNA interference decreased expression of survivin, bcl-2 and EGFR suggesting that these oncoproteins are regulated by Sp transcription factors in CCF-STTG1 cells. Moreover concentrations of CBD (10-15 μM) that decreased EGFR, survivin, and bcl-2 expression also downregulated Sp1, Sp3 and Sp4 in CCF-STTG1 cells. Furthermore, treatment of CCF-STTG1 cells with 15 μM of CBD and co-treatment with 1 μM of AM 251 and AM630, cannabinoid receptor antagonists 1 and 2 respectively failed to reverse the effects of CBD on Sp proteins suggesting that CBD-dependent Sp downregulation is cannabinoid receptor-independent. These results demonstrate for the first time that the anticancer activity of CBD in gliomas may be due, in part, to downregulation of Sp transcription factors and Sp-dependent genes and the mechanism of action involved in Sp protein repression is currently being investigated.

1511 Role of ROS in the Anticancer Activity of PEITC in Pancreatic Cancer

J. D. Itohara1, A. S. Guthrie1, G. Chadapakpa1 and S. H. Safe1. Veterinary Physiology and Pharmacology, College Station, TX.

Phenethyl isothiocyanate (PEITC) is a natural compound found in cruciferous vegetables and has been shown to have anticancer activity in various cancers including pancreatic cancer. Few studies have shown that PEITC induces reactive oxygen species (ROS) and selectively kills cancer cells. In this study, PEITC decreased cell proliferation, induced ROS and cleaved PARP which was further confirmed by Annexin V staining in Panc1, Panc28 and L3.6pl pancreatic cancer cell lines. PEITC decreased mitochondrial membrane potential (MMP) which was confirmed using JC-staining and transmission electron microscopy (TEM). PEITC also decreased Sp proteins Sp1, Sp3 and Sp4 and several Sp-regulated genes involved in cell survival (survivin, Bcl2), angiogenesis (VEGF, VEGFR1) and growth (cyclin D1, EGFR, cMet). Repression of Sp and Sp-dependent genes by PEITC was due to downregulation of microRNA-23a~27a and induction of zinc finger and BTB domain (ZBTB) containing proteins 4, 10 and 34. These responses were reversed by antioxidants such as glutathione (GSH) indicating the mechanism of action of PEITC is through induction of oxidative stress. Thus, the anticancer activity of PEITC is due, in part, to activation of ROS, which in turn targets miR-23a~27a/ZBTB5-Sp transcription factor axis. This results in decreased expression of Sp-regulated genes, growth inhibition, apoptosis and antiangiogenic responses. Studies have also shown that elevated levels of ROS can cause dynamic changes in surrounding chromatin including changes in nucleosome positioning. Cpg island-containing promoters of genes such as ACTB, cMyc, SFRP5 and TIMP3 resulting in changes in histone marks, transcription and DNA methylation. Additionally, PEITC decreased cMyc as early as 3 hrs in panc1 and L3.6pl, and these responses are currently being investigated.

1512 Diidinolymethane (DIM) Analog As a New Class of NR4A1 Antagonists

X. Li1,2, S. Lee1 and S. H. Safe3,1. 1College of Medicine, Texas A&M Health Science Center, College Station, TX, 2Institute of Biosciences and Technology, Texas A&M Health Science Center, Houston, TX and 3Veterinary Physiology and Pharmacology, Texas A&M University, College Station, TX.

The nuclear receptor NR4A1 (TR, Nur77) is highly expressed in solid tumors and result of knockdown by RNA interference (RNAi) indicates that NR4A1 exhibits pro-oncogenic activity. Transfection of RKO and SW480 colon cancer cells with oligonucleotides that target NR4A1 (siNR4A1) inhibited cell proliferation and induced apoptosis and this was accompanied by decreased expression of Bcl-2 and survivin. A series of 1,1-bis(3’-indolyl)-1-(p-substituted phenyl)methane analogs (C-DIMs) was screened for potential NR4A1 antagonist activity using luciferase
the degradation products of hyaluronan (HA) are reported to stimulate endothelial-cell proliferation, migration, tube formation and promote neovascularization associated with angiogenesis whilst native high-molecular-weight HA is inhibitory to these processes (1,2). When degraded into oligosaccharides of 3 to 10 disaccharides units (o-HA) an angiogenic effect has previously been demonstrated on the chicken chorioallantoic membrane and in rat skin where the blood vessel numbers were found to increase (3). It is speculated if HA degraded into o-HA may represent a safety issue in the human body due to stimulation of endothelial cell proliferation.

We have investigated the effects on endothelial cell proliferation of bacillus subtilis derived HA. We used oligosaccharides of 3-10 disaccharides units, 1.35 - 4.5 kDa and native HA of 2162 disaccharides units, 865 kDa. HVEC (human umbilical vein endothelial cell) and MVEC (human foreskin microvascular endothelial cell) and different cell lines of MVEC were stimulated with o-HA at concentrations of 1, 10 and 25 μg/mL and with native HA at dose concentrations of 5 to 100 μg/mL.

Results: We were unable to induce stimulation of endothelial cell proliferation by oligosaccharides. Treatment of endothelial cells by native HA did not inhibit endothelial cell proliferation or caused a decrease of tube formation in 3-D assay.

Conclusion: Based on the current data the degradation of hyaluronan into oligosaccharides gives no cause for concern in terms of stimulation of endothelial cell proliferation, migration and potential neovascularization.

Recent studies have reported an association with higher OC levels in people with T2D compared to non-diabetics. OC compounds associated with greater prevalence of T2D include the legacy pesticides, such as DDT. Exposure to OC compounds is predicted to be higher in agricultural areas, such as the Mississippi Delta region, where OC pesticides were heavily used. Soil samples were analyzed for OC residues from 60 randomly selected sites in the Delta region and 60 sites in a non-Delta region. Serum samples were randomly collected from patients from both the Delta and non-Delta regions at the Veterans' Administration Hospital in Jackson, MS. Following IRB approved informed consent, male subjects who were either Caucasian (C) or African American (AA) and were at least 45 years of age were selected for participation. Serum samples and de-identified clinical and demographic data were collected from each subject. Serum and soil samples were analyzed by GC-MS for OC residues including DDE, the bioaccumulative metabolite of DDT, which was detected most often in both soils and people. 80% of the Delta soil samples had quantifiable levels of DDE compared to 23% of the non-Delta soil samples and were 10-fold higher. About half of the proposed 300 serum samples have been collected and analyzed. DDE levels were adjusted based on serum lipid levels and were about 1.2-fold higher in diabetics than non-diabetics, 1320 and 1160 ng/g lipid, respectively. Subjects from the Delta region had about 1.5-fold higher DDE levels than non-Delta subjects, 1560 and 1012 ng/g lipid, respectively. AA subjects had 2.6-fold higher DDE levels than C subjects, 1992 and 761 ng/g lipid, respectively. AA and C diabetics both had higher DDE levels than AA and C non-diabetics. These results suggest that higher environmental residue levels of OC compounds, such as DDE, may result in higher serum levels and may be important for developing a biomarker of T2D.

Pb and Cd-Contaminated Soil May Cause Metal Accumulation and Epigenetic Alteration in Rat Tissues

Y. B. Yohannes1, S. M. Nakayama1, Y. Ikenaka1, B. Oroszlányi1, N. Bontey-Sam1, K. Muzandu2, J. Yabe3, T. Umemura1 and M. Ishizuka1. Hokkaido Univ, Sapporo, Japan and 2University of Zambia, Lusaka, Zambia.

Metal pollution in African countries is serious problem. Metal and metallothionein (MT) levels in wild black rats (Rattus rattus) collected in mining area (Kabwe and Chingola) and control area (Lusaka) of Zambia were compared in order to assess effects of metal pollution on wild terrestrial animals. In addition, we exposed laboratory Wistar rat (Rattus norvegicus) to metal contaminated soil from Kabwe for 1 year in order to clarify biological and epigenetic effects of metals. In the laboratory soil exposure, male Wistar rats were divided to three groups by type of soil exposure: A) without soil exposed control, B) soil containing low metal levels (Pb: 75 mg/kg, Cd: 0.4 mg/kg) and C) soil containing high metal levels (Pb: 3757, Cd: 6). We analyzed metal and MT levels in various tissues of rats after 1 year exposure. Genome wide methylation status was determined in the liver, kidney and testis using LUMA (Lumimetric methylation assay). Levels of DNA methyltransferase (DNmt 1, 3a and 3b) mRNA expressions in tissues were analyzed by quantitative real-time RT-PCR. In the field study, R. rattus in Kabwe accumulated significantly higher concentrations of Pb and Cd in various organs than rats from Lusaka. Higher MT-1/2 mRNA expression levels in R. rattus from Kabwe than those in rats from Lusaka were also observed. In the laboratory soil exposure, rats in the group C accumulated significantly high concentrations of Pb and Cd in liver, kidney, lung, brain and tibia compared to other groups. Significantly higher levels of MT-2 mRNA were expressed in the kidney of group C. Interestingly, Dnmt 3a/3b mRNA expressions and genome wide methylation status in testes were significantly higher in rats of group C, suggesting that Pb and Cd contaminated soil caused metal accumulation and epigenetic alteration in rat.
1520 Oxidized Cardiolipins As a Biomarker of Mitochondrial Dysfunction Triggered by Pesticide, Rotenone

Y. Tyurina1, A. Vilkulina1, V. Kapralova1, D. Winnica1, L. Sanders2, T. Greenamyre2, V. A. Tyurin1 and V. E. Kagan1, EOH, University of Pittsburgh, Pittsburgh, PA and 2Neurology, University of Pittsburgh, Pittsburgh, PA.

Exposure to a commonly used pesticide, rotenone, has been associated with the development of Parkinson’s disease. We demonstrated that treatment of human blood lymphocytes with rotenone resulted in decreased mitochondrial membrane potential, inhibition of mitochondrial respiratory complex I, induction of apoptosis and selective oxidation of mitochondrial phospholipid, cardiolipin (CL). Here, we used rat rotenone-infusion Parkinson disease model to assess possible accumulation of peroxidized phospholipids. Adult male Lewis rats (6 months old) were exposed to rotenone daily (5 mg/kg, i.p.) and sacrificed 1, 5 and 10-14 days thereafter. Substantia nigra was isolated and lipids were extracted. To enhance the sensitivity of LC-MS protocols for the detection of oxidation products, phospholipids were treated either with phospholipase A1 from Thermomyces lanuginosus (10 μl/μmol phospholipids) or phospholipase A2 form porcine pancreas (10U/μmol of phospholipids) to release fatty acids residues from sn-1 and sn-2 position, respectively. Using the combination of lipidomics and oxidative epitope-targeted enzymatic digestion of total phospholipids we found a decrease of polyunsaturated fatty acid (PUFA) species containing CL and accumulation of its oxygenated molecular species was observed. We conclude that this method, the limits of quantitation for AAMA and GAMA in urine were 6ng/mL and 0.5mg/mL, respectively; the inter-day and intra-day precision of AAMA and GAMA ranged from 2.7% and 7.3%, and the recoveries ranged from 99.6% to 105.3%. The method is simple, sensitive and accurate. The developed method was also applied to analysis urines of smokers and nonsmokers, results showed that amount of AAMA, GAMA in smokers urine were much higher than that in nonsmokers, indicating that AAMA and GAMA may be effective biomarkers to estimate acrylamide exposure in smoking.

1521 N⁰-Formylly sine As a Biomarker of Formaldehyde Exposure: Inhalation Studies in Rats Reveal Formation and Accumulation of N⁰-Formylly sine Adducts in Natal Epithelium

B. Edrisi1, K. Tafizhadeh2, B. C. Moeller1, L. R. Yu3, L. Kracko4, M. Doyle4, J. A. Swenberg1, 2, W. Bodnar2, L. Collins2 and J. A. Swenberg1, 2, 6Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC and 6NCI, NIH, RTP, NC.

There is increasing recognition that aberrant protein modifications play an important role in the pathophysiology of many human diseases. N⁰-Formylly sine, a chemiluminescent adduct in white blood cells, has recently emerged as a widespread modification of proteins. With formaldehyde as the major source of N⁰-formylly sine, we quantified endogenous and exogenous adducts in nasal epithelium of rats exposed by inhalation to 0.7, 2, 5, 8, and 9.1 ppm [¹³C₄H₄]-formaldehyde for 7, 14, 21, and 28 days (6hr/day) and determined the loss of N⁰-formylly sine over a 7 day post exposure period. In vivo results showed detection and accumulation of exogenous adducts in nasal epithelium and not lung, liver, or bone marrow, with exogenous N⁰-formylly sine levels showing a 2-fold increase over a 3-week exposure period. The post exposure studies indicated t₁/₂ = ~50 h for this adduct in total proteins. Formation and accumulation of N⁰-formylly sine in proteins, including histones with important epigenetic regulatory roles, could be another mechanism contributing to formaldehyde toxicity and carcinogenicity.

1522 Serial Measurements of BPA and BPS in Texas Mother-Infant Pairs from the 3rd Trimester of Pregnancy through the 4th Month of Lactation

A. L. Scheckter1, D. Cherry2, C. Liao3, S. Yun3, K. Kaman3, J. Moyer4, N. Thies5, W. C. Shoemaker6 and L. S. Birnbaum6, 7University of Texas School of Public Health, Dallas, TX, 2University of Washington, Seattle, WA, 3Wadsworth Laboratory, Albany, NY, 4NICHD, NIH, Bethesda, MD, 5South Dakota State University, Brookings, SD and 6NICI, NIH, RTP, NC.

Relatively little is known about in utero or early infancy exposure to Bisphenol A (BPA) and related bisphenols. Here we report on a formative prospective cohort study to monitor exposure to BPA and a BPA substitute, Bisphenol S (BPS), in mother-infant pairs in a rural Texas county. Participants were recruited from a pool of consented National Children’s Study (NCS) mothers as well as volunteers from a local clinic as part of an NCS contract with the University of Texas. The use of human subjects was approved by the IRB of the University of Texas Health Science Center at Houston and Bartelle’s IRB. Specimens were collected prospectively from the third trimester of pregnancy through the fourth month of lactation from 10 mother-infant pairs who completed the protocol. BPA and BPS were analyzed in 86 urine, 50 breast milk, and 7 plasma samples utilizing enzymatic hydrolysis followed by high performance liquid chromatography coupled with electrospray triple-quadrupole mass spectrometry. These data document measurement of BPA and BPS in each of these matrices: urine, plasma, and milk. Maternal urine specimens here had higher geometric mean (GM) concentrations of BPA (2.04 ng/ mL wet wt [ww]) and BPS (0.52 ng/mL ww) than infant urine BPA (1.85 ng/ mL ww) and BPS (0.19 ng/mL ww). The breast milk GM concentration of BPA (0.52 ng/mL) was higher than the BPS concentration (0.07 ng/mL). BPA and BPS breast milk GM concentrations increased from one month (0.41 and 0.06 ng/mL respectively) to four months postpartum (0.64 and 0.14 ng/mL respectively). This study documents that a BPA substitute, BPS, is detectable in human urine, plasma and breast milk and suggests the importance of monitoring for potentially toxic chemical substitutes for BPA. This study was funded by NIH.
The New York State Angler Cohort (NYSAC) was established to assess the association between past and current consumption of contaminated sport fish and wild life (duck and turtle) and both short-term and long-term health effects. Based upon reported consumption of Lake Ontario fish and wildlife and validated exposures to halogenated aromatic hydrocarbons (serum PCB153 and Mirex) a subgroup of the cohort was selected to participate in studies that would examine the effect that fish or fish/wildlife consumption has on different hematological and immune markers. Participants were divided into two groups; consumers with the highest serum PCB153 and Mirex levels that also self reported consumption of Lake Ontario wildlife (n=27) and non-consumers who were matched to by age, sex and geographic area and reported having never consumed Lake Ontario wildlife (n=16). The objective of the current study was to analyze differences in hematological parameters in these groups including white blood count, red blood count, hemoglobin levels, hematocrit levels, platelet count and full leukocyte differential. In anglers with serum DDE levels (n=14) higher than that observed in non-consumers, our results showed positive correlations (albeit clinically insignificant) with increased red blood cell levels, platelet count and full leukocyte differential. In anglers with serum DDE levels (n=14) higher than that observed in non-consumers, our results showed positive correlations (albeit clinically insignificant) with increased red blood cell levels, platelet count and full leukocyte differential. From these data we concluded that long term consumption of fish and/or wildlife contaminated with long-term serum biomarkers to reflect steady state exposures and associated health outcomes. Based upon the results of this study, we concluded that long-term consumption of contaminated sport fish and wildlife contaminated with persistent Great Lakes pollutants does not significantly alter hematological markers in humans. (Supported in part by ATSDR, Grant H75-ATH 298338).

**1526 Biomarkers of Aflatoxin Exposure in Bexar and Surrounding Counties: Enhanced Incidence in Humans following Severe Drought**
S. Elmore1, L. Tang2, M. Rodriguez3, M. F. Carden4, H. G. Hayes5, A. A. Romoser1, J. Wang2, B. H. Pollock6 and T. D. Phillips7. 1Veterinary Integrative Biosciences, Texas A&M University, College Station, TX, 2College of Public Health, University of Georgia, Athens, GA and 3University of Texas Health Science Center-San Antonio, San Antonio, TX.

Aflatoxins (AF) are produced as metabolites by the fungi *Aspergillus flavus* and *A. parasiticus* and frequently contaminate important commodities such as corn and peanuts. Drought and plant stress promote the growth of these fungi which can lead to the production of AFs. Aflatoxin B1 is the most prevalent and toxic of the AF congeners and is a known risk factor for development of hepatocellular carcinoma. The area between 40° N and S of the equator is now considered to be a "hotspot" for exposure, which includes parts of the Southern and Midwestern United States. With greater than 75% of the U.S. experiencing moderate to exceptional drought in 2012, and climate change that favors fungal growth, a wider distribution of *Aspergillus* and higher prevalence of AF contamination in staple foods such as corn is expected. In an ongoing clinical trial initiated in August 2012, a predominantly Hispanic study population in South Texas was screened for AF exposure through analysis of a short-term urinary AF biomarker, AFM1. AFM1 was detected in 22.05% (45/204) of study participant urines with an overall mean and range of 4.73±19.78 and ND-180.73 pg/mg creatinine, respectively. The levels and prevalence of AFM1 detected in 2012 were sustained throughout most of the sampling conducted in 2013, suggesting that the drought of 2012 played a key role in human AF exposures. Detection of urinary AFM1 was significantly associated with increased frequency of tortilla (p=0.0157) and peanut (p=0.0084) consumption, in addition to the amount of Mexican food (p=0.0006) and corn products (p=0.0208) ingested. Further work is warranted to correlate our findings with long-term serum biomarkers to reflect steady state exposures and associated impacts on health. This research was supported by NIH 1R01MD005819-01.
Biomarkers have been proposed as potential tools to assess the toxicity and disease risk of tobacco product use. Two key requirements of such biomarkers are that they are able to consistently distinguish between smokers and non-smokers, and that they are reversible upon smoking cessation. Candidate biomarkers were recently assessed for these requirements in a six month, clinical study based in Germany. Biomarker levels from the baseline study time point were compared in 143 smokers, 61 never-smokers and 61 ex-smokers who were otherwise healthy and age/gender matched. Of the 27 candidate biomarkers assessed, the following were found to be significantly different between smokers and never-smokers: urinary 8-epi-PGF2αx (Type III) and 11-dehydrothromboxane B2 (P<0.0001), plasma MCP-1, neutrophil elastase, leukotriene B4, ascorbic acid, HDL and oxidised LDL cholesterol (all P<0.0001), erythrocyte catalase activity and malondialdehyde (all P<0.0001), serum total anti-oxidant capacity (P<0.0001) and total white blood cell (WBC), neutrophil and monocyte count (all P<0.0001). Of these biomarkers urinary 8-epi-PGF2αx (Type III), plasma MCP-1, neutrophil elastase, leukotriene B4, ascorbic acid, HDL and oxidised LDL cholesterol, erythrocyte catalase activity and serum total anti-oxidant capacity, total white blood cell (WBC), neutrophil and monocyte count were also found to be significantly different between current and ex-smokers (P<0.05), and hence indicate the potential for reversibility. These data indicate that 12 of 27 candidate biomarkers assessed in this study are potentially useful tools for the assessment of altered biological effects following a switch from a conventional combustible tobacco product, to a novel tobacco product with reduced machine-smoked toxicant yields or non-combustible nicotine delivery products, and in smoking cessation studies.

**Effects of Cadmium on Olfactory-Mediated Behaviors and Molecular Biomarkers in Coho Salmon**

C. R. Williams and E. P. Gallagher. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

The salmon olfactory system is sensitive to the toxic effects of metals. We analyzed olfactory-mediated alarm response behaviors, epithelial injury, and a suite of molecular biomarkers of olfactory function in juvenile coho salmon following acute exposures to cadmium (Cd). The molecular biomarkers analyzed included: four G-protein coupled receptors (GPCRs) representing the two major classes of odorant receptors (salmon olfactory receptor sorb and vomeronasal receptors srrv, svrb, and gpr27); a marker of neurite outgrowth (nn1); and markers of antioxidant responses to metals, including heme oxygenase 1 (hmox1) and peroxiredoxin 1 (prdx1). Coho received acute exposures to 3.7 ppb or 347 ppb Cd, and a subset of treated fish was then housed in clean water for 16 days before analysis. Coho exposed to 347 ppb Cd over 48 hrs exhibited a reduction in freeze responses as well as an extensive loss of olfaction accompanied by histological injury to the olfactory epithelium. This olfactory injury was accompanied by significant decreases in gene expression of the olfactory GPCRs and increased expression of hmox1. Persistent behavioral deficits, histological injury and altered expression of a subset of olfactory biomarkers were still evident in Cd-exposed coho following a 16-day depuration. Exposure to 3.7 ppb Cd also resulted in reduced freeze responses and histological changes to the olfactory epithelium within 48 hrs of Cd exposure, although the extent of olfactory injury was less severe than observed for fish in the high dose Cd group. Furthermore adverse behavioral effects were present in some coho receiving the low dose of Cd even following a 16-day depuration. In summary, acute exposures to environmental levels of Cd can cause persistent olfactory injury in coho salmon. Mechanism-based biomarkers of oxidative stress and olfactory structures can augment the evaluation of olfactory injury manifested at the physiological level. Supported by NIEHS P42 ES04696.

**The Effect of Cigarette Smoke Exposure on the Proteomic Composition of Human Bronchial Epithelial Cell Airway Surface Liquid**

G. J. Phillips1, L. E. Hawsell2, G. Meredith1, W. Fields3, L. McIntosh1, D. Chelsky1, L. Cortes1 and P. Croteau2. 1Bioassessment, British American Tobacco, Southampton, United Kingdom. 2Bioassessment, R.J Reynolds Co, Winston-Salem, NC and 3Caprion Proteomics Inc, Montreal, QC, Canada.

Human bronchial epithelial cells (HBEC) cultured in vitro secrete mucins and other proteins that mimic in vivo airway surface liquid (ASL). This study used proteomic void to determine HBEC-ASL composition and the effect of cigarette smoke exposure. A mass spectrometry multiple reaction monitoring (MRM) assay was also developed to quantify the ASL proteins that significantly changed after smoke exposure. HBECs were exposed to low dose or high dose cigarette smoke or air. ASL was collected, processed and analysed by reversed phase liquid chromatography-mass spectrometry and tandem mass spectrometry. ASL characterization identified 487 proteins with high confidence, these included mucins and non-mucin proteins involved in cytoskeletal, signalling, proteolytic, calcium binding and immune system pathways. Smoke exposure resulted in significant differential protein expression with the greatest changes occurring 48 hours after low dose smoke exposure. The majority of differently expressed proteins were related to inflammation and immune response, calcium binding and homeostasis, squamous cell differentiation and keratinocytes, protein metabolism, and oxidative stress. A MRM assay was developed for 154 proteins, of which 133 proteins were detected in ASL samples. Over 180 proteins were differentially expressed, with most proteins being up-regulated 48 hours after low dose smoke exposure. ASL analysis has been shown to be compatible with a proteomic approach. Many of the proteins identified have been previously detected in sputum, indicating HBEC ASL may be used to model smoke exposure in vitro. Construction of a smoke exposure specific MRM assay enables the quantitation of over 100 proteins in a single sample which may be used to further investigate the effects of smoke exposure in both in vitro ASL and in vivo sputum samples.

**Effect of Cadmium on Olfactory-Mediated Behaviors and Molecular Biomarkers in Coho Salmon**

1529

**Metabolomic Analysis of the Effect of Occupational Exposure to Pyrethroid Pesticides**

M. Ratelle1, M. Bouchard1 and C. Lin1, 1Department of Environmental Health and Occupational Health, University of Montréal, Montréal, QC, Canada and 2Institute of Environmental Health, National Tsing Hua University, Taipei, Taiwan.

Pyrethroids are one of the most commonly used insecticides in agriculture. They can cause neurotoxic, immune and endocrine effects. Perturbations of mechanistic pathways leading to such effects are however poorly understood. A recent approach in toxicology is to observe changes in endogenous metabolites to inform on mechanisms of toxicity. In an attempt to identify a possible spectrum of biomarkers of adverse effects of pyrethroids, a preliminary metabolomic analysis of urine samples of workers exposed to pyrethroids was conducted. Thirty agricultural workers from three different farms exposed to cypermethrin provided a complete first morning urine void before and after application or work in a treated area (following the required re-entry delay). Metabolomic analyses of urine samples were conducted by 1H nuclear magnetic resonance (NMR) followed by orthogonal partial least squares discriminant analysis (OPLS-DA). Non-parametric Wilcoxon statistical analyses were conducted given the small sample size and the neither normal nor log-normal distribution of biomarkers. The results of OPLS-DA model show two different clusters between the pre-exposure and the post-exposure samples. Higher hippurate levels were found in post-exposure urine samples (p<0.0001), but lower excretion levels of betaine (p=0.019), guanidinoacetate (p=0.004), lysine (p<0.05), alanine (p=0.07) and threonine (p=0.008). Hippurate is produced in presence of benzoic acid coming from exogenous or endogenous precursors and glycine. The main exogenous metabolite of pyrethroids is 3-phenoxy-benzoic acid, a possible substrate to hippurate. Hippurate is an uremic toxin, which interferes with normal physiological and metabolic processes; it is involved in the correction of metabolic acidosis, developing into one of the key consequences of kidney function reduction and acceleration of kidney disease progression. These metabolic changes warrant further investigations of the possible mode of action of pyrethroids.

**Development of Method for Detection of Aflatoxin B1-Lysine Adduct in Dried Blood Spot Samples**

K. S. Xue, L. Tang, Y. Wang, M. Kang and J. Wang. University of Georgia, Athens, GA.

There is an increasing concern on aflatoxin (AF) associated growth and development inhibition among children. Previously, longer AF exposure was mainly previously assessed by analyses of serum AFB-lysine adduct. However, serum anal-
ys involved withdrawal of blood with needle stick which limits the applicability to infants and young children. In this study we developed a method to detect AFB-Lysine adduct in dried blood spots (DBS) samples. Commercially available DBS cards were evaluated for accuracy to hold different quantity of whole blood. Different washing strategies were tested to effectively elute bound blood components, especially for total protein and albumin spotted on DBS card. The recovery is >95% with the optimized washing conditions. To further validate the method, F344 rats were dosed with a single dose of AFB1 of 0, 25, 75, 225, or 675 μg/kg bw or a repeated dose of AFB1 of 5, 10, 25, and 75 μg/kg bw for two weeks. Whole blood samples from dosed animals were collected via cardiopuncture before sacrifice and immediately processed to DBS cards (6 cards per animal) and stored at 4°C until analysis. The remaining blood was prepared for serum to serve as the control. The DBS cards containing AFB-lsine adducts were washed and extracted for recovering the total protein and albumin, which were measured and digested with protease to release mono-AFB-lsine adduct. The digests were further concentrated and purified with the solid-phase extraction. The eluate was dried and reconstituted for analysis with HPLC-fluorescence detection using the same protocol for analysis of serum samples. The similar limit of detection of AFB-lsine adduct was achieved with the DBS cards, however, the recovery of the spiked levels of AFB-lsine adduct was lower (10-20%) in the whole blood DBS than the serum, which suggested that certain components in the whole blood may interfere with the recovery. Further study would aim to resolve the interference factors, in particular the hemoglobin components, in the colorimetric reading for protein quantification as well as the adduct enrichment process.

1533 Toxic Effects of Low-Level Arsenic Exposure on Erythrocyte and Its Membrane Proteins in Male Rats

Q. Pei1, J. Zhang1, Y. Gao1, F. Tian1, N. Ma2, C. Ma1, Y. Miao1 and X. Qin1.
1Shanxi Medical University, Taiyuan, Shanxi, China, 2Suzuka University of Medical Science, Suzuka, Japan

Aim: The purpose of this study was to examine changes of the erythrocyte and RBC membrane proteins in male rats exposed to low-level arsenic through drinking water and to further explore the potential biomarkers of chronic arsenic poisoning.

Methods: 40 male Sprague-Dawley rats (body weight 140-160g) were randomly divided into 4 equal groups and repetitively provided ad libitum access to drinking water containing sodium arsenite dissolved in tap water at arsenic levels of 0, 10, 60 and 360 μg/L for 30 days. The RBC toxic effects were detected by different indicators and methods, including RBC parameters (Automated Hematology Analyzer), erytrocyte rate (Flow Cytometry), erythrocyte morphology (Scanning Electron Microscopy). Erythrocyte membrane proteins were analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and Immunofluorescence Assay (IFA).

Results: The results revealed that, compared with the control group, RBC parameters have not abnormal changes in exposure groups, but erytrocyte rate increased significantly in 360 μg/L arsenic exposure group. In the As treatment groups, and particularly in 360 μg/L group, we observed more irregular-shaped erythrocytes and spherocytes. Electrophoretic analysis showed decreased ankyrin expression and increased band 3 expression in 360μg/L dose group. Immunofluorescence confirmed that band 3 and CD35 increased and clustered to the RBC membrane in rats exposed to arsenic.

Conclusions: This study suggests that low levels of arsenic exposure can produce toxic effects on erythrocyte, resulting in increased erytrocyte and abnormal RBC morphology, which may be related to erythrocyte membrane proteins abnormalities. Erythrocyte membrane proteins are more sensitive to low-level arsenic than RBC number and morphology. Erythrocyte membrane proteins may be the early biomarkers in patients of chronic arsenic poisoning.

1534 Determination of Aflatoxin M1 in Breast Milk As a Biomarker of Maternal and Infant Exposure in Colombia

P. Sánchez1 and G. Díaz1.
1Salud Animal - Facultad de Veterinaria, Universidad Nacional de Colombia, Bogota, Colombia and 2Toxicología - Facultad de Medicina, Universidad Nacional de Colombia, Bogota, Colombia.

Aflatoxins are secondary fungal metabolites that can contaminate human food supplies. Four aflatoxins are produced by fungi, being aflatoxin B1 (AFB1) the most common and toxic. AFB1 is considered to be the most potent natural occurring liver carcinogen known to humans. Chronic exposure causes hepatocellular carcinoma with prevalence 16--32 times higher in developing countries compared to first-world countries. Aflatoxin M1 (AFM1) is a monohydroxylated metabolite from AFB1 that is secreted in milk and can be used as a biomarker of exposure to AFB1. Ingestion of contaminated food during pregnancy and lactation may expose the newborn to the deleterious effects of aflatoxins. For these reason, efforts made to measure toxins in breast milk are important to establish the contribution of these toxins to public health, especially to the health of the newborn.

The aim of the present study was to determine AFM1 levels in human breast milk using immunoaffinity column cleanup with high performance liquid chromatography and fluorescence detection. An in-house version of the ISO method used for cow's milk was performed. Breast milk samples were obtained from 50 nursery mothers chosen from those attending The Mercy Hospital Foundation located in Bogota, Colombia. Volunteers filled in a questionnaire giving their consent to analyze their samples and details of their socio-economic, demographic and clinical data. The intake of dietary sources of aflatoxins was assessed using a food frequency questionnaire.

A total of 45 of the samples tested positive for AFM1 (median 5.2 ng/L; range 0.9-18.5 ng/L). The present study demonstrates a high exposure of mothers and neonates to AFB1 and AFM1 in Colombia, and shows the need to regulate the presence of aflatoxins in human foods. Further research is needed to determine the presence of mycotoxins in foods and biological fluids as well as to device protection strategies in a country where mycotoxins in human foods are not regulated.

1535 Association of Neuroantibodies (NAb), Lead (Pb), Vascular, and Inflammatory Biomarkers in Hemodialysis Patients (HD)

D. Mason1 and H.A. El-Fawal2, 1ANephRx Core Laboratory, Albany College of Pharmacy and Health Sciences, Albany, NY and 2Neurotoxicology Laboratory, Albany College of Pharmacy and Health Sciences, Albany, NY.

Vascular disease, a complication of renal failure, contributes to neurodegeneration. Cognitive decline, with white matter involvement, and heavy metal accumulation have been reported in HD patients. This study investigated the association of Pb, intravascular- and vascular cell adhesion molecules (ICAM and VCAM), fibroblast growth factor-23 (FGF23) and Fetuin-A (FA) with NAb, IgG, against neurofilaments (NF-L, NF-M, NF-H), GFAP and myelin basic protein (MBP) in 229 HD patients. NAB against all proteins were significantly prevalent in HD, with anti-NF-H and anti-GFAP (90 and 80%, respectively) the most prevalent. All titers significantly correlated with each other (r=0.4-0.5; p<0.0001). Anti-NF-M, VCAM and FGF23 (p<0.05) correlated with Pb, but not VCAM, directly (p=0.001) correlated with all NAb titers, while FA and FGF23 inversely correlated with Pb (p=0.01). Multivariable regression (R²=0.2-0.4) indicated that the major determinants of anti-NF-M, NF-H, GFAP and MBP titers were PfP (p=0.02), FA (p=0.001) and VCAM (p=0.01). ICAM was a significant (p=0.001) determinant for all, but GFAP. For anti-NF-L (R²=0.4), the major determinants were FA (p=0.001) and ICAM (p<0.01). The present study demonstrates a strong association between PbP in HD patients and biomarkers of nervous system insult, as well as the association with vascular markers. ICAM and VCAM biomarkers have been associated with neurodegenerative diseases and cognitive decline. FA is believed to be neuroprotective, its decline indicating risk as suggested in the literature. While FGF23 may pose a risk for cardiovascular disease, its activities mediated through klotho are believed to be protective. This is consistent with the reverse association with Nabs. Taken together, this study demonstrates the utility of NAB as biomarkers and their strong association with factors that may contribute to neurodegeneration in HD patients.

1536 Identification of Marker Components in the Volatile Organic Emissions of Fusarium Fungi

The metabolomics of microorganisms, in particular, Fusarium micromycetes, places special focus on the quantitative and qualitative composition of their emitted volatile organic compounds (VOC), because the latter serve as markers in the identification and differentiation of toxin-producing fungi. The profile of VOCs emitted by microorganisms and, consequently, the set of markers indicative of the presence of certain microorganisms in the analyzed object depend on the experimental conditions. For reproducible metabolic profiles some standard experimental conditions should be developed and commonly accepted. To this end, more information on the metabolic profiles of microorganisms in various experimental conditions should be accumulated.
We performed a comparative study of the VOC profiles of F. cerutis, F. culorum, F. graminearum, F. langiaeae, F. poae, and F. sporotrichoides strains at varied times of culturing in potato dextrose agar, using gas chromatography-mass spectrometry combined with solid-phase microextraction. The parameters subject to standardization in this technique are the type of microfiber and sampling temperature. The experiments involved passive sampling VOCs on a carbon microfiber at 40°C from the equilibrum vapor over live toxin-producing fungi cultures grown in GC vials.

Evidence was obtained for close correlation between the quantity of trichodiene (marker of trichothecene toxins) emitted by Fusarium fungi and the quantity and composition of sesquiterpenes in the emissions. A series of marker VOCs emitted by Fusarium fungi in much higher concentrations than trichodiene were detected and structurally characterized. Research on their specificity is in progress. The work was supported in part by the Russian Foundation for Basic Research (project no. 12-04-00927-a).

Traditional biomarkers of nephrotoxicity, blood urea nitrogen (BUN) and serum creatinine (sCRE), are relatively insensitive to acute renal damage, generally requiring a loss of up to two-thirds of kidney function to initiate significant changes. We have evaluated a new generation of urinary renal biomarkers (LIP0-2, clusterin, osteopontin, TIM-1, Albumin) using MesoScale Discovery® (MSD) kits. Fifteen male rats were administered either vancomycin (70 or 300 mg/kg) or puromycin (10 or 40 mg/kg) via intraperitoneal (ip) dosing daily for 7 days. Male rats (5/timepoint) were sacrificed on Days 2, 8 and 21. Blood for clinical pathology as well as urine was collected on Days 2, 8, 13 and 21. Microscopic pathology revealed necrosis, inflammation, fibrosis, and regeneration in male rats treated with either 300 mg/kg or 40 mg/kg of vancomycin or puromycin. Vancomycin at 300 mg/kg produced elevations in sCRE (1.4- and 1.9-fold) and BUN (1.5- and 1.9-fold) on Days 2 and 8, respectively. Puromycin (40 mg/kg) produced elevations in sCRE (3.1-fold) on Day 13 and BUN (1.5- and 1.8-fold) on Days 8 and 13, respectively; however, of the traditional markers of kidney function, only BUN showed significant changes that were outside the levels of historical controls. In contrast, 300 mg/kg vancomycin produced elevations in urinary albumin (6.0-fold) on Day 8 only, while urinary clusterin (6.0- and 16.3-fold), LIP0-2 (2.7- and 2.1-fold), osteopontin (4.3- and 2.9-fold), and TIM-1 (40.3- and 24.5-fold) were elevated on Days 2 and 8, respectively. Puromycin (40 mg/kg) produced elevations in albumin (65.7-fold) on Day 2 only and clusterin (5.4- and 2.1-fold), LIP0-2 (4.5- and 1.5-fold), and TIM-1 (23- and 3.3-fold) were elevated on Days 13 and 21, respectively. No significant changes in renal histopathology or biomarkers were observed at lower doses of vancomycin or puromycin. These results indicate that the MSD kits provide excellent sensitivity for detection of renal toxicity in rats following treatment with either vancomycin or puromycin. Work supported by NIAID Contract N01-AI-70043.

Diabetes occurs spontaneously in aged cynomolgus monkeys and its diagnosis or potential for development must be considered when using aged monkeys on long term toxicology studies. Standard clinical pathology parameters are shown to be inadequate in diagnosing diabetes. Serum glucose (GLU) levels in aged monkeys can vary significantly and GLU measurements are also insufficient to detect persistent hyperglycemia. Glycated hemoglobin (HbA1c) is formed by the non-enzymatic addition of GLU to Hgb. Its formation in blood is positively correlated with the magnitude and duration of hyperglycemia. HbA1c half-life is 2-3 months and its removal from the blood is dependent on the degradation of hemoglobin. Transient hyperglycemia does not significantly affect the concentrations of HbA1c. HbA1c is a recognized marker of long term hyperglycemic status. The HbA1c assay was validated using whole blood in EDTA collected from healthy and confirmed diabetic cynomolgus monkeys. The Roche Diagnostic HbA1c kit immunoturbidimetric assay (Tina-quant HbA1c®) was adapted to use with an automated chemistry analyzer (Modular Analytcs, Hitachi®) to measure HbA1c in hemolyzed whole blood. The HbA1c limit of detection was 0.2-2.6 g/dL for hemoglobin values between 4-40 g/dL. Intra-assay and inter assay coefficients of variation were 0.1 and 8.4 % respectively. Linearity of dilution was acceptable down to dilutions of 15:100. Hemolyzed samples were stable for 24 hrs at room temperature, 3 days at 2-8°C, and 2 months at -20°C, and over 3 freeze/thaw cycles. Stability of whole blood in EDTA was 3 days at room temperature or at 2-8°C. Reference values for HbA1c obtained in healthy cynomolgus monkeys were: 0.3-0.4 g/dL, or 1.8-3.0% of total hemoglobin for glucose values below 112 mg/dL. Values obtained in diabetic monkeys were 0.6-0.7 g/dL for GLU values between 120-256 mg/dL. The addition of HbA1c measurements to the clinical chemistry health screen panel allows a better identification of aged animals at risk for diabetes and a better health monitoring of these animals during the study conduct.
**1541** Insulin-Stimulated Urinary Chromium Excretion Is Not a Biomarker for Chromium Nutritional Status  
S. T. Love1, K. R. DiBong1, S. Halder Sinha1, D. McAldroy1, B. R. Skinner1, J. F. Rasco1 and J. B. Vincent1. 1Chemistry, The University of Alabama, Tuscaloosa, AL and 2Biological Sciences, The University of Alabama, Tuscaloosa, AL.

Recent studies have suggested that the status of chromium as an essential element should be reconsidered because the effects of chromium supplementation appear to be more pharmacological rather than nutritional. The pharmacological basis for chromium’s effects may explain the inability of investigators to identify a biomarker for chromium status. One potential biomarker, urinary chromium excretion in response to a glucose or insulin challenge, has not been examined to date. Chromium is known to be mobilized in the body in response to insulin (or insulin release in response to a glucose challenge), resulting in an increase in urinary chromium excretion. In this study, the magnitude of increase in urinary chromium loss as a function of dietary chromium intake was evaluated as a potential biomarker for chromium. Zucker lean rats housed under carefully controlled metal-free conditions were fed a series of purified diets containing variable amounts of chromium (from 16 μg/kg diet to 2000 μg/kg) for 4 months. The 16 μg/kg diet contained less chromium than any diet examined to date. Urine samples were collected pre- and post-insulin and glucose challenges (0, 2 hours, 6 hours and 12 hours post injection). Urinary chromium levels were analyzed by the standard method of addition using graphite furnace atomic absorption. Rat blood iron levels were also measured to determine if the addition of chromium to the diet altered iron status. The study demonstrated that the chromium content of the diet had no effect on blood iron levels and also confirmed that insulin-stimulated urinary chromium excretion is not a useful biomarker for chromium nutritional status.

**1542** Sensitive Sites of Glycation of the Fibrinolytic System Protein Plasminogen: Implications for T2D Vascular Complications  
O. R. Kenney1, A. M. Williams1, T. L. Hargraves1, G. Tsapralis1, T. L. Monks1 and S. S. Lay2. 1Southwest Environmental Health Sciences Center, Department of Pharm/ Tax, College of Pharmacy, University of Arizona, Tucson, AZ.

Reactive dicarbonyls, such as methylglyoxal (MG), are present in blood and react with arginines (R) of target proteins, leading to diabetic micro- and macrovascular complications. MG plasma concentrations reach 4.5 μM, which can triple as diabetic complications progress. Protein-MG adducts may drive retinopathy, neuropathy, and other common diabetic complications. The irreversible modification of R residues by dicarbonyls causes a net loss of positive charge, most commonly via hydroxymidazole formation. Previous studies in our laboratory identified the fibrinolytic system protein plasminogen (Pg) as a sensitive target of MG addition, with functional significance. Thus, molecular modeling indicated that modification of R561 at the cleavage site of Pg would impact enzymatic activation due to drastically altered energy of interaction. The current work has identified, via 2D gel and subsequent in-gel digestion, the most sensitive sites of R modification (R504, R530) by MG on the protein, both of which may have functional effects. Although R561 was found as an early target for modification, it was not amongst the first sites hit. The functional significance of Pg adduction by MG was further tested in vitro. Pg activation was significantly delayed via modification with 50 μM MG, as determined by cleavage of a chromogenic substrate (S-2251) by plasmin, the product of Pg activation. A preliminary group of ten human plasma samples were selected and analyzed via Orbitrap mass spectrometry to detect modifications. Two patients with a history of cardiovascular disease showed R modifications of Pg at R504 and R530. At the present time, Pg modification in human plasma samples are being examined in a cohort >150 samples. The findings indicate that MG-modification of Pg may disrupt the fibrinolytic cascade sufficient to represent an underlying mechanism of vascular complications in diabetics. (R24DW083948, ABRC, ES016652, T32ES07091, P30ES00694).

**1543** A Practical and Complementary Approach to De-Risk the Potential Nephrotoxic Liability of a Drug Candidate at an Early Stage of Development  
F. Brouta1, M. Cornet1, S. H. Dhalhini2 and B. O. Depelchin1. 1Non-Clinical Development, UCB Pharma, Brussels, IERead, Belgium and 2NPS, joint R&D Alliance Management, UCB Pharma, Andeleraelt, Belgium.

UCBs, a compound intended for potential use in cognitive disorders, was stopped in preclinical development because of kidney toxicity observed in a 4-week GLP rat toxicity study. Adverse histopathological findings in the kidneys were characterized by dose-related tubular degeneration/necrosis along with tubular basophilia. Urine analysis performed using both Meso Scale Discovery (MSD) and Luminex plat-
7.8 fold higher levels upon flutamide treatment. Similar results were obtained in rats in vivo. None of the measured liver enzymes were increased upon flutamide treatment. Plasma levels of oxidative stress markers were considerably changed: 15R-Prostaglandin D2 was 12.5 fold higher in treated animals and substantial levels of 5-ISO Prostaglandin F2α-VI were detected in treated animals, not in vehicle controls.

These results show that enhanced formation of isoprostanes in rat hepatocytes translates to the in vivo situation. Human cells exert a similar response upon flutamide treatment. The quantitation of oxidative stress biomarkers in human hepatocytes is suggested as an optimistic tool to early address a drug’s susceptibility to cause hepatic injury especially in man especially when bioactivation is involved.

1546 Qualification of Novel Urine Biomarkers of Nephrotoxicity in Rodents on MSD Platform

A. V. Lyubimov, A. Kuzmis, Y. Chen, A. Zakharev and A. Banerjee, Pharmacology, Toxicology Research Laboratory, UIC, Chicago, IL.

The kidney is a common target organ for drug-induced injury, which is routinely assessed during safety evaluations. A panel of novel kidney injury markers has been recently identified, allowing diagnosis of nephrotoxicity with sufficient sensitivity and specificity in comparison to the conventional markers (serum creatinine and blood urea nitrogen (BUN)). As a result, there is a need for efficient methods for quantification of these novel biomarkers in early kidney toxicity screening. The goal of this study was to perform an analysis of urinary biomarkers on rodent models of kidney injury with an ultimate aim to enable more informed preclinical monitoring of kidney function. Concentration of kidney injury biomarkers was determined in urine using standard multiplexed (rat panel) or singleplex (mouse) assays based on the MesoScale Discovery (MSD) platform that was developed by us. Evaluated injury response biomarkers included: albumin, NGAL (Lipocalin-2), T cell-immunoglobulin-mucin (TIM-1), and osteopontin. TIM-1 and NGAL MSD rat panel did not detect mouse proteins. Assays for these two markers were developed and qualified at our laboratory. Kidney injury was induced by cisplatin (7 mg/kg, single i.p.) as well as gentamicin (100 mg/kg, 7 daily SQ injections) in two species, Sprague Dawley and C57Bl/6 mice. Normal ranges in rodent plasma were established and found to be above the LLOD for both species. Albumin, NGAL, and TIM-1 demonstrated high sensitivity in detection of kidney impairment. However, elevated NGAL and TIM-levels were detected at earlier time points than that of albumin. Osteopontin was a good indicator of tubular injury in rats but not in mice. Further optimization of the MSD methods are being undertaken to provide more sensitive assays for multiplexed detection of excerted biomarkers of kidney injury. In addition, a sensitive creatinine LC/MS/MS method was developed and validated as the routinely used clinical chemistry analyzer method is below the limit of quantitation in mouse urine.

PS 1547 Validation of an Electrochemiluminescence Multiplexed Immunoassay for Mouse Inflammation: The V-PLEX™

M. J. Cameron1, D. B. Gemmii, J. Coashi2 and A. Aulbach,1 Immunology, MPI Research, Mattawan, MI and 2Clinical Pathology, MPI Research, Mattawan, MI.

To support preclinical safety studies a new, commercially available mouse cytokine multiplex kit (IFN-gamma, IL-1 beta, IL-2, IL-4, IL-5, IL-6, KC/GRO, IL-10, IL-12p70 and TNF-alpha) from Meso Scale Discovery was validated under GLP (Good Laboratory Practice) conditions. V-PLEX products allow the end user flexibility to pick and choose analytes from a predefined menu. To demonstrate biological relevance and create positive controls, mice were dosed with LPS via intraperitoneal injection. Serum samples were collected at 30 minutes and 1, 4, 8, 12, 24, and 48 hours post-LPS administration. LPS treatment in the mouse caused significant up-regulation of IFN-gamma, IL-10, IL-12, IL-beta, IL-5, IL-6, KC/GRO and TNF-alpha beginning by 1 to 4 hours post dose. The analytical validation consisted of 6 independent immunoassay runs. Quality Control Samples (QC’s) were made by spiking calibrator into mouse serum. Inter assay precision and accuracy (ULOQ and LLOQ), intra-assay precision (intra-day and inter-day precisions of all HAAs were 0.80-6.06 and 2.65-20.20pg/mL, respectively. The intra-day and inter-day precisions of all HAAs were ≤10%. For the high sensitivity and good precision, the method was successfully applied to analysis of HAAs in urines of smokers and non-smokers. The limits of detection and quantification of all target HAAs approached 0.80-6.06 and 2.65-20.20pg/mL, respectively. These results show that enhanced formation of isoprostanes in rat hepatocytes translates to the in vivo situation. Human cells exert a similar response upon flutamide treatment. The quantitation of oxidative stress biomarkers in human hepatocytes is suggested as an optimistic tool to early address a drug’s susceptibility to cause hepatic injury especially in man especially when bioactivation is involved.

A sensitive UHPLC-MS/MS method for the simultaneously determination of 15 heterocyclic aromatic amines (HAAs) was developed and applied to the analysis of human urines of smokers and non-smokers. The limits of detection and quantification of all target HAAs approached 0.80-6.06 and 2.65-20.20pg/mL, respectively. These results show that enhanced formation of isoprostanes in rat hepatocytes translates to the in vivo situation. Human cells exert a similar response upon flutamide treatment. The quantitation of oxidative stress biomarkers in human hepatocytes is suggested as an optimistic tool to early address a drug’s susceptibility to cause hepatic injury especially in man especially when bioactivation is involved.

PS 1548 A Modern Assessment of Clinical Pathology Biomarker Correlation between Nonclinical Species and Humans

Translatability of biomarkers from nonclinical species to humans is vital when predicting for toxicity and monitorable biomarkers in the clinic. To that end, we have used the database Pharmapendium to perform correlation analyses on commonly observed adverse alterations in standard clinical pathology endpoints used in nonclinical and clinical studies. Human data was compared with 3 commonly used nonclinical species: rat, dog, and primate. Analyses are limited to those drugs where clinical data only exists from the year 2000 to present. Our data show that there is no significant difference between either sensitivity or specificity values across species. The maximum difference observed was 8%, with the exception of circulating reticulocytes which showed increased specificity of 15% to 17% in primates as compared to dogs and rats, respectively. This finding gives credence to the statement that lesser animal models are as useful as higher animal models for predicting these clinical pathology changes in humans. Additionally, the standard nonclinical toxicology evaluation practice of using a rodent and non-roden species (rat and dog or rat and monkey) slightly increased sensitivity by 2% to 17% while marginally reducing specificity by 0% to 8%. Interestingly, a further correlation analysis between species indicated that there was no significant overlap between clinical pathology changes in both rat and dog and rat and monkey. There were 7-10 drugs where both the rat and dog were tested and where the dog showed the change in the clinical pathology parameter of interest. In these cases, the rat showed a false negative rate up to 85%. There were 2 to 49 drugs where both the rat and primate were tested and where the primate showed the change in the clinical pathology parameter of interest. In these cases, the rat showed a false negative rate of up to 100%. These data give credence to the use of two animal species in order to safely choose biomarkers for monitoring in the clinic.

PS 1549 Simultaneous Determination of 15 Heterocyclic Aromatic Amines in Urines of Smoker and Nonsmoker Using HPLC-MS/MS

A sensitive UHPLC-MS/MS method for the simultaneously determination of 15 heterocyclic aromatic amines (HAAs) was developed and applied to the analysis of human urines of smokers and non-smokers. The limits of detection and quantification of all target HAAs approached 0.80-6.06 and 2.65-20.20pg/mL, respectively. These results show that enhanced formation of isoprostanes in rat hepatocytes translates to the in vivo situation. Human cells exert a similar response upon flutamide treatment. The quantitation of oxidative stress biomarkers in human hepatocytes is suggested as an optimistic tool to early address a drug’s susceptibility to cause hepatic injury especially in man especially when bioactivation is involved.

PS 1549a Cross-Site Analytical Validation of the Cardiac Biomarker NT-proANP in Rat

A sensitive UHPLC-MS/MS method for the simultaneously determination of 15 heterocyclic aromatic amines (HAAs) was developed and applied to the analysis of human urines of smokers and non-smokers. The limits of detection and quantification of all target HAAs approached 0.80-6.06 and 2.65-20.20pg/mL, respectively. These results show that enhanced formation of isoprostanes in rat hepatocytes translates to the in vivo situation. Human cells exert a similar response upon flutamide treatment. The quantitation of oxidative stress biomarkers in human hepatocytes is suggested as an optimistic tool to early address a drug’s susceptibility to cause hepatic injury especially in man especially when bioactivation is involved.

Natriuretic peptides have proven utility in human medicine and are candidate non-invasive translational cardiac safety biomarkers for drug development studies in rats. A working group within PSTC is qualifying NT-proANP as a circulating biomarker of drug-induced hemodynamic stress. Analytical validation of an ELISA specific for human but cross-reacting with rat NT-proANP (Biomedica / Alpco Diagnostics, Cat No 04-BI-20892) was conducted by 5 different laboratories. The following aspects were assessed: intra- and inter-assay precision, accuracy, dilutional linearity, limit of detection (LOD), upper and lower limit of quantification (ULOQ and LLOQ), sample freeze/thaw (F/T) stability and inter-laboratory reproducibility. The standard curve showed acceptable analytical performance in all laboratories, defined as CV ≤ 20% and accuracy ≤ 20%. Intra- and inter-assay

IL-2 suggest that these assays should be used with caution. The V-PLEX product is a new multiplexing product offering greater end user flexibility and may become a valuable tool for mouse cytokine analysis.
1,3-Butadiene is a well-documented environmental pollutant that is a component of tobacco smoke and is a known human carcinogen that is used in polymer manufacture and is found in gasoline vapor and automobile exhaust. Despite the presence of 1,3-butadiene in the environment, there is no widely used biomarker for this chemical in humans. A recent study with rat urine samples was used to evaluate a human specific ELISA kit with a colorimetric detection system. The study was conducted through remote evaluation methods did not improve biomarker performance assessments when compared to typical semi-quantitative evaluations averaged across all pathologists.

1549b Implications of Histopathology Methods in Biomarker Qualification

R. L. Reese, M. Min, K. Shea, S. Stewart and T. Colatsky. CDER, U. S. FDA, Silver Spring, MD.

Identification of candidate biomarkers detecting very early tissue injury and attempts to qualify these novel biomarkers for regulatory consideration have placed a spotlight on the histological and histopathological methods used in evaluating candidate biomarkers. The number and locations of organ samples, the impact of non-blinded evaluations, the methodology for inclusion or exclusion of spontaneous changes, and inherent differences in pathologists are sources of variation that could potentially impact biomarker assessment. Three FDA pathologists were recruited to participate in studies that were conducted through remote evaluation of digital images of hematoxylin and eosin stained slides of kidneys. Initial studies were created to maximize variability between pathologists by providing no specific data sources or guidelines for providing noncontextual information, and by allowing no collaboration or consultation between pathologists. Later studies were designed to minimize inter-pathologist variability. The same five image sets were used to generate quantitative estimates of proximal tubular tissue volume and epithelial cell counts in stereology software. Tissue sections serial to the H&E stained sections were immunohistochemically stained for the candidate biomarker and the biomarker was quantified through digital image analysis software. Log-linear modeling for variability was conducted using SAS PROC GENMOD and LogXact from Cytel, Inc. Receiver Operating Characteristic (ROC) analysis was used to assess biomarker performance. Results indicate that differences between pathologists are the largest source of variability in evaluations and that blinding does not generally make a significant difference. Pathologist variability can significantly influence biomarker performance assessments but can be minimized by using techniques to increase pathologist consensus. Quantitative stereology and digital image analysis methods did not improve biomarker performance assessments when compared to typical semi-quantitative evaluations averaged across all pathologists.

1,3-Butadiene is a known human carcinogen that is used in polymer production, and is detected in gasoline vapor, automobile exhaust, and tobacco smoke. Urine samples collected as part of NHANES 2005–2006 were assayed for 1,3-butadiene exposure biomarkers [N-acetyl-S-(1-hydroxymethyl-2-propenyl)-L-cysteine (MHBMA3), N-acetyl-S-(4-hydroxy-2-butanyl)-L-cysteine (MHBMA3), and N-acetyl-S-(3,4-dihydroxybutyl)-L-cysteine (DHBMA)] using ultra high performance liquid chromatography coupled with electrospray ionization triple quad mass spectrometry (UPLC/ESI-MSMS). MHBMA3 was the most abundant among the monohydroxy metabolites. The limits of detection in urine for MHBMA3 and DHBMA were 0.6 and 5 ng/mL respectively. In sample-weighted statistical analysis of NHANES 2005–2006 data, the median MHBMA3 and DHBMA levels among smokers (n=600) were 334 and 28 ng/g creatinine, respectively, compared to 250 and 5 ng/g creatinine for non-smokers (n=2467). Linear regression analysis showed that serum cotinine among smokers is a positive predictor of 1,3-butadiene exposure as measured by urinary MHBMA3 (linear slope p = 0.0002) and DHBMA (borderline p = 0.10), consistent with tobacco smoke as a primary exposure source for 1,3-butadiene. The sample-weighted median metabolic molar ratio (DHBMA/[DHBMA + MHBMA3]) was significantly lower among smokers (0.92; p < 0.0001) compared to non-smokers (0.98). Also, among smokers the sample-weighted median metabolic molar ratio was significantly higher among non-Hispanic Blacks (0.93; p = 0.04) and Mexican Americans (0.95; p = 0.0001) compared with non-Hispanic Whites (0.92). Among smokers, the sample-weighted Pearson correlations of serum cotinine with both MHBMA3 (r = 0.61, p < 0.0001) and DHBMA (r = 0.19, p < 0.0001) were statistically significant. This study provides the first nation-

ally representative characterization of butadiene exposure as measured by urinary MHBMA3 and DHBMA, and underscores tobacco smoke as a major source of butadiene exposure.

1549d Novel Rat Kidney Injury Biomarker Assays Using a Gyro Nanotechnology Platform

A leading cause of failure to any drug development program is toxicity in various organs such as the kidney. Traditional tests may not be specific enough for what is occurring and often cannot be detected until damage is irreversible. Many nephrotoxicity biomarkers may aid in the detection of damage to the kidneys and offer clues to specific kidney tissue injury in a more timely manner. We have developed rat KIM-1 and rat Clusterin GyroMark™ HT Biomarker assays as the first two toxicity biomarker assays in the Gyrolab™ xP Workstation platform. This automated compact disc-based nanotechnology uses microfluidic technology for sandwich ELISA immunoassay analysis using a biotinylated capture antibody and a fluorescence labeled detection antibody. This Gyros technology has features including small sample size (200 – 1000 nL), high sensitivity, broad dynamic range, and short assay time (1 hour per assay). The KIM-1 assay has a dynamic range, sensitivity, spike recovery, dilution linearity, intra-, and inter-assay variations of 0.054-40 ng/mL, 0.04ng/mL, 94%, 110%, < 5% and < 10%, respectively for 1:2 diluted rat urine samples. The Clusterin assay has a dynamic range, sensitivity, spike recovery, dilution linearity, intra-, and inter-assay variations of 0.36-1500 ng/mL, 0.3ng/mL, 93%, 100%, < 10% and < 10% respectively for 1:10 diluted rat urine samples. Using these new GyroMark™ HT Biomarker assays, we evaluated rats treated with no, low, and high doses of gentamicin. Urine samples (n=36) were collected on day 0, 3, 7, and 14. A significant increase in these markers was observed at day 3, tapering off as animals recovered towards day 14. The KIM-1 and Clusterin assays were compared to a leading commercial ELISA platform and vancomycin treated rat urine samples (n=36) correlation was r = 0.97 and 0.87 respectively. The analytical and biological validation data demonstrate that our GyroMark™ HT toxicity biomarker assays, rat KIM-1 and rat Clusterin, are highly robust and reproducible, using a 1000 nL sample size and can be a useful tool in detecting kidney damage in rat urine samples for drug development and basic research.

1549e Comparison of Two Commercial Immunoassays for Determination of Atrial Natriuretic Peptide in Sprague-Dawley Rat Serum

Atrial natriuretic peptide prohormone (proANP) is synthesized by the atrial myocytes. A stretch of the cardiomyocyte stimulates the release of proANP into the circulatory system. In circulation, proANP splits into a biologically active peptide known as t-ANP and an inactive N-terminal peptide (NT-proANP). NT-proANP has a long half-life and is less sensitive to the pulsatile secretions of ANP. Therefore, blood concentration of NT-proANP is used as a biomarker to evaluate cardiac health. Accurate determination of NT-proANP in preclinical animal models is important in safety and efficacy assessment of drug candidates. The objective of this study was to investigate two commercially available immunoassays for determination of NT-proANP in rat serum. Serum samples from 12 male and 12 female Sprague Dawley rats (10-14 weeks old) and plasma samples from a left anterior descending coronary artery-ligation (LADX) myocardial infarction study (n = 7) were used to evaluate a human specific ELISA kit with a colorimetric detection system from ALPCO (Salem, NH) and a rat-specific kit with an electrochemistry nesence detection system from Meso Scale Discovery (MSD, Gaithersburg, MD). The coefficient of variation (CV) was <16% using the ALPCO kit and <10% using the MSD kit. The spike-recovery using the ALPCO kit standard in pooled rat serum was 89 ± 9% and using the MSD kit standard in pooled rat serum was 110 ± 10%. No significant interference up to 4+ hemolysis was observed for either kit. Good correlation (r = 0.92) was observed between the two kits and NT-proANP was shown to be stable up to three freeze-thaw cycles in rat serum. Compared to the control rats, NT-proANP mean values were significantly higher (p < 0.05) in the LADX groups. In conclusion, both assays meet the feasibility acceptance criteria for application of non-blinded evaluations, the methodology for inclusion or exclusion of spontaneous changes, and inherent differences in pathologists are sources of variation that could potentially impact biomarker assessment. Three FDA pathologists were recruited to participate in studies that were conducted through remote evaluation of digital images of hematoxylin and eosin stained slides of kidneys. Initial studies were created to maximize variability between pathologists by providing no specific data sources or guidelines for providing noncontextual information, and by allowing no collaboration or consultation between pathologists. Later studies were designed to minimize inter-pathologist variability. The same five image sets were used to generate quantitative estimates of proximal tubular tissue volume and epithelial cell counts in stereology software. Tissue sections serial to the H&E stained sections were immunohistochemically stained for the candidate biomarker and the biomarker was quantified through digital image analysis software. Log-linear modeling for variability was conducted using SAS PROC GENMOD and LogXact from Cytel, Inc. Receiver Operating Characteristic (ROC) analysis was used to assess biomarker performance. Results indicate that differences between pathologists are the largest source of variability in evaluations and that blinding does not generally make a significant difference. Pathologist variability can significantly influence biomarker performance assessment analyses but can be minimized by using techniques to increase pathologist consensus. Quantitative stereology and digital image analysis methods did not improve biomarker performance assessments when compared to typical semi-quantitative evaluations averaged across all pathologists.
vascular injury is a common finding during the pre-clinical safety study of drugs. A lack of understanding of mechanisms of drug-induced vascular injury (DIVI) in animals and the absence of qualified biomarkers have become significant barriers in the development of new therapeutic agents. Recently, a number of promising candidate biomarkers for DIVI have been nominated. However, any effort to further validate and evaluate these markers is impeded by the lack of qualified high-throughput assays.

Based on Luminex xMAP® technology, we developed three panels of multiplexed immunooassays to quantify 17 potential DIVI biomarkers in rat serum and plasma samples. These biomarkers included caveolin-1, CTGF, PAI-1, IL-6, MCP-1, CINC-1, TIMP-1, VEGF, TNF-alpha, adiponectin, sICAM-1, E-selectin, von Willebrand Factor (vWF), alpha-2-macroglobulin (AZM), alpha-1-acid glycoprotein (AGP), fibrinogen and haptoglobin. Furthermore, fenoldopam induced rat DIVI models were used to validate the sensitivity and specificity of these markers to induce vascular injury, rats were treated with the vasodilator compound fenoldopam mesylate (FM). FM was administered by continuous intravenous infusion over 24 hours with a dose of 6 mg/kg/h. Subsequently to the infusion, serum and plasma samples were collected from each group of three rats on post-infusion day 1, 3, and 7. Sterile 0.9% saline was used in the vehicle control cohorts. MILLIPLEX® MAP Rat Vascular Injury Magnetic Bead Assays were used to measure 17 candidate protein biomarkers simultaneously from the rat serum and plasma samples. Fenoldopam treatment resulted in significant increase in blood biomarkers, consistent with its well described vasotoxic effect. Several biomarkers were found promising in this study, including AZM, sICAM-1, CTGF, vWF and TIMP-1. The simultaneous measurement of these proteins with multiplex technology offered a robust and convenient method to study these biomarkers. Taken together, our data demonstrate the feasibility of using the multiplex biomarker approach to detect the onset and progression of DIVI in pre-clinical drug safety studies.
Approach: Indoor and outdoor household dust samples were collected in communities with an active smelting plant (n=178), with historically active plants (n=166), and a control site (n=99), leached with 7.5N HNO3 and analyzed for Mn, Al, Fe, Cd, Cr, Cu, Pb, and Zn by ICP-AES.

Results: Household dust Mn levels were significantly different between all three study sites, with levels highest in the community with an active smelting plant (median = 2060 µg/g, range 130 – 183,000) and lowest in the reference community (median = 320 µg/g, range 20 – 1050); dust Mn levels were ~3 to 7-fold higher in outdoor versus indoor samples across all three sites.

In homes of adolescents providing biomarker samples (n=98), there was a highly significant correlation (p<0.001, r=0.639) between dust Mn concentrations and household dust Mn loading levels, and a highly significant association between dust Mn concentrations and hair Mn levels (r=0.3254, p<0.001, n=98). There was no association between dust Mn loading and hair Mn (r=0.1201, p=0.265), or between dust Mn concentrations and Mn levels in other biomarker tissues (r<0.1104, p<0.3426, p<0.22).

Conclusion: Dust Mn levels provide an informative measure of environmental Mn contamination from smeltery pollution emissions, and their association with a biomarker of Mn exposure suggests that dust may serve as an important Mn exposure pathway for adolescents.
with an excess cancer risk. According to the calculations for workers, the potential health risks associated with handling smelter material were very low and did not exceed acceptable risk levels.

1556 Arsenic Speciation in the Copper Tailings with the Effects of Magnetite Removal

Arsenic is considered as one of severe metalloid pollutants in the copper tailings, which may pose risks to the environment and human health. It is known that iron oxides are one of the most important adsorbents of minor elements due to their reactivity and large specific surface area, which can coprecipitate and adsorb arsenic. Magnetite (Fe3O4), counting for over 30% of in copper tailings, may act as a sink mineral to prevent arsenic mobilization. However, the ore processing has recently changed to remove magnetite as a by-product for economic benefit, which reduce arsenic concentration from 20–30% to 5%. Thus may affect arsenic speciation and consequently mobilize arsenic in tailings. In this study, we compared the sequential leaching results from the old copper tailings (total arsenic concentration 330 mg/kg) with magnetite and new copper tailing without magnetite. There was 34% arsenic adsorbed with iron in old tailing, comparing to 7% arsenate in new tailings. Organic matter (biochar and mulch) were added in those tailings and two types of Australian native plants were planted in the pot experiment. The leachate was collected which may display the different adsorption effects of organic matter on arsenic due to the reduction of the arsenic adsorption caused by magnetite removal. The results will allow us to understand the changes of arsenic speciation under the effects of magnetite removal in copper tailings and show the effects of organic matter addition to the tailings. The results will be interpreted in terms of the influence of magnetite and organic matter, which will provide essential information for further phytoremediation practice.

1557 Antioxidant Status and Levels of Some Essential Trace Elements and Heavy Metals in Individuals Occupationally Exposed to Municipal Solid Wastes
A. O. Odewal and M. Ekor. 1Chemical Pathology and Immunology, Olaode Onaobajo University Teaching Hospital, Sagamu, Nigeria and 2Department of Pharmacology, School of Medical Sciences, University of Cape Coast, Cape Coast, Ghana.

Objectives: Waste management workers (WMW) in Nigeria are at risk of work-related disorders. One aim of the present study was to determine blood concentrations of some essential trace elements (Se, Zn, Cu, Mg, Mn, Fe), toxic metals (Pb, Cr, Hg), and antioxidant/prooxidant markers [ferric reducing ability of plasma (FRAP), ceruloplasmin and thiobarbituric acid reactive substances (TBARS)] in municipal solid waste workers of Sagamu, South West Nigeria. Materials and Methods: A total of 75 subjects consisting of 30 WMW and 45 Non-WMW were recruited by purposive sampling. The element concentrations were measured by means of an atomic absorption spectrophotometer after wet-acid digestion. The validity and accuracy was checked by using certified reference materials. Ceruloplasmin, TBARS and FRAP were determined using standard procedures. Results: WMW exhibited significantly higher lipid peroxidation, depletion of antioxidant and alterations of levels of trace element and heavy metals. Significant (p < 0.001) elevation of ceruloplasmin (Cp) was associated with significant (p < 0.001) increase in TBARS and significant decrease (p < 0.001) in FRAP when compared with control. Apart from significant (p < 0.05) decrease level of iron (Fe) and significant (p < 0.001) increase in lead (Pb) and copper (Cu) observed in WMW, other trace elements and heavy metals analyzed (manganese (Mn), magnesium (Mg), chromium (Cr), mercury (Hg), selenium (Se) and zinc (Zn)) did not change significantly (p > 0.05) when compared with the control. A negative correlation between Cp (r = −0.182; p > 0.05) and lead as well as a positive correlation between FRAP (r = 0.277; p<0.05), zinc (r = 0.230; p<0.05) and lead and between copper (r = 0.541; p > 0.001) and iron were observed in WMW. Conclusions: Exposure to MSW predisposes to oxidative stress and lead toxicity and Cp appears promising to monitor lead overload in Nigerian WMW.

1558 Deriving Algorithms for Matrix-to-Matrix Relations and Reverse Dosimetry of Selenium from Pooled Biomonitoring Data
N. Noisel1, M. Bouchard2 and G. Carrier*2. 2Dept de Santé Environnementale et Santé au Travail, Université de Montréal, Montréal, QC, Canada and 2Direction de la Santé Environnementale et de la Toxiquologie, Institut National de Santé Publique du Québec (INSPQ), Montréal, QC, Canada.

Biomonitoring is increasingly used to assess exposure to selenium (Se) in the population. However, there is little harmonization among protocols used in the different studies varying biological matrices, differences in expression of results (concentrations versus amounts, units)). This makes inter-comparison of biomonitoring results across studies difficult. Hence, the aim of this study was to perform a systematic meta-analysis of the relationships between Se intakes and concentrations in different accessible biological matrices from an extended review of Se biomonitoring studies. Inclusion and exclusion criteria were used and led to select 75 published biomonitoring studies in humans. This represents 8628 individuals who provided biological samples aiming at documenting Se exposure and/or Se concentrations in two or more biological matrices. Mathematical algorithms that relate Se intakes to biological concentrations and establish matrix-to-matrix associations were derived from these pooled biomonitoring data. Logarithmic regressions showed good correlations between Se intakes and whole blood concentrations (R2 = 0.884), plasma concentrations (R2 = 0.863) and urinary excretion rates (R2 = 0.958). Blood and plasma concentrations were also strongly related (R2 = 0.874), as were whole blood concentrations and urinary excretion rates (R2 = 0.953). The log-regression coefficients allowed interpreting Se physiology. Se concentrations in plasma tend to plateau when daily intake exceed 150 μg/d, whereas Se in urine increases rapidly above this threshold. The application of the algorithms to other independent data sets confirmed that interpretation of results on the basis of Se in hair and toenail may be misleading if external contamination is not avoided. Finally, this approach based on pooled data has the advantage to cover a wide range of exposure and to provide results with a high level of confidence.

1559 Semen Uranium Concentrations in Gulf War I Depleted Uranium-Exposed Veterans
K. S. Suguhi1, 2, D. Hoover1, 2, S. E. Hines1, 2, P. Guerci1, 2, T. I. Todorov3, J. Centeno1, 2, M. Oliver1, 2, J. Gaitens1, 2 and M. McDermid1, 2. 1Dept of Veterans Affairs Medical Center, Baltimore, MD, 2UM School of Medicine, Baltimore, MD, 3Food and Drug Administration, College Park, MD and 4Joint Pathology Center, Silver Spring, MD.

The Department of Veterans Affairs’ (VA) Depleted Uranium (DU) Follow-up Program provides health surveillance for Gulf War I and OIF Veterans who were in friendly-fire events involving DU munitions. Members of this cohort with retained embedded fragments continue to excrete high levels of uranium (uU) with a DU isotopic signature. The purpose of this study was to determine if 1) semen U levels are elevated in this cohort and 2) if they are correlated with U in other body compartments (urine, blood and plasma). Participants in the 2009 biennial surveillance visit provided blood, semen and 24-hour urine specimens. After collection, thirty-five (35) semen samples were incubated at 370°C for liquefaction; then transferred to acid-washed Teflon vials for sample preparation and U analysis by ICP-MS. Concentrations of U in semen ranged from <0.03–3.50 pg/g with a median of 4.2 pg/g. Associations were explored between U concentrations in semen, urine, blood and plasma using Spearman correlations. Semen U was positively correlated with other body compartment U concentrations for all participants: urine U (r=0.85), blood U (r=0.73), and plasma U (r=0.82) (p<0.000 for all correlations). Results indicate that U levels in semen reflect systemic concentrations, which have remained high for > 20 years in Veterans with DU embedded fragments. Data suggest that urine samples may be used to estimate semen U levels. Our previous work demonstrated no significant semen or sperm abnormalities when correlated with uU levels; thus, these data suggest that U is not a significant reproductive toxicant at low concentrations. Supported by the Department of Veterans Affairs and approved by the Baltimore VA Medical Center’s Office of Research and Development and University of Maryland’s School of Medicine Institutional Review Board.

1560 On-Site Monitoring of Marcellus Drilling Operations
M. McCawley and T. L. Knuckles. West Virginia University, Morgantown, WV.

The West Virginia Natural Gas Horizontal Well Control Act of 2011 required determination of the effectiveness of a 625 foot setbacks from the center of the pad of a horizontal well drilling site. An investigation was conducted at seven drilling sites to collect data on particulate matter (PM), volatile organic compounds.
(VOCs), noise, radiation, and light levels. Measurements of air contaminants were taken during active drilling to characterize levels that might be found at 625 ft from the well pad center at unconventional gas drilling sites. While PM and VOC’s were detected at the well sites, none were above National Ambient Air Quality standards (NAAQS) at the 625 ft setback limit. Activities at the well site however did not allow for a consensus comparison to the NAAQS values. Some benzene concentrations were found to be 85ppb, 10 fold higher than what the CDC calls the “the minimum risk level for no health effects” and sound levels could exceed 95 decibels. Since, not all of the studied contaminants emanate from the center of the pad, regulations could consider other exposure points (such as those on the periphery) from which to measure a setback distance but there does not appear to be a simple solution to specifying a single point to assure control. The activities follow the terrain of the site and the needs of the process. Activities associated with some possible sources of the studied contaminants can occur closer than 625 feet from a sensitive receptor. Studies have also shown that the meteorology (and topography) may be a more important factor than distance measured on a map (or determining air contaminant concentration. While the levels of contaminants that were seen were not unexpected based on previous studies they did fluctuate over a wide range. Consideration needs to be given to increased quality control monitoring of the process using direct-reading monitors at sensitive locations near the well pad, connected wirelessly to the operations center at the pad which in turn can control output from all sources.

**1561 Potential for Exacerbation of Pediatric Asthma Due to Ultrafine Particle Exposure from Marcellus Shale Gas Drilling Operations**

E. Eyota1, M. McCawley1, S. Chatterjee2, W. C. Mercer3, W. W. Harris4, T. K. Knuckles4 and H. P. Gumble3, 1West Virginia University, Morgantown, WV and 2Ohio County Health Department, Wheeling, WV.

Marcellus Shale drilling operations utilize diesel engines which result in a release of ultrafine particles (UFPs; particles less than 0.1 μm) during combustion processes. Recent epidemiological studies have found a positive association between UFPs and pulmonary health effects in humans. Furthermore, UFPs are of increasing concern because studies show they exacerbate asthma symptoms, especially in children. In this paper, we describe sampling conducted in Ohio County, West Virginia using a new, battery-operated, portable differential mobility analyzer to measure the concentration and size distribution of UFPs to predict health effects that may occur in areas where the wells are located. This allowed not only total particle number concentration to be determined but also the lung dose to be estimated based on established lung deposition models. We measured concentrations that averaged as low as 4,000 to as high as 46,000 particles per cm3 in areas around drilling operations. These concentrations were generally found to be higher than the 8,000 particles/cm3 concentration associated with increased emergency room admissions for pediatric asthma. Moreover, these concentrations were consistent with ambient air particle counts of obtained near mountaintop mining operations, which have high levels of cardiovascular disease and cancer in the population. The concentrations of UFPs were similar to those of the two industrial sites. Collectively, these data suggest substantial ultrafine particle exposure burden to the populace proximal to the mining and drilling operations, which may be driving some of the adverse respiratory and cardiovascular effects. Currently, the Environmental Protection Agency does not monitor ultrafine particle concentrations in these areas, nor are respiratory and cardiovascular effects. Currently, the Environmental Protection Agency does not monitor ultrafine particle concentrations in these areas, nor are respiratory and cardiovascular effects. Currently, the Environmental Protection Agency does not monitor ultrafine particle concentrations in these areas, nor are respiratory and cardiovascular effects. Currently, the Environmental Protection Agency does not monitor ultrafine particle concentrations in these areas, nor are respiratory and cardiovascular effects. Currently, the Environmental Protection Agency does not monitor ultrafine particle concentrations in these areas, nor are respiratory and cardiovascular effects. Currently, the Environmental Protection Agency does not monitor ultrafine particle concentrations in these areas, nor are respiratory and cardiovascular effects.

**1562 Comparison of Airborne Exposures from Diesel and Biodiesel Emissions**

Introduction: Biodiesel mixtures are being used in the mining industry as an alternative to diesel to meet emission standards set by the Mining Safety and Health Administration (MSHA). This study compares the airborne exposures of diesel and biodiesel-blend emissions in an underground mine.

Methods: Twenty-two non-smoking subjects were exposed to emissions from diesel fuel and, separately, a biodiesel-blend (75% biodiesel, 25% diesel) while operating a load-haul-dump (LHD) vehicle in an underground mine. Personal samples were collected for total diesel particulate matter (DPM), respirable DPM, respirable dust, formaldehyde, acetaldehyde, naphthalene, nitric oxide (NO), and nitrogen dioxide (NO2) and analyzed according to National Institute for Occupational Safety and Health (NIOSH) methods.

Results: The average sampling time was 203 ±18.7 minutes. Mean respirable DPM (309 ±134 and 207 ±111 ug/m3, p=0.006), acetaldehyde (0.044 ±0.04 and 0.029 ±0.01 ppm, p=0.021), and naphthalene (0.0013 ±0.0007 and 0.0006 ±0.0003 ppm, p=0.002) time-weighted average (TWA) exposure concentrations were greater for diesel fuel than the biodiesel-blend, while total DPM (539 ±209 and 753 ±243 ug/m3, p=0.014) and respirable dust (0.60 ±0.38 and 0.86 ±0.29 mg/m3, p=0.035) TWA concentrations were less for diesel compared to the biodiesel-blend. There was no observed difference in TWA concentrations for formaldehyde (0.136 ±0.129 and 0.09 ±0.022, p=0.114), NO (10.9 ±4.2 and 12.0 ±4.8, p=0.259), or NO2 (1.33 ±0.66 and 1.26 ±0.61, p=0.049) between the diesel and biodiesel-blend.

Discussion: Our study demonstrates that use of biodiesel blends may reduce exposures to respirable DPM, acetaldehyde, and naphthalene.

**1563 Comparison of Acute Human Health Effects from Diesel and Biodiesel Emissions**

Human and animal studies suggest that diesel exhaust (DE) not only impairs vascular and pulmonary function, but is a probable carcinogen. Within the mining industry, there has been a shift toward replacing diesel with a diesel/biodiesel mixture, despite what little is known about the acute health effects of biodiesel exhaust (BE) inhalation. Using a cross-over study design, 22 participants were exposed to DE and BE (the latter from a 25% diesel/75% biodiesel mixture) in an underground mine. Pre- and post-exposure flow mediated dilation (FMD) of the brachial artery, exhaled carbon monoxide (CO), exhaled nitric oxide (NO), and spirometry (forced expiratory volume in one second, FEV1) were evaluated. DE and BE exposure periods were separated by approximately 3 months for each participant. The changes in baseline and peak FMD readings pre- and post-exposure to diesel were not significantly different than those measured for biodiesel. There was a statistically significant increase in post-exposure exhaled CO measurements for both fuel types tested and in post-exposure exhaled NO measurements for DE only; however, these changes were not different between the two fuel types. There was a statistically significant decrease from the baseline FEV1 value of 4.22L to post-exposure values for both DE and BE exhaust (3.98L, p=0.0001; 4.13L, p=0.0461, respectively), as well as a difference between the two fuel types (p=0.022), with a greater decrease in FEV1 in participants exposed to DE. These findings indicate that inhalation of both DE and BE result in acute health effects. There were no differences in the changes in biomarkers between the two fuel types, except in the case of FEV1. Based on these limited data, switching from diesel to biodiesel resulted in only a small improvement in acute health effects.

**1564 Airborne Impacts of the Richmond, California, Chevron Refinery Fire: A Case Study Showing the Difficulty of Correlating Real-Time Data, Exposure Assessment, and Public Health Impacts**

S. B. DoTrean, Office of Emergency Response, California Air Resources Board, Sacramento, CA.

Shortly after 6:30 p.m. on August 6, 2012, hazardous materials responders and firefighters were called to a fire at the Chevron Refinery in Richmond, California. A shelter-in-place order was quickly issued for surrounding communities warning residents to stay inside and reduce exposure to the smoke. During the fire, Chevron personnel took 17 direct readings of air contaminants on the refinery property as well as 19 air grab samples downwind from the fire. All readings were either below the limit of detection and/or below the Reference Exposure Levels (RELS) established by the Office of Environmental Health Hazard Assessment (OEHHAA) for sulfur compounds and hydrocarbons. Local environmental health and air quality agencies collected additional air grab samples in neighborhoods downwind from the fire. The samples were analyzed for toxic air contaminants with the results showing the presence of approximately 20 volatile chemicals. Concentrations were above typical background levels but below levels associated with adverse health effects. The exception was one sample that contained 7.41 g/m3 acrolein, well above the OEHHAA acute REL of 0.25 mg/m3. Concentrations of particulate matter from the smoke were below state and federal air quality standards, although marginally higher when compared to seasonally adjusted concentrations. With the exception of acrolein, no toxic air contaminants were detected at levels associated with adverse health effects and real-time matter levels were near normal. Even so, on the day of the fire over 360 patients were seen in area emergency departments and one adult and two children were hospitalized. In the ensuing weeks, over 15,000 individuals sought medical care mostly for minor nose, throat, or eye irritation or respiratory effects. This incident underscores the difficulty of conducting an exposure assessment for short-term releases as well as the challenge of aligning real-time concentration data with reported public health impacts.
1565 Health Surveillance Study on Printed Electronics (PE) Workplace

J. Lee1, E. Sohn1, J. Ahn1, K. Ahn1, K. Kim1, T. Lee4, J. Shin3, Y. Chung1 and I. Yu1. 1Institute of Nanoproduct Safety Research, Hose University, Asan, Republic of Korea, 2Department of Mechanical Engineering, Hanyang University, Ansan, Republic of Korea, 3Korea Institute of Machinery and Materials, Daejeon, Republic of Korea, and 4Occupational Lung Diseases Institute, KCOMWEL, Ansan, Republic of Korea.

PE using converging technologies, such as printing, fine mechanics, nanotechnology, electronics, and other new technologies raise additional health and safety concerns to those experienced in the traditional printing industry. We have conducted a health surveillance study in a PE workplace based on a walk-through survey and personal and area sampling, and collection of blood and urine samples. There was no indication of exposure to excess silver nanoparticles or carbon nanotubes. Exposure to organic solvents was lower than current occupational exposure limits in terms of TWA, yet there were some organic solvent exposure exceeding current OELs during short work duration. Lack of engineering controls, such as local exhaust ventilation, correct enclosure, and duct connection were found in the walk-through survey. Most workers showed normal range of blood biochemistry and hematology values except one worker who was advised to be checked by physician immediately. Some workers showed exceed levels of BEIs including carboxyhemoglobin (marker for methylene chloride exposure) and acetone (marker for isopropyl alcohol). The levels for hippuric acid and methyl hippuric were within normal ranges, indicating low exposure to toluene and xylene. Few office workers were exposed to low concentrations of methylene chloride, which was under investigation to find cause. Cleaning work, a major emission operation, was not conducted within a hood, and waste from the cleaning work was not properly disposed of. Therefore, the present health surveillance study on PE results suggested that the PE industry should take care of organic solvent exposure to protect workers from occupational safety and health risks. If PE process was in full scale with full shift operation to find cause. Cleaning work, a major emission operation, was not conducted within a hood, and waste from the cleaning work was not properly disposed of.

1566 Microcystin Extraction from Human Blood Serum: Pitfalls and Solutions

A. Heussner1, D. R. Dietrich1, S. Altraner1, L. Kamp2 and F. Rubio2. 1Human & Environmental Toxotoxicology, University of Konstanz, Konstanz, Germany and 2Abraxis, Warminster, PA.

Microcystins (MCs) contaminate water bodies due to cyanobacterial blooms all over the world leading to a public risk of intoxication by exposure to contaminated water, food (e.g. fish) or algal food supplements. In order to enable monitoring of human exposure, sensitive screening methods are needed. ELISA has been demonstrated as a robust routine tool for MC quantification in environmental samples. However, some problems regularly occur during sample preparation leading to MC loss and therefore underestimation of the true concentration. The aim of the current study was to assess the pitfalls of the MC-extraction method from complex media with more detail.

For this, MCs (MC-LR, MC-YR, MC-LA, MC-LW, MC-LF and defined MC mixtures: 1-1000 µg/L) were spiked into human blood serum as a surrogate for very complex sample media and quantified using the commercially available Adda-ELISA (Abraxis, Warminster, PA, USA) after standard extraction (methanol extraction with subsequent SPE). To detect the potential influence of sample storage and preparation materials different types of material such as glass, standard polypropylene and surface-treated polypropylene were compared. Loss of MC during preparation and storage is largely dependent on (i) the handling of the stored material, (ii) the ‘surface’ of the storage material and (iii) the hydrophobicity of the MCs.

1567 Vegetable Uptake and Human Exposure Assessment from a Community Garden with Elevated ∑DDT

F. N. Liberta1 and L. J. Tuuij2. 1School of Occupational and Public Health, Ryerson University, Toronto, ON, Canada and 2Environment and Resource Studies/Health Studies, University of Waterloo, Waterloo, ON, Canada.

Introduction

Two agroforestry gardens and an open garden were prepared to grow vegetables in a remote Canadian First Nation community. Soil was sampled at the beginning of the project while, at the end of the season potatoes and beans were collected and matched to the previous soil plots. Contaminant analysis consisted of a suite of organochlorines including DDT/DDE/DDD (2,4-DDT, 4,4-DDT, 2,4-DDE, 4,4-DDE, 2,4-DDD, 4,4-DDD) and a suite of metals. Based on our ∑DDT findings, we performed an exposure assessment associated with ingestion of contaminated vegetables.

Methods

Soil samples were taken randomly in each of the three plots (Plot A and B were the agroforestry sites, while Plot C was the open site), and vegetable samples were later matched to the soil samples. Soil samples were taken to the depth of the rooting zone. All samples were sent directly to Queen’s University, Analytical Services Unit, for organochlorine analysis via GC-MS and metal analysis via ICP-OES. Exposure assessment was based on the analytical results and standard Canadian food consumption data set by Health Canada.

Conclusion and Discussion

Exposure analyses associated with the ingestion of vegetables from Plot A, the elevated ∑DDT site, were orders of magnitude less than the regulatory guidelines (e.g., acceptable daily intake [ADI] or reference dose [RfD]). Soil levels of ∑DDT were found to exceed Canadian regulatory guidelines of 0.7 mg/kg for agricultural or residential/parkland use only in Plot A. Contaminated soil from Plot A was correlated with vegetable tissue concentrations. While human exposure to the contaminated vegetables through ingestion may not pose a health risk, the contaminated soil did exceed regulatory guidelines. Thus, produce from Plot A was not distributed to residents and use of the site was discontinued.

1568 Population Variation in Biomonitoring Data for Persistent Analytes: An Examination of Multiple Population-Based Datasets

L. Aelward1 and J. Mueller1. 1Summit Toxicology, LLP, Falls Church, VA and 2ENTOX, University of Queensland, Brisbane, QLD, Australia.

National biomonitoring efforts designed to characterize the levels and distribution of pollutants in populations have typically relied upon a resource-intensive sampling strategy and analysis of hundreds or thousands of individual biological samples. In Australia, a series of studies relying on pooled sample approaches, a less resource-intensive approach, has been employed to characterize central tendencies of concentrations of selected persistent analytes, but this approach does not provide estimates of typical upper bound concentrations. This analysis assesses the feasibility of an empirical approach to estimating population upper bound reference values based on the examination of population variation from available biomonitoring datasets from the US, Canada, Germany, and the Catalan region of Spain, with the results tested against data from the Flemish population of Belgium. Arithmetic mean concentrations and the ratio of the 95th percentile to the mean (P95:mean) were assessed in each study for defined age subgroups for three polychlorinated biphenyls (PCBs 138, 153, and 180), hexachlorobenzene (HCB), and p,p'-dichlorodiphenylchloroethylene (DDDE). While arithmetic mean concentrations of each analyte varied widely across surveys, the P95:mean ratios were consistently less than one across surveys for each analyte, with no clear variation across age groups. The results are consistent with generally lognormal distributions of analyte concentrations in the populations studied, with similar geometric standard deviations across surveys, even when the population means were significantly different. The central tendency estimate of P95:mean was approximately 2.2 for the three PCBs and HCB and 3.0 for DDE, and the approach accurately predicted the 95th percentiles in the Flemish dataset. These results can be used in combination with the Australian pooled sampling results to estimate upper bound reference values for use in evaluating individual biomonitoring data for the included analytes.

1569 Serum Steatohepatitis Biomarker and Proinflammatory Cytokine Elevation in Response to Polychlorinated Biphenyl Exposures in the Anniston Community Health Study (ACHS)

H. Clair1, K. C. Falkner2, B. A. Prough2 and M. Cave1,3. 1Department of Medicine/GI, University of Louisville, Louisville, KY, 2Biochemistry, University of Louisville, Louisville, KY and 3Robley Rex VAMC, Louisville, KY.

Monsanto Corporation previously operated a PCB production facility in Anniston, Alabama, and high-level environmental polychlorinated biphenyl (PCB) contamination is present there. In order to study the health effects of PCBs, a residential adult cohort (Anniston Community Health Study – ACHS) was previously assembled. Hypertension and diabetes were linked to PCB exposures in the ACHS. Nonalcoholic steatohepatitis (NASH) has previously been associated with PCB exposures in the National Health and Nutrition Examination Survey (NHANES). The objective of this study is to determine whether NASH biomarker and adipocytokine abnormalities are present in the ACHS cohort. Archived fasting serum samples were obtained from ACHS (n=625), an unexposed healthy control group (HC, negative controls, n=11), and unexposed subjects with biopsy-proven steatohepatitis related to obesity (NASH, positive controls, n=34). Cytokinin 18
(CK18) M30 and M65 (hepatocellular apoptosis and necrosis biomarkers) and adiponectin were measured. Group means were compared by ANOVA with significance set at p<0.05. CK18 M65 was increased in ACHS vs. HC, while CK18 M30 was decreased. Both CK18 M65 and M30 were decreased in ACHS vs. NASH. IL-8 and IL-6 were increased in ACHS vs. HC and NASH. Both HC and NASH IL-8 were increased to the greatest extent in ACHS (52 fold vs. HC). TNFα was increased in ACHS vs. NASH. Compared to HC, adiponectin was decreased and leptin increased to similar degrees in both ACHS and NASH. Insulin was increased in NASH vs. both ACHS and HC. Steatohepatitis biomarkers were abnormal in ACHS. Some differences existed between ACHS and unexposed subjects with NASH apparently related to obesity. Liver injury in ACHS was characterized by necrosis with high-level elevation of IL-8. These data further implicate PCB exposures in steatohepatitis and systemic inflammation.

1570  Quantification of Tissue Bisphenol A and Global Methylation Profiles in Kidney, Liver, and Placenta from 1st and 2nd Trimester Human Clinical Samples

M. S. Nahar1, C. Liao2, K. Kannan3 and D. Dolinoy1. "Environmental Health Science, University of Michigan, Ann Arbor, MI and 2Wadsworth Center, New York State Department of Health, Albany, NY.

The ubiquitous monomer, bisphenol A (BPA), is an endocrine active compound used in a variety of consumer products. BPA has been associated with adverse health outcomes ranging from reproductive dysfunction to chronic diseases. Studies suggest that BPA operates by altering DNA methylation or other epigenetic markers, especially during critical windows of development. Characterization of BPA levels and epigenetic profiles across multiple tissues are currently limited to animal models or no data at all. Herein, we report tissue concentrations of BPA and global DNA methylation levels in healthy 1st and 2nd trimester human kidney, liver, and placental specimens (matched N=12 per tissue) obtained from the University of Washington Laboratory of Developmental Biology. Total BPA concentrations, measured using liquid chromatography tandem mass spectrometry, significantly differed across matched specimens (p-value: 0.002) with geometric means at 0.81, 9.19, and 1.62 ng/g for kidney, liver, and placenta, respectively. When global methylation was quantified at long interspersed retrotransposons (LINE1) repetitive elements using pyrosequencing and at CCGG sites across the genome using the Luminometric Methylation Assay (LUMA), methylation significantly differed across kidney, liver, and placenta (p-values <0.001). Average LUMA methylation was 77.9% in kidney, 79.5% in liver, and 58.3% in placenta, while average LUMA methylation across kidney, liver, and placenta (p-values <0.001). Average LINE1 methylation was 76.9% in kidney, 66.4% in liver, and 51.9% in placenta. No significant association was observed between total BPA and global methylation in fetal kidney or liver. However, there was a 0.23% increase in LINE1 methylation with 1 ng/g increase in total BPA in placenta (p-value: 0.002). Results suggest that BPA concentrations and methylation profiles are tissue specific in early life, and characterizing these differences will be important for exposure and risk assessment.

1571  Biochemical Parameters and Fluoride Levels in Serum and Urine of Livestock Animals Accidentally Exposed to Hydrofluoric Acid

This study aimed to evaluate the exposure of hydrofluoric acid and health status in cattle and other livestock animals raised near hydrofluoric acid accident place by determining the level of fluoride ion and biochemical parameters in urine and serum. Cattle (n=111), goats (n=25) and chickens (n=5) raised near the accident place were selected. Urine or blood serum samples were taken from 10-20 % of cattle and other livestock animals raised near hydrofluoric acid accident place by deafence. For uptake/clearance studies, immortalized Par C10 cells (parotid gland origin) grown on a Transwell® insert (3 μm pore) were used to quantify the uptake and clearance of TCPy with cells, and apical concentrations of TCPy were proportional to dose. These in vitro results are consistent with in vivo pharmacokinetic model predictions where the fer from blood to saliva is via passive transcellular diffusion. These experiments have established the feasibility of utilizing an in vitro cell based uptake/clearance assay from blood to saliva is via passive transcellular diffusion. These experiments have established the feasibility of utilizing an in vitro cell based uptake/clearance assay coupled with pharmacokinetic modeling as a novel chemical screening strategy to identify ideal chemical candidates for saliva biomonitoring. This approach will be further evaluated using a broader range of pesticides with varying physical and chemical properties. Once established, this approach can be exploited for biomonitoring without the need to conduct more challenging in vivo saliva clearance studies. Supported by CDC/NIOHS grant R01 OH008173.

1572  Comparison of the Kinetics of Various Biomarkers of Benzo[a]pyrene Exposure following Different Routes of Entry in Rats

M. Moreau1 and M. Bouchard2, 1Department of Environmental and Occupational Health, University of Montreal, Montreal, QC, Canada and 2Chair in Toxicological Risk Assessment and Management, University of Montreal, Montreal, QC, Canada.

Exposure to benzo[a]pyrene (BaP), a polycyclic aromatic hydrocarbon (PAH) classified as a known carcinogen in humans (IARC), is of great health concern for both workers and the general population. The project aimed at comparing the kinetics of key biomarkers of BaP exposure in rats following different routes of entry. Blood and excretion time courses of BaP and key biomarkers were assessed in rats exposed to a single intravenous, intratracheal, oral and cutaneous dose of 40μmol/kg BaP. BaP and several metabolites (3- and 7-OH-BaP, 4,5- and 7,8-diol-BaP, testosterone, 1,6 Δ, 3- and 7,8-dione-BaP) were measured in blood, urine and feces collected at frequent intervals over 72 h post-treatment, using HPLC/fluorescence. Only 3-OH-BaP was detectable in blood at all time points. In urine, total amounts of BaP metabolites peaked 24 h (p<0.001) after treatment, 4,5-diol-BaP≥7-OHBaP≥7,8-diolBaP following intravenous injection and intratracheal instillation, 3-OHBaP≥7-OHBaP≥4,5-diolBaP≥7,8-diolBaP after cutaneous application and 3-OH-BaP≥4,5-diolBaP≥7-OHBaP≥7,8-diolBaP following oral administration. In feces, total amounts of BaP metabolites recovered over the same period were: 7-OHBaP≥3-OHBaP≥4,5-diolBaP≥7,8-diolBaP following all administration routes. Diones were not detectable using the developed method. For all routes of administration, excretion of 4,5-diol-BaP was almost complete over the 0-24 h in contrast with 3- and 7-OH-BaP. After intravenous injection, intratracheal instillation and oral treatment, peak excretion of 3- and 7-OH-BaP was reached in the 0-24 h period but only after 48 h post-treatment following cutaneous application. This study confirms the interest of measuring multiple metabolites due to the route-to-route differences in relative excretion of the different biomarkers and in time courses of diolep BaP versus OH-BaP. Concentration ratio of the different metabolites may help indicate time and main route of exposure.

1573  A Cellular Model to Evaluate Salivary Gland Uptake and Clearance of Pesticides: A Novel Non-Invasive Biomonitoring Strategy

C. Tischalk, J. N. Smith and T. L. Weber. Systems Toxicology, Pacific Northwest National Laboratory, Richland, WA.

The use of saliva as a biomonitoring matrix has potential to significantly advance quantitative dosimetry as an integral component within epidemiology studies. A major limitation for saliva biomonitoring has been an inability to identify which chemicals are readily cleared in saliva, at levels that can be detected analytically. To address this limitation, immortalized Par C10 cells (parotid gland origin) grown on a Transwell® insert (3 μm pore) were used to quantify the uptake and clearance of trichloropyridinol (TCPy) the metabolite of the insecticide chlorpyrifos. Cells seeded on Transwell inserts were maintained until 7-days post-confluence at which time they displayed expression of parotid acinar cell proteins and localization of tight junction proteins at points of cell-cell contact. For uptake/clearance studies a range of TCPy concentrations (0.2-10 μg/mL) were evaluated. TCPy was added to the basolateral chamber (lower chamber) and sampled from the apical chamber (upper chamber) longitudinally for 4 hours. In the absence of cells, TCPy rapidly diffused across the transwell; whereas, the transport rate was substantially reduced with cells, and apical concentrations of TCPy were proportional to dose. These in vitro results are consistent with in vivo pharmacokinetic model predictions where TCPy salivary gland clearance is described with a 1-compartment model and transfer from blood to saliva is via passive transcellular diffusion. These experiments have established the feasibility of utilizing an in vitro cell based uptake/clearance assay coupled with pharmacokinetic modeling as a novel chemical screening strategy to identify ideal chemical candidates for saliva biomonitoring. This approach will be further evaluated using a broader range of pesticides with varying physical and chemical properties. Once established, this approach can be exploited for biomonitoring without the need to conduct more challenging in vivo saliva clearance studies. Supported by CDC/NIOHS grant R01 OH008173.
1574 Concentrations of Diacetyl and 2, 3-Pentanedione in Mainstream Cigarette Smoke: A Comparison to Workplace Exposures

J.S. Pierce1, A. Abelmann1, L. J. Spicer1, R. Adams2 and B. L. Finley1. Cardno ChemRisk, Chicago, IL and 2Cardno ChemRisk, Brooklyn, NY.

Diacetyl and 2,3-pentanedione inhalation have been suggested as causes of severe respiratory disease, including bronchiolitis obliterans, in food/flavoring manufacturing workers. Both compounds are present in many food items, tobacco, and other consumer products, but estimates of exposures associated with the use of these goods are scant.

A study was conducted to characterize exposures to diacetyl and 2,3-pentanedi-one associated with cigarette smoking. The yields (ug/cigarette) of diacetyl and 2,3-pentanedi-one in mainstream (MS) cigarette smoke were evaluated for six tobacco products (e.g., both full-flavor and light cigarettes of three different brands) under three smoking regimens (ISO, Massachusetts Department of Public Health, and Health Canada Intense) using a standard smoking machine. The mean diacetyl concentrations in MS smoke ranged from 250-361 ppm for all tobacco products and smoking regimens, and the mean cumulative exposures associated with 1 pack-year ranged from 1.1-1.9 ppm-years. For 2,3-pentanedi-one, the mean concentrations in MS smoke ranged from 32.2-50.1 ppm, and the mean cumulative exposures associated with 1 pack-year ranged from 0.14-0.26 ppm-years. We found that diacetyl and 2,3-pentanedi-one exposures from cigarette smoking far exceed occupational diacetyl exposures for most food/flavoring workers who smoke. This suggests that previous claims of a significant exposure-response relationship between diacetyl inhalation and respiratory disease in food/flavoring workers were confounded, because none of the investigations accounted for non-occupational diacetyl exposure, yet all of the cohorts evaluated had considerable smoking histories. Further, because smoking has not been shown to be a risk factor for bronchiolitis obliterans, our findings suggest that diacetyl and/or 2,3-pentanedi-one exposure is not a risk factor for this disease.

1575 Headspace and Small-Chamber Studies of Airborne Diacetyl Concentrations Associated with Selected Food Flavoring Mixtures

The accuracy and consistency of airborne diacetyl measurements can be significantly affected by a number of environmental and analytical factors that may increase variability of field measurements. Accordingly, airborne emissions modeling may augment field measurements in evaluating probable exposures to workers and others in a wide variety of settings where this common buttery food flavoring component may be found. We conducted a series of laboratory studies of emissions from pure diacetyl and spiked mixtures of selected vehicles used for adding flavorings to foods. The test materials included diacetyl (99% purity), 0.015 to 1.5% diacetyl in a water/propanol/propylene glycol mixture, deionized water, or soybean oil, and 3% diacetyl in a commercial steam distillate of milk fermentation known as ‘butter starter distillate’. Diacetyl was quantified after direct injection via gas chromatography with flame ionization detection. Measured headspace concentrations were compared to estimated concentrations utilizing Raoul’s law with and without UNIFAC activity coefficient corrections for each mixture. Headspace measurements averaged 60 to 90% higher than the ideal (Raoult’s law) estimated values and the activity coefficient-adjusted estimates were 17 to 20% higher but within analytical error for the aqueous mixtures. At 1.5% diacetyl content, the magnitude of emissions from greatest to least was: steam distillate > water > water/propanol > propylene glycol > soybean oil. Furthermore, small chamber studies (ASTM D-5116) at 4 air changes per hour were compared to estimated values using a surface spillover model; measured and modeled values were within 20% after incorporating the activity coefficient adjustments. We conclude that headspace (static) and small chamber (dynamic) measurements of airborne diacetyl are consistent with model-estimated concentrations after mixture-specific adjustment for activity coefficients.

1576 Determination of Illicit Drug on the Hands of High-Volume Money Collectors Using LC-MS/MS

A. I. Hinds. Toxicology, Colorado State University, Fort Collins, CO.

Illicit drug use in the United States has been steadily increasing over the years. Contact transfer of illicit drugs from currency to the hands of individuals during the acts of drug trafficking has been seen in many countries worldwide. While this contamination of currency has been highly examined, the downstream transfer of illicit drug in occupational exposure has not been explored. This study examines whether high volume money collectors accumulate illicit drugs via contact transfer from the natural parameters of their occupation. Utilizing LC-MS/MS, ten hand samples from bank tellers were evaluated for content of cocaine, methamphetamine and oxycodone and other drugs. Samples were obtained from both hands of 5 individuals; four individuals work in a high volume money handling position. The fifth sample was a baseline comparison from an individual with no known background in this occupation. Cocaine was detected in ranges of 35ng-450ng. Oxycodone and methamphetamine were detected in lower levels of 2ng-7ng. The quantifiable presence of cocaine, oxycodone and methamphetamine illustrates the ability of crystal- and tablet-form drugs to affix in the fabric matrix of currency and transfer to skin via contact transfer under normal occupational parameters. These results further indicate that illicit drugs have the ability to transfer from currency to hands of high volume money collectors in detectable amounts. To our knowledge, this is the first research to demonstrate this occupational exposure and illustrates the need for more expansive investigation into this unique route of occupational exposure to illicit drug.

1577 Development of a Targeted LC/MS Approach to Screen for 182 Pesticides in Urine Samples

A. Somers1, T. Senn2, D. Whittington3, M. Vredelings4, E. M. Vrijen4, E. M. Faustman1, and Y. Lin5. 1Life Sciences, Salish Kootenai College, Pablo, MT, 2Pharmaceutics, University of Washington, Seattle, WA, 3Medicinal Chemistry, University of Washington, Seattle, WA and 4Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

Pesticides are used all over the world and are found in many environments such as farmlands, agriculture facilities and residences. Many methods have been developed to detect specific pesticide residues in food and water. Exposure to high levels of pesticides can be harmful to agricultural workers and their families. Our goal on these studies was to develop a urinary screening method to determine whether individuals might be exposed to pesticides. We used mixtures of pesticide standards to develop a liquid chromatography tandem mass spectrometry method. A semi-quantitative curve was created by diluting the standard pesticide solutions. Urine samples were prepared by the addition of acetonitrile to precipitate proteins, and the supernatant was removed, evaporated and reconstituted for analysis. Standards and samples were analyzed using a Waters Xevo TQD UPLC-MS/MS. We monitored 182 pesticides using this method and screened 108 urine samples from adults and children. We found various pesticides present in the urine samples with the lower limits of detection ranging from 0.1 to 10 ng/mL. Examples include, but are not limited to, carbendazim, imidacloprid, isoxaben, methathifos, and quinalphos. Using this method, we can screen for pesticide exposure in urine samples from both adults and children. This screening technique will inform adaptive monitoring programs in which pesticides targeted are studied using specific and sensitive assays for more quantitative measurements of exposure.

1578 NMR Analysis of the Antibiotic “Amoxicillin” in Urine

The aminopenicillin, Amoxicillin, is used in many treatments against bacterial infections such as pneumonia, ulcers and urinary tract infections. However, when it is used incorrectly in combination with other drugs undesirable side effects can occur. Therefore, it is crucial to develop a method to accurately detect and quantify Amoxicillin in human biofluids. This research focuses on using 1H NMR spectroscopy for the analysis of Amoxicillin in urine samples. NMR spectroscopy is a powerful tool to analyze chemical structures. In addition, if a water suppression technique is used, direct analysis of aqueous based samples such as urine is possible without the need for separation and/or derivatization steps. We present here initial results regarding the direct analysis of amoxicillin in urine using 1H NMR and a new water suppression technique PURGE (Presaturation Utilizing Relaxation Gradients and Echoes). We found that at small concentration, an extraction method of Amoxicillin from urine is necessary as some signals from the matrix interfere with those of Amoxicillin. We therefore also present a solid phase extraction method to isolate amoxicillin in urine samples at low concentrations before NMR analysis.
Active-sampling approaches are commonly used for personal monitoring, but are limited by energy usage and data that may not represent bioavailable concentrations. Current passive techniques are popular, but often involve extensive preparation, or are developed for only a small number of targeted compounds. In this work, we present a novel application for measuring environmental, bioavailable exposure with silicone wristbands as personal passive samplers. Laboratory methodology affecting pre-cleaning, infusion, and extraction were developed using commercially available silicone, and chromatographic background interference was reduced after solvent cleaning with good extraction efficiency (>96%). After finalizing laboratory methods, 49 compounds were sequestered during an ambient deployment which encompassed a diverse set of compounds including polycyclic aromatic hydrocarbons (PAHs), consumer products, personal care products, pesticides, phthalates, and other industrial compounds ranging in log Kow from -0.07 (caffeine) to 9.49 (tris(2-ethylhexyl) phosphate). In two hot asphalt occupational settings, silicone passive samplers sequestered 25 PAHs during 8- and 40-hour exposures, as well as 2 oxygenated-PAHs (benzofluorenone and fluorenone) suggesting sensitivity of the passive samplers sequestered 25 PAHs during 8- and 40-hour exposures, as well as 2 oxygenated-PAHs (benzofluorenone and fluorenone) suggesting sensitivity of the devices over a single work day or week (p<0.05, power = 0.85). Additionally, the amount of PAH sequestered differed between worksites (p<0.05, power = 0.99), suggesting evidence of spatial sensitivity and diverse applications.

Probabilistic Modeling of Baby Wipe Lotion Exposure

Reliable exposure data are essential in evaluating the safety of ingredients in any consumer product. Appropriate exposure assessment is particularly important for products targeted for children because children differ from adults in basic behavior patterns or product use pattern. The purpose of this study was to estimate the amount of lotion transferred from baby wipes to the babies’ skin (mg/kg bw/ day) using a probabilistic modeling approach. Three different variables, number of wipes used per day, body weight, and lotion transferred from baby wipes to baby skin, were combined to establish a distribution of lotion transfer values across the studied diaper wearing population. Habits and practice data on wipes usage from both the US and Germany were included. Gender, age, and weight were evaluated for their influence on the transfer. The data were analyzed using a probabilistic Monte Carlo simulation and a statistical population model of exposure was constructed to calculate total daily lotion transfer. The estimated 50th, 90th, and 95th percentiles of lotion transferred were predicted by the model against the child’s age in months and percentiles of weight per day. Overall, the model indicates that exposure (mg/kg/day) declines in association with use of fewer wipes per day, as the child gets older. The average daily lotion transfer for a diapering period of 0-36 months ranged between 160 – 180 mg/kg/day (50th percentile) and 330 – 340 mg/kg/day (95th percentile) for US and Germany populations. This poster will provide a breakdown of age and gender specific value for lotion exposure. This model can be used for future assessments of exposure to baby wipe ingredient.

Air Pollution Exposure Model for Individuals (EMI) in Health Studies: Predicting Spatiotemporal Variability of Residential Air Exchange Rates

In health studies, traffic-related air pollution is associated with adverse respiratory effects. Due to cost and participant burden of personal measurements, health studies often estimate exposures using local ambient air monitors. Since outdoor levels do not necessarily reflect personal exposures, we developed the Exposure Model for Individuals (EMI) in health studies. A critical aspect of EMI is estimation of the air exchange rate (AER) for individual homes where people spend most of their time. The AER, which is the airflow into and out of buildings, can substantially impact indoor air pollutant concentrations and resulting occupant exposures. Our goal was to evaluate and apply an AER model to predict residential AER for the Near-Road Exposures and Effects of Urban Air Pollutants Study (NEXUS), which is examining traffic-related air pollution exposures and respiratory effects in asthmatic children living near major roads in Detroit, Michigan. We developed an AER model to predict AER from building characteristics related to air leakage; local airport temperatures and wind speeds; and open windows. Cross validation was used with a subset of NEXUS homes (N=24) with daily AER measured on five consecutive days during fall 2010 and spring 2011. Individual predicted and measured AER closely matched with median absolute differences of 36% and 24% for the fall and spring, respectively. The model was then applied to predict hourly AER for all NEXUS homes (N=121) during the study (Sept. 2010 - Dec. 2012). The AER predictions show (1) substantial house-to-house (spatial) variations (0.1 - 2.0 h⁻¹) from low to high leakage differences; (2) slow oscillations from seasonal temperature changes; and (3) large transients from wind speed fluctuations. This study demonstrates the ability to predict spatiotemporal variability of residential AER in support of improving health study exposure assessments.

Comparative Toxicity of Epicatechin vs. Borohydride-Reduced Nanosilver in Prokaryotic and Eukaryotic Models

Nanosilver is increasingly finding use as an antibacterial agent in consumer goods and water purification in developing countries. Despite claims that it has no harmful effects on eukaryotes, toxicity tests in vitro and in vivo suggest otherwise. Powerful reducants used in traditional nanosilver synthesis may contribute to its toxicity. To test this hypothesis, we utilized epicatechin reduced AgNPs and compared their in vivo and in vitro toxicity to sodium borohydride reduced AgNPs. We also examined the antimicrobial activity of the two kinds of AgNPs using gram positive and gram negative microbial experimental systems. Both epicatechin (12nm) and sodium borohydride synthesized nanosilver (10nm) were effective antibacterial agents against Pseudomonas aeruginosa (Gram negative) and Staphylococcus aureus (Gram positive), however sodium borohydride reduced AgNPs were more effective. Conversely, only traditionally synthesized AgNPs were toxic to eukaryotic organisms. HcLA cell culture experiments resulted in a LC50 of 113.56 μg/mL and Drosophila melanogaster ingestion experiments showed a LC50 of 26.14 μg/mL. Doses of epicatechin nanosilver up to 200μg/mL showed no toxicity in either eukaryotic model. Of great interest was the more sensitive effect of traditional AgNP on a whole organism compared to our in vitro system. Although the epicatechin
Absorption of Cosmetic Ingredients

This project is a post-market re-evaluation, initiated by the Office of Food Additive Safety (OFAS) to ensure that current exposures are accurately captured and the safety assessment considers all relevant toxicological information available since the time of premarket approval. The trigger for the postmarket evaluation of Irganox 1076 (stearyl 3,5-di-tert-butyl-4-hydroxyhydrocinnamate, CAS Reg. No. 2082-79-3) was an increase in submissions notifying for the food contact substance (FCS) in calendar year 2012. In order to assess the safety of Irganox 1076 from food contact applications, the US Food and Drug Administration (FDA) reviewed the available chemical information on food contact applications, including the US regulatory status, uses, levels in food, and alternative approaches to calculate exposure. Upon completion of this in-depth market analysis, the cumulative dietary concentration (CDC) was determined to be 1.5 ppm (4.5 mg/p/d). A rigorous evaluation of the available toxicological information was performed, incorporating both the data submitted for the premarket notification and any new toxicology data published subsequently. A 2-year chronic rat feeding assay was selected as the critical study with a no-observed effect level (NOEL) of 64 mg/kg/d. This NOEL and the revised CDC provides a margin of exposure (MOE) of 850, which provides an adequate margin of safety (MOS) and remains protective of human health for the regulated uses.

Safety Assessment of R,S-Equol As a Dietary Supplement for Benign Prostatic Hyperplasia

Equol is a polyphenol, more specifically an isoflavonoid. Polyphenols are common micronutrients in the human diet and have been studied for their role in the prevention of cancer, cardiovascular, and age-related diseases. Several thousand molecules with a polyphenol structure exist in higher plants, and several hundred are found in edible plants. Equol was first discovered in the early 1980s in the urine of humans consuming soy foods (a key metabolite of daidzein). More recently, equol has been reported in fermented soybean foods at relatively high concentrations. Unlike other isoflavonoids (i.e., genistein or daidzein), equol has a chiral carbon; therefore it can occur as R- and S-isomers. R,S-Equol can be prepared by catalytic hydrogenation of daidzein to yield RS-equol > 99 %. Equol is known for its anti-oxidant and anti-andrological activities where both S- and R-equol specifically bind 5α-dihydrotestosterone (DHT) with high affinity, and thereby prevent it from binding the androgen receptor. Equol also binds to estrogen receptor beta & estrogen related receptor gamma that are beneficial for treating benign prostatic hyperplasia (BPH). The available toxicity data on R,S-equol and/or its isomers, combined with the widely disseminated knowledge concerning the normal human metabolism of daidzein to equol and the long history of consumption of equol from food provide a sufficient basis for assessment of the safety of R,S-Equol as a dietary supplement for BPH. Studies include absorption, distribution, metabolism & excretion (ADME)/toxicokinetic results, acute/subchronic toxicity, genotoxicity, reproductive & developmental toxicity findings. Also, clinical intervention results display safety, feasibility and efficacy of R,S-equol (6 mg twice/day) to treat middle-aged men with moderate to severe BPH symptoms. In conclusion, all data support the use of R,S-equol to be safe, well-tolerated and provide rapid beneficial therapy (within days to weeks) for BPH that can be used alone or in combination with current pharmaceuticals to improve prostate health.

Application of QSAR Models to Evaluate the Dermal Absorption of Cosmetic Ingredients

Systemic exposure to cosmetic ingredients is an important factor to take into account during human health safety evaluation of cosmetic products. The information on dermal absorption is critical in order to accurately evaluate the systemic exposure. In vitro methods have been widely applied to determine the dermal absorption of cosmetic ingredients. Also, QSAR models have been proposed and utilized to predict the dermal absorption of chemicals based on their chemical properties. To evaluate the performance of various QSAR models to predict the dermal absorption of cosmetic ingredients, an in vitro dermal absorption study was conducted using a porcine (pig) skin model. Diglycerin is a common humectant used in cosmetic products and was used as a model ingredient in the current study. The dermal absorption profile over a 24-hour exposure period was evaluated and the kinetic data were fitted to various diffusion models and a combined diffusion/binding model. The permeability coefficient (Kp) and lag time (t) were estimated with these models. The Kp value was compared with those predicted from publicly available QSAR models. The maximum flux values (Jmax) were calculated from the Kp values. Based on the Jmax values, 3% dermal absorption (Knes et al., 2007) through the skin per 24 hours ranged from 40% to 80%. The dermal absorption determined from the actual data is generally in agreement with the QSAR model prediction. The current study supports the use of QSAR models to predict dermal absorption for safety assessment of cosmetic ingredients. We suggest that multiple prediction models for dermal absorption should be applied in the absence of experimental data and that the most conservative prediction should be used in systemic exposure assessment of cosmetic ingredients.

An Immune Human Reconstructed Epidermis Model to Assess Baby Personal Care Product Ranges

The personal care market for children is rapidly expanding and increasingly requires a specific approach. Recent publications have re-evaluated the old notion that skin is fully matured at birth and have shown that baby skin differs in structure, function and composition from that of adults. In consequence, these qualitative and quantitative differences may facilitate the development of pathological conditions, such as atopic dermatitis and irritant contact dermatitis. Therefore, the risk assessment of raw materials and finished products for baby cannot be extrapolated from human adult data but must be considered as a new approach with adapted models. In order to respect the morphology and properties of baby skin, especially the stratum corneum, an “immature” human reconstructed epidermis has been developed. It was used, at first, to assess skin irritation for a range of baby products. This new model is derived from a previously in-house developed human reconstructed epidermis model (VitroDerm).

During an internal validation, 67 infant formulations classified into 13 personal care product families (cleansing milk, shower gel, nappy cream, cleansing water, foam bath, limiment, wipes, protective stick, moisturizing milk, sun cream, hydristick, body cream, cold cream) were tested on both mature and immature epidermis. After 20h exposure on the mature model, none of the formulations reduced the percentage of cell viability to below 50% and were therefore classified as potentially non-irritant. However, 10 formulations decreased the cell viability to below 50% on immature epidermis, allowing the identification of potentially irritating formulations. A statistically significant difference (t-test; p<0.05) was found when mature and immature models were compared as a whole. This difference became more relevant when stratified analysis was made between rinse off and leave on products. The improvement in the prediction of irritation with this new model allows a better risk assessment during the development of baby products and can be used as a tool to select the most appropriate ingredients during formulation.

Instant On-Site Glucose Measurements in Dogs

In the pre-clinical studies where blood glucose levels are expected to be affected (e.g. tests of insulin and its analogues), instant on-site glucose measurement in small blood sample provides clear ethical and practical benefits. Methods for direct glucose measurements in whole blood are well established. However, the equipment is normally calibrated only for human use, and its suitability for glucose measurements in e.g. dog blood was therefore evaluated. We performed a study with the objective being to validate One Touch® UltraEasy® glucometer (the glucometer) for direct glucose measurements in dog blood as compared to standard laboratory measurement (Hitachi). Furthermore we evaluated the quality of blood samples collected from different sites (veins in the ear, foreleg or neck). Samples measured using the glucometer were compared to samples analysed using the Hitachi. There was a linear relation between whole blood glucose measurements in a broad range of glucose levels (R2=0.93 for whole blood versus plasma or serum). Glucose levels corresponding to plasma glucose levels down to 3.4 mmol/L, can be measured successfully using the glucometer. Levels below that are outside the limit range, and would require plasma/serum glucose measurements. Site of sample collection did not affect the results. However, ear sampling appeared to be more traumatic for the animals and is therefore not recommended for multiple sampling.
In conclusion, the glucometer can be used successfully for monitoring of glucose status in dogs, resulting in less stress for the animals, faster delivery of results, and economical benefits.

In the past years it has been shown that metabolomics can serve as a powerful tool in toxicological research. BASF’s Experimental Toxicology and metabolomics have developed the MetaMap®Tox database with rat plasma metabolome data for more than 500 reference compounds based on 28 day rat studies (OECD 407 design). Metabolome analysis in plasma was performed after 7, 14 and 28 days and relative levels of endogenous metabolites in treated rats versus controls were analyzed. These data are now routinely used to predict the systemic toxicity of new compounds at BASF. For many chemicals we have seen consistent changes of metabolites over all three time points. The purpose of the research reported here was to investigate for a number of compounds if these metabolic changes would also occur at earlier time points. Therefore, groups of five female and male animals each were treated with four compounds for which time-consistent effects had been previously observed (Vinclozolin, Methimazole, MCPA, Cyclosporin A). Plasma samples were taken on day 3, 5, and 7, the metabolome analyzed and the results compared against the data already present in the database. At day 7 there generally was a good concordance (> 80%) with the previous 28 day studies. The number of metabolites changed in the correct direction, and the strength of the change was reduced at day 5, but overall patterns were still identified. At day 3 metabolites changes diminished further. MCPA produced a clear pattern of metabolite changes at day 3 that was comparable to that of the 28 day study. Furthermore, a time-dependent increase in the strength of the metabolome changes was observed in this study. These results confirm the previously shown reproducibility and robustness of metabolome data and show a potential applicability of metabolomics also in shorter term toxicity studies.

Understanding how substances or particles cross biological barriers is an essential element in toxicological and pharmacological studies. Changes in the integrity of such barriers can be assessed in relevant organotypic models by measuring the TransEpithelial Electrical Resistance (TEER). However it requires full immersion of the cells, making it impossible for model systems, growing at the air-liquid-interface (MuclAir, epithelix) to be analyzed in a representative and realistic way. This is however circumvented by using a new method (AirTEER) which allows electrical contact with the apical (air) side of the organotypic model via an aqueous drop that forms a conductive liquid bridge between the electrodes and the cells in the culture. The addition feature implemented into AirTEER enable continuous, real-time measurements over longer period of time, which circumvent the need for repeated removal of the cultures from the Incubator. The system also allows the simultaneous measurement of up to 16 culture wells at a time. Pilot experiments, applying known toxicants clearly demonstrated a loss in electrical resistance after exposure of MuclAir tissue samples to toxic vapors or single substances applied from the apical side. Additional experiments will be carried out to assess robustness of the system and confirmation of continuous TEER measurements over longer time periods will not harm MuclAir tissues. Taken together, the possibility of real-time measurements using AirTEER would greatly facilitate access to a range of data that are currently not available. Notably, it would allow detecting subtle alterations in membrane integrity of aerosol exposed cells in a realistic fashion and potentially indicate whether or not the observed toxicity is reversible over time.
is that mammalian bioavailability would decrease as molecular weight increased. If this could be demonstrated experimentally, the case for read across would be strengthened, reducing the need for toxicity studies on all of the chemicals. The aim of this study was to determine and rank the absorption potential of a series of alpha-olefins using an in vitro everted rat small intestinal sac model. Everted rat intestinal sacs were prepared by evertting a freshly excised proximal small intestine over a glass stirring rod. The everted intestines were filled with oxygenated Fed State Simulated Intestinal Fluid (FeSSIF, the serosal medium, Galia et al., Pharm. Res. 15, 698, [1998]) and divided into sacs (~2.5 cm) using sutures. Sacs were incubated (1 hr, 37°C) in flasks containing FeSSIF saturated with individual al-pha-olefins. The serosal fluids were extracted with isopropanol and analysed for olefin content using GC-FID. The absorption of 30 olefins with carbon chains of C6 to C27 was investigated. Marked inter-compound differences in absorption were observed, with the degree of absorption decreasing with increasing carbon number. C6 to C10 olefins were well absorbed, while those of C14 and above were either not absorbed or very poorly absorbed. Data such as these could be used to select representative compounds from a series to study further in vivo. This study was funded by the Higher Olefins and Polyalphaolefins Reach Consortium (HOPA), c/o Pennin Consulting bvba, Brussels.

1594  Evaluation of Nose-Only Inhalation Exposure to Aerosolized Benzyl Acetate in Sprague-Dawley Rats

J. Randazzo1, D. T. Kirkpatrick1, D. Vitale1 and M. Singal1, 1Respiratory Science Program, RIFM, Inc., Woodcliff Lake, NJ and 2Inhalation Toxicology, WIL Research, Ashland, OH.

Benzyl acetate is a commonly used fragrance material that has been associated with skin sensitization. The study objective was to understand the effects of inhalation exposure in Sprague-Dawley (SD) rats when aerosolized benzyl acetate was administered by nose-only inhalation at 6.1, 6.14, and 614 mg/m3 (equivalent to 1, 10, and 100 ppm), for 2 weeks (6 hours/day, 5 days/week) for a total of 10 exposures. Standard endpoints evaluated included: clinical observation; body and organ weights; hematology and serum chemistry evaluation; macroscopic/microscopic examination of selected organs; and bronchoalveolar lavage fluid (BALF) analysis for cellular markers of inflammation (i.e., clinical pathology parameters and cytology). As a positive control to validate the utility of various endpoint measures as indicators of pulmonary inflammation, a nose-only inhalation pilot was conducted with 25 mg/m3 amorphous silica (0, 1, 2, 5 or 10 exposures). At all exposure levels, benzyl acetate was well tolerated. A nonadverse test substance-related effect was observed in the nasal cavity at the 790 mg/m3 exposure concentration. Therefore, the no-observed-adverse-effect level (NOAEL) was considered to be 10 ppm (equivalent to 79 mg/m3), the middle exposure concentration tested.

1595  Development of In Vitro Screens for Chemical Disruptors of the Retinol Signaling Pathway

Y. Chen and D. H. Reese. CFSAN/OARSA, U.S. FDA, Laurel, MD.

Retinoic acid (RA), which regulates the expression of hundreds of protein coding and non-coding RNA genes, is essential for normal embryonic development and maintenance of cellular phenotype in adult animals. Intracellular levels of RA are controlled by the retinol signaling pathway (RSP) that regulates RA synthesis (from vitamin A; retinol) and its catabolism. Chemical disruption of the RSP can cause abnormally low or high cellular levels of RA resulting in abnormal embryonic development and adult disease. Our research focus is on the development and ap- plication of in vitro test systems for assessing the safety of chemicals in foods, food additives, dietary supplements, cosmetics and other consumer products. We are particularly interested in identifying chemicals that disrupt essential developmental signaling pathways such as the RSP. We recently described the development of a rapid, medium-throughput, gene-expression (RT-PCR) assay that uses the mouse P19 pluripotent stem cell to detect chemicals that disrupt the RSP. To provide enhanced throughput capability of our screen system, a new reporter assay was developed. A lentiviral vector was used to establish stable clones of the retinol-re- sponsive C3H10T1/2 mouse multipotent stem cell that contain the Luc reporter gene under the control of the retinoic acid response element (RARE). Preliminary tests using this new RARE-Luc cell on several positive compounds demonstrate its ability to detect RSP disruptors. The assay can be optimized to be used in a Tox21 high-throughput screening platform. The RT-PCR-based assays will provide the flexibility of assessing the effect of chemicals using a broader range of endpoints. The advantages of these assays will be discussed. Assays for assessing chemical ef-fects on other important developmental toxicity pathways can also be established using similar methods.

1596  Evaluation of Nose-Only Inhalation Exposure to Aerosolized β-Ionone in Sprague-Dawley Rats

D. T. Kirkpatrick1, J. Randazzo2, D. Vitale1 and M. Singal1, 1Respiratory Science Program, RIFM, Inc., Woodcliff Lake, NJ and 2Inhalation Toxicology, WIL Research, Ashland, OH.

β-Ionone is a commonly used fragrance material that has been associated with skin sensitization. The study objective was to understand the effects of inhalation expo- sure in Sprague-Dawley (SD) rats when aerosolized β-Ionone was administered by nose-only inhalation at 7.9, 79, and 790 mg/m3 (equivalent to 1, 10, and 100 ppm) for 2 weeks (6 hours/day, 5 days/week) for a total of 10 exposures. Standard endpoints evaluated included: clinical observation; body and organ weights; hemato- matology and serum chemistry evaluation; macroscopic/microscopic examination of selected organs; and bronchoalveolar lavage fluid (BALF) analysis for cellular markers of inflammation (i.e., clinical pathology parameters and cytology). As a positive control to validate the utility of various endpoint measures as indicators of pulmonary inflammation, a nose-only inhalation pilot was conducted with 25 mg/m3 amorphous silica (0, 1, 2, 5 or 10 exposures). At all exposure levels, β-Ionone was well tolerated; however, adverse test substance-related effects were observed in the nasal cavity at the 790 mg/m3 exposure concentration. Therefore, the no-observed-adverse-effect level (NOAEL) was considered to be 10 ppm (equivalent to 79 mg/m3), the middle exposure concentration tested.

1597  Evaluation of Nose-Only Inhalation Exposure to Aerosolized Phenyl Ethyl Alcohol in Sprague-Dawley Rats

D. Vitale1, J. Randazzo2, D. T. Kirkpatrick1 and M. Singal1, 1Respiratory Science Program, RIFM, Inc., Woodcliff Lake, NJ and 2Inhalation Toxicology, WIL Research, Ashland, OH.

Phenyl ethyl alcohol is a commonly used fragrance material that has been associated with skin sensitization. The study objective was to understand the effects of inhala- tion exposure in Sprague-Dawley (SD) rats when aerosolized phenyl ethyl alcohol was administered by nose-only inhalation at 0.5, 5, and 50 mg/m3 (equivalent to 0.1, 1, and 10 ppm), for 2 weeks (6 hours/day, 5 days/week) for a total of 10 exposures. Standard endpoints evaluated included: clinical observation; body and organ weights; hematology and serum chemistry evaluation; macroscopic/microscopic examination of selected organs; and bronchoalveolar lavage fluid (BALF) analysis for cellular markers of inflammation (i.e., clinical pathology parameters and cytology). As a positive control to validate the utility of various endpoint measures as indicators of pulmonary inflammation, a nose-only inhalation pilot was conducted with 25 mg/m3 amorphous silica (0, 1, 2, 5 or 10 exposures). At all exposure levels, phenyl ethyl alcohol was well tolerated. However, test substance-re- lated microscopic findings were noted in nasal levels II through VI in the 50 mg/m3 group males, level VI in the 0.5 mg/m3 group males, levels IV and V in all test substance-exposed female groups, and level VI in the 5 and 50 mg/m3 group females, and exhibited increased incidence or severity of luminal secretions consis- tent with mucous hyperplasia. These nasal mucosa changes were more commonly observed and tended to be more severe in the caudal nasal sections (V and VI). In addition, test substance-related mononuclear infiltrates in the liver and histiocytic infiltrates in the lungs were noted in the 50 mg/m3 group females, but were considered nonad- verse. Therefore, the no-observed-adverse-effect level (NOAEL) was considered to be 10 ppm (equivalent to 50 mg/m3), the highest exposure concentration tested.

1598  Evaluation of Nose-Only Inhalation Exposure to Aerosolized Methyl Dihydro Jasmonate in Sprague-Dawley Rats

M. Singal1, J. Randazzo2, D. T. Kirkpatrick2, F. G. Burleson1 and D. Vitale1.

1Respiratory Science Program, RIFM, Inc., Woodcliff Lake, NJ and 2Inhalation Toxicology, WIL Research, Ashland, OH and 3Burleson Research Technologies, Morrisville, NC.

Methyl dihydro jasmonate is a commonly used fragrance material that has been associated with skin sensitization. The study objective was to understand the effects of inhalation exposure in Sprague-Dawley (SD) rats when aerosolized methyl dihydro jasmonate was administered by nose-only inhalation at 0.53, 9.3, and 93 mg/m3 (equivalent to 0.1, 1, and 10 ppm), for 2 weeks (6 hours/day, 5 days/ week) for a total of 10 exposures. Standard endpoints evaluated included: clinical observation; body and organ weights; hematology and serum chemistry evaluation; macroscopic/microscopic examination of selected organs; and bronchoalveolar lavage fluid (BALF) analysis for cellular markers of inflammation (i.e., cytokines). As a positive control to validate the utility of cytokine measures as indicators of pulmonary inflammation, a nose-only inhalation pilot was conducted with 25 mg/m3 amorphous silica (0, 1, 2, 5 or 10 exposures). At all exposure levels, methyl di-
hydro jasmonate was well tolerated with no test substance-related effects observed. Therefore, the no-observed-adverse-effect level (NOAEL) was considered to be 10 ppm (equivalent to 93 mg/m³), the highest exposure concentration tested.

1599 Evaluation of Nose-Only Inhalation Exposure to Aerosolized Hydroxyoctronellal in Sprague-Dawley Rats
E. G. Burleson1, M. Singal1, J. Randazzo2, D. T. Kirkpatrick3 and D. Vitale4.
1Respiratory Science Program, RIFM, Inc., Woodcliff Lake, NJ; 2Inhalation Toxicology, WIL Research, Ashland, OH and 3Burleson Research Technologies, Morrisville, NC.

Hydroxyoctronellal is a commonly used fragrance material that has been associated with skin sensitization. The study objective was to understand the effects of inhalation exposure in Sprague-Dawley (SD) rats when aerosolized hydroxyoctronellal was administered by nose-only inhalation at 0.70, 7.0, and 70 mg/m³ (equivalent to 0.1, 1, and 10 ppm) for 2 weeks (6 hours/day, 5 days/week) for a total of 10 exposures. Standard endpoints evaluated included: clinical observation; body and organ weights; hematology and serum chemistry evaluation; macroscopic/microscopic examination of selected organs; and bronchoalveolar lavage fluid (BALF) analysis for cellular markers of inflammation (i.e., cytokines). As a positive control to validate the utility of cytokine measures as indicators of pulmonary inflammation, a nose-only inhalation pilot was conducted with 25 mg/m³ amorphous silica (0, 1, 2, 5 or 10 exposures). At all exposure levels, hydroxyoctronellal was well tolerated with test substance-related effects limited to non-adverse microscopic findings in the nasal cavity in the 70 mg/m³ females. Therefore, the no-observed-adverse-effect level (NOAEL) was considered to be 10 ppm (equivalent to 70 mg/m³), the highest exposure concentration tested.

1600 Development of an Alternative Photosafety Assessment Approach for Cosmetic Ingredients Based on the Photochemical and Photo-Biochemical Properties
H. Nishida1, M. Hirota1, M. Kitagaki2, S. Onoue2, M. Kato2, G. Suzuki2, S. Yamada2 and H. Kouzuki1.
1Respi Research Center, Shiseido Co. Ltd., Yokohama, Japan and 2Department of Pharmacokinetics and Pharmacodynamics, School of Pharmaceutical Sciences, University of Shizuoka, Shizuoka, Japan. Sponsor: T. Yoshida.

Development of non-animal safety evaluation methods for chemicals is necessary from the viewpoint of animal welfare and to meet the 7th Amendment of the European Cosmetics Directive. The purpose of the present study is to establish a photosafety assessment strategy for cosmetic ingredients using several in vitro assays. The strategy was based on photochemical and photo-biochemical properties of chemicals (51 chemicals including 34 phototoxins), which were investigated by U/VIS spectral analysis, reactive oxygen species (ROS) assay and 3T3 neutral red uptake phototoxicity test (3T3 NRU PT). At first step, molar extinction coefficients (MEC) were calculated by U/VIS spectral analysis to identify photochemical characters. Most phototoxins exhibited potent U/VIS absorption with MEC of over 1000 L mol⁻¹ cm⁻¹ according to the positive criteria of ICH S10 draft guideline while false negative prediction occurred only on two cosmetic ingredients. The ROS assay was applied for further photochemical characterization to lessen the false negative results. The ROS assay did not provide any false negative predictions at least in this study, thus the ROS assay might be useful as photosafety assessment of cosmetic ingredients. In order to justify false positives from two assays, 3T3 NRU PT was conducted. Three chemicals that predicted as false positive in U/VIS spectral analysis or ROS assay were evaluated as negative in 3T3 NRU PT. The tiered approach using these in vitro methods could be a promising non-animal test method for hazard identification of photoactive chemicals.

1601 Evaluation of the Subchronic Toxicity of Acetoxydihydrodicyclopentadiene
V. T. Politano and A. Api, Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ.

The subchronic toxicity of acetoxydihydrodicyclopentadiene, a widely used fragrance ingredient, was investigated in an enhanced OECD 408 dietary 90-day toxicity study. Sprague-Dawley rats were fed dietary concentrations of 0, 200, 2000, 6000 and 20000 ppm acetoxydihydrodicyclopentadiene, equivalent of 0.15, 15.9, 154.9, 464.1 and 1504.6 mg/kg bw/day, respectively, for 90 consecutive days. In addition to the repeated dose endpoints, estrous cycling and sperm analyses were conducted. Statistically significant reductions in body weight gains were detected for males treated with 20000, 6000 and 2000 ppm and in females treated with 20000 ppm. Corresponding reductions in food consumption and efficiency were observed in the 20000 ppm group only. Males treated with 6000 and 20000 ppm showed statistically significant changes in clinical chemistry parameters. Increased kidney weights and reduced prostate and pituitary weights were recorded for all treated males. Males treated with 20000 ppm also had increased liver and adrenal weights. Females treated with 2000 and 6000 ppm had decreased liver weights. The treatment related histopathological findings were recorded only for males in kidneys (hyaline droplet nephropathy and renal tubular degeneration/regeneration), liver (hepatocellular hypertrophy and vacuolation), and adrenals (vacuolation of the zona fasciculata). No toxicologically significant effects were detected in females treated with 6000, 2000 or 200 ppm therefore the NOAEL for females was considered to be 6000 ppm. The kidney effects detected in males from all treatment groups were considered consistent with well documented changes related to alpha-2-agonist accumulation and are peculiar to the male rat in response to treatment with some hydrocarbons. This effect is not indicative of a hazard to human health and, for the purposes of hazard evaluation the NOAEL for males should be regarded as 2000 ppm, or 154.9 mg/kg/day, based on alanine aminotransferase levels. Based on the current total systemic exposure from fragrance use of 0.0008 mg/kg/day, the margin of exposure is greater than 190000.

1602 Optimization of a Primary Hepatocyte Assay for Prediction of Liver Carcinogenicity in Agrochemical Development
J. A. Murphy1, L. Kan1, M. L LeBaron1, D. R. Borgerhoff2, J. Bailey3, C. Terry4, R. Billington2 and R. J. Rasoulpour5.
1The Dow Chemical Company, Midland, MI and 2Dow AgSciences, Indianapolis, IN.

Many chemicals, including agrochemical molecules, may induce rodent liver tumors through non-genotoxic mechanisms, and characterization of the mode-of-action (MoA) can have important implications for human health risk assessments. Prediction of this MoA early in molecule development may facilitate lead optimization of analogues and inform the subsequent integration of MoA endpoints into in vivo regulatory studies. Nuclear receptor (NR) activation (i.e.,aryl hydrocarbon receptor (AhR), constitutive androstane receptor (CAR), pregnane X receptor (PXR), and peroxisome proliferator-activated receptor alpha (PPARα)), can be an initial molecular event for in vivo non-genotoxic rodent liver tumorigenesis. Primary hepatocytes are a relevant system to predict in vivo hepatic NR activation and also have metabolic capacity. To optimize this assay, rat primary hepatocytes were exposed to prototypical NR activators 3-methylcholanthrene (AhR), phenobarbital (CAR), dexamethasone (PXR), or Wyeth-14643 (PPARα) followed by Cyp biomarker gene expression analyses to determine dynamic range and non-specific induction of Cyp responses, and establish criteria for positive NR activation responses. Halauxefin-methyl, a novel herbicide, was also analyzed in this assay to determine correlation of in vitro and in vivo gene expression responses. The in vitro Cyp responses for prototypical NR activators and halauxefin-methyl were consistent with in vivo Cyp induction. Although, variability in hepatocyte preparations can affect the dynamic range for Cyp induction, prototypical NR activators were run concurrently with each hepatocyte lot to define the inducibility of the system. A molecule was deemed positive for NR activation if Cyp gene expression responses were ≥40% of the prototypical NR activator response. This interpretation strategy was applied to assess NR activation potential of several new chemical entities and results indicate correlation between in vitro and in vivo gene expression responses.

1603 Academic and Commercial Partnership: Identifying Sustainable Flame Retardants by Rapid In Vivo Screening
B. L. Tanguay. Environmental and Molecular Toxicology, Oregon State Univ, Corvallis, OR.

Fire prevention often requires the use of fire hardening strategies for combustible materials used in consumer products. Flexible polyurethane foams, widely used as cushioning and/or padding materials, are typical and fire hardening is often achieved with the addition of chemicals that interfere and resist combustion. It is well known that humans can be exposed to various compounds found in these products and there are mounting concerns that some of these chemicals may pose human health risks. Manufacturers are spending considerable effort to identify alternative high performing chemicals that are also inherently safer to use and need a robust and cost effective toxicity screening technique early in the product development process. A major complexity in assessing the potential hazard and risk posed by flame retardants is the diversity of chemical structures; and the chemical structure and toxicity relationships are not yet established for these compounds. We propose that a rapid multi-dimensional whole animal testing platform can be a powerful tool to screen for, and identify chemicals with differential hazard potential. To test this hypothesis, we obtained 9 flame retardant chemicals from ICI Industrial Products for testing in our high throughput zebrafish testing facility. The identity of the compounds was blinded to the laboratory. We performed
Our standard rapid throughput assessment of developmental and neurotoxicity in zebrafish. Broad concentration ranges, and all exposures were initiated at 6 hours post fertilization (hpf) and were continuous until 120 hpf. At 120 hpf, larvae were assessed for photo-induced locomotor activity and changes in a suite of 20 morphological endpoints. Five reactive compounds displayed toxicity only at the highest test concentrations (64μM), one produced toxic effects at concentrations as low as 6.4 μM, and importantly, two of the compounds produced no adverse effects at any test concentration. These data indicate that it may be possible to proactively identify commercially important compounds with reduced hazard potential.

1604 Development of Three-Dimensional Reconstructed Model for Human Skin Irritation and Corrosive Tests

In vitro models to study irritation, corrosivity and phototoxity are important tools for research and development in the pharmaceuticals and cosmetic industries. Human skin is the best possible model for such in vitro studies. The commercially reconstructed human epidermis models are similar to the morphology, lipid composition and biomarkers of native human tissue and have been approved by European Centre for the Validation of Alternative Methods (ECVAM) for the validation of cosmetics. The models are available in many nations but not in China. Here, we describe the development of a constructed three-dimensional (3D) model using Chinese human skin cells, which consists of a “dermis” with fibroblasts embedded in rat type I collagen matrix and an “epidermis” comprised of differentiated keratinocytes. The main objectives of this study were to use our reconstructed 3D skin tissues for validation on in vitro tests for human skin irritation and corrosion, and for reliability and relevance to published references. For irritation study, the 3D skin tissues were exposed with cosmetics collected from both Western nations and China. MTT assay was performed for cell viability and ELISA was conducted for IL-1 release. For corrosive study, reference chemicals including severely corrosive and non-corrosive compounds were used to validate whether our 3D skin model matched the criteria used by ECVAM. The results demonstrated our skin model could meet the criteria. Our data indicate that the reconstructed 3D Chinese skin model is a reproducible and sensitive tool to assess skin irritation and corrosion to cosmetics and chemicals.

1605 Lauric Aldehyde: Ninety-Day Repeated-Dose Oral (Dietary) Toxicity in Rats

G. Ritacco, V. T. Poliziano and A. Api, Research Institute for Fragrance Materials, Woodcliff Lake, NJ.

Lauric aldehyde is a widely used as a fragrance material. This enhanced OECD 408 compliant study investigated the systemic toxicity of lauric aldehyde by dietary exposure. Ten rats /sex /dose were fed diets containing 0, 200, 2000, 6000 or 20,000 ppm lauric aldehyde for 90 days. Observations included clinical observations, outside cage observations, food consumption, body weights, functional observational battery, ophthalmoscopy, hematology, plasma chemistry, urinalysis, estrous cycling (weeks 6-7 and 12-13), sperm analyses, gross necropsy, and histopathology. There were no unscheduled deaths. No adverse effect in overall food consumption or food efficiency was detected. There were no toxicologically significant changes in clinical observations, functional battery tests, body weights, hematology, blood chemistry, or organ weights; no toxicologically significant abnormalities were detected at necropsy. There were no toxicologically significant effects on the concentration, motility or morphology of samples of epididymal sperm. There were no treatment related effects on the concentration of homogenization resistant epididymal or testicular spermatozoon. Males treated with 20,000 ppm lauric aldehyde showed a statistically significant increase in the number of abnormal sperm during morphological assessment, not associated with any other sperm related effects. Sperm morphological analyses were extended to the low and mid dose groups and sperm staging was conducted on all groups; no effects were observed. Therefore, it was considered not to be toxicologically relevant. There were no treatment related changes in any other parameters measured. Dietary administration of 200, 2000, 6000 and 20,000 ppm lauric aldehyde to rats did not result in any toxicologically significant effects. The No Observed Adverse Effect Level (NOAEL) was considered to be 20,000 ppm (equivalent to a mean achieved dose of 1410 mg/kg/d). With total systemic exposure of 0.0043 mg/kg/d, the margin of exposure for lauric aldehyde is >300,000, indicating a very low potential for toxicity.

1606 Formulation, Analysis Method Development, and Validation for Dimethylaminoethanol Bitartrate in Gavage Dose Formulations

J. C. Blake, S. D. Cooper, M. C. Best, R. A. Fernando, V. G. Robinson and S. Waidyanatha, 1Analytical Chemistry and Pharmaceutical, RTI International, Research Triangle Park, NC and 2Division of the National Toxicology Program, NIEHS, Research Triangle Park, NC. Sponsor: K. Levine.

Dimethylaminoethanol (DMEA) and several of its salts are produced in quantities greater than 1,000 tons per year, thus are included in the category of High Production Volume Chemicals. DMEA and its salts are extensively used in waste water treatment, manufacture of polyurethane foams, water-based paints and surface coatings. Dimethylaminoethanol bitartrate (DMEA bitartrate) can be found in a number of dietary supplements, touted for its anti-aging effects in both skin and brain function.

The purposes of the current study were to formulate DMEA bitartrate in sterile water, and to develop and validate a formulation analysis method for DMEA bitartrate in sterile water. The DMEA bitartrate was completely soluble in the vehicle up to 300 mg/mL. The method was successfully validated over the range 2.5 to 225 mg/mL and with a dilution verification to extend the range up to 300 mg/mL. The accuracy (relative error) was ± 9.4% and precision (percent relative standard deviation) was ± 2.0%. The limit of detection was determined to be 0.2 mg/mL and the limit of quantitation was 0.5 mg/mL. The range of pH of the formulations was between 3.4 and 3.6. The 10 mg/mL formulation demonstrated acceptable stability for 14 days showing recoveries of 93.7% and 94.8%, respectively. The composition of the DMEA bitartrate was also verified by the analysis of tartaric acid including the analyses after formulation storage. To date tartaric acid was found to be at a 1:1 molar ratio with DMEA through 21 days of storage.
Skin sensitization is an important endpoint for risk assessment of new ingredients. The latest amendment of the EU Cosmetic Directive/Regulation and animal welfare call for implementation of animal-free alternatives for hazard assessment. Although in vitro testing has been successful for endpoints such as skin irritation, no single in vitro test can provide sufficient information about the potential of ingredients. Several in silico and in vitro tests have been developed and validated considering the mechanism that trigger skin sensitization, and can be used as part of an Integrated Testing Strategies that ensure a reliable prediction. In this study, we combine heterogeneous input sources using a Random Forest and Bayesian Network to develop a probabilistic approach to hazard identification. These models were built on a combination of in silico and in vitro available data for 145 chemicals tested on two cell-based assays (KeratinoSens®, U-937), in chemico Direct Peptide Reactivity Assay, in silico data from Times, and skin penetration (Jaworska et al., 2013) to estimate skin sensitization potency as assessed by local lymph node assay. Furthermore, we develop and evaluate algorithms for the creation of conditional testing strategies from complex generative models. Our models are able to predict with an average balanced accuracies for four classes of skin sensitizers of approximately 61%, of 74% of accuracy when moderate and strong sensitizers had been treated as one class. At the moment we try to integrate additional data from chemicals and assays (e.g. Michael acceptor, h-CLAT, Lusens). Our results suggest that the development of an animal-free alternative for the assessment of skin sensitization will be mandatory for the future of the cosmetic industry.
manufacturing of EC RFs. A subset of the 72 RFs were duplicate products, these were also evaluated by visual comparison of fluid coloration. A HPLC method was specifically created for the nicotine quantification of EC fluids. A Hewlett Packard Series 1100 HPLC with a Thermo Scientific Hypersil ODS C18, 200mm x 4.6mm reversed phase column was used with a flow rate of 0.8 mL/min and an injection volume of 5µL. An isotric method was applied using a mobile phase of 76.9% water, 23% acetonitrile, and 0.1% triethylamine at a pH of 7.6. 50 of the 54 RFs labeled as containing nicotine had quantified nicotine concentrations that varied significantly from the manufacturer labels with a predominance of fluids (46 of 50) being in excess of labeled values. RFs labeled as nicotine free were found to be nicotine free. Five products were unlabeled for nicotine concentration; three contained no nicotine, while the remaining two contained nicotine concentrations in excess of 100mg/mL. In duplicate comparisons of nicotine containing RFs, 16 of the 18 duplicates varied significantly in nicotine concentration from their mates. Of the 23 total duplicate pairs, 15 of 23 varied in coloration from their mates. Nicotine concentration labeling on EC refill products was often inaccurate, and some bottles that were not labeled had nicotine concentrations that would be lethal if inadvertently consumed by a child or adult. To ensure the reliability and safety of RFs, it is necessary to establish quality control guidelines for the manufacturing and labeling of RF products.

1613 Cytotoxicity of Electronic Cigarette Refill Fluid Aerosols

R. Z. Behar, A. Razo and P. Talbot. Cell Biology and Neuroscience, University of California, Riverside, Riverside, CA.

Electronic cigarettes (EC) are nicotine delivery devices, often advertised for smoking cessation. The fluids used to refill these devices typically contain nicotine, a humectant, such as propylene glycol or vegetable glycerin, flavorings and contaminants. Few scientific studies have assessed possible health effects of EC aerosols on users, and it remains unclear whether they pose a health concern. Previously, 19 EC refill fluids from four companies were screened for cytotoxicity using human pulmonary fibroblasts (hPF) via the MTT assay. In this extension of the previous study, we produced aerosols from these fluids using the Vea EC from Johnson Creek and then tested them for cytotoxicity in the MTT assay on hPF, which model the adult lung. A comparison was made between the refill fluids applied to hPF and the aerosols produced from the fluids which were then used to treat the cells. Aerosol yields ranged in IC50 values (dose that inhibits survival by 50%) from 0.1054% to >1% (12 had low-cytotoxicity and 7 were moderately cytotoxic). For 68% of refill fluids (13 of 19), the corresponding aerosols had similar cytotoxicity. 11% of the fluids (2 of 19) were more cytotoxic than their aerosols. Finally, 21% of the products (4 of 19) were more potent as aerosols than as fluids. This latter observation is important as it shows that heating refill fluid can increase its cytotoxicity. The data further show that when screening for cytotoxicity of EC products, testing refill fluids on cells is not always representative of the effects of an aerosol on cell survival. Additionally, 2 of the 19 aerosols produced vapor effects at their high dose, and the dose range was then adjusted to eliminate vapor transfer into neighboring cell cultures. This study is the first to compare the cytotoxicity of EC refill fluids and their aerosols on human cells. In addition, this study provides valuable insight into which of these EC refill products may be potentially harmful to users.

1614 Apparent Lack of Cytotoxicity in Brands of e-Liquids Previously Reported As Being Cytotoxic

J. H. Lauterbach. Lauterbach & Associates, LLC, Macon, GA.

US sales of e-cigarettes (e-cigs) and e-liquids reportedly will exceed $1 billion in 2013. While there is much evidence to indicate that short-term use of e-cigarettes as a smoking cessation tool does not present undue health risks in healthy adults, little is known about health risks associated with long-term use of the product. To date there appears to have been only one report of in vitro toxicological assays that are commonly used to assess the toxicity of mainstream cigarette smoke being applied to the mainstream aerosol from e-cigs (Romagna et al., 2013); but that research used puffing conditions now known to be inappropriate for e-cigs; and puffing of e-cigs is also known to give cytotoxic substances such as acrolein when dry puffs are taken (Faralinos et al., 2013). Thus, it makes sense to determine e-liquid cytotoxicity first. There has been one report (Bahl et al., 2012) that described the use of the MTT assay with three different cell lines (hESC, mNSC, hPF) to estimate the cytotoxicity of e-liquids used to refill the reservoirs of e-cigs. While several e-liquids were reported to be cytotoxic, no cytotoxic compounds were identified in that report. For this reason, four of the same brand-style e-liquids were obtained. An additional brand-style of e-liquid was obtained from another manufacturer. All five samples were assayed with the Neutral Red Uptake (NRU) cytotoxicity assays with CHO cells (assays were purchased from Labstat International ULC, Kitchener, ON, Canada), and a modification of Health Canada Method T-502 was used. There was no cytotoxicity at a concentration of 0.1%. In addition, each e-liquid was analyzed by GC-MS, and none of the compounds reported to cause e-liquid cytotoxicity such as allyl alcohol and diacetyl were found. However, one e-liquid was found to contain eugenol and cinnamaldehyde, compounds not usually used in cigarettes sold in the US.

1615 VUSE Electronic Cigarette Aerosol Characterization

Electronic cigarettes (e-cigs) are of high interest worldwide as alternatives to combustible cigarettes. R. J. Reynolds Vapor Company has introduced VUSE, an e-cig, in the US market in 2012. A main criticism of e-cigs from various groups is that there are not enough data on exposure to nicotine or other potential toxicants of interest. This poster presents mainstream aerosol chemistry data for different commercial VUSE products. Aerosol was collected using a 55/30/3 machine packing regimen and either bell shaped or square wave puffing profiles. The test programs included evaluations of a subset of compounds currently listed on FDA’s Harmful and Potentially Harmful Constituents list for combustible cigarettes. Individual constituent yields and chromatographic profiling data for different commercial VUSE products tested over different time intervals consistently indicated that: 1) compounds intentionally added to the formulation of the e-liquids (e.g., nicotine, glycerin) were measured in the aerosol, as expected; 2) toxicants of concern for combustible cigarettes were either below the limit of quantification or below the limit of detection in VUSE aerosols; and 3) VUSE aerosols were significantly less complex than mainstream smoke emitted from combustible cigarettes.

1616 Safety Assessment of Potential Food Ingredients on Canine Primary Hepatocytes

L. W. Zhang1, B. Jeffery, J. E. Riviere and N. A. Monteiro-Riviere1. 1Department of Anatomy and Physiology, Kansas State University, Manhattan, KS and 2Global Quality and Food Safety, MARS Inc., McLean, VA.

Toxicity screening of pet food ingredients must first be conducted to assess their safety in dog food. Canine hepatocytes (CH) were isolated from the livers of dogs (n=5), euthanized for clinical reasons with owner consent, using a two-step collagenase perfusion method. CH were evaluated for viability with alamarBlue (aB) mitochondrial membrane potential (MMP) and reactive oxygen species (ROS) for 24h in some of the compounds. In addition, human and rat hepatocytes were used to compare to CH. Aflatoxin B1 (AB) and acetaminophen (APAP) were assessed to characterize and screen early toxic responses in CH and in pet food ingredients like clove leaf oil (CLO) and eugenol (EUG). CH showed a decrease in viability with an LC50 of 3.80µg/mL of APAP with an LC50 of 3.11mg/mL while the LD50 of human hepatocytes was 4.47µg/mL for AB and 3.45mg/mL for APAP, and rat LC50 of 5.36µg/mL for AB and 2.35mg/mL for APAP. MMP in CH showed a significant decrease by AB and APAP, and an increase in ROS especially with superoxide. In addition, CLO and EUG dosed at 1.5-fold dilution series ranging from 0.1% to 0.0029% in CH showed an increase in intracellular vacuoles when dosed at high concentrations greater than 0.0088%. CLO and EUG showed a decreased viability from 0.030% at 24h with the same LC50 of 0.037%. In conclusion, CH were successfully isolated and well characterized for the assessment of toxicants and pet food ingredients, which is comparable to human and rat hepatocytes. The variable responses may be attributable to age and breed of dogs. (Supported by Mars Inc.)

1616a Development of Formulation and Analysis Methods for Triphenyl Phosphate (TPP) in Rodent Feed for Toxicology Studies

B. Collins1, A. Mitchell2, W. Vandaveer2, V. Ault2, N. Dolll2, S. Beckwith2, N. Pearson1, A. Mainey2, K. Aillon2, J. Algaier2 and R. Harris2. 1National Toxicology Program (NTP) NIEHS, Research Triangle Park, NC and 2MRIGlobal, Kansas City, MO.

Aromatic phosphates (AP) are rapidly replacing brominated flame-retardants in commercial products. Most commercial APs are multi-component products containing ~20% TPP. Due to the lack of comprehensive toxicology data, TPP is under evaluation by the NTP. In support of planned toxicology studies, analytical methods were developed and validated for dose formulation characterization, including dose concentration, homogeneity, and stability of TPP in NIH-07 and NTP 2000 rodent meal feed. TPP-dosed feed (10 g) was extracted with 100 mL of acetonitrile (ACN);acetic acid (99.1%; NIH-07) or 100 mL of ACN (NTP-2000)
and analyzed by HPLC/UV on an X-Terra RP18, 5μm column using a water:ACN gradient. This method, which was validated over a range of 200 – 5,000 ppm, was linear (r > 0.999), accurate (percent relative error < ±0.9%), and precise (relative standard deviation (% RSD) < 0.4%). TPP feed formulations were evaluated for factors influencing homogeneity including TPP and feed particle size. Commercial TPP is supplied as 1-9 mm pellets, making formulation challenging. In this study, a ball-mill was used to grind TPP to a median diameter of ~420 μm to approximate feed particle diameter (median ~270 μm determined for 5 meal types). Homogeneity in NIH-07 and NTP 2000 was evaluated for two mixing procedures: feed flour or an acetone/feed slurry. Both mixing procedures produced homogenous formulations at 240 or 40,000 ppm (%RSD ≤ 5.0%), but the feed flour approach resulted in large TPP/feed agglomerates requiring extensive post-formulation particle size reduction. The 240-ppm TPP formulation was stable for 42 days in both diets, when stored at 4 or ~20°C, and for 7 days at ambient temperature when exposed to air and light in open feeders, but displayed an ~10% loss (NTP-2000) or an ~17% loss (NIH-07) after 24 hours when exposed to rodent urine/feces.

1616b Using Cluster Approaches to Assess the Safety of Chemicals Used in Consumer Products

C. Bjer Anderson1, C. Rudisill2, M. Morlacci3, M. Adams4, B. Drake1, J. Tunkel2 and K. Mayo1.

There is a growing interest in the use of cluster-supported read across to obtain more efficient and accurate hazard assessments. While the practice of using structural analogs to evaluate data-poor chemicals is well established, the narrow approach of “one analog to evaluate one chemical” can lead to inconsistent and inaccurate results, particularly when there is a need to assess a large number of chemicals. Assessing hazards in the context of small groups (“clusters”) of structurally related chemicals increases the overall confidence and the consistency of the chemical assessments. This poster illustrates how the US EPA Design for the Environment Branch (DfE) is using chemical clusters to streamline hazard evaluation in a voluntary program that promotes the use of safer chemicals in consumer products. Clusters can be assembled by professional judgment, but clustering software such as ChemACE, developed by US EPA to quickly create discrete clusters from user-defined chemical lists and with minimal refinement, can save time and effort during the initial grouping exercise. DfE uses ChemACE in the development of chemical clusters to evaluate chemicals against DfE’s ecological, environmental fate, and human health criteria. Examples such as allyl esters, polycyclic musks and macrocyclic lactones, are used to illustrate how clusters are defined, used for read-across and provide assistance in decision-making. In addition to streamlining the evaluation process within DfE, this approach could be of further help for companies that are conducting hazard assessments under their own internal sustainability initiatives.

1616c Toxicity of Tris(Chloropropyl)phosphate (TCPF) Dietary Exposure for 13 Weeks in Harlan Sprague-Dawley Rats and BeC3F1/N Mice

TCPF is a high production volume flame retardant and plasticizer. It is recognized as a global contaminant but the hazard to humans remains unknown. The objective of this study was to evaluate the toxicity of TCPF in male and female mice and rats exposed via diet for 13 weeks at 0, 1250 (mice only), 2500, 5000, 10000, 20000 and 40000 (rats only) ppm. In rats, perinatal exposure from gestation day 6 through postnatal day 21 (weaning) preceded the 13-week exposure. Exposure in mice began at 5-6 weeks of age. All rats dam exposed to 40000 ppm (gestation) and all male pups (first week post-weaning) from the 20000 ppm group either died or were humanely terminated due to overt toxicity. Body weights in all rats at weaning were 13-30% lower than controls, indicating an effect on weight gain. In mice, no treatment-related mortality or clinical signs of toxicity were observed. Terminal body weights were 12% (rats) and 29% (mice) lower than controls. Relative liver (rats, mice) and thymus (rats) weights were increased. Rats displayed increased serum cholesterol and decreases in hepatic enzymes; mice exhibited decreased blood leukocyte counts. In rats, microscopic changes included minimal to mild bilirubin hyperplasia and cortical hyperplasia in the thymus. In mice, hepatic centrolobular hypertrophy and cytoplasmic alteration of male renal tubular epithelium were noted. In genotoxicity tests, TCPF did not induce mutagenicity in bacteria or chromosomal damage in peripheral blood of male or female rats, or female mice. Chromosomal damage in the form of micronucleated erythrocytes was seen in male mice. In summary, subchronic exposure to TCPF in feed resulted in reduced dam and pup survival (rats) and the liver, thymus and kidney were considered primary targets of toxicity. The NTP is currently evaluating the effects of TCPF on development, chronic toxicity, and carcinogenicity. This work was supported by the NIH.

1616d Use of Chemical Safety Assessment and the TTC to Evaluate the Potential Toxicity of an Endoscopic Guidewire

N. S. Goud, M. Beauchante, J. Kapitan and E. E. Reveryter.

Corporate Toxicology and Biocompatibility, Boston Scientific Corporation, Natick, MA.

An endoscopic, non-vascular guidewire (limited, less than 24-hour tissue contacting device) underwent a material and process change. To assess the potential impact of these changes to patient safety, the device was extracted with hexane or saline at 50 deg C and the resulting solutions were analyzed by various analytical test methods for extractable substances. GC-MS showed the presence of benzaldehyde, a commonly used food additive. The dose of benzaldehyde (10 μg) to which patients might be exposed from the use of guide wire was calculated to be about 70,000 times less than the published oral reference dose to man. Similarly, the total amount of 2-hydroxy-isoo-butyrophenone present in the device (0.05 μg) was calculated to be 1000 times less than the proposed 90 μg/day dose limit for a Class III compound using the Threshold of Toxicological Concern (TTC) guidelines, implying a negligible genotoxicity or carcinogenic risk. The ICP-MS data showed the presence of several metallic elements such as zinc to which humans are exposed through various dietary sources. The estimated patient exposure to zinc from the use of the guidewire was calculated to be 285.7/14 times less than the prescribed daily upper intake level from US Food and Nutrition Board. Lastly, the device extract also showed the presence of tungsten (38 μg) which, based on the published NOAEL data, resulted in 138 times less than the tolerable exposure dose. The device extract passed the required biocompatibility tests for safety evaluation. In summary, this study showed that chemical characterization of device extract is useful in determining potential toxicological risks, which may obviate the need for conducting further in vivo biocompatibility assays.
Chemical Characterization and Biocompatibility
Investigation of One Drug-Combo Implant Devices for Neural Implication—Medtronic Antibiotics Impregnated Catheters
K. Deng, J. Bertrand and D. Amery, Medtronic, Jacksonville, FL.

Medtronic Antibiotics Impregnated Catheters (ARES) catheters are silicone elastomer catheters which are subsequently impregnated with proprietary antibiotics, which is the first drug-combo implant device in Medtronic Neurosurgery division. These catheters are permanently implanted ventricular and peritoneal catheters used as components of a shunt system in the treatment of hydrocephalus. The antibiotic impregnated ventricular and peritoneal catheters are line extensions of the currently offered standard Medtronic Neurosurgery catheters for use as components of a shunt system. To investigate the biological safety of the product for its usage as brain implant devices, series of chemical characterization and biocompatibility testing are undertaken. Drug elution study showed that the antibiotic is eluting at a rate and level that is not anticipated to cause significant patient adverse reactions. This product did not cause cytotoxicity in SK-N-MC neuronal cells after 48 hours exposure nor did it cause acute systemic toxicity in Swiss Albino mice. It did not induce skin irritation in rabbits or sensitization reactions in Guinea Pigs. More importantly, New Zealand White rabbits implanted with ARES did not demonstrate differences in measured parameters (clinical observation, clinical chemistry/hematology and histological pathology) that were considered to be attributable to ARES for a period of 13 weeks. As expected, ARES, which includes antibiotics, caused toxicity in some strains of the S. typhimurium tested in the bacteria reverse mutation assay. However, in the remaining bacteria strain, ARES did not induce any mutagenicity and it did not induce any genotoxic response in mouse lymphoma L5178Y cell lines. The base materials and impregnated antibiotics of the ARES catheters have been used in clinical settings for a long time without known genotoxic and carcinogenic response, indicating low risk of genotoxicity and carcinogenicity for the ARES catheters.

In Vitro Assessment of Cardiotoxicity Hazard of Environmental Compounds Using Fast Fluorescence Imaging of Beating iPSC-Derived Cardiomyocytes

A large number of environmental agents, with potential for human exposure, remain inadequately tested for toxicological effects. As an effort to develop and characterize in vitro model systems for toxicological screening, we used fast kinetic fluorescence imaging that monitored changes in intracellular Ca2+ using a calcium sensitive dye to screen a library of environmental chemicals and drugs for their ability to alter beating patterns in human iPS-derived cardiomyocytes. These cardiomyocytes were exposed to a diverse set of 80 environmental chemicals. Compounds were screened for cardiotoxicity across a 7-point concentration at 30 min and 24 h of treatment. A number of physiological parameters of cardiomyocyte beating, such as beat rate, peak shape (amplitude, width, raise, decay, etc.) and regularity were collected using automated data analysis. Concentration-response profiles were evaluated using logistic modeling to derive a benchmark concentration (BMC) point-of-departure value, based on one standard deviation departure from the estimated baseline in vehicle treated cells. BMC values were used for cardiotoxicity classification and ranking. We found that number of environmental chemicals such as pesticides (permethrin, heptachlor, deltamethrin, dieldrin, carbaryl); flame retardants (isophorolified phenyl phosphate, 2-ethylhexyl diphenyl phosphate, 2,2,4,4-tetrabromodiphenyl ether); polycyclic aromatic hydrocarbons (acenaphthene, acenaphthylene and benzo[a]pyrene); and metalloids (arsenic, lead, and mercury) inhibit in vitro cardiac function. We applied the Toxicological Prioritization Index approach to integrate and display data across many collected parameters, to derive “cardiotoxicity” ranking of tested compounds. This approach can be utilized to prioritize suspected cardiotoxicants for in vivo hazard characterization and mechanistic follow-up studies.

Analysis of Four Hepatotoxins Using the xCELLigence Analytical System and HepaRG Cells
C. Jin1, D. Steen1, C. Chesne1 and Y. A. Abassi2, 1Biopredic International, St. Gregoire, France and 2ACEA Biosciences Inc, San Diego, CA.

Hepatotoxins act through different mechanisms and kinetics, and we reasoned that an analytical system allowing for convenient, kinetic monitoring of relevant effects would be very valuable in the in vitro prediction of hepatic cell toxicity. We developed a protocol to use the xCELLigence Real-time Cell Analyser (RTCA) to facilitate recognition of the risk of hepatotoxicity. Our protocol involved culturing cryopreserved, differentiated HepaRG cells onto the xCELLigence 96-well cell culture plate, and after a four-day adaptation period, treating them with different concentrations of four compounds with known risk of hepatotoxicity—APAP, amiodarone, CsA, and troglitazone— and its eventual replacement the PPAR agonist rosiglitazone. The Cell Index (CI), an expression of the electrical impedance of adherent cells as measured on sensors in the culture plate wells by the xCELLigence Cell Analyzer, of treated cells was compared to the CI from HepaRG cells exposed to a 0.5% DMSO control at post-treatment time points 24, 48, 72, 96, and 168 h, during which the medium was replenished every 48 h. The CI was also assessed at 2, 5, 10, and 20 hours after treatment with eight APAP concentrations and control to determine if damage to the cells could be detected rapidly, since McGill et al reported significant glutathione depletion within three hours after exposing HepaRG to APAP. With the exception of low concentrations, time and concentration-dependent effects were detected for all hepatotoxicants. 72 hours after treatment with 6µM of APAP and 50µM of amiodarone, the NCI of treated cells declined 70% and 83% respectively compared to the control cells. A marked CI decline in APAP treated cells vs control was detected within 10hrs. At 72 hrs, exposure to 200µM troglitazone demonstrated much stronger effect on the CI than 450µM of rosiglitazone. We conclude that the combination of the HepaRG cells and xCELLigence system may sensitively detect risk of hepatotoxicity across a range of mechanisms.

1618 Modeling of Inflammation-Mediated Liver Injury In Vitro
K. Balavenkatraman1, B. Bertschi1, M. Magnifico2, A. Haitchard1, S. Chibout3, M. Uteng1, J. Mathiow2, P. J. Devine2, E. Pignan1 and A. Wolf1, 1Novartis Pharma AG, Basel, Switzerland and 2Novartis Pharma AG, Cambridge, MA.

Drug induced liver injury (DILI) is one of the leading causes for the discontinuation of drugs both in development and in post-marketing phase. Pre-existing liver inflammatory status might sometimes predispose patients to drug-induced hepatotoxicity. A major contributor to liver inflammation is the resident macrophages, also referred to as Kupffer cells. However it is not feasible to profile all compounds during drug development in vivo for studies for their role in inflammation mediated liver injury in all preclinical species. An alternative is the use of in vitro approaches such as co-culture of hepatocytes together with Kupffer cells or to treat hepatocytes with immunomodulators such as TNFα to mimic inflammation mediated liver injury. Mouse, rat, dog and human primary hepatocytes were cultured in a collagen-matrigel sandwich configuration and were primed with the immunomodulator TNFα to validate this inflammatory model for liver injury. Cellular ATP (Adenosine Triphosphate) content and leakage of LDH (Lactate dehydrogenase) into the supernatant were measured. Trovafloxacin, known to trigger hepatotoxicity in vivo, induced cytoxicity in all tested species only in the presence of TNFα whereas Levofloxacin, which is innocuous in vivo, did not. A good correlation between the cellular ATP levels as well as the LDH released into the supernatant was observed. When hepatocytes were cultured without TNFα, both Trovafloxacin and Levofloxacin were devoid of any cytoxicity. This inflammatory-like model for drug-induced liver injury could be used to test compounds that are in development across various species.

1619 Developing an Impedance-Based Cellular Assay with Human iPSC-Derived Cardiomyocytes to Quantify Modulators of Cardiac Contractility
C. W. Scott1, X. Zhang1, N. Abi Gerges1, Y. A. Abassi2 and M. Peters1, 1Drug Safety and Metabolism, AstreaZenea, Wallingham, MA and 2ACEA Biosciences, San Diego, CA.

Cardiovascular toxicity is a prominent reason for late-stage failures in drug development, resulting in the demand for in vitro assays that can predict this liability in early drug discovery. Current in vitro cardiovascular safety testing primarily focuses on ion channel modulation and low throughput cardiomyocyte contractility measurements. The xCELLigence Real-Time Cell Analyser (RTCA) Cardio system utilizes label-free impedance technology to quantify beating properties of spontaneously beating cardiomyocytes in a medium throughput (96-well) mode. We tested both human induced pluripotent stem cell-derived cardiomyocytes (hPSC-CMs) and rat neonatal cardiomyocytes (rat-CMs) on the Cardio system. A set of 50 reference compounds were tested in concentration-response mode and the potency values for effects on beat rate and beat amplitude were determined. These compounds had previously been tested in vivo as well as in a low throughput in vitro optical-based contractility assay using electrically paced canine cardiomyo-
cytes (Toxicol Appl Pharmacol (2012) 260:162) and included negative and positive inotropes and no effect compounds. By comparing to the known in vivo contractility effects, hiPSC-CM impedance had assay sensitivity, specificity and accuracy values of 90%, 74%, and 84%, respectively. These values compared favorably to the in vivo contractility in canine assay (83%, 86%, 82%) and were slightly better than im- pedance using rat-CMs (80%, 74%, 76%). The hiPSC-CM and rat-CM impedance potency values spanned 5 orders of magnitude and correlated with values from the canine optical assay (r2=0.76 and 0.70, respectively). The Cardio system had >5X higher throughput than the optical assay. Thus, the hiPSC-CM Cardio system assay can help detect the human cardiotoxic potential of novel therapeutics early in drug discovery and, if a hazard is identified, support the design-make-test-analyze cycle to mitigate this liability.

1620 Assessment of Prolactin-Mediated Changes and Their Reversal in Molindone Treated Rats

Molindone, an antipsychotic, is known to modulate prolactin levels linked with reproductive changes in rodents. Such effects were further investigated in the current 6-month rat study with a reversal phase to better characterize changes for risk assessment. Wistar rats (12/sex/group) were dosed daily by gavage with molindone (males at 1, 3 and 10 mg/kg; females at 5, 20 and 60 mg/kg). Blood samples were analyzed for molindone and prolactin on Days 1, 180 and at a 2-month reversal period. Histopathology was performed on reproductive tissues. Results showed that plasma levels of molindone were more than dose proportional with Tmax between 0.25 to 1h postdose (PD). Prolactin levels peaked within 1h PD and were 284 and 335 ng/ml in males and 613 and 884 ng/ml in females, respectively, for Days 1 and 180. Prolactin levels remained elevated up to 2h PD in males and 8h in females. After 2-month recovery, prolactin levels reached basal levels, suggesting complete reversibility. Histopathologically, on Day 180, an increased vacuolation of mammary gland epithelium was noted in males at 3 and 10 mg/kg. In females, a diffuse glandular hyperplasia in mammary tissue was noted in all treated groups with minimal severity in 5 mg/kg, and minimal to mild severity in 20 and 60 mg/ kg. At the end of recovery, histopathology changes in males were completely reversed; in females, they were completely reversed at 5 mg/kg, with signs of reversal at 20 and 60 mg/kg. Reversibility in prolactin and histopathology seen in this study validates the pharmacologically mediated effects of molindone and corroborate with the known role of prolactin in hormonal homeostasis and reproductive physiology. These changes are considered species-specific, similar to those seen with other antipsychotics in this class of drugs. It is concluded that the transient prolac- tin-mediated histopathology changes seen in this study are of negligible risk, if any, to humans, as such changes have not been reported in humans taking molindone as a therapeutic.

1621 In Vitro Assessment of Intestinal Toxicity of Drugs Using an Electronic Impedance-Based Cell Monitoring System

Intestinal toxicity is a common problem in pharmaceutical development. In par- ticular, the potential for diarrhea not caused by cytotoxicity is difficult to detect in rodent study because of the difference in the intestinal structures between rodent and human. As such, it is often first identified in dog or non-human primate study, or furthermore, in a clinical trial. Transepithelial electrical resistance (TEER) measure- ment has been used for the in vitro detection of diarrhea potential, especially due to barrier disruption, although its throughput was quite low. In this study, we further investigated the usefulness of a real-time impedance-based cell monitoring system, xCELLigence (ACEA Biosciences, Inc.), which has a measurement principle similar to that of TEER, was evaluated as an effective assay system for detection of the potential for diarrhea in human. HT29 cells, a human colon adenocarcinoma cell line, were seeded on 96-well E-plates, in which a sensor electrode array is incorporated in each well, and moni- toring of cell impedance was initiated using xCELLigence. After 48 hrs incubation, the cells formed a confluent monolayer and the impedance became constant; then cells were exposed to 19 compounds with or without diarrhea potential and cell impedance were monitored for 24 hrs. As a result, remarkable reductions (>20% vs. vehicle control) of cell impedance were observed in the compounds that induced diarrhea due to barrier disruption: cytchalasin D, ethanol and okadaic acid. Slight reductions (15-20% vs. vehicle control) of cell impedance were observed in the compounds that induced secretory diarrhea, forskolin, slidingfil, IBMX and quinidine. On the other hand, no appar- ent change was observed in the compounds that induced diarrhea due to intestinal hypermotility, erythromycin and betahaneol, and in seven non-diarrhea-inducing compounds, except for loperamide. These results suggest the usefulness of the xCELLigence system as an effective assay to detect the potential for diarrhea in human.

1622 A Comparison of Human Hepatocyte Systems and Conditions for Hepatotoxicity Screening
C. Storck, F. Wang, J. Kwagh, J. Megill and O. Flint. Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ.

Cultures of primary human hepatocytes (PHH), human induced pluripotent stem cell derived hepatocytes (hiPSC-H; CDE, Madison, WI), and 5 immortalized THLE-5B (ATCC CRL 11113) human hepatocyte cell lines (one parental clone, Tc5, lacking CYP450 expression and 4 clones expressing either human CYP2C9, 2C19, 2D6 or 3A4) were compared for detection of hepatotoxicity (reduction of cellular ATP by 50% [IC50] at concentrations ≤ 50 μM). We used 40 hepatotoxic drugs (HD) labeled with a warning for serious (SHD, n = 20) or variable (VHD, n = 20) hepatotoxicity in human patients and 20 drugs not reported to be hepatotoxic (NHD). Cells were exposed to compounds at concentrations ≤ 200 μM for 4 days. In parental Tc5 cells, IC50 values of ≤ 50 μM were generated for 78% HD (31/40) and 15% of NHD (3/20). Metabolism by the Tc5 CYP expressing clones did not significantly increase the number of HD with IC50 values ≤ 50 μM but re- duced the IC50 values for 5 SHD and 8 VHD and increased the IC50 values of 2/3 NHD to > 50 μM. In iPSC-H and PHH, IC50 values ≤ 50 μM were respectively generated by 55% (22/40) and 53% (21/40) HD. PHH and hiPSC-H generated the same number of false positives (5% [1/20]). These results support using the non-metabolizing Tc5 parent line to evaluate hepatotoxicity routinely, and use of the Tc5 clones subsequently to investigate the potential for toxification or deteri- orization. The iPSC-H and PHH detect fewer HD and may be better reserved for compound specific mechanism studies. Finally, others have reported increases in the predictive value of hepatocyte cell systems co-treated with 1) DL-buthionine- (S,R)-sulfoximine to deplete glutathione, 2) a cytokine cocktail (TNFα, LPS, IL1a, IL6) to model immune stimulation under inflammatory conditions, or 3) galactose substituted medium to alter cell respiratory status. However, we found that these conditions did not improve the detection of HD in Tc5 cells after 4 days of culture.

1623 A Chemical Derivative of Naturally Occurring Isothiocyanate, DJ4, Blocks Stress Fiber Formation
V. P. Kale, D. Desai, S. Amin, J. Hengst, S. Sung and J. Yun. Pharmacology, Penn State College of Medicine, Hershey, PA.

Isothiocyanates (ITC) are naturally occurring compounds found in many vegeta- bles and are known for their antitumor properties. We have developed a series of novel derivatives of ITC as a part of a cancer drug discovery program. Among the many derivatives tested, DJ4, dramatically altered the morphology of multiple cell types including cancer cells. Using confocal microscopy, detailed examination of the cytoskeletal structures of DJ4 treated cells revealed that DJ4 totally disrupted stress fiber formation without affecting microtubules. Given the known role of Rho family GTPases in cytoskeletal regulation, we hypothesized that DJ4 may exert its effects on stress fibers through modulation of signal pathways downstream of the Rho GTPases. Cellular mechanistic studies revealed that the DJ4-induced disruption of stress fibers was mediated by inhibition of Rho-associated kinases (ROCK) and myosin dystrophy-related Cdc42-binding kinase (MRCK). In in vitro kinase activity studies, DJ4 inhibited phosphorylation of endogenous MYPT1 (myosin binding subunit of myosin phosphatase) which is a downstream substrate of ROCK and MRCK. Molecular docking of DJ4 onto the crystal structures of these kinases suggested that DJ4 binds at the ATP binding site of these kinases. In vitro biochemical studies using recombinant ROCK/MRCK and MYPT1 pro- teins confirmed that DJ4 potently inhibited ROCK1/2 and MRCKβ in an ATP competitive manner. Together these results demonstrated that DJ4-induced loss of stress fibers in the cells is at least, in part, mediated by direct inhibition of ROCK1, ROCK2 and MRCKβ. As stress fiber formation is involved in migration/invasion of cancer cells, these results further indicate the potential utility of DJ4 as a novel anti-metastatic agent.

PS 1620 Assessment of Prolactin-Mediated Changes and Their Reversal in Molindone Treated Rats

Molindone, an antipsychotic, is known to modulate prolactin levels linked with reproductive changes in rodents. Such effects were further investigated in the current 6-month rat study with a reversal phase to better characterize changes for risk assessment. Wistar rats (12/sex/group) were dosed daily by gavage with molindone (males at 1, 3 and 10 mg/kg; females at 5, 20 and 60 mg/kg). Blood samples were analyzed for molindone and prolactin on Days 1, 180 and at a 2-month reversal period. Histopathology was performed on reproductive tissues. Results showed that plasma levels of molindone were more than dose proportional with Tmax between 0.25 to 1h postdose (PD). Prolactin levels peaked within 1h PD and were 284 and 335 ng/ml in males and 613 and 884 ng/ml in females, respectively, for Days 1 and 180. Prolactin levels remained elevated up to 2h PD in males and 8h in females. After 2-month recovery, prolactin levels reached basal levels, suggesting complete reversibility. Histopathologically, on Day 180, an increased vacuolation of mammary gland epithelium was noted in males at 3 and 10 mg/kg. In females, a diffuse glandular hyperplasia in mammary tissue was noted in all treated groups with minimal severity in 5 mg/kg, and minimal to mild severity in 20 and 60 mg/ kg. At the end of recovery, histopathology changes in males were completely reversed; in females, they were completely reversed at 5 mg/kg, with signs of reversal at 20 and 60 mg/kg. Reversibility in prolactin and histopathology seen in this study validates the pharmacologically mediated effects of molindone and corroborate with the known role of prolactin in hormonal homeostasis and reproductive physiology. These changes are considered species-specie
Identification of trace impurities in drugs and their structural elucidation is attaining much more interest due to their significant influence on drug activity. 1, 2 This structural information is very fundamental to know toxicity of trace impurities and their effect on drug activity especially at the preclinical stage. The octadentate ligand 3,4,3-LI(1,2-HOPO), composed of four 1-hydroxy-pyridin-2-one (1,2-HOPO) units linked to a spermine scaffold through amide linkages, is undergoing preclinical development as an actinide decomposition agent that removes radioactive actinides from the body. In this study, 18 trace impurities were detected with the 3,4,3-LI(1,2-HOPO) ligand, using ultra-performance liquid chromatography coupled with photo-diode array UV detection and Electrospray Ionization-Quadrupole Time of Flight Mass spectrometry (UPLC-ESI TOFMS) via induced-in-source or collision induced mass fragmentation (Nozzle-Skinner Fragmentation). Molecular ions were fragmented within the nozzle-skimmer region of the ESI mass spectrometer equipped with a TOF detector. Of these 18 impurities, 8 are considered major impurities (detected over 0.1% threshold) and need to be characterized according to ICH guidelines. Structural elucidation of all 18 impurities was carried out via analysis of generated fragment ions using mass fragmenter, elemental composition softwares obtained from Waters Corporation (USA) and Molecular Fragment Calculator software. Proposed structures of impurities were further confirmed via isotopic modeling.

In vitro cytotoxicity is inextricably linked to a combination of compound dosage, exposure period, and intrinsic cell susceptibility. Current screening paradigms which utilize only endpoint measures in a defined cell type adequately address effects due to dosage, but often fail to define important toxicokinetic profiles or inherent mechanistic sensitivities. We investigated the use of a real-time cytotoxicity probe applied at the time of dosing with staurosporine, panobinostat, imatinib, terfenadine, colchicine, aflatoxin B1, bortezomib, camptothecin, valinomycin, nocardazole, mitomycin C and imonomycin. Serial dilutions of these model compounds with the probe were delivered to iPSC-derived, terminally differentiated hepatocytes and proliferating hepatitis and enterohepatic cell lines. Cytotoxicity data were collected at 4, 24, 48 and 72hr followed by a same-well multiplexed viability assay. The collated data revealed striking differences in toxicokinetics, potency and magnitude of response which positively correlated with known mechanism of action for the model compounds. The multiplexed viability data further served to either confirm observed cytotoxicity by inverse signal concordance, or suggest replicative perturbation in susceptible replicating cells. Furthermore, the use of cell types with differential capacity for phase I metabolism, allowed us to stratify cytotoxic risk based on mode-of-action of parent molecule toxicity and/or metabolic by-products owing to biotransformation. Lastly, the experimental approach taken was sufficiently predictive and informative to merit consideration for adoption as a new safety screening paradigm for new chemical entities.

1629 Antimycobacterial Activity and Cytotoxicity of South African Rubiaceae Species, a Potential Source of Promising Antituberculous Remedies

Tuberculosis is an airborne contagious disease which has infected about one-third of the world’s population with 1 in 10 latently infected individuals developing active disease in a lifetime. Although, the mortality rates of TB have reduced to about 1,7 million per annum, the incidence of new cases has increased due to the upsurge of HIV/AIDS. Toxicity associated with the presently available anti-TB drugs is a limitation to the treatment of TB leading to the failure of patient’s compliance to the treatment. Medicinal plants are used in many part of southern Africa to treat TB-related symptoms including chest pain and coughing. In a preliminary screening process, plant species from the Rubiaceae family showed good activity against Mycobacterium smegmatis. Sixteen genera from the Rubiaceae family indigenous to South Africa were screened for their anti-TB activity against *M. smegmatis* and *M. aurum* using a two-fold serial microdilution assay while cytotoxicity was determined by MTT assay against C3A liver cells and Vero kidney cells. The selectivity index (SI) values were calculated. Six of the extracts showed good minimum inhibitory concentration (MIC) values ranging from 0.04-0.12 mg/ml. Thirteen extracts were relatively non-cytotoxic with LC50 values ranging from 0.1-0.7 mg/ml. *Oxyanthus speciosus* had the highest SI values (LC50/MIC) of 4.9 and 6.5 against *M. smegmatis* and *M. aurum* respectively (C3A cells) and 2.6 and 3.4 respectively (Vero cells). All cells were more sensitive to *Psychotria zambontana* and *Pavetta lanceolata* than Vero cells, while *Psychotria capensis* was toxic to both C3A and Vero cell lines. In conclusion, *O. speciosus* may contain compounds which can act as leads for the development of new anti-TB drugs. Extracts containing several active compounds may also be promising remedies to act in conjunction with known anti-TB drugs to enhance their activity. Further work is continuing on isolation and identification of these compounds, and evaluation of fractions of the extracts for antimycobacterial activity.

1630 Investigation of the Effects of Pyrrolamide Antibiotic Agents on Temperature in Rats

L. Wright1, C. Sadler1, J. Maynard2, W. S. Redfern1, J. McKay1, H. Powell1, J. Ekins1 and S. Richet1.
1DSM, AstraZeneca, Macclesfield, United Kingdom and 2Pharmaceuticals R&D, AstraZeneca, Macclesfield, United Kingdom. Sponsor: P. Duffy.

Administration of pyrrolamide antibiotic agents to rats was shown to be associated with reductions in core body temperature. We utilised a series of different techniques to gain an understanding of whether the changes in body temperature were related to effects in brown adipose tissue (BAT).

Core body temperature was assessed using digital rectal probes and transponders implanted subcutaneously into the interscapular region. Both methods demonstrated a decrease in core body temperature, which was variable between individual animals. Thermal imaging of the rats demonstrated a reduction in interscapular temperature suggesting decreased heat production, whilst there was no evidence of heat loss via the tail.

Metabolic rate (assessed using an oxygen open circuit calorimeter) demonstrated a slight decrease in group mean metabolic rate following administration of single doses of pyrrolamide compounds to rats when compared to controls; again with more marked effects seen in individual animals.

1631 Enhanced Sensitivity of Human and Animal Hepatocytes to Hepatotoxicants after a Prolonged Treatment Duration of 96 Hours

A. P. Li and U. Doshi. In Vitro Toxicology, In Vitro ADMET Laboratories, Columbia, MD.

In vitro hepatotoxicity evaluation in hepatocytes allows the selection of new chemical entities with reduced hepatotoxic liability for further development. Furthermore, multispecies evaluation in vitro aids the selection of the most appropriate animal for in vivo assessment of human hepatotoxic potential. We report here results with 12 model drugs with known animal in vivo and human clinical hepatotoxic potential: acetaminophen, aflatoxin B1, amiodarone, cyclophosphamide, triazolam, mitoxantrone, ketaconazole, cerivastatin, fluvastatin, simvastatin, tacrine, and tamoxifen. Platelet cryopreserved hepatocytes from three human donors, Cynomolgus monkey, SD rat, CD-1 mouse and beagle dog were simultaneously evaluated in the same experiment for the assessment of potential species differences. The hepatocytes were plated in collagen-coated 384-well plates, with treatment initiated 4 hrs after plating for two treatment durations of 24 hrs and 96 hrs followed by quantification of cellular ATP contents. Increased cytotoxicity was observed for all hepatotoxicants at the prolonged treatment duration of 96 hrs. For several hepatotoxicants, the 96-hr treatment allowed clear distinction of species-differences which could not be observed with the 24-hr treatment. For instance, the hepatotoxic cerivastatin was highly cytotoxic (96-hr EC50 <3 uM) in human, monkey and dog hepatocytes, and substantially less cytotoxic in mouse and rat hepatocytes. Similarly, tacrine was cytotoxic after 96-hr treatment in human and monkey hepatocytes (EC50 of 19 to 41 uM) but non-cytotoxic to CD-1 mouse, SD-rat, and beagle dog hepatocytes. Neither cerivastatin nor tacrine was cytotoxic to human or animal hepatocytes up to the highest concentration evaluated of 100 uM at the shorter treatment time of 24-hrs. The results suggest that the prolonged 96-hr treatment of the hepatocytes significantly enhance the sensitivity of the cells to hepatotoxicants. Species-differences observed in vitro in this assay may aid the selection of the most appropriate animal model for in vivo safety evaluation.

1632 A Novel 19-Substituted Benzoquinone Ansamycin Ameliorates A53T Alpha-Synuclein-Induced Toxicity in a SH-SY5Y Cell Model of Parkinson’s Disease through the Upregulation of Heat Shock Proteins and the Induction of Autophagy

1Shkay School of Pharmacy and Pharmaceutical Sciences, University of Colorado Anschutz Medical Campus, Aurora, CO. 2School of Medicine, University of Colorado Anschutz Medical Campus, Aurora, CO and 3School of Chemistry, University of Nottingham, Nottingham, United Kingdom.

A major cause of neurodegenerative diseases including Parkinson’s disease (PD) is the accumulation of misfolded protein aggregates that in turn leads to neurotoxicity. Targeting Hsp90 has been proposed as an attractive strategy to halt neurodegenerative diseases, and the benzoquinone ansamycin (BQA) Hsp90 inhib...
itors such as geldanamycin (GA) and 17-AAG have been found to protect against A53T α-synuclein induced toxicity in cell models of PD. However, current BQA inhibitors are relatively hepatotoxic in animal models, and a major mechanism of toxicity involves glutathione depletion as a result of arylation at the C19 position of the BQA. We have developed novel 19-substituted BQAs (19BQAs) as a means to prevent arylation and have validated that these compounds are unreactive at the 19-position using model thiols including glutathione. Our results show that 19BQAs exhibited little toxicity in SH-SYSY cells relative to their parent quinones (GA, 17-AAG and 17-DMAG) using trypan blue, MTT and Annexin/PD apoptosis assays, while they retained the ability to induce heat shock proteins (HSPs) and autophagy as determined by increased levels of Hsp70, Hsp27, and LC3 II respectively. Transduction of mutant A53T human α-synuclein adenovirus in SH-SYSY cells was further utilized to determine whether 19BQAs could ameliorate the neurototoxicity of mutant α-synuclein. 19-phenyl-GA, which caused potent induction of Hsp70, Hsp27, and LC3 II, significantly attenuated A53T α-synuclein-induced toxicity. These results indicate that 19BQAs may provide a means to modulate protein-handling systems in neural cells thereby ameliorating the aggregation and toxicity of proteins such as mutant A53T α-synuclein (supported by CAS51210, ES018943 and Parkinsons UK).

### High-Throughput In Vitro Toxicity Screening Using Autonomously Bioluminescent Human Cells in 2D and 3D Cultures

T. Xu1,2, J. D. Webb1, A. Rogers1,2, D. Close2, S. Ripp1,2 and G. S. Sayler1,2.
1The University of Tennessee, Knoxville, TN and 240 Bio-Tech Inc., Knoxville, TN.

In vitro cell culture-based assays have increasingly become fast, high-throughput, and low cost alternative to in vivo animal tests for tier 1 cytotoxicity screening of a large and still growing number of small molecule candidates in the drug development pipeline. Most of the current cell assays employ endpoint measurements that require cell destruction and/or substrate addition, thus limiting informational output to only intermittent single time point snapshots as well as requiring large numbers of samples be analyzed in parallel for basic toxicological kinetics studies. To overcome this disadvantage, we have demonstrated substrate-independent bioluminescent imaging in living human cells using a synthetically optimized bacterial bioluminescence ($\text{luc}$) reporter system. To evaluate its application for toxicity screening, $\text{lux}$-expressing autobioluminescent HEK293 cells were treated with the antibiotic Zeocin, whose toxicity was measured using the $\text{luc}$-based autobiloluminescent assay, and the traditional MTT assay every 24 hours for 4 days. While the MTT assay required an individual set of samples for each time point, the substrate-free nature of the $\text{luc}$-system allowed for repetitive, near real-time monitoring of the same cell population over time. Exposure to 1000× of Zeocin resulted in 500× activity to 11.9% and 13.9% compared to untreated cells after 2 days of exposure monitoring of the same cell population over time. Exposure to 1000× Zeocin allowed for repetitive, near real-time $\text{lux}$-tobioluminescent assay, and the traditional MTT assay every 24 hours for 4 days.

### Lack of Neuropathy after Long-Term Tedizolid Phosphate Administration in Rats

H. Hosako1, A. Radovsky1, D. Dragano1, J. Vijal and K. Barrantal1,1,2
1Toxicology, WIL Research, Ashland, OH and 2Cubist Pharmaceuticals, San Diego, CA.

A number of antibiotics, including linezolid (LZD), are associated with mitochondrial toxicity that can manifest as serious optic and/or peripheral neuropathy, primarily during long-term therapy. In a 6 month rat study, sciatric and optic nerve degeneration was observed with LZD exposures similar to those in humans. Tedizolid phosphate, a novel antibiotic prodruk given once/d for 6 days demonstrated noninferior efficacy to LZD twice/d for 10 days and may have less potential for mitochondrial toxicity. The neurotoxic potential of tedizolid phosphate in rats was examined in a robust 9 month study. Tedizolid phosphate in vehicle was administered orally to Long Evans rats (N = 366) once/d for 13, 3, 6, or 9 months at 7.5, 15, and 30 mg/kg (males) and 2.5, 5, and 10 mg/kg (females); dose levels were chosen to cover tedizolid exposures up to 10-fold of those in patients. Concurrent controls (N = 366) received vehicle only. The neurotoxic potential of tedizolid phosphate was thoroughly evaluated by a number of behavioral and neuropathological assessments. Toxicokinetics of the active moiety tedizolid were assessed throughout the study. There were no drug-related effects on survival, food consumption, functional observational battery assessments, locomotor activity, brain weight/measurements, ocular examinations, and macroscopic and microscopic neuropathological findings (including sciatic and optic nerves); of note, 9 month microscopic data are still being analyzed. Tedizolid exposure generally increased proportionally to dose, with little accumulation over time. Average and 9 month peak steady-state exposures were 6.6-fold and 8-fold, respectively, of those in humans with standard 200 mg/d dose. This rigorous animal study showed no evidence of neurotoxic effects during long-term administration of tedizolid phosphate at systemic exposures considerably higher than achieved at the human therapeutic dose. These results suggest a reduced neurotoxicity risk with long-term tedizolid phosphate treatment relative to LZD.

### Sequence Motifs Associated with Hepatotoxicity of Locked Nucleic Acid (LNA)-Modified Antisense Oligonucleotides

B. D. Hollingshead1, A. D. Burdick1, S. Sciabola2, S. R. Mantena1, R. Stanton2, J. Warneke1, M. Zeng1, E. Martensen1, A. Medvedev1, S. S. Makarov1, L. Reed1, J. Davis1 and L. O. Whiteley1,1
1Drug Safety Research and Development, Pfizer, Cambridge, MA, 2Oligonucleotide Therapeutic Unit, Pfizer, Cambridge, MA and 3Atogense Inc, Morrisville, NC.

Locked Nucleic Acids (LNAs) are third generation antisense oligonucleotide (ASO) modifications that improve target affinity, RNase H activation and stability. LNA modifications may increase the risk of hepatotoxicity compared to other types of ribose modifications. In vitro cytotoxicity screens have not been reliable predictors of hepatic toxicity in non-clinical testing; however, mice are considered to be a sensitive test species. To better understand the relationship between nucleotide sequence and hepatotoxicity, a structure-toxicity analysis was performed using two-week safety studies in mice administered with LNA-modified ASOs at a dose of 25 mg/kg. ASOs targeting human Apolipoprotein C3 (ApoC3), CREB (CRMP Response Element Binding Protein) Regulated Translocation Coactivator 2 (Crtc2) or Glucocorticoid Receptor (GR, NR3C1) were classified based on the presence or absence of hepatotoxicity in mice. From these data, a Random Forest classification model built from nucleotide sequence motif descriptors revealed two motifs (TCC and TGC) that were present only in hepatotoxic sequences. We found that motif containing sequences had higher propensity for binding hepatocellular macromolecules and increased P53 and NRF2 stress pathway activity. These results suggest in silico approaches can be utilized to establish structure-toxicity relationships of LNA-modified ASOs and decrease the likelihood of hepatotoxicity in preclinical testing.

### PARP Inhibitors and Centrosome Declustering: Bone Marrow Safety Implications

M. Crosby1, R. Caccone1, M. V. Nadel1a, K. Mikule2 and J. Sasaki1.
1Drug Safety and Metabolism, AstraZeneca Pharmaceuticals, LP, Waltham, MA and 2Oncology Innovative Medicines Unit, AstraZeneca, Waltham, MA.

PARP inhibitors may selectively target cancer cells via centrosome declustering (CD). We explored the bone marrow (BM) safety profile of PARP inhibitors that induce CD and/or multipolar spindles (MPS) through in vitro and in vivo experiments. PARP inhibitors were synthesized and ranked according to CD and MPS-forming activities. Efficacy data suggested that this activity was PARP6-mediated. Although PARP6-dependent activity was considered to be cancer cell-specific, BM toxicity was observed in efficacy in vivo studies. To address the hypothesis that compounds inhibiting PARP1-3 could be responsible for the observed BM toxicity, we performed in vitro colony-forming cell (CFC) assays. We investigated 15 compounds with different MPS-inducing and PARP1 activities. The compounds’ potencies in the CFC assays aligned with MPS-inducing activity, but not with PARP1 inhibition. To confirm the relationship between CD/MPS and BM toxicity in vivo, studies were conducted using enantiomers with differential MPS-inducing potencies (EC50s of 0.02 μM vs. inactive), but with similar PARP1 activities. The two compounds were dosed to give equivalent exposure over the course of 10 days (oral). Complete blood counts (CBCs) and BM flow cytometry revealed that BM toxicity occurred only in animals dosed with the enantiomer that caused MPS. Whereas there were peripheral, panmyelopenic-suppressive changes with the active enantiomer, the inactive enantiomer showed no significant changes in CBCs. BM flow cytometry analyses showed significant reductions in lymphoid, myeloid, and erythroid cell populations, ranging from 70–100% over the course of the experiment with the active enantiomer. This was in contrast to the inactive enantiomer, which showed mild (10–20%) reductions in the same BM cell populations. The enantiomer experiment revealed that the proposed mechanism of PARP6-associated CD/MPS induction was independent of PARP1 and was directly associated with BM toxicity. Interestingly, this reflects a novel role for PARP6 in the BM.
Despite 30 years of extensive research on therapeutic development, the 5-year survival rate for patients diagnosed with glioblastoma remains less than 5%. The aggressive nature of glioblastoma often renders radiation and surgery ineffective. Thus, discovering new compounds that mitigate glioblastoma progression is vital to improving patient survival. We utilize an innovative orthotopic zebrafish xenograft model to assess drug efficacy in inhibiting human glioblastoma proliferation, invasion and angiogenesis within a 3-day time frame. Zinc oxide nanoparticles (ZnO-NPs) demonstrate preferential cytotoxicity to cancer cells in culture; therefore, we are interested in confirming whether this selective toxicity is conserved in vivo. Although ZnO-NPs prevented glioblastoma cell proliferation in vitro, preliminary experiments at exposure levels tolerable to the zebrafish revealed the ZnO-NPs significantly enhanced proliferation in the xenograft model. Knockdown of calpain 2 reduces glioblastoma invasion by ~90%; therefore, we are also interested in using our model to identify novel therapeutics that impede glioblastoma invasion through calpain 2 inhibition. In vitro testing of calpain 2 inhibitors identified two compounds that block glioblastoma invasion at low μM concentrations while causing minimal toxicity to the zebrafish, making ideal candidates for testing in the xenograft model. The results of screening putative anti-proliferative NPs and anti-invasive calpain 2 inhibitors will be compared to known chemotherapeutics LY294002, temozolomide and acivicin. Our approach holds promise for efficiently prioritizing novel glioblastoma therapeutics for future development. Research support: NSF 134468; NIEHS P30ES00210; ES016896 and T32ES070600.

Chagas disease is a protozoan zoonosis caused by Trypanosoma cruzi that has infected a large number of people. So far there is no effective drug for Chagas disease treatment. So, the Institute of Pharmacutical Technology at Fiocruz has designed three nitro analogs of the nitroimidazole-thiadiazole megazol: PTAL 05-02 (5-(1-methyl-5-nitro-1H-2-imidazolyl)-1H-1,2,4-triazol-3-amine), PAMD 09 (2-amine-N-(1-methyl-4-nitro-1Himidazolyl)-5-(trifluoromethyl)-1H-1,2,4triazole) and PTAL 04-09 (1-(1-methyl-4-nitro-1H-imidazol-5-yl)-1H-pirazole), whose toxicological properties were not evaluated. Thus, this work investigates the mutagenic, cytotoxic and genotoxic activities of megazol and its nitro analogs. The Salmonella microsome assay was performed using the pre-incubation protocol with different strains of Salmonella enterica serovar Typhimurium (TA97, TA98, TA100, TA1535; TA102), and the Micronucleus assay was carried out with RAW264.7 macrophage rat cells. The assays were performed in accordance with OECD (1997 and 2010) standards. Megazol showed dose-dependent mutagenic and cytotoxic activity at very low concentration (0.05 μg/mL) for all S. enterica strains, with and without metabolic activation (95% mix). PTAL 04-09 was the only analog to present mutagenic activity (TA100) at the higher concentration (50 μg/mL), with and without S9 mix. All of the nitro analogs presented cytotoxic activity to at least one strain (TA100 and/or TA1535), only with S9 mix. Moreover, all of them were capable of inducing micronucleus formation and showed cytotoxic effects (apoptosis and necrosis) at all concentrations (1.0 to 100 μg/mL). Our results showed that advances can be made in the development of new safe compounds to the Chagas disease treatment.
of which were exposed to TCDD. Expression pattern of EGFP in the reporter zebrafish mirrored that of endogenous cyp1a mRNA. Using this transgenic cyp1a reporter zebrafish, we screened 6,400 small molecules for inhibitors of dioxin toxicity and identified several compounds that almost completely suppressed pericardial edema, a characteristic feature of zebrafish embryos. We are currently testing efficacy of various derivatives of these compounds in the zebrafish embryos. Development of dioxin inhibitors will further understanding of dioxin toxicology and contribute to the treatment of dioxin intoxication.

1639c Magnetic 3D Bio-Printing: A Novel High-Content Assay for Drug Toxicity Screening

H. Tseng, J. A. Gage, W. L. Haider, S. K. Neeley, G. R. Souza and T. C. Kilián. NanoBiomed, Houston, TX, 2Biomedical Engineering, Rice University, Houston, TX and 3Physics, Rice University, Houston, TX. Sponsor: M. Wagner.

A growing demand exists for the development of 3D cell culture models for drug screening that predict in vivo response more accurately than traditional 2D models. To meet this demand, we developed a real-time and dynamic 3D assay for drug screening based on magnetically bio-printed 3D cultures. This assay is based on the use of magnetic nanoparticles to rapidly assemble and print cells into 3D cellularized dots or rings that contract over time, and at rates that can vary with drug concentration. Here, this assay was validated using 3T3 murine embryonic fibroblasts. 3T3s were first incubated overnight with the magnetic nanoparticle assembly and bio-printed the next day either into 3D dots or rings, and allowed to shrink over 5 hours. Contraction due to cell-cell interaction and migration was captured using a mobile device programmed to image whole plates of 3D cultures at specific timepoints, eliminating the need to image rings constantly under a microscope. This assay is label-free that allows for post-assay experimentation to explore mechanisms of action and yield more content per experiment. This assay was validated as both a measure of drug response in 3D by comparing it to a 2D viability assay, as well as a high-content assay by fluorescent staining for viability and cytoskeletal organization, and compared to a 2D viability assay. With increasingly toxic drug concentrations, 3T3 dots and rings shrank at a slower rate, became less viable, and lost cytoskeletal organization. This assay was validated using retinoic acid, dexamethasone, doxorubicin, forskolin, fluorouracil, and nor-epinephrine, showing higher drug sensitivity compared to cells in 2D. Other cell types have been tested, including cancer cell lines, such as MCF-10A, and primary cell lines, like vascular smooth muscle cells.

1640 Ocular Anatomical Features in Rabbits, Dogs, and Monkeys: a Comparison with Human Data

In non-clinical studies for the development of ophthalmic products, laboratory animals such as rabbits, dogs, and cynomolgus monkeys are used frequently. The comparative researches for the ocular anatomy are essential for interpreting of data and extrapolating to human. However, the information has been scattered, and there is less comprehensive literatures easily to compare between the species. The purpose of this study is to provide direct and systematical comparison data of the ocular anatomical features from rabbits, dogs, and monkeys, and to compare with human data which were already established. The eyeballs from animals were all obtained from the purpose-breed animals ethically euthanized. After measuring the eyeball size (axial length, weight and volume), they were frozen. The frozen samples were dissected and measured for lens and vitreous size parameters during gradual throwing. As the result, the present study provided anatomical measurement values comprehensively for whole eyeball, lens, vitreous as well as body weight in each animal species. In comparison with human, the ratio were 0.39, 0.82 and 0.46-fold against human value (as 1) for eyeball weight, 1.71, 2.48 and 0.53-fold for lens weight, and 0.34, 0.73 and 0.55-fold for vitreous volume in rabbits, dogs, and monkeys respectively. Vitreous size was not directly depended on body weight of animals itself. This result enables us to set the dosage volume of drugs based on the size of animal eye. Furthermore, the ratio of dosage volume to eyeball size makes extrapolating to human more precise. In conclusion, this study provided a direct comparative data of ocular anatomical features in rabbits, dogs and monkeys and compared with human data. This would be useful for evaluating the non-clinical studies for ophthalmic products.
Mitochondrial Toxicity: Assessing In Vitro-In Vivo Correlative Risk in the Antiviral Human Rhinovirus Project (HRP)

Mammalian mitochondria possess a bacterial and viral ancestry [1]; as a consequence, antibacterial as well as some antiviral therapies could be prone to increased potential for mitochondrial toxicity. One such antiviral program, HRP identified a potential mitochondrial toxicity liability, during in-vitro screening using the glucose/galactose assay. AZN001, the original lead, had a Glu/Gal ratio of 8.5 that translated to IC50=15μM in the mitochondrial oxygen consumption assay. Although these in-vitro assays are considered predictive for mitochondrial toxicity, their actual translations in-vivo, including a quantitative in-vivo - in-vivo relationship and finding a molecular mechanism, are yet to be established. To address these points, AZN001 (top dose 750 mg/kg/d) has been tested in a 7-day rat study. Several parameters that can suggest mitochondrial dysfunction, including plasma lactate and transmission electron microscopy (TEM), were included in the study. As monitored by these in-vivo end points, a clear translation of in-vitro effects was observed. No clear guidance for a quantitative in-vitro and in-vivo relationship could be established. Additionally, an in depth in-vitro mechanism study involving AZN001 and mitochondrial respiratory enzymes indicated potential inhibitions of mitochondrial complex I and/or complex V. In the light of these observations, the HRP team has implemented a suitable testing strategy for development of follow up lead candidates.

Rapid Screening of Master Viral Stocks for Wild-Type Contamination

G. K. Massey2, G. P. Gambill2, A. D. Penman1,2 and K. K. Daniels1.

Adenovirus 5 (Ad5) vectors are commonly used for vaccines and gene therapy. The E1A gene is required for viral replication. Some therapies take advantage of this property by inserting a therapeutic gene of interest in place of E1A. Since vector production requires the trans-complementation E1A, cell lines were generated to include the Ad5 sequence needed for replication. However, homologous recombination can occur during propagation, resulting in wild-type vector. These vectors are monitored for recombination to wild-type by their ability to infect cells lines without trans-complementation factors. Other gene therapy vectors take advantage of viral replication. For these vectors, a selective promoter replaces the E1A promoter so replication only occurs in cells of interest. These vectors are able to replicate, but only in the presence of cellular factors that activate the new promoter. If propagated in cell lines with wild-type sequence, homologous recombination can also occur, resulting in wild-type vector. Since both vectors are replication competent, there is difficulty distinguishing modified vector from wild-type Ad5. Therefore, a more specific test is needed to ensure vector stocks do not contain wild-type Ad5. To the specific and quantitative nature of real-time PCR, an assay for the wild-type promoter can be used to monitor for wild-type contamination of master viral stocks. Our method allows for the identification of 1-10 copies of wild-type Ad5 in the presence of 108 copies of modified vector. The method takes approximately 3-4 hours, allowing for same day results. Utilizing vectors from preclinical and/or clinical studies, we will present data demonstrating that using our method, 2 of the 4 vectors tested had appreciable levels of wild-type contamination.

Understanding Mechanisms of Drug-Induced Liver Injury Using Primary Human Cell and Coculture Systems

Drug-induced liver injury (DILI) still remains a challenge to the pharmaceutical industries and regulatory authorities due to its idiosyncratic nature. Elucidating the mechanisms by which injury occurs in human hepatocytes and other liver cells is focus of attention. Here, we attempt to understand the mechanisms of DILI...
using complex co-cultures of primary human cells (BioMAP systems). 10 discontinued Pfizer compounds and 25 known drugs (withdrawn from market or with black boxed-warnings) with clinical DILI and a small set of non-DILI compounds were retrieved from ToxCast Phase II dataset. These compounds were profiled in eight primary human cell cultures (at multiple concentrations) including endothelial, epithelial, smooth muscle, fibroblasts and immune cells, stimulated with specific combination of inflammatory mediators, with activity in total of 87 protein readouts. Compounds were classified based on their similarity to BioMAP profiles, which resulted in a number of unique clusters for DILI compounds. Some of these compounds exhibited overt cytotoxicity in multiple cell types, whereas others showed only low activity in one cell type. A subset of these clusters were also studied using a validated clinical assay. Specific metabolites of each cluster were sequenced to identify a unique set of metabolites associated with each profile. Efforts were made to use these clusters to develop a robust computational model for predicting DILI risk.

1648 Assessment of Phencyclidine in the Evaluation of Physical Dependence in Rats Using the Nonprecipitated Withdrawal Test

P. Attenborough, J. Tookey, T. Pringle, M. Bennett and K. Landis. WIL Research, Ashland, OH.

Physical dependency assessments are conducted as part of the FDA and EMEA requirements pertaining to the medicinal product scheduling and investigation of dependence potential. Due to specific and often unique mechanisms of action for each drug class, it is necessary to evaluate and establish appropriate paradigms to assess physical dependency as part of a larger drug abuse liability (DAL) program. Therefore, the use of a validated and robust rodent model with appropriate non-precipitated withdrawal tests is necessary to adequately determine dependence potential. The objectives of this study were to establish standard withdrawal scores, changes in qualitative motor activity, and alterations in operant behavior assessments following chronic administration of the NMDA-R antagonist, phencyclidine (PCP). Phencyclidine was administered by subcutaneous injection to 8 groups of Wistar or Sprague Dawley adult male rats (n=6 rats/group) on an escalating dose regimen (up to 80 mg/kg/day) over the course of 21 to 28 days, followed by 1 to 2 week withdrawal period. During the treatment and withdrawal phases, animals were monitored for body weight (BW), food consumption (FC), qualitative motor activity (MA), neurobehavioral/clinical observations (OBS), and operant scheduled behavior (OPB). During treatment, BW, FC, OBS, MA, and OPB were relatively consistent across PCP treatment groups, with characteristic increased motor activity and decreased motor coordination. Following the cessation of PCP dosing, OBS and initial MA were not significantly different across treatment groups, suggesting a lack of robust withdrawal behaviors. However, OPB assessments exhibited a significant decrease in OPB following the cessation of PCP dosing. These results demonstrate the importance of proper paradigm selection when designing specific DAL studies.

1649 Investigation of the Method of Oral Mucosal Irritation Test by Oral Instillation in Rats

Evaluation for oral mucosal irritation is requested at the time of submission of new drug application when the clinical route of drug candidate intends to be introrally administered. Generally, oral mucosal irritation tests have been conducted by applying test substances on the mucosa of cheek pouch in hamsters. In the present study, we conducted a cumulative oral mucosal irritation test in rats to evaluate the irritation potential of sodium dodecyl sulfate (SDS) according to the Cosmetic, Toiletry and Fragrance Association (CTFA) guidelines. Macroscopic and histopathological examination of oral mucosa was investigated. SDS was administered 4 times daily at 1-hr intervals for 4 or 10 days to rats under the different conditions as follows: instillation of 0.5%, 4% and 15% SDS (0.1 mL) into the oral cavity and application of 4% SDS (0.1 mL) with a paint brush to the labial mucosa and incisor gingiva of the mandibular oral vestibule. The irritation potential of SDS was evaluated on the basis of the daily mean total score (DMTS) and was classified as follows: Nonirritant (DMTS: 0), Mild irritant (DMTS: 0.5-1.0), Moderate irritant (DMTS: 1.1-2.0) and Severe irritant (DMTS: 2.1 and over). Macroscopic observations included sloughing on the incisor gingiva in the 4% SDS application and 15% SDS instillation groups. In addition, discoloration was a notable effect observed in the 15% SDS instillation group. The DMTS for 4% SDS application and 15% SDS instillation were 0.6 and 1.3, respectively. Therefore, SDS in each experiment was evaluated as “Mild irritant” and “Moderate irritant”, respectively. By contrast, no oral mucosal irritation was observed in the 0.5% or 4% SDS instillation groups. In the histopathological examination, parakeratosis and thickening of the mucosal epithelium were observed on the labial mucosa in the 4% SDS application and 15% SDS instillation groups. It is suggested that this oral mucosal irritation test method by oral instillation in rats could be helpful to evaluate liquid drugs.

1650 Comparative Subchronic Toxicity Studies in Rats of LY2963016 (LY), an Insulin Glargine Product, with USA-Sourced Lantus® (US–L) and EU-Sourced Lantus® (EU–L)

LY2963016 is an insulin glargine product, with an identical amino acid sequence to Lantus® insulin glargine. To support human clinical trials and in agreement with regulatory guidance for follow-on biologics, the toxicity of LY was characterized in rats alongside two reference insulin glargine products: US-L (Study 1) and EU-L (Study 2). Dosing was daily via subcutaneous injection for 4 wk. In Study 1, LY or US-L doses of 0, 0.3, 1.0, and 3.0/2.0 mg/kg were given. In Study 2, LY or EU-L doses of 0, 0.3, 1.0, and 2.0 mg/kg were given. The findings in Studies 1 and 2 were related to hypoglycemia or hyperinsulinemia at all LY and Lantus doses; the severity and duration of hypoglycemia was dose related. In Study 1, dosing was suspended at 3 mg/kg LY or US-L for 3 d due to multiple mortalities and associated severe hypoglycemia and then resumed at 2 mg/kg for the remainder of the study. Overall, the maximum tolerated dose (MTD) was exceeded in Studies 1 and 2 for LY, US-L and EU-L at ≥1.0 mg/kg based on hypoglycemia related mortalities. Hypoglycemia also occurred, but was tolerable with no associated mortality in the 0.3 mg/kg doses for LY, US-L and EU-L. Statistic nerve degeneration, a common sequelae of sustained hypoglycemia, occurred at the high dose with LY, US-L and EU-L. At study termination, rebound hyperglycemia and pancreatic islet cell atrophy were observed at ≥1.0 mg/kg of LY, US-L or EU-L and was most likely due to down regulation of endogenous insulin synthesis secondary to hyperinsulinemia. Increased fat was observed in the skin, subcutis and injection sites at all doses of LY, US-L and EU-L consistent with lipogenic pharmacology typical of insulins. Based on the occurrence of intolerable hypoglycemia in rats at doses ≥1.0 mg/kg, the MTD and NOAEL (no-observed-adverse-effect level) was 0.3 mg/kg for LY, US-L and EU-L. Therefore, we conclude that the toxicity profiles of LY, US-L and EU-L are highly similar.

1651 Glucocorticoid-Induced Bone Loss in Aged Rats Is Not Reversible

The objective of this study was to investigate the effects of methylprednisolone (a glucocorticoid, 5 mg/kg/day) on bone when administered to aged rats (19 week old female Wistar Hannover) with an inactive growth plate. Experimental animals were dosed 13 weeks followed by an 8-week recovery period. Effects on bone densitometry and bone geometry were evaluated (using pQCT) at baseline and Weeks 4, 13 and 19. In addition, body weight, food consumption, selected serum biochemistry and bone turnover markers were evaluated to add perspective on mechanisms underlying bone effects. Sharp decreases in bone weight, bone length and bone mineral density were observed at all doses of LY, US-L and EU-L consistent with lipogenic pharmacology typical of insulins. Based on the occurrence of intolerable hypoglycemia in rats at doses ≥1.0 mg/kg, the MTD and NOAEL (no-observed-adverse-effect level) was 0.3 mg/kg for LY, US-L and EU-L. Therefore, we conclude that the toxicity profiles of LY, US-L and EU-L are highly similar.

The objective of this study was to investigate the effects of methylprednisolone (a glucocorticoid, 5 mg/kg/day) on bone when administered to aged rats (19 week old female Wistar Hannover) with an inactive growth plate. 1652 Rat-Specific MOA for Tumor Formation in Rats with the SGLT2 Inhibitor Canagliflozin

B. Feyen1, E. Moesen1, S. De Jonghe1, P. Vinken1, J. Ying Ma2, M. D. Johnson2, M. Srinivas2, W. Coussement1, Y. Van Bekkum1 and L. Lammens1. 1Drug Safety Sciences, Janssen, Beerse, Belgium and 2Drug Safety Sciences, Janssen, Raritan, NJ.

Canagliflozin, a sodium glucose cotransporter 2 (SGLT2) inhibitor, caused renal tubular rutos (RTTs) and pheochromocytomas in a 24-month rat carcinogenicity study at the high dose. Canagliflozin is also a low potency inhibitor of SGLT1 and causes carbohydrate (CHO) malabsorption at high doses in rats via inhibition of intestinal glucose transport leading to increased intestinal calcium absorption (secondary to acidification), hypercalcuria and hyperostosis. This carbohydrate malabsorption was believed to play a role in the induction of the renal and adrenal tumors. A 6-month mechanistic study (with a 1 and 3 month interim evaluation) was performed in which rats were fed a glucose-free 40% fructose diet. The purpose of this study was to prevent carbohydrate malabsorption and its sequelae. Urinary calcium, development of hyperostosis, and serum 1,25-dihydroxyvitamin D and parathyroid hormone (PTH) were used to confirm the effectiveness of the intervention. In addition, cell proliferation was evaluated in kidneys and adrenal medulla by BrdU-immunohistochemistry and kidney injury was evaluated by KIM-1 immunohistochemistry, to evaluate the link between CHO malabsorption and kidney injury/cell proliferation (as proximal steps in tumorigenesis) in these target tissues. Utilization of a glucose-free fructose diet prevented the effect on CHO malabsorption and its sequelae including hyperostosis and increased calcium absorption. Cell proliferation in the kidney and adrenal medulla was increased in rats administered canagliflozin (cana) fed a standard diet, and immunostaining was increased for the proliferation marker Ki67. These effects were inhibited in cana-treated rats maintained on the glucose-free fructose diet indicating they are secondary to CHO malabsorption and are not direct effects of canagliflozin. CHO malabsorption was absent in humans at clinical doses indicating that the tumor findings in rats are not clinically relevant.

1653 Expanded Therapeutic Index of Antithrombin Silencing and Correction of APTT in a Hemophilia A Mouse Model

ALN-AT3, a subcutaneously administered RNAi therapeutic targeting antithrombin (AT), is currently being developed for the treatment of hemophilia and rare bleeding disorders. It has previously been demonstrated that once weekly dosing of ALN-AT3 results in potent, dose-dependent and reversible silencing of plasma AT in multiple preclinical species. In the mouse, steady state ED50 knockdown was achieved following weekly doses of 0.5 mg/kg. This study evaluated the exaggerated pharmacology of ALN-AT3 when administered via weekly SC injections (x 7 wks) to wild-type (WT) vs. hemophilia A (HA) mice at 0, 10, 30, and 100 mg/kg (20-, 60- and 200-fold dose multiples of the mouse ED50). Test article-related effects were evaluated by clinical signs, BW, clinical pathology, organ weights, and histopathology of select tissues (eye, heart, kidney, liver, lung, spleen). The PD of ALN-AT3 was evaluated by plasma AT protein levels. Repeat dosing of a 10 mg/kg ALN-AT3 to WT mice was not tolerated, as evidenced by early mortality, adverse clinical signs (ocular abnormalities, craniofacial swelling, lethargy), weight loss, clinical pathology changes (±PLT, ±NEU), ± spleen weights, and microscopic findings in heart (thrombi) and eye (hemorrhage). Residual plasma AT protein in all tumor findings in rats are not clinically relevant.

Body weight, food consumption, rectal temperature, and ophthalmology were evaluated prior to, during and after treatment. Hematology, coagulation, blood biochemistry and C-Reactive Protein (CRP) levels were evaluated prior to treatment and on days 2, 8, 53, 58, 64 and 85. After the treatment period all animals in each subgroup were sacrificed and examined macroscopically. Selected tissues were weighed and preserved. Microscopic examinations were performed on the kidneys only on day 58, and on all preserved tissues on day 60. No unscheduled deaths occurred during the study and no signs of systemic toxicity were observed. Animals treated with PLG had a higher incidence of reactions (mainly erythema) at injection sites relative to the controls, which persisted for up to 19 days. Since all local reactions were reversible, PLG was considered well tolerated locally. Mean body weight and food consumption were unaffected by PLG treatment. No remarkable effects on rectal temperature or ophthalmological findings were observed in the control or PLG groups. Hematology, coagulation parameters, blood biochemistry and CRP levels were unaffected by PLG exposure. IM administration of PLG did not induce any significant histopathological findings compared to saline, in particular, no kidney findings. The exipient PLG was considered to be well tolerated both locally and systemically following repeated IM injections in the rabbit.

1654 Repeated-Dose Intramuscular (IM) Toxicity Study with Poly-α-L-Glutamic Acid (PLG) in New Zealand White Rabbits

L. Segal1, É. Grosdidier2, C. Sobry3, G. Giordano3, M. Damsten1, R. Forster1, K. Frazer2 and E. Destexhe1. 1GlassmSmithKline Vaccine, Waver, Belgium; 2GlassmSmithKline Pharma, Upper Merrton, PA and 3CIToXLAB, Erreux, France.

The potential local and systemic toxic effects of five IM injections at 2 weeks intervals of the excipient PLG MW 2083 Da were studied in New Zealand White rabbits. PLG was administered at a dose of 6.25 mg/injection and compared with saline treatment. The PLG concentration, pH, osmolality, sterility and endotoxin levels were verified at each day of injection. Rabbits were distributed in 3 subgroups (5/sex) sacrificed 1, 3 or 28 days post last dose (days 58, 60 or 85). Animals were observed for mortality/morbidity, clinical signs, and local injection site reactions. Body weight, food consumption, rectal temperature, and ophthalmology were evaluated prior to, during and after treatment. Hematotoxicity, coagulation, blood biochemistry and C-Reactive Protein (CRP) levels were evaluated prior to treatment and on days 2, 8, 53, 58, 64 and 85. After the treatment period all animals in each subgroup were sacrificed and examined macroscopically. Selected tissues were weighed and preserved. Microscopic examinations were performed on the kidneys only on day 58, and on all preserved tissues on day 60. No unscheduled deaths occurred during the study and no signs of systemic toxicity were observed. Animals treated with PLG had a higher incidence of reactions (mainly erythema) at injection sites relative to the controls, which persisted for up to 19 days. Since all local reactions were reversible, PLG was considered well tolerated locally. Mean body weight and food consumption were unaffected by PLG treatment. No remarkable effects on rectal temperature or ophthalmological findings were observed in the control or PLG groups. Hematology, coagulation parameters, blood biochemistry and CRP levels were unaffected by PLG exposure. IM administration of PLG did not induce any significant histopathological findings compared to saline, in particular, no kidney findings. The exipient PLG was considered to be well tolerated both locally and systemically following repeated IM injections in the rabbit.

1655 Preclinical Safety Development of a New HSV-2 Prophylactic Candidate Vaccine to Support a First-in-Human Phase I Clinical Trial

D. Paul1, V. Barbar2, A. Popineau3 and S. J. Gould1. 1NonClinical Safety, Sanofi Pasteur, Marcy l’Etoile, France and 2NonClinical Product Performance, Sanofi Pasteur, Marcy l’Etoile, France.

Herpes simplex type-1 (HSV-1) and type-2 (HSV-2) viruses belong to the herpesviridae family of viruses (members of the alphaherpesvirus subfamily), which can cause prevalent, lifelong genital, dermal and ocular infections resulting in a spectrum of clinical symptoms including cold sores, genital ulceration, corneal blindness and encephalitis. HSV529, a viral vaccine candidate against HSV-2 wild type virus, is being developed to prevent HSV-2 genital infection. The vaccine is derived from a HSV-2 186 syn+1 wild-type virus, where the U5L and UL29 genes have been deleted, which are essential for viral replication.

To support a first-in-human study in healthy adults (18 to 40 years, ClinicalTrial.gov study code NCT01915212), a repeat dose toxicity and biodistribution studies were conducted in the guinea pig, which was selected as it is pathogenically sensitive to HSV-2 virus, closely mimics the human genital HSV-2 infection, and develops a positive humoral response to the vaccine.

The repeat dose study was conducted to assess the systemic toxicity and local tolerability and the biodistribution study was designed to evaluate the distribution, persistence, the ability to shed and to establish latency. In the repeat dose toxicity study, 4 intramuscular (IM) injections of a human dose (107 PFU/0.5 mL injection) induced a robust immune response. Effects were limited to reversible local reactogenicity and changes in the draining lymph nodes, related to immune stimulation. A transient minimal decrease in platelet count was also noted. The biodistribution study showed that following one IM injection at a human dose, no HSV529 was detected in any HSV-2 target organs and biofluids at the time points assessed. The study confirmed HSV529 was unable to distribute, propagate/replicate, shed or establish latency up to 45 days post injection. This data supported moving forward in a Phase 1 clinical trial with monitoring of local reactogenicity and platelet counts.
M. Davies

In conclusion, NKTR-192 toxicology studies in rats and dogs support the safety of NKTR-192 based on NOAEL and 45-fold for sedation, while oxycodone has narrower safety margins of 11-fold. Compared to a standard opioid (oxycodone), NKTR-192 demonstrates a clear separation of analgesia from CNS side effects with safety margins of 11-fold.

NKTR-192 was evaluated in 28-day repeat dose toxicity studies with a 2-week recovery observation period at oral BID doses up to 180 mg/kg/day in rats and 30 mg/kg/day in dogs. PLAT-bound PAI was not measured in the 2 euthanized monkeys from the 6-month study. PLAT-bound PAI was not measured in the 2 euthanized monkeys from the 6-month study. PLATs recovered at the end of 1-month recovery period. Plasma BMS-986001 levels for these 3 monkeys were similar to other monkeys given the same dose; thus higher BMS-986001 exposure did not explain the PLAT reductions.

Drug-induced PLAT reduction can be caused by anti-drug antibodies (ADA). To determine if PLAT reductions were mediated by ADA, serum platelet-associated immunoglobulin (PAI) levels were measured using PLAT-coated 96-well ELISA and by FACS analyses. No circulating PAI was detected in serum of any affected monkey by ELISA. However, PLAT-bound PAI was detected in CD42+ PLATs (IgG-PE mean fluorescence intensity [MFI]: 27 - 109; control MFI ≤7) correlating with the PLAT reduction in the 1 affected monkey, measured in the 9-month study. PLAT-bound PAI was not measured in the 2 euthanized monkeys from the 6-month study. These results suggest that BMS-986001-induced PLAT reduction in monkeys may have been due to PLAT-bound ADA and only in the presence of BMS-986001. Despite moderate levels of PLAT-bound IgG (MFI: 26) in the 1 affected monkey in the 9-month study, PLAT counts recovered to pretest values at the end of drug-free recovery period.

MTL-005 (copper meso-5,15-Bis[3-[(1,2-Dicarba-closo-dodecaboranyl)methoxy]phenyl]-meso-10,20-dinitroporphyrin) is under development as a radiosensitizer for use in head and neck cancer. In vivo it slows growth of murine squamous cell carcinomas and adenocarcinomas. Given i.p. to mice, it is cleared from the circulation and taken up by both normal tissues and tumors, with tumor concentrations up to 6 times higher than in muscle, skin, and brain. It concentrates in the liver and spleen and can be detected in both tumors and liver for at least 62 days post administration.

4 i.v. toxicology studies were carried out in rats and 2 in dogs. MTL-005 was dissolved in a mixture of dimethylacetamide, Solutol HS15 and PEG300 and diluted with 0.9% saline. Components of this vehicle are known to have toxic effects, especially in dogs. Rats were given 0, 20, 40 and 60 mg/kg (divided over 2 consecutive days) and dogs with 2 doses of 0, 1, 5 or 10 mg/kg given 14 days apart. Toxicities observed included body weight loss, reduced food consumption, dark discoloration of several organs, and reversible gastric epithelial hyperplasia (in rat at doses up to 30 mg/kg/day); and inflammatory changes at the infusion site, liver changes, and the death of 1 dog at 10 mg/kg. The vehicle may have contributed to the body weight, food consumption, and liver effects, as most of these signs were also observed in the vehicle controls. The MTD in rats was 40 mg/kg but a NOAEL could not be established due to the body weight losses observed both treated and control groups.

Dogs tolerated 1 or 5 mg/kg well but the vehicle contributed to the effects seen at 10 mg/kg. Liver histopathology findings and plasma chemistry changes associated with the vehicle were seen in all groups and liver histopathology findings persisted for 28 days. Injection site changes were reversible over 28 days. Again, a NOAEL could not be established.

These preclinical data were sufficient for regulatory approval of a Phase I clinical study of MTL-005 as an adjunct to radiotherapy in patients and this has now been initiated.

MTL-005, a Novel Polymer Conjugated Opioid Agonist, Demonstrates a Superior Preclinical Safety Profile to Traditional Opioids

C. Li, X. Ge, E. G. Tonkin, M. K. Sieverd and T. D. Swenson. 1Toxicology, Nektar Therapeutics, San Francisco, CA and 2Covance Laboratories, Madison, WI.

NKTR-192 is a new chemical entity mu opioid agonist that uses Nektar’s advanced polymer conjugate technology to achieve slow CNS uptake while maintaining adequate brain exposure with analgesia and is being developed for the treatment of moderate to severe acute pain. NKTR-192 produces full analgesic efficacy comparable to oxycodone in the mouse acetic acid writhing model. Orally administered NKTR-192 was evaluated in 28-day repeat dose toxicity studies with a 2-week recovery observation period at oral BID doses up to 180 mg/kg/day in rats and 30 mg/kg/day in dogs. Findings observed in both species are consistent with the pharmacology of a mu opioid agonist. Major dose-limiting toxicities with NKTR-192 included emesis in the dog, shallow respiration and hypooxygenization in both dog and rat. Doses exceeding the MTD in dog (>20 mg/kg as a single dose) caused severe respiratory depression and sedation that required naloxone reversal. In rats given >150 mg/kg as a single dose, target organ toxicities (dilation and/or hemorrhage) were observed in the urinary bladder and kidney. These findings were completely reversed after a 2-week recovery period. On the 28-day repeat dose toxicity studies, NOAELs of 120 mg/kg/day (BID) and 30 mg/kg/day (BID) were established in rats and dogs, respectively. A dose of 120 mg/kg/day NKTR-192 in rats provides an adequate animal to human safety margin to support clinical development. Compared to a standard opioid (oxycodone), NKTR-192 demonstrates a clear separation of analgesia from CNS side effects with safety margins of 11-fold based on NOAEL and 45-fold for sedation, while oxycodone has narrower safety margins of 3-fold for toxicity and 24-fold for sedation.

In conclusion, NKTR-192 toxicology studies in rats and dogs support the safety of NKTR-192 for clinical development and appears to have a superior therapeutic index relative to traditional opioids.
Onset of infusion, allowing review of the CP data prior to dose escalation. In conclusion, the other end of the infusion line was connected to a portable pump secured to a subcutaneously implanted vascular access port (VAP) and accessed via needle. The animal was dosed on D1 at 27.5mL/kg over 24hrs and CS were reviewed every 4hrs. Daily bodyweight and food consumption was recorded and CP samples were collected 20hrs into infusion, allowing review of the CP data prior to dose escalation. In conclusion, animals tolerated infusion of large volumes of LE; however, precise monitoring and stepwise volume escalation were critical.

### 1662a The Science behind Personal Care Products: A Hands-On Approach to Engaging K–12 Students

K. Sprugel1 and R. Weeks2, 1Angen Inc, Seattle, WA and 2NWABR Volunteer, Seattle, WA.

Making science relevant and hands-on is critical to engaging middle and high school students. Northwest Association for Biomedical Research (NWABR) has developed a four lesson curriculum, “Consumer Awareness: Personal Care Products Safety and Labeling” that investigates the science, labeling and safety testing behind personal care products. The lessons, which include a lotion-making lab, have been presented by teachers and toxicologists to diverse student audiences in classrooms and informal education workshops.

This four lesson curriculum reminds students that science is part of their everyday lives, especially if they are to be informed consumers. It makes science and toxicology relevant through the exploration of the science and safety testing behind personal care products. It emphasizes critical evaluation skills and a basic understanding of science and regulations. The curriculum guides students through the analysis of personal care products by incorporating multiple aspects of:

- Science: biology, chemistry, toxicology, math
- Research: drug development process, experimental design, evaluating sources of information
- Ethics: safety testing on animals and humans
- Social Responsibility: risk assessment and safety policies, consumer advocacy

The lessons and workshops can be tailored in length and depth to engage the target audiences in formal and informal learning environments. Training with the curriculum has been offered to over 270 teachers across the country. The Kit loan program for teachers has reached over 11,400 students. Two hour workshops highlighting the lotion making lab and labeling have also been conducted with other groups such as Girl Scouts, after school programs and summer camps (~1000 students). The curriculum guides students through the analysis of personal care products by incorporating multiple aspects of:

- Science: biology, chemistry, toxicology, math
- Research: drug development process, experimental design, evaluating sources of information
- Ethics: safety testing on animals and humans
- Social Responsibility: risk assessment and safety policies, consumer advocacy

### 1662b Strategy to Develop Expertise in Risk Assessment in Developing Countries

S. B. Barrios1, E. S. Nascimento1, J. V. Camargo2, E. M. Faustman3, A. Hayes1, L. Rosenheck4 and G. D. Umbuzeiro5, 1USP, Sao Paulo, Brazil, 2UNESP, Botucatu, Brazil, 3U of Washington, Seattle, WA, 4Harvard University, Boston, MA, 5LR Risk Consulting Inc, Greensboro, NC, and 6UNICAMP, Limeira, Brazil.

Although basic principles of toxicology are taught in undergraduate courses in Latin America (LA), chemical risk assessment (RA) is not a topic generally discussed even in graduate programs. To fill this gap, the Brazilian Society of Toxicology and IUTOX developed since 2008 a six days workshop, based on the IUTOX Risk Assessment Summer School concept, to respond to this need for well trained Risk Assessors and Managers (RAM) in both government and industry and to give current and future regulators an improved perspective on how toxicological

1660 Nonclinical Safety Assessment of Tofacitinib in the Juvenile Rat and Monkey

C. I. Bowman, M. Collinge, Z. Rada, T. T. Kawabata, W. M. Vogel and D. J. Ball, Pfizer, Groton, CT.

Tofacitinib (Xeljanz) is a novel oral inhibitor of intracellular Janus kinases (pan-JAK inhibitor) for the treatment of rheumatoid arthritis. JAK is critical for intracellular signaling transduction of activated cytokine receptors, including those important for lymphocyte activation, proliferation and function. To support the use in pediatric patients as young as 2 years old with juvenile idiopathic arthritis, toxicity studies in juvenile rats and cynomolgus monkeys were conducted. Based on previous findings in adult animals, the immune, hematopoietic and reproductive systems were targeted for evaluation. A 39-week juvenile monkey study (with 26-week recovery) initiated in 14 month-old animals revealed decreased red blood cell parameters, lymphocyte and lymphocyte subset numbers, primary T-dependent antibody response and immune system organ weights during the dosing phase but partially to fully recovered by the end of the dose-free period. A one-month juvenile rat study with 2-month recovery was initiated in 3-week old rats to enable evaluation in animals roughly equivalent to the youngest patient age of 2 years old. In juvenile rats, expected effects on immune and hematopoietic parameters were observed by the end of dosing but were no longer present at the end of the recovery period. Overall, the immune and hematopoietic effects observed in juvenile rats and monkeys were reversible and consistent with JAK inhibition and effects observed in adult animals. Lastly, effects on fertility were evaluated following tofacitinib oral administration in rats from weaning (3 weeks old) to sexual maturity. No effects on male or female reproduction were observed indicating no effect on development of reproductive system in juvenile animals. In summary, the results of these studies in rat and cynomolgus monkey demonstrate that in juvenile animals there were no novel toxicities, no permanent changes and no increased sensitivities relative to known effects of tofacitinib in adult animals thus supporting clinical trials in pediatrics.

1661 Case Study: The Evolving Cardiac Risk Assessment for a Novel Anticancer Agent

R. J. Knight and C. Pollard, Drug Safety and Metabolism, AstraZeneca, Alderley Park, Cheshire, United Kingdom.

AZD7762 is a check point kinase 1/2 inhibitor that was being developed as a first in class treatment for advanced solid tumours in combination with DNA-damaging agents. AZD7762 was well-tolerated in tumour-bearing mice, significantly enhancing the efficacious effects of chemotherapy or radiation. However, cardiovascular safety signals in preclinical studies led to a complicated and species-dependent cardiovascular risk profile. A profound, irreversible decrease in blood pressure and cardiovascular risk profile. A profound, irreversible decrease in blood pressure and LVdP/dt max (up to 36% vs vehicle). There were no signs indicative of a similar haemodynamic change in the rat. However in toxicity studies in rats from weaning (3 weeks old) to sexual maturity. No effects on male or female reproduction were observed indicating no effect on development of reproductive system in juvenile animals. In summary, the results of these studies in rat and cynomolgus monkey demonstrate that in juvenile animals there were no novel toxicities, no permanent changes and no increased sensitivities relative to known effects of tofacitinib in adult animals thus supporting clinical trials in pediatrics.
The World Wide Web is a powerful tool that can educate and provide information to educators, parents, and students. We plan to utilize the web to make K-12 education outreach available to members and educators across the globe. This presentation is an opportunity to for the K-12 Sub-Committee to interact with SOT members who might have access to valuable teaching resources, which will benefit members and the public. We need your excitement and interest – submit your K-12 activities to the SOT web portal! 

1663 K-12 Education and Outreach: Inspiring Students Towards Careers in Toxicology, Technology, Engineering, and Math (STEM) 

V. S. Blum1, R. Donofrio2, K. LeVanser3, A. Brackman1, L. C. English1, R. Cox1, A. Gador1 and A. D. Pfeffer1. 1Toxicology Services Dept., NSF International, Ann Arbor, MI, 2Applied Research Center, NSF International, Ann Arbor, MI and 3Chemistry Laboratory, NSF International, Ann Arbor, MI.

Headquartered in Ann Arbor, Michigan since 1944, NSF International is an independent, not-for-profit organization dedicated not only to improving global human and environmental health, but also to fostering future stewards for this mission. Toxicologists, microbiologists, chemists, and engineers from NSF have led hands-on experiments to promote STEM education and mentor future leaders in public health and safety. Learning modules were developed to explore polymers by creating elegant toothpaste确定剂用 dish soap, yeast and hydrogen peroxide. Other experiments emphasizing sustainable futures involved recycling, biodegradation, and homemade pH paper to learn about acid rain. Participating at local events such as the Maker Faire science festival in Detroit, Earth Day activities at the Science and Nature Center, workshops at the Hands-On Museum, and judging high school science fairs proves as rewarding for the mentors as the students. In conjunction with the American Red Cross and the Partnership for Food Safety Education, NSF International created the Scrub Club® (www.scrubclub.org), a fun website that teaches K-3rd grade children proper hand washing. The Centers for Disease Control and Prevention estimated that 164 million school days are lost each day due to illness. The site contains a webpage, interactive games, music and educational materials for teachers, parents, and kids. Materials are available for download in English, Spanish and French. NSF sponsored a Scrub Club® “Clean Hands” game for schools nationwide and toxicologists have visited local schools with stickers, magnets and tattoos. A growing number of local and regional school districts and public health departments also use this resource. NSF International’s Applied Research Center is also a proud supporter of this year’s SOT K-12 education outreach event for high school students and their mentors on Saturday March 22, 2014.
Ps 1665 A Model for a Residential High School Summer Research-Based Engagement Program to Inspire Students toward STEM Disciplines and Toxicology

Y. Franco1, M. M. Bourgeois1 and R. S. Pollență1. 1Cell Biology, University of South Florida, Tampa, FL. 2Secondary Education, University of South Florida, Tampa, FL. and 3Public Health, University of South Florida, Tampa, FL.

Persistence of undergraduate students in STEM disciplines is an issue of national concern. This issue is particularly relevant to the field of toxicology because the number of BS-level toxicology programs is limited and undergraduates matriculation to graduate level toxicology programs is from other STEM disciplines. In addition, the ability to inspire undergraduate students toward the field of toxicology at institutions that do not offer a BS level toxicology degrees is typically through upper level toxicology-based elective courses that students who leave the STEM may never have a chance to take. Reports show that persistence can be increased if students participate in “high-engagement” STEM-based activities in high school and early in college. USF has developed summer residential STEM Academies that provides high school students an intensive 6-day program in several STEM disciplines. The Academy engages domestic and international students in inquiry, discovery, creativity and hands-on research. Faculty from key research centers and colleges, collaborate to emerge students in basic, clinical and translational research. Students are also exposed to the multitude of professional career options that interface with the STEM degree. Professional educators from local high schools and colleges build community within the cohort through individualized and group mentoring. To date 64 students have completed three different Academies and 100% of the participants have indicated that they are inspired toward a STEM degree program. In addition 100% of rising seniors who completed the program in 2012, enrolled in STEM undergraduate programs in Fall 2013. The presentation will outline i) the structure of the program, ii) the details for the engagement exercises, iii) the cost to implement, iv) assessment instruments and v) a model for a STEM Academy with focus on Environmental Health and Toxicology to be offered in summer 2014.

Ps 1666 Creating Undergraduate Research Opportunities within Structured Courses through the CREATTE Initiative: Processes, Case Studies, and Outcomes

R. S. Pollență, Cell Biology, University of South Florida, Tampa, FL.

Numerous reports show that early engagement of undergraduates in research activities improves academic performance, engagement in the discipline and the probability that the student will graduate within the discipline. Since there are national issues related to persistence in STEM disciplines, innovative methods to engage students in research activities are a focus on many curricular reform efforts. In addition, many large research universities face significant issues regarding the mentorship capacity to offer all students a research opportunity. To address these issues the Office for Undergraduate Research (OUR) developed the CREATTE program (Creating Research Experience and Activities Through Teaching Enhancement). CREATTE provides faculty teaching undergraduate courses modest funds to support a graduate student (2-3 hrs week) and sustainable supplies in support of research projects that are integrated into the course curriculum. During 2012-13, CREATTE program supported >700 students in research projects through this initiative. Courses in Public Health (Environ. Health Sci., Ecotoxicology), Integrative Biology (Epigenetics, Coastal Ecosystems), and Psychology (Statistics) all have relevance to students who may consider toxicology careers and graduate school. A post survey of participating CREATTE undergraduate researchers indicated a strong agreement that they developed enhanced research competencies, had a deeper understanding of the course material and would engage in additional research activities. The presentation will outline i) the structure of the program, ii) case studies of research activities related to toxicology, iii) faculty time commitment, iv) and the assessment instruments used to validate the learning outcomes.

Ps 1667 Escape from Toxic Island (Life Size!): A Toxicology Awareness Program Using Demonstrations and Hands-On Activities

D. Harder1, 2 and L. M. Hoffman1, 2. 1Pharmaceutical Sciences, St. John’s University, Jamaica, NY and 2MASOT, Bordentown, NJ.

“Escape from Toxic Island (Life Size)”, is an educational program that was developed by the MASOT Education and Outreach Committee to teach basic toxicology concepts to middle school aged children. The program builds on the former program, “Escape from Toxic Island”, by utilizing the participants as life-sized game pieces that are introduced to basic toxicology concepts and activities from station to station to view or participate in toxicology related tasks. An introduction, called the island tribunal, was first provided for the participants. This included basic concepts such as the dose-response, common terminology and introduction to Paracelsus. A demonstration of dose response followed the introduction. Participants proceeded to toxicology-related demonstrations or hands-on activities. The stations included, Lemons and Onions, a demonstration that linked exposure to mildy irritating substances to risk, Science Sleuth where participants learned about reading labels to determine hazards and classifying chemical agents, No Water Off a Duck’s Back, that allowed participants to explore what happens to birds, humans and aquatic nature when oil spills into the sea, and Baggie Science, a station that investigated chemical changes. These resources were already available on SOT’s website and were modified to fit the needs of the present program. A Poison Control Squad was added as a demonstration to bring awareness of the dangers of medicines that might mimic the look of popular candy and also the dangers of household chemicals that look like commonly ingested liquids, for example, pine cleaner and apple juice. For each activity, participants engaged in active dialog with the presenters so that assessment of the participant’s prior knowledge of the topic could be made. Once the activities were completed, participants and presenters discussed their findings to verify the participants understanding of the topics.

Ps 1668 Creating Research Opportunities in K–12 Outreach for Undergraduate Students

A. J. Abratis and M. M. Bourgeois. EOH, USF COPH, Tampa, FL.

K12 outreach is a vital component in our mission to educate the community about scientific issues, particularly toxicology and risk assessment. Using funds from the Office for Undergraduate Research at the University of South Florida, undergraduate students participate in an authentic research experience within a structured course. Each autumn, 15 – 20 undergraduate students develop short science lectures and age appropriate activities for traditionally underserved schools in the Tampa Bay area. These student offer these demonstrations as part of the Annual Great American Teach In (GATI), held during the celebration of American Education Week. They identify a relevant environmental or occupational health topic, conduct research and create presentations designed to convey their findings in age appropriate lecture and hands on activities. The experience is designed to meet three core criteria: i) Pose or work from defined research question, ii) Work individually or in groups to apply relevant methods of inquiry to produce original findings/products, iii) Present the findings/products to peers and professionals in formal (e.g. Undergraduate Research Colloquium or professional meetings) and informal (e.g. course setting) venues. Past projects have involved an exploration of dose, response and toxicity using familiar measurements and household substances, sustainable gardens and pesticide safety, environmental pollutants and water sanitation. The GATI project fosters community outreach at the K–12 level, introducing the importance of toxicology to a range of primary and secondary level students while allowing project undergraduates to learn the art of outreach, develop skills in critical thinking, and gain a pedagogical background on which to build an academic future, should they so choose.

Ps 1669 Evaluation of Technical and Knowledge-Based Outcomes following Participation in a One-Week High School Research Program in Toxicology and Environmental Health Sciences

G. E. Custo1, 2, J. E. Moscovitz1, A. Venersa3, L. M. Aleksunes1, 2, A. Gusa1, 2 and D. E. Laskin1, 2. 1Pharmacology and Toxicology, Rutgers University, Piscataway, NJ. 2 Environmental and Occupational Health Sciences Institute, Rutgers University, Piscataway, NJ and 3Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ.

As an applied science, students are often not exposed to the fields of toxicology and environmental health sciences until their undergraduate or graduate studies. The purpose of this summer program was to introduce rising sophomore, junior, and senior high school participants to the concepts of toxicology, provide hands-on laboratory training, and highlight various careers in toxicology and environmental sciences. Two groups of 23 students (n=46 total) participated in a non-residential, one-week summer program at Rutgers University that consisted of didactic (70%) and laboratory (30%) activities organized by toxicology graduate student and faculty instructors. Activities focused on dose-response relationships, experimental design, clinical toxicology, histology and pathology, epidemiology, and genetics. Pre- and post-student surveys aimed to assess student motivation to participate in the program, research and technical abilities, and basic toxicology knowledge. Students indicated that the greatest motivating factors to participate included an opportunity to explore their interest in science and gain hands-on laboratory experience. Self-assessment surveys revealed improved presentation skills (24%), labo-
1670 Using a Case Study Followed by a Lab Exercise to Examine Acetylcholinesterase Activity

M. J. Pomeroy-Black. Biology, LaGrange College, LaGrange, GA.

Allowing students to design and implement an experiment engages students far more than “cookbook labs”. However, it can be difficult to create toxicology lab activities that require the students to do this. Using a case involving the paralysis of several dogs, students were drawn into the case prior to asking them to design and implement an experiment. Students were given background information about the dog’s behavior and environment at which point they discussed possible causes of the paralysis, including demyelination and enzyme inhibition. They were presented with ambiguous data and ran lab tests to determine the cause of the paralysis in order that the dogs could be treated. Prior to running the tests students determined the appropriate controls, formulated a hypothesis and described the procedure for running the tests. Using a spectrophotometer and observing the intensity of fluorescence allowed the students to determine if the cause of the paralysis was acetylcholinesterase inhibition or demyelination. The instructor may ask students to present their research using an “integrated approach” to writing a research report.

1671 A Toxicological Study Using Zebrafish (Danio rerio) As a Model

M. Reynolds-Walsh. Washington College, Chesterton, MD.

Only recently has it been adequately recognized that substances present in the environment can have adverse effects on developing organisms. Now, with environmental pollutants accumulating at an unprecedented rate, and with pharmaceuticals dominating western medicine, it is particularly important that we understand the effects of the substances to which we are exposed. Zebrafish (Danio rerio) has become a widely used model system for the study of vertebrate development. This system is particularly amenable for use in undergraduate laboratories because of the ease of collection and manipulation and the rapid rate of development. In this lab, students use zebrafish to examine the effects of nicotine, ethanol, and retinoic acid on normal development. Students first examine normal development and compare it to overall growth, dry weight, and behavior of zebrafish exposed to these chemicals. The students also collect data on LC50 and noxious length. The quantitative data is evaluated for statistically significant differences between treatments. Finally, students write a research proposal for an independent experiment in which they expose embryos to a toxicant of their choice, carry out the experiment, and present their findings. This lab introduces students to the use of animal models and incorporates experimental design and data analysis. More importantly, it introduces students to concepts and models in toxicology to increase their awareness and interest.

1672 Incorporation of Evolution and Toxicology Enhances Conceptual Learning in Undergraduate Neuroscience Courses

S. K. Infante and C. P. Carrau. Biological Science, Northern Kentucky University, Highland Heights, KY.

The field of neuroscience is inherently integrative and often requires understanding concepts from fields including molecular biology, toxicology, and evolution. Yet, few undergraduate courses focus on more than human neuroanatomy and physiology or rodent behavior. Therefore, we developed a transdisciplinary Advanced Neurobiology course from an evolutionary perspective, using toxicology principles to highlight gene-environment interactions and adaptations across major phyla. This lecture-lab course was also designed to align with the curricular objectives of the interdisciplinary Neuroscience minor. This presented the added challenge of creating an advanced course that serves students from different disciplines. Both lecture and lab highlighted evolutionary changes in the Animal Kingdom, beginning with sponges (Phylum Porifera) and moving through invertebrates (Phylum Cnidaria, Platyhelminthes, Nematoda, Annelida, Arthropoda, and Mollusca) before focusing on vertebrates in Phylum Chordata. We incorporated historically relevant models in toxicology and neuroscience including C. elegans, Drosophila, Aplysia, zebrafish, and mice. For example, using C. elegans, students assessed chemotaxis and dose response to benzaldehyde. Students examined sex differences in alcohol preference using Drosophila hydrelae. To accommodate different learning styles, we used various pedagogical tools to achieve each lab’s learning objectives. We heavily emphasized problem-based and team-based learning in the laboratory setting and used similar tools in lecture. We also used various methods of assessment, including group activities, lab notebooks, presentations, and student peer reviews. Toxicological concepts (dose response, ADME, and duration of exposure) were emphasized when students designed and executed group experiments on the behavior of C57BL/6j mice treated with nicotine and caffeine. Overall, our course succeeded in providing undergraduate students with a well-rounded perspective of complex concepts in neuroscience and toxicology.

1673 Sparking Toxicology Interest in High School Students

M. Lindsey1,2 and H. Ingram2. ’Southwest Environmental Health Sciences Center, University of Arizona, Tucson, AZ and 2BIOS Institute, University of Arizona, Tucson, AZ.

SCOPE AND RATIONALE: “High school is where the pipeline begins.” –Serine S. Lau, PhD. The University of Arizona’s (UA) KEYS High School Summer Research Internship has successfully hosted 188 high school students in toxicology and biosciences laboratories, who received academic credit for their internships. DESCRIPTION: Highly achieving students, with interests in biosciences, bio-medical science, toxicology, environmental health and bioengineering, apply for this competitive 7-week program. Applicants submit a letter of interest, teacher recommendations, and transcripts. Accepted interns are interviewed to make compatible placements. In week 1, they develop hands-on laboratory research techniques, learn to read research papers, and hear about cutting-edge research. In weeks 2 through 7, they complete a research component for their lab. The program ends with a poster session, well attended by faculty members, graduate students, friends, and family members.

EVALUATION AND ASSESSMENT: Student work is assessed to gauge increased knowledge of research methodology, biotechnology skills, toxicology and environmental health. Assessors also measure self-confidence and communication skills. Faculty evaluations, intern formative evaluations, summative evaluations, and alumni surveys inform the development of KEYS. All 9 interns from the 2007 class have earned baccalaureate degrees and 8 are pursuing graduate, medical or pharmacy degrees. Interns have also been recognized in theses and dissertations.

CONCLUSIONS: High school students are capable of understanding and positively contributing to complex bioscience research such as toxicology. Real world science experiences, instruction, technical and science literacy, and supportive nurturing during and after the program are essential elements that promote student success. “It is an important program because it exposes the interns to all the aspects of the science community and career.” –Georg Wondrak, PhD.

1674 Implementation of an Academic Service Learning (AS-L) Project within an Undergraduate Course in Pharmacology

B. Billack. St John’s University, Jamaica, NY.

Academic service learning (AS-L) is a type of active learning in which a student demonstrates knowledge and understanding through service to the community and reflection. The present report describes an activity in which AS-L was implemented as part of an undergraduate pharmacology course. The course is common to the curricula of the Doctor of Pharmacy, Physician Assistant and Toxicology programs at St. John’s University. In the AS-L project, teams of up to 5 students were charged to develop a presentation concerning the nature of drugs or pharmaceuticals and their effects on the human body. Students could form their presentation around discussion topics such as drugs versus natural substances, the medical benefits of drugs, the possible toxicities of drugs both legal and illegal, or the mechanisms by which drugs enter or leave our bodies. The student teams then traveled to various service sites throughout the greater university community with the goal of community outreach through education. Included among the service sites was an “after school/weekend” program for teenagers in foster care, and “weekend” program for young students in middle school (grades 6-8), and a local food pantry with an adult cohort. Strengths and limitations of the AS-L project were noted. The major strength of the project, as indicated from student reflection papers, was that each student in the team became an active learner and the otherwise “passive learning” environment of the classroom became an active one at the service site. All students in the team presented and answered questions. A limitation of the activity is finding a suitable instrument for assessing student learning. Future ASL courses of this type are anticipated to include pre and post surveys. The details of this AS-L project have been submitted for publication in the Journal of Toxicological Education (www.JToxEd.org).

SOT 2014 ANNUAL MEETING

436
In September 2011, a southwest section of Garfield, NJ was designated an EPA superfund site, following a 1983 chromic acid (hexavalent chromium [CrVI]) spill from a partially-buried storage tank at a local electroplating plant. CrVI-contaminated water (and a resulting dust) was first found seeping into a local firehouse basement in Garfield in 1993, followed by 13 residential properties in 2000, and more recently in wells south of the Cr plume area and under the Passaic River to the neighboring town of Passaic. As part of the Community Outreach and Engagement Core of the NYU NIEHS Center of Excellence, residents of Garfield have begun participating in a community health survey as a way to express their concerns within the community. The demographics of the survey respondents demonstrated that 55% were female, 79% were white, 29% Hispanic, and a majority had finished high school. Thirty-two percent of the respondents said they were ‘unsure’ if they were exposed to chemicals or pollutants where they live, which suggests a limited awareness of chromium exposure in their community. When asked about environmental issues in their community, 67% and 71% of respondents were concerned about air and water quality, respectively. The top three health issues of concern were cancer (64%), asthma (48.5%) and respiratory illness (47%). While residents are still being recruited to participate in the community survey, healthy, non-smoking residents 18-65 yr-old who lived in Garfield for > 2 yr are being recruited to donate toenail clippings to identify potential total Cr exposure in residents within the last 18 months. If elevated Cr levels are detected in any of the toenail samples of residents, they will be asked to come back and provide a blood sample to determine whether there has been any recent Cr exposure (within the last 2 months). This community-based participatory research will help gauge the needs of the community and possibly relieve the anxiety of the Garfield residents concerning Cr exposure (NYUNIENHS Ctr COEC ES017427).

North Birmingham, AL has recently been the subject of environmental concerns due to heightened levels of arsenic and benzo(a)pyrene found in the soil and air. In Jan. 2012, areas surrounding several major industries were designated a Superfund emergency response area. Working with community partners, environmental health priorities were established. As a starting point and to address education needs in the community, we implemented an environmental health education program at Hudson K-8 school for children ages 8-15 and their families. We developed an inquiry-based curriculum and evaluation constructs in collaboration with community members and teachers at Hudson Elementary. The curriculum included hands-on, age appropriate programs with a focus on the environmental issues North Birmingham residents currently face. The ultimate goal of the program was to increase knowledge of how contamination is measured, how risks to health are determined, and demonstrate ways to identify and assess environmental health issues in your neighborhood. The program culminated in a final interactive demonstration of results led by the children, which was presented at a community-wide event in North Birmingham. Knowledge gained and risk perception was evaluated through pre and post- tests. In addition, community members also took a risk perception survey regarding the environmental issues in their community. They reported concern of chemicals in the community, concern that key decision-makers lack a good plan for addressing the needs of the community, and a willingness to become actively involved in projects to improve the social or environmental quality of their community. Outcomes of this initial program have resulted in the development of a plan to continue and potentially expand Education to Action to other area schools.

It is difficult to assess pollution in remote areas of less developed regions due to limited availability of energy, equipment, technology, trained personnel, and other key resources. Passive sampling devices (PSDs) are technologically simple analytical tools that sequester and concentrate bioavailable organic contaminants from the environment. Scientists from Oregon State University and the Centre Regional de Recherches en Ecotoxicology et de Sécurité Environnementale (CERES) in Senegal developed a partnership to build capacity at CERES and to develop a pesticide monitoring project using PSDs. The partnership and dynamic process developed is applicable to equivalent capacity building programs. The project culminated in a held and laboratory study where paired PSD samples were simultaneously analyzed in African and US laboratories with quality control evaluation and traceability. The joint study included sampling from 63 sites across 6 western Africa countries, generating a 9,000 data point pesticide database with virtual access to all study participants.
affiliated with nor endorsed by the SOT, but fully supports the SOT educational mission and initiatives, and many of its editors serve or have served on educational committees of the SOT. *ToxEd* is actively seeking additional authors, reviewers, and editors.

### 1680 A Unique Collaboration Producing Highly-Trained Toxicologic Pathologists: The MPI Research/Michigan State University Toxicologic Pathology Training Program

K. G. Nelson1, S. D. Fitzgerald2 and D. J. Patrick3. 1Pathology, MPI Research, Mattawan, MI and 2Diagnostic Center for Population Animal Health, Michigan State University, East Lansing, MI. Sponsor: C. Amuzie.

Well-trained toxicologic pathologists are a key component in the pharmaceutical, biomedical, chemical, and research toxicology fields, where interaction between toxicologists and pathologists familiar with toxicology is a vital aspect of compound and device development and research. Approximately 30% of entry-level pathologists are going into pharmaceutical, chemical, or contract research positions upon completion of their training programs. However, currently there are very few training programs that are oriented towards producing pathologists with extensive experience in laboratory animal pathology or toxicologic pathology. The MPI Research/Michigan State University Toxicologic Pathology training program was created in 2002 to address a shortage of these well-trained, board-certified toxicologic pathologists. This unique residency consists of two years of a traditional anatomic veterinary pathology residency program at Michigan State University, followed by 12-15 months of focused toxicologic pathology training at MPI Research, a contract research organization that provides preclinical and early clinical research services. The program has included 10 anatomic pathology residents to date; of which seven have completed the program (two are currently in the program). The MPI/MSU combined residency program has produced residents that are well-prepared for the veterinary pathology board exam (100% pass rate) and produced well-trained and qualified toxicologic pathologists (86% employed in toxicologic pathology). The toxicologic pathologist employment environment has shifted since the program’s inception, but a need for entry-level pathologists and researchers possessing focused knowledge and training in toxicologic pathology and the demands of the biopharmaceutical industry remains high. This program may serve as a model for developing other cooperative toxicologic pathology-focused training programs between industrial and academic interests.

### 1680a Pedagogy and Policy: Teaching Effectiveness, Efficiency, and Equity

T. Dodd-Butera. Nursing, CSU San Bernardino, College of Natural Sciences, San Bernardino, CA.

Multiple conceptual frameworks exist for addressing health policy. Integrating a “3E” approach into class work can introduce principles of effectiveness, efficiency, and equity; and cultivate future policy makers in toxicology and public health. A logic model provides an illustration of an underlying conceptual framework and the logical connection within and between systems. Students in a course entitled, “Program Planning and Evaluation,” constructed a logic model, using the example of policies addressing toxic exposures to the maternal-fetal environment. Incorporating tenets of public health and equity, the underlying assumption is that the “10 Essential Public Health Services” and “CDC Framework for Program Evaluation” provide the context for the “3E” strategies to decrease toxic exposures before, during, and after pregnancy. Inputs involve cooperation of government and non-governmental organizations, development of community-campus partnerships, integration of research data and health education materials, and consideration of the importance of training current and future professionals of toxicology and public health. Proposed activities are assessed for effectiveness, cost and personnel efficiency, and determinants of health equity and social justice. Short and long-term outcomes are considered in relation to feasibility, propriety, and accuracy, in order to assess and evaluate programs and policies. Program and policy development in class work empowers students through education and experiential learning. Using a logic model provides an instructor with a reusable learning tool, which students can apply to other public health and toxicology issues for policy development in coursework and for future professional development.

### 1681 Dioxin Exposure during Sexual Differentiation Causes Transgenerational Toxicity in Zebrafish

T. Baker1,2, R. E. Peterson1 and W. Heideman1,2. 1Pharmacy School, University of Wisconsin-Madison, Madison, WI and 2Molecular and Environmental Toxicology Center, University of Wisconsin-Madison, Madison, WI.

Transient exposure of juvenile zebrafish to waterborne 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD, 50 pg/ml) during gonad differentiation at 3 and 7 weeks post fertilization, respectively, causes changes in sex ratios, decreases in reproductive capacity, and increases in skeletal abnormalities of F0 generation adults. The goal of the present study was to determine if the adverse effects of TCDD exposure on the F0 generation would persist in the next two generations of TCDD lineage offspring (F1 and F2). It was found that changes in sex ratios, skeletal abnormalities, and reproductive capacity continued to be observed in the TCDD lineage F1 and F2 generations. While the F1 generation may have been exposed to TCDD as germ cells, the F2 generation was never exposed to TCDD. In the TCDD lineage F1 and F2 generations, the sex ratios showed both a significantly higher percentage of females and greater incidence of skeletal abnormalities with a scoliosis-like kink in the spinal column being most common. Decreased reproductive capacity also was observed in TCDD lineage F1 and F2 generations with both egg release and percentage of eggs fertilized significantly decreased compared to controls. Spawning of the TCDD lineage F2 generation males (never exposed to TCDD) with control females revealed that decreased egg release and egg fertilization was caused by the TCDD lineage F2 males. Thus, toxicity observed in three generations (F0, F1 and F2) of TCDD lineage zebrafish as well as in a TCDD lineage F2 male generation outcross, suggests that epigenetic transgenerational inheritance of TCDD toxicity occurs through the male germline. (Supported by UW Sea Grant, NIEHS, and NCATS)

### 1682 Metabolic Analysis of Embryonic Zebrafish Indicates Hyaluronic Acid As A Biomarker of Arsenic Exposure

V. Nkumah-Elie1, J. Kirkwood, J. Stevens, E. Ho and R. L. Tanguay. Environmental Health Sciences Center, Oregon State University, Corvallis, OR.

Arsenic exposure has been associated with a myriad of human diseases including cardiovascular disease, cancers and neurological disorders; and developmental arsenic exposure may be relevant in the fetal onset of disease. The goal of this study was to use metabolomics to identify novel developmental targets of arsenic that may lead to adult onset diseases. To evaluate the impact of arsenic exposure in early development, dechorionated 5D zebrafish (Danio rerio) embryos were placed in control embryo media or embryo media containing 10 μM sodium arsenite at six hours post fertilization (hpf). Embryos were placed in the dark and allowed to develop uninterrupted in a 28 degree incubator. At 120 hpf, the embryos were prepared for metabolomics analysis. Briefly, 10 larvae were pooled in triplicate and metabolites were extracted using MeOH:RO water, 80:20, v/v, chilled to -80 degrees. Untargeted, unbiased metabolome profiles were developed using LC/MS/ MS technology. ANOVA was utilized to compare resulting mass spectrometry features in the control and arsenic exposed zebrafish embryos. Arsenic exposure resulted in significantly altered features (P<0.05, 2-fold change) in the positive and negative ion modes, as modeled by principal component analysis and volcano plots. Preliminary analysis indicates that hyaluronic acid (HA) as one of the most significantly increased metabolites (4.57-fold change, P=0.00094) resulting from arsenic exposure. HA is a glycosaminoglycan produced by hyaluronan synthase 2 and is involved in cardiac valve development and migration of myocardial cells. HA has been shown to be overexpressed in arsenic induced liver dysfunction, is used as a biomarker of bladder cancer. Additionally, the HA receptor, CD44, is overexpressed in ovarian cancer. HA may be a biomarker of embryonic arsenic exposure and may help to elucidate the role of arsenic in the fetal onset of chronic diseases.

### 1683 Multigenerational Effects of Benzo[a]pyrene Exposure on Survival and Developmental Deformities in Zebrafish Larvae

K. L. Willett, J. Corrales, C. Thornton and M. B. White. Pharmacology and Environmental Toxicology, University of Mississippi, University, MS.

Multigenerational impacts of polycyclic aromatic hydrocarbon (PAH) exposure are suggested in human cohort studies. To investigate mechanisms and developmental phenotypes associated with a dietary benzo[a]pyrene exposure, zebrafish were used. Only F0 adult zebrafish were fed 0, 10, 114, or 1012 μg BaP/g diet at a feed rate of 1% body weight twice/day (equivalent to 0, 0.21, 2.3 and 20 μg BaP/g fish) for 21 days. Three subsequent untreated generations of offspring (F1-F3) were assessed for mortality and time to hatch at 24, 32, 48, 56, 72, 80, and 96 hours post fertilization (hpf) and developmental deformities at 96 hpf. F1 mortality significantly increased in the higher BaP dose groups (2.3 and 20 μg BaP/g fish), but there
were no differences in the F2, F3, or F4 generations. Time to hatch in the higher doses significantly decreased in only the F1 and F4 generations. Multigenerational phenotypic impacts were caused in three generations (F1, F2, and F3) following the F0 exposure. Body morphology deformities (e.g. shape of body, tail and pectoral fins) were most extreme in the F1 generation although still present in the F2 generation. Craniofacial structures (e.g. length of brain regions and size of optic and otic vesicles), although not significantly affected in the F1 generation, emerged as significant deformities in the F2 generation and persisted through the F3 generation. Swim bladder impacts in the F1 generation corresponded to Bal2 treatment, but in the F3 generation fish in all treatments had affected swim bladders. Molecular analysis is now being used to elucidate mechanisms that are associated with the phenotypic deformities detected across generations. Supported by NEIHS R21ES019940.

1684 Benzo(a)pyrene Exposure Induces Global Methylation, Dampens Met Expression, and Induces Negative Behavioral Responses in Offspring Mice

D. B. Hood1,2,3, Z. Liu1, M. Maguire1, R. E. Rhoades1, M. McCallister1 and L. Rothblat2,3. 1Department of Neuroscience and Pharmacology, Center for Molecular and Behavioral Neuroscience, Meharry Medical College, Nashville, TN; 2Department of Psychology, George Washington University, Washington, DC; 3Division of Environmental Health Sciences, College of Public Health, Department of Neuroscience, College of Medicine, The Ohio State University, Columbus, OH.

MET, an oleoic receptor tyrosine kinase implicated in multiple cellular processes during development and is an autism risk gene. This study tested the hypothesis that in utero exposure to B(a)P aerosol during the critical period of neurogenesis negatively modifies putaminal Met expression towards later-life behavioral phenotypes. On embryonic day 14-17, dams were exposed to B(a)P aerosol 100ug/m3 or carbon black only for 4 hours/day by nose only inhalation. Birth indices and growth curves did not reveal any effects from exposure in offspring pups. Epigenetic assays revealed upregulation of global methylation in exposed Cprlox/lox offspring relative to controls. Developmental expression profiling for Met demonstrated negative modulation in B(a)P-exposed Met+/+/Emx1cre and Cprlox/lox offspring, in vivo microdialysis, spatial discrimination and executive learning, paradigms were used. Met offspring that were exposed in utero demonstrated a robust decrease in prefrontal cortical glutamate concentrations as compared to control Cprlox/lox offspring. In separate behavioral paradigms, Cprlox/lox offspring that were exposed in utero 100mg/m3 exhibited significant impairments in 1) spatial discrimination or 2) contextual rule switching paradigms when required to respond in a context-appropriate manner. These data provide insights into the potential mechanisms of Met action.

1685 In Vivo Aryl Hydrocarbon Receptor-Mediated Developmental Toxicity Impairs the Adult Cardiovascular System

V. S. Carreira1, Y. Fan1, M. Jiang2, S. Koch2, M. Naticchioni2, M. Smith2, J. Rubinstein1 and A. Puga1. 1Department of Environmental Health, University of Cincinnati, Cincinnati, OH and 2Internal Medicine, University of Cincinnati, Cincinnati, OH.

Perturbations of developmental programs are key contributors to adult disease. Specifically, disruption of arylhydrocarbon receptor (AHR) homeostatic levels in vitro suggests that developmental exposure to the ubiquitous environmentally persistent organic pollutant (POP) 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) culminates in abnormalities of cardiomyocyte structure and function. TCDD is a prototypical AHR agonist, and the AHR pathway has been suggested to coordinate a complex regulatory network underlying attainment and maintenance of cardiovascular homeostasis during development. Nevertheless, the pathogenesis and phenotypes of TCDD developmental toxicity remains vague. The present work aims at understanding how an abnormal AHR homeostatic level during embryogenesis affects the adult cardiovascular system. C57BL/6J pregnant mice were oral-gavaged with TCDD (0.1 to 50 μg/Kg dosages) or vehicle control at key cardiogenesis time points. Embryos were harvested at representative time points or carried to term and adulthood. Naïve C57BL/6J Ahr-/- mice were also included for each time point. At all studied doses, embryos could be carried to term; however, all pups died within 24 hours post-partum at the three highest doses. Cardiac alterations consisted of sexually-dimorphic changes in molecular, functional, and structural endpoints, including altered compartment-specific transcripts, cardiac morphometry, altered proliferation, as well as cardiac hypertrophy and failure protein markers, changes in baseline blood pressure, echocardiographic parameters, and cardiovascular chal- lenge tolerance. Our findings underscore the developing heart as a target for developmental disruption by in-utero exposure to a POP and the role of this receptor in cardiovascular development and disease. Supported by NIH Grant 5R01ES06273.

1686 The Effects of Endocrine Disruption on the Maturation of the Developing Human Fetal Prostate

C. M. Saffarini1, E. V. McDonnell1, A. Amin1,2, S. M. Huse1, D. Spade2, S. Kostadinov3, S. J. Hall1 and K. Boekelheide1. 1Pathology and Laboratory Medicine, Brown University, Providence, RI; 2Pathology and Laboratory Medicine, Rhode Island Hospital, Providence, RI and 3Pathology and Laboratory Medicine, Women and Infants Hospital, Providence, RI.

The etiology of prostate cancer is unknown, although it has been suggested that early life exposures to various toxicants, such as estrogenic chemicals, may play an important role. Previous studies in animal models have demonstrated that early life exposures to estrogens are responsible for epithelial and stromal hyperplasia, inflammation, and prostatic intraepithelial neoplasia (PIN) lesions. We have de- veloped a xenograft rodent model, using the renal subcapsular space as the implantation site, to characterize the growth and differentiation of human fetal prostate implants (gestational age 12-24 weeks) in athymic nude mice. This model evaluates the effects of both early and later-life exposures to either corn oil (control) or 250 μg/kg/body weight of 17β-estradiol 3-benzoate post-transplant. Key characteristic prostatic markers responsible for epithelial and stromal maturation were assessed in both control and treated xenografts. The prostate markers, p63, Ki-67, Chromogranin A, prostate specific antigen, caldesmon, smooth muscle alpha actin, estrogen receptor-α and estrogen receptor-β were stained in 7, 30, 90, and 200 day xenografts. The endogenous rodent prostates exhibited atypical hyperplasia along with the presence of massive cellular debris after estrogen exposure, while the human prostates displayed basal cell hyperplasia as indicated by p63 staining. Utilizing a PCR array, a select panel of 40 prostate specific genes was chosen for analysis. Results from the PCR arrays revealed changes in genes responsible for mesenchymal development and ducal morphogenesis, as well as changes in the prostate cancer pathway. This study of human fetal prostate tissue will allow for future mechanistic studies investigating the origins of neoplastic prostatic disease, and the effects of estrogenic endocrine disrupting chemicals.

1687 Application of a Novel Method for Identification of Murine Metastable Epialleles to Human Populations

C. Weinhouse, J. Kim, M. S. Nahar, K. F. Sang and D. Dolinoy. Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, MI.

Metastable epialleles (MEs) represent genomic regions with highly variable, stochastically established epigenetic marks that respond to early life environmental exposures. We previously identified murine MEs using genome-wide expression array analysis of liver, kidney, and brain tissue of 10-month-old F1 offspring for candidates with a high R-values, or ratios of inter-individual: inter-tissue variances in expression. DNA methylation at these loci is established early in development, when MEs are most vulnerable to disruptive reprogramming. Two murine candi- dates MEs identified via this novel method, Dnaaj1 (R = 1.67) and Glic1 (R = 1.61), were validated in Aβ mouse liver tissue. Percent liver methylation was variable in a promoter CpG island in Dnaaj1 (N = 11, 0-19%) and at two ERV class II repeats in Glic1 (Repeat 1, N = 10, 92-100%; Repeat 2, N = 9, 79-100%). Mean liver DNA methylation at Glic1 Repeat 1 was altered following in utero exposure to 50 mg bisphephen A (BPA)/kg diet (N = 91), as compared to controls (N = 79) (p < 0.0001), indicating environmental lability. Here, we demonstrate applicability of this microarray method in identifying human MEs (N = 10 males, N = 10 females). Validation of the top two candidate MEs, DDX3Y (R-value = 14.1, N = 28) and NUMA1 (R-value = 10.6, N = 47), in 1st and 2nd trimester human fetal liver, revealed large inter-individual variability in DNA methylation. Percent liver methylation at seven CpG sites at the DDX3Y locus ranged from 10%-32%, with site-specific variances of 6 to 57. Percent liver methylation at five CpG sites at the NUMA1 locus ranged from 14%–43% with site-specific variances of 20 to 98. These data represent preliminary validation of a novel expression microarray method for ME identification in humans, which was previously validated in mice. Identification of human MEs is an important step in focusing studies of population level epigenetic responses to toxicant exposures.
Background: Maternal inflammation contributes to premature delivery and premature infants routinely receive therapeutic oxygen. The long-term pulmonary consequences of perinatal inflammation are unclear. We tested the hypothesis that a hostile perinatal environment induces chronic inflammation into adulthood causing increased oxidative stress and apoptosis. Furthermore, we hypothesize that these changes are modulated through activation on Notch-1 and Notch-2 signaling.

Methods. Pregnant C3H/HeN mice were injected with LPS or saline and placed on control or DHA supplemented diets on embryonic day 16. Once born, offspring were placed in room air (RA) or 85% O2 for 14 d then returned to RA for an additional 6 weeks. GSH and GSSG levels were measured in lung tissues using biochemical assays. 8-isoprostanates were measured by LC/MS/MS. Caspase 3, p53, and Bcl-2 were measured by western blots as markers of apoptosis. Notch-1 and -2 levels and downstream signaling cascade were assessed in lung tissues by western blot and immunohistochemistry.

Results: At 8 weeks of age, lower levels of GSSG and 8-isoprostanates were observed in the lungs of DHA supplemented mice. Decreases in caspase 3, p53 and Bcl-2 were observed in similar tissues. Total Notch-1 and -2 protein contents and nuclear localization were decreased in the lung tissues from DHA supplemented mice.

Conclusion: Perinatal inflammation causes long-term consequences which results in increases in oxidative stress and apoptosis into adulthood. These changes are likely to be modulated by alterations in Notch signaling. Maternal DHA supplementation prevented the long-term changes due to early inflammation and hyperoxia exposure indicating therapeutic potential for DHA for preterm infants.

1689 Gestational Nanomaterial Exposure: What Does the Future Hold?
T. R. Nurkiewicz1, P. G. Stapleton1, C. E. Nichols2, L. G. Y. C. Minarchick1 and J. M. Hollander2, Physi. and Pharm., WVU, Morgantown, WV and 4Exercise Phys., WVU, Morgantown, WV.

As the potential for engineered nanomaterials (ENM) develops, so does the risk of inevitable exposure within non-occupational settings, including expecting mothers and their unborn young. This fetal programming after maternal ENM exposure may have effects lasting well into adulthood. Pregnant (GD 10) Sprague-Dawley rats were exposed to nano-titanium dioxide aerosols (count mode aerodynamic diameter of 144±8 nm, 110±3 mg/m3, 4 hrs/day) for an average of 5.5±0.5 days to the adult consequences of gestational ENM exposure. The calculated cumulative maternal deposition over the exposure time was 85±3 µg. This study focused on the microvascular health of the heart and uterus (c<150 µm) of the surviving adult (8-10 weeks) female progeny using an isolated microvess preparation. Coronary microvascular responsiveness is impaired after gestational ENM exposure, represented by an impaired endothelium-dependent dilatation to mechanical (increased intraluminal flow, Flow, 5-30 µL/min), and metabolic stimuli (acetylcholine, ACh, 10-9-10-4 M), delayed smooth muscle relaxation (permeability-NONOate, 10-9-10-4 M), and a blunted endothelium-dependent adenosine response of the smooth muscle (phenylephrine, 10-9-10-4 M). Uterine arteriolar endothelial reactivity was also significantly impaired overall. This dysfunction presented as abolished endothelium-dependent reactivity (ACh), impaired flow induced dilatation (Flow), and reduced myogenic responsiveness (transmural pressure, 15-120 mm Hg). Mechanistically, we isolated and evaluated the mitochondria of the left ventricle, indicating a mitochondrial defect. This could have the propensity to increase oxidative stress production, thereby affecting NO bioavailability. Collectively, gestational ENM exposure may lead to independent cardiovascular consequences for the exposed progeny. These impairments may increase cardiovascular disease susceptibility for future generations.

NIH-F33-ES023435 (PAS) NIH-RO1-ES015022 (TRN) NSF-1003907 (VCN)

1690 Mono-2-Ethylhexyl Phthalate (MEHP) Exposure Modifies Embryonic Nutrition, One-Carbon Metabolism, and Epigenetic Programming during Organogenesis-Stage Mouse Conceptuses
K. E. Sant, L. L. Jilek, D. Dolinoy and C. Harris, Environmental Health Sciences, University of Michigan, Ann Arbor, MI.

Mono-2-ethylhexyl phthalate (MEHP) is a ubiquitous environmental and industrial plasticizer. MEHP stimulates embryonic growth and delays closure of the neural tube (NTD). These defects can be prevented by supplementation of nutrients for one-carbon (C1) metabolism indicating a vital role for C1 activity in mechanisms of toxicity. These nutrients may alter DNA and histone methylation because they provide the methyl groups required for epigenetic modifications. Abnormal epigenetic programming during development has the potential to alter tissue patterning and disease susceptibility throughout the life course. This study sought to determine whether MEHP alters embryonic nutrition and epigenetic programming during organogenesis. Gestational day (GD) 8 mouse conceptuses were explanted into whole embryo culture and exposed to low (-100 µg/ml) and high-doses (250 µg/ml) of MEHP for 24 h. Uptake of FITC-albumin was used to assess histotrophic nutrition pathways (HNP), and MEHP significantly reduced HNP activity (p<0.01). Nutrient substrates of C1 pathways were measured using mass spectrometry. Vitamin B12 was reduced in low-dose samples (p<0.001) but remained unchanged at the high-dose. Choline and homocysteine also became reduced in the low-dose and unchanged in the high-dose. Betaine was reduced in both the low- and high-dose conceptuses (p<0.01). Folate also followed this trend but changes were not significant. Methionine, cysteine, and S-adenosylmethionine all increased with dose, but changes were not significant due to high intersample variability. Histone methylation at H3K4 and H3K27 loci was examined using a case-control design for MEHP treatment and NTDs. H3K4 was hypermethylated in embryos (EMB) that had NTDs (p<0.015). Treatment increased methylation at H3K27 in EMB (p<0.074). Overall, visceral yolk sacs were hypomethylated when compared to EMB (p<0.01). This work demonstrates the ability of MEHP to modify embryonic nutrition, C1 substrates, and epigenetics during organogenesis.

NIH-F33-ES023435 (PAS) NIH-RO1-ES015022 (TRN) NSF-1003907 (VCN)
Exposure to PM2.5 during pregnancy promotes reduced birthweight, and the associated adverse intrauterine conditions may also promote adult risk of cardiovascular disease. Here, we investigated the potential for in utero exposure to diesel exhaust (DE) air pollution, a major source of urban PM2.5, to promote adverse intrauterine conditions and influence adult susceptibility to disease. We exposed pregnant female C57Bl/6J mice to DE (≈300 μg/m3 PM2.5, 6 hrs/day, 5 days/week) from embryonic day (E) 0.5 to 17.5. At E17.5 embryos were collected for gravimetric and pathological analysis. In addition, some dams exposed to DE were allowed to give birth to pups and raise offspring in filtered air (FA) conditions. At 10-weeks of age, body weight and blood pressure were measured. At 12-weeks of age, cardiac function was assessed by echocardiography. Susceptibility to pressure-load-induced heart failure was then determined after transverse aortic constriction surgery. We found that in utero exposure to DE increases embryo resorption, and promotes placental hemorrhage, focal necrosis, compaction of labyrinth vascular spaces, inflammatory cell infiltration and oxidative stress. In addition, we observed that in utero DE exposure increased body weight, but counterintuitively reduced blood pressure without any changes in baseline cardiac function in adult male mice. Importantly, we observed these mice to have increased susceptibility to pressure-overload induced heart failure, suggesting this in utero exposure to DE ‘reprograms’ the heart to a heightened susceptibility to failure. These observations provide important data to suggest that developmental exposure to air pollution may strongly influence adult susceptibility to cardiovascular disease.

### Reproductive Parameters in a 90-Day Toxicity Study of Smart Herbal Purifier® - A Poly Herbal Supplement in Male Rats

Z. N. Igezewa, O. E. Orisakwe, and A. W. Obianime

**Pharmacology and Toxicology, Madonna University, Elele, Rivers State, Nigeria.**

**Toxicology Unit, Faculty of Pharmacy, University of Port-Harcourt, Port-Harcourt, Rivers State, Nigeria and Department of Pharmacology, School of Basic Medical Sciences, University of Port-Harcourt, Port-Harcourt, Rivers State, Nigeria.**

Cases of reproductive failure after prolonged intake of herbal supplements have been reported in Nigeria. This study evaluates the testicular effects of Smart Herbal Purifier - a poly herbal supplement SHP in sexually albino rats. Subchronic toxicity of SHP was investigated in a 90 day repeated dose toxicity test in male Sprague-Dawley rats. The rats were divided into 30 per group received 0, 48, 240, and 480 mg/kg/day of SHP. Animals were sacrificed at 30, 60, and 90 days. Body weight and male reproductive parameters, weight of testes, testicular and epididymal sperm count, motility, morphology, debris and viability were recorded. Testosterone, leutinizing hormone, prolactin, follicular stimulation hormone and malondealdehyde in the plasma and seminal vesicles were analysed. Histology of the testes was examined. A Mann–Whitney U-test was used in data analysis. Testicular sperm motility significantly decreased from 71.87±12.98% (control group) to 27.13±6.64% (480 mg/kg SHP) treated group. There was significant % increase in both testicular (19.10±3.78 in control group to 57.50±6.89 in 480 mg/kg SHP) and epididymal (14±0.00 in control group to 50.0±1.53 in 480 mg/kg SHP) sperm debris. SHP significantly (p<0.05) increased the FSH from 0.82±0.45 to 1.24±0.93 (I/L) in the control and the 240mg/kg SHP treated groups respectively. Malondialdehyde was significantly (p<0.05) increased from 0.98±0.13 to 1.20±0.26 in the control and 480mg/kg SHP treated groups respectively. Histology of the testes of the treated group showed necrosis of the seminiferous tubules. SHP might be associated with some male reproductive toxicity concerns.
In occupational settings there is a concern that high levels of exposure to manganese may occur and that this, in combination with continued low level exposure over long periods of time, may lead to some adverse health effects. Contradictory findings exist regarding reproductive performance following such exposures. The aim of this study was to investigate if manganese is a reprotoxicant. Manganese chloride was selected as the most suitable form of manganese to assess reprotoxicity. Four groups of Sprague-Dawley rats, 20 per group (10 males and 10 females) were exposed to MnCl$_2$ via the inhalation exposure route (nose only) for 9 weeks at target concentrations of 0 (control air only), 5, 10 and 30 mg/L of Mn.$^2+$. A slight intergroup difference in body weight gains and food consumption was seen in the low and mid doses but this was not positively attributed to MnCl$_2$ exposure. At the high dose level (30 mg/L) adverse clinical signs, including irregular respiration, were observed in 1 male and 2 females resulting in the premature sacrifice of these animals, and the cessation of exposure to the remaining animals in this group after approximately 3 weeks of treatment (early gestation). At the end of the study, it was concluded that, under the conditions of this study, MnCl$_2$ exposure at target levels of 5 and 10 mg/L did not have an effect on mating performance; fertility or the duration of gestation and hence manganese was not considered to be a reprotoxicant at these exposure levels.

1696 N-Acetylcysteine, but Not the Suspension of Treatment, Reverses the Effects of Arsenic Trioxide on the Mouse Male Reproductive System

1State University of Curitiba, Curitiba, Brazil. 2Instituto de Biociências, Universidade Federal do Rio de Janeiro, RJ, Brazil. 3Pharmacology, State University of São Paulo, Botucatu, SP, Brazil and 4Pharmacology, State University of São Paulo, Botucatu, SP, Brazil.

Arsenic trioxide (AT) has been shown effective in the treatment of acute leukemia. Due to its apoptosis-inducing activity, it can affect germ cells. The aim of this study was to evaluate the immediate effects of treatment with AT on reproductive system of Swiss mice, after 30 days of suspension of the treatment and with the co-administration of the antioxidant N-acetylcysteine (NAC). For this, adult male Swiss mice were treated with distilled water (vehicle), 0.3 or 3.0 mg/kg/day of AT (ACROS 1327-53-3), subcutaneously in 25 applications. At the end of treatment half of animals were killed to evaluate the effects on sperm parameters and the other half were kept without the drug for 50 days (spermatogenesis + sperm transit time) and then killed for assessment of possible reversibility of the effects. In another experiment, animals were treated with vehicle, 3.0 mg/kg/day of AT, NAC and NAC + AT. The following material was obtained/determined at necropsy: viril and reproductive organs weights, sperm from the vas deferens for motility analysis and tests for determination of daily sperm production. The differences among groups were compared using ANOVA and Kruskal-Wallis, followed by Dunnnett or Dunn’s tests, respectively, with p<0.05. The animals treated with the higher dose of AT and killed right after the end of treatment showed reduction in seminal gland weight, number of motile sperm and daily sperm production, which remained altered after the suspension of treatment. However, when NAC was given in conjunction with AT these parameters were similar to the control group. The results show that AT was toxic for the mouse male, compromising sperm quality and quantity, and that these effects were persistent even after the suspension of the treatment. Furthermore, the administration of an antioxidant prevented the harmful effects of the drug on the male reproductive system.

1697 Assessment of the Reproductive Toxicity of Inhalation Exposure to Ethyl Tertiary Butyl Ether in Male Mice with Normal, Low-Active, and Inactive ALDH2

R. Wang$^1$, Z. Weng$^1$, K. Ohtani$^1$, M. Suda$^1$ and Y. Yanagab$^1$. 1Japan National Institute of Occupational Safety and Health, Kawasaki, Japan and 2NCTR, Jefferson, AR.

Sponsor: N. Mei.

Ethyl Tertiary Butyl Ether (ETBE) has been used in recent years as a biofuel additive. Previous reports have shown that ETBE is low toxicity with the NOAEL at 500 ppm. However, ETBE is metabolized to acetaldehyde and other aldehydes, which are known with high toxicity. Aldehyde dehydrogenase2 (ALDH2) is the main enzyme to metabolize aldehydes, but approximately 40% East Asians are deficient in the enzyme activity. So far no data are available regarding ALDH2 polymorphisms related to the reproductive toxicity of ETBE. In this study, a series of experiments were performed in Aldh2 knockout (KO), heterogeneous (HT) and wild type (WT) C57BL/6 male mice exposed to ETBE and the data about general toxicity, testicular histopathology, sperm head numbers, sperm motility and sperm DNA damage were collected. The results showed that 13-week exposure to 500, 1750 and 5000 ppm ETBE significantly decreased sperm motility and increased levels of oxidized DNA strand breaks and 8-hydroxy-deoxyguanosin in both WT and KO mice; the effects were found in 1750 and 5000 ppm groups of WT mice but in all three exposed groups of KO mice. In the 9-week experiment of exposure to lower concentrations of ETBE (50, 200 and 500 ppm), the remarkable effects of ETBE on sperm head numbers, sperm motility and sperm DNA damage were found in mice in KO and HT mice exposed to 200 ppm ETBE, but not in WT mice. Our findings suggested that only exposure to high concentrations of ETBE might result in reproductive damage in mice with normal active ALDH2, while low active and inactive ALDH2 enzyme can significantly enhance ETBE-induced reproductive damage even at low concentrations of ETBE, mainly due to the accumulation of acetaldehyde as a primary metabolite of ETBE.
significantly decreased during gestation in cynomolgous monkeys. Since lymphopoiesis of B-cells has been reported to be negatively affected by steroids, the decreased B-lymphocytes during pregnancy may be due to increased estradiol levels. Our data support the observation that there are species-specific differences in background levels of selected parameters during pregnancy. Some of the background changes in pregnant cynomolgus monkeys can be potentially similar to the metabolism of the drug being tested and/or different than observed in pregnant women, therefore posing unique challenges for interpreting DART data.

1700 Telmisartan Attenuates the Somatic and Germ Cells Damage in Streptozotocin-Induced Diabetic Rat: Cellular and Molecular Mechanisms

S. Kushwaha and G. Jena. Department of Pharmacology and Toxicology, National Institute of Pharmaceutical Education and Research, Mohali, Punjab, India.

Diabetes is a metabolic disorder that affects nearly every organ system. Telmisartan, an angiotensin type 1 receptor blocker, used in diabetes associated hypertension. Besides controlling blood pressure, telmisartan exhibits several other beneficial effects and provides new avenues in end-organ protection. Present study explored the possible protective mechanisms of telmisartan, in kidney and testes of diabetic rat. Male Sprague Dawley rats randomized into six groups: control, telmisartan control, diabetic control and diabetic group treated with telmisartan at the doses of 3, 6 and 12 mg/kg /day, per oral for 4 weeks. Animals were made diabetic by single dose of streptozotocin, i.p. (55 mg/kg). Results showed that telmisartan significantly protects kidney as observed from decreased DNA damage, cell death and reduced expression of nuclear factor kappa B (NF-KB), cyclooxygenase (COX-2) and connective tissue growth factor (CTGF). Telmisartan also attenuates testicular toxicity as observed by restored sperm counts, decreased sperm DNA damage and apoptotic cell death. Immunohistochemistry of 8-oxo-dG (8-oxo-7,8-dihydro-2′-deoxyguanosine) and 3-nitrotyrosine confirmed that telmisartan significantly reduced oxidative and nitrosative damage. Western blot analysis showed that telmisartan decreased the levels of NF-KB, interleukin 6 (IL-6), tumor necrosis factor alpha (TNF-α), phosphorylated extracellular signal-regulated kinase (p-ERK1/2), inducible nitric oxide synthase (iNOS), caspase-3 and increased peroxisome proliferator-activated receptor gamma (PPAR-γ) expression. Present results showed that telmisartan restored the status of the antioxidant enzymes, oxidative and nitrosative stress, reduced inflammation and cell death in kidney and testis of diabetic rat. Further, research is needed to validate the usefulness of angiotensin receptor blocker, telmisartan in diabetes associated end organ damage.

1701 Expression and Localization of Xenobiotic Transporters in the Male Reproductive System

D. M. Klein1, N. J. Cherrington1 and S. H. Wright2. 1Pharmacology/Toxicology, University of Arizona, Tucson, AZ and 2Physiology, University of Arizona, Tucson, AZ.

The blood-testis barrier (BTB) prevents the entry of many compounds into the male genital tract (MGT) which is beneficial for the exclusion of reproductive toxicants. However, the BTB also prevents the exclusion of toxicants, and the BTB can be disrupted during treatment with certain drugs or environmental compounds. Exposure to these compounds can have adverse effects on male reproductive health. The aim of this study was to determine subcellular localization of MRP transporters in rodent, macaque, and human testes and to determine mRNA expression of 30 xenobiotic transporters in different sections of the MGT isolated from rats. Using immunohistochemistry, we determined that in all species, MRPL is restricted to the basolateral membrane of Sertoli cells. MRPL is located in Leydig cells, and MRPC is located in round spermatids. MRPC is expressed on the basolateral membrane of Sertoli cells in human and macaques, but on the apical membrane in rats. By using branched DNA signal amplification, we determined that the epididymis expressed at least moderate levels of 19 transporters, while the vas deferens expressed 15, seminal vesicles 23, and prostate 19. Knowledge of which transporters are expressed in each tissue may provide insight into how xenobiotics are able to bypass this distinct compartment thereby increasing efficacy of medications needing access to the MGT for full therapeutic effect.

1702 Phtalate Metabolism and Kinetics in an In Vitro Model of Testes Development

S. Harris1, S. Wegner1, S. Hong1, 2 and E. M. Faustman1, 2. 1Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and 2Institute for Risk Analysis and Risk Communication, University of Washington, Seattle, WA.

We developed an in vitro model of testes development (3D-TCS) using rat testicular cells overlaid with extracellular matrix, allowing for three dimensional growth and a physiologically stable culture system. One barrier preventing utilization of in vitro models in toxicity testing is the lack of metabolic systems which are present in vivo but not in vitro. Another challenge in interpretation of results from in vitro models is the lack of kinetic data for many compounds in in vitro systems. In the current study, we sought to perform a preliminary characterization of the inherent metabolic capabilities of the 3D-TCS as well as investigate the kinetic behavior of some common male reproductive toxicants (phthalates). 3D-TCS cells were cultured with three phthalate diesters (DEP, DBP and DEHP). Concentrations of phthalate parent compounds and monoester metabolites were then measured at 2, 8 and 24 hours post exposure in culture media and cell lysis via mass spectrometry. We used detected levels of monoester metabolites as an indication of phase I metabolism of phthalates diesters to monoesters via non-specific lipase activity. Monoester metabolites were detected in all phthalate treated cell media and cell lysate samples. Metabolite levels ranged from <0.01-16% of initial concentration of parent compound. Phthalate diesters partitioned between media and lystate in a manner dependent on each compound’s logKow value. In addition, analysis of 3D-TCS microarray data indicated gene expression of several lipases as well as CYP450's involved in steroid or lipid metabolism. These results provide evidence for the presence of significant CYP450's, the metabolism of phthalate diesters in our testicular co-cultures and also provide important information about the kinetic behavior of phthalates in the 3D-TCS.

1703 The Role of H19 Hypomethylation in Male Reproductive Toxicity Induced by Endocrine Disruptors p,p′-DDE

Y. Song. Zhejiang Academy of Medical Sciences, Hangzhou, China.

p,p′-Dichlorodiphenyldichloroethene (p,p′-DDE), the major metabolite of dichlorodiphenylchloroethane (DDT), is a known environmental pollutant and male reproductive toxicant. However, the exact mechanism remains limited. Objective In the present study, we try to investigate the role of methylation of imprinted gene H19 in male reproductive toxicity induced by p,p′-DDE. Methods Timed-pregnant Sprague-Dawley rats were obtained from experimental animal center in Zhejiang Province. Young adult female rats were cohabited with male rats overnight, and onset of pregnancy was determined by the presence of a copulation plug after overnight mating (gestation day (GD) 0). From GD8 to GD15, the pregnant rats were dosed daily by gavage with corn oil as vehicle control or 100 mg p,p′-DDE per kilogram of body weight. There were 6 dams in each group. The pups of each group were randomly reduced to 10 at birth to ensure uniformity, and pups were kept with their respective dams until weaning on postnatal day (PND) 21, at which point litter mates of the same sex were housed up to 4 per cage till PND90. Results We found that transient exposure (daily gavage of 100 mg/kg body weight) of a gestating female rat to p,p′-DDE from gestation day 8 to 15 caused reduced sperm quality associated with IgJ2-H19 ICR hypomethylation in the adult male F1 generation. Conclusion Reprogramming of imprinted gene may play critical roles in male reproductive toxicity induced by p,p′-DDE.

1704 Developing a Screen for Analysis of Environmental Epigenetic Effects

I. A. Camacho and P. Allard. Molecular Toxicology, UCLA, Los Angeles, CA.

Many factors challenge the efficiency of assessing chemicals found in the environment. These include the vast number of compounds and toxicity endpoints to be tested as well as the vital need to replace rodents in order to quickly, economically and ethically assess chemical safety. Another important issue at hand is the long lasting effect, potentially spanning several generations, of chemicals in our environment and the lack of tools to comprehensively identify these. In order to address these issues, we propose the development of new technologies that can accurately determine the safety of chemicals for endpoints that are hard to study in vertebrate models. Here, we establish the use of the genetic model system, the worm Caenorhabditis elegans, as a relevant model for epigenetic and reproductive toxicity assessment. We are taking advantage of C. elegans genetic tools to detect chemical disruption of the germline chromatin and in particular of evolutionary conserved epigenetic
marks. To this aim, we are making use of a worm strain where GFP is specifically epigenetically silenced in the germline. In order to validate the approach, the strain is exposed to inhibitors of histone modifications that have been well characterized in mammalian systems. These inhibitors should disrupt proper establishment and/or maintenance of epigenetic marks, and lead to desilencing of the transgene in the germline. Here, we report that exposure to the histone deacetylase inhibitor valproic acid causes a de-repression of the GFP transgene expression in germ cells indicating that continuous histone deacetylation is required for the epigenetic repression of the transgene in the germline. To our knowledge, this had not previously been shown in C. elegans or other species. These preliminary results offer us a reliable control to further test against environmental chemicals. Further work will examine the sum of pathways and enzymatic activities that lead to proper regulation of chromatin states in the germline. Together, we are designing a strategy that should offer a more comprehensive examination of the environmental effects of the epigenome.

1707 Dynamic Expression of Imprinted Genes and Epigenetic Factors in an In Vitro Testicular Coculture

S. Wegner, S. Harris, S. E. Pacheco and E. M. Faustman. Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

Male reproductive developmental processes are an important target of environmental contaminants. However, there are no validated in vitro models for screening the chemicals that remain untested for male reproductive toxicity. Perturbation of epigenetic factors during tests development is of particular concern given the importance of epigenetic regulation for spermatogenesis and the potential for epigenetic programming of germ cells to influence disease. Our lab has previously developed a 3D testis co-culture isolated from postnatal day 5 rats that corresponds to a key phase of male reproductive development in vivo. This in vitro culture can accurately distinguish between reproducitively toxic and nontoxic phthalate esters, making it a promising model for toxicity testing. To characterize the developmental pathway dynamics and epigenetic transitions captured in our in vitro model, we evaluated global gene expression through time in culture. Primary rat testicular cells were co-cultured with a Matrigel overlay. Gene expression was measured using Affymetrix 1.0 ST arrays. Genes significantly changed over time were identified by univariate t-test (FDR < 0.1). Over the course of 72 hours in culture (corresponding to postnatal days 7–10 in vivo) expression of genes involved in spermatogenesis such as AR, Dazl, Dibh, Storb, and Ace was significantly increased. A pathway analysis of gene expression in this 72 hour period reveals significant changes in GO terms related to DNA methylation and epigenetic regulation. This suggests dynamic epigenetic modulation of gene expression through time. In parallel we see significant changes in expression of a panel of genes known or predicted to be epimarked paternally (e.g. Cpx4, H19, Tmem88) or maternally (e.g. Spon2, Sox8, Fertm2). This baseline characterization indicates that our model provides a strong platform for evaluating the potential effects of environmental factors on imprinting and the epigenetic regulators of developmental processes. (FDA 1U01FD004242-01, and NIEHS T32 ES007032-35)

1706 Epigenetic Mechanisms of Cadmium-Induced Placental Insufficiency

Cadmium is an environmental toxicant primarily released from trash incineration and burning fossil fuels. Smoking is the most significant source of human cadmium exposure, followed by diet, air, and drinking water. Cadmium exposure during pregnancy has been identified as a cause of placental insufficiency (PI) and intrauterine growth restriction, but the mechanism is not fully understood. Cadmium can disrupt normal cell function by epigenetic mechanisms, including global DNA and promoter methylation changes and altered microRNA (miR) expression. Although observed in other tissues, such epigenetic effects have not been studied in the placenta. We hypothesized that cadmium induces PI by epigenetic mechanisms. Female C57BL/6 mice (~100 day old) were administered 20 ppm cadmium chloride in drinking water ad libitum 2 weeks before mating and throughout pregnancy. On gestational day 15.5, umbilical artery (UA) blood velocity was assessed via the Doppler pulse method, and then dams were euthanized. Fetal and placental tissues were weighed and evaluated by histopathology, TUNEL staining, Western blot, global DNA methylation analysis, and miR was quantified. Compared to controls, cadmium-exposed dams had significantly lower UA systolic velocity, increased placental cell death, smaller litter size, and increased fetal resorption rate. Cadmium-exposed placental had altered expression of angiogenesis-related proteins, including increased VEGF receptor 2, and decreased eNOS and heat shock protein 90. Maternal hearts showed global hypomethylation with cadmium exposure. Placentas had significantly decreased expression of angiogenesis-related miR-126-5P. Cadmium exposure induced PI in this model. Cadmium altered the expression of angiogenesis related proteins and miRs in the placenta, and induced global hypomethylation in maternal hearts, providing evidence that cadmium induces PI via epigenetic mechanisms. Further investigations will seek to identify specific mechanisms.

1705 Epigenetic Transgenerational Actions of Dibutyl Phthalate and Male Fertility

Increased occurrence of reproductive disorders has raised concerns regarding the impact of endocrine-disrupting chemicals on reproductive health, especially when such exposure occurs during fetal life. A novel mechanism of posttranscriptional control mediated by microRNAs (miRNAs) has lately emerged as an important regulator of spermatogenesis. This study sought to investigate the epigenetic transgenerational effect of endocrine disrupting chemical dibutyl phthalate (DBP) on male fertility. Gestation female rats were dosed with corn oil or DBP (5, 50, or 500 mg/kg/day, per os) during the period of gonadal sex determination (between embryonic days 8 and 15). We determined the expression levels of 760 mature miRNAs in F3 rat testes with or without prenatal DBP exposure using a miRNA microarray technique, verified by quantitative real-time PCR from F1 to F4. Dose-related effects on male offspring included reduced sperm counts, sperm motility, and testicular and epididymal malformations. Of the screened miRNAs, 7 miRNAs were up-regulated and 152 miRNAs down-regulated (fold change > 2) in 5 mg/kg/day DBP treated group when compared with controls. There were 6 miRNAs up-regulated and 212 down-regulated in 500 mg/kg/day DBP treated group. The target genes of 15 aberrantly expressed miRNAs (fold change > 8) were involved in P3R-Akt signaling pathway, Axon guidance, Erbb signaling pathway and Focal adhesion pathways. We found permanent alterations in expression levels of multiple miRNAs suggesting an epigenetic mechanism of action. We propose that the deleterious effects of DBP on the male reproductive system are mediated by aberrantly miRNA expression in the testes. Overall, these results suggest that DBP can alter miRNA expression in F3 testes, a potentially novel mode of DBP transgenerational effect.

1708 Age-Dependent Macrophage Infiltration into the Testis of Rats and Mice after Mono-(2-Ethylhexyl) Phthalate (MEHP) Exposure

C. Murphy, A. Stermer and J. H. Richburg. Pharmacology & Toxicology, University of Texas at Austin, Austin, TX.

The testis is an immune privileged organ, however infectious and non-infectious inflammation of the testis has been shown to cause infertility. Phthalates are chemical plasticizers that are known Sertoli cell toxicants. Here we characterize the infiltration of macrophages into the testis of immature (21d, 28d, and 35d) and mature aged Fisher rats (56d) at 12, 24, and 48 hours after a single dose (1 g/kg) of mono-(2-ethylhexyl) phthalate (MEHP). The testis of rats at 21 and 28d had a peak increase in the number of CD11b+ immune reactive cells (neutrophils, macrophages, and dendritic cells) at 12h after MEHP treatment as quantified by flow cytometry. In 28d rats, CD11b+ cells remained significantly elevated at 48h while, in 21d rats it returned to control levels by 24h. The peak number of CD11b+ cells in 35d rats was delayed until 24h, remaining significantly elevated at 48h. In mature rats there was no increase in CD11b+ cells demonstrating differential responses of the testicular immune system at different developmental ages. Immuno histochemistry confirmed the increase of newly arrived macrophages (CD68+ cells). In all immature rats, monocyte chemoattractant protein-1 ( MCP-1), the primary chemokine produced in the testis, was significantly increased at 12h after MEHP treatment. This was followed by peak germ cell apoptosis (85-95% of seminiferous tubules contained ≥4 TUNEL positive germ cells) at 24h post-treatment in immature rats. The timing of peak germ cell apoptosis was similar in mature rats, however they displayed a significantly lower incidence of MEHP-induced germ cell apoptosis (8% of seminiferous tubules contained ≥4 TUNEL positive cells). Taken together, these results suggest that MEHP-induced an increase in MCP-1, triggering migration of macrophages into the immature rat testis prior to the initiation of germ cell apoptosis. Thus, signifying a role of macrophages in exacerbating MEHP-induced germ cell apoptosis in an age-dependent manner.
DNA damage from x-radiation can lead to apoptosis through p53 signaling. In the mouse testis, germ cell death resulting from x-radiation is dependent on p53 signaling. We hypothesized that p53 was also essential for germ cell apoptosis in response to x-radiation in the rat testis. We exposed wild-type Sprague-Dawley and novel p53 knockout rats (SD- Tp53 tm1sage) (age 60 d), to 0, 0.5, or 5 Gy x-ray. Rats were euthanized at 3 h, 12 h, and 42 d after exposure. Body, testis, and epididymis weights were recorded. The terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) assay, a measure of apoptosis, was performed in paraffin-embedded testes. Real-time RT-PCR for the death receptor gene Fas was performed. 13 d BrdU labeling was performed to characterize the spermatogonial stem cell population in unexposed knockout rats, and whole-mounted tubules were labeled for GFP-α, a marker of type A spermatogonia. X-radiation resulted in a significant increase in TUNEL labeling after 12 h in wild-type rats. However, frequent TUNEL positive cells, most often spermatocytes, were observed in p53-/- rats in all treatment groups, p53-/- rats displayed frequent, but variable, atrophy of seminiferous tubules and lower average testis weight. While Fas mRNA levels followed a similar trend to TUNEL frequencies, they did not differ significantly by treatment. GFP-α staining showed similar populations of A spermatogonia in wild-type and p53-/- rats, and BrdU labeling in p53-/- testes gave an average 37% germ stem cell labeling index, indicating normal proliferative activity. Therefore, we conclude that the frequent TUNEL signal in p53-/- rats likely results from unresolved homologous recombination in spermatocytes during meiosis. Our data indicate that p53 plays a critical role in maintenance of spermatogenesis in the rat. While p53 is known to participate in resolution of DNA double-strand breaks in meiotic recombination, this represents a significant difference from data previously obtained in the mouse.

Testicular effects of chemical mixtures may differ from those of the individual chemical constituents. This study assesses the co-exposure effects of the model germ cell- and Sertoli cell-specific toxicants, X-radiation (x-ray) and 2,5-hexanediol (HD), respectively. X-ray induces germ cell apoptosis and in high dose studies, HD has been shown to attenuate the x-ray induced germ cell apoptosis. Here, adult rats were exposed to different levels of x-ray (0.5Gy, 1Gy, 2Gy) or HD in the drinking water for 18 days (0.33%), alone or in combination. To assess cell type-specific attenuation of HD effects with x-ray co-exposure, we used laser capture microdissection (LCM) to examine a panel of apoptosis-related transcripts using PCR arrays. The apoptosis PCR arrays identified significant dose-dependent treatment effects on several genes (Table 1). Stathelin, Casp7, NAALAD, Sirt3, Casp3, and upregulation of Fas. Both Casp7 and DR5 are key pro-apoptotic factors in the apoptosis pathway, and had the strongest down-regulation following 0.33% + 0.5Gy exposure, with maximum fold decreases of -6.37 and -4.17, respectively. The significant and simultaneous downregulation of pro- and anti-apoptotic transcripts is exacerbated, rather than ameliorated, by the addition of HD to the low dose of x-ray. These results indicate that the attenuation effect seen with the high dose co-exposure does not persist into the low dose range. However, the downregulation of anti- and pro-apoptotic transcripts as a result of 0.5Gy x-ray exposure may be an adaptive mechanism employed by the injured spermatogonia to evade apoptosis. These studies provide insight into cell-specific toxicant co-exposures and illustrate that low dose and high dose responses can differ, and that the low dose response in not necessarily an extrapolation of the effects seen at high doses.

Surface Charged Iron Oxide Nanoparticles May Influence Reproductive and Developmental Toxicity in CD-1 Mice

Iron oxide nanoparticles (NPs) are currently being investigated for many uses including biomedical imaging, soil/groundwater remediation, and drug delivery. The risk to pregnant women and the developing fetus is high, as the NPs have the potential to cross the placenta due their small size. Our lab has previously shown that pregnant CD-1 mice given a low (10 mg/kg body mass) intraperitoneal dose of NPs coated with either poly acrylic acid (PAA, negatively-charged) or polyethyleneimine (PEI, positively-charged) for 8 consecutive days had significantly decreased maternal weight gain, increased fetal resorptions, and increased fetal liver iron concentrations compared to controls. These results raise concern about NP reproductive toxicity and how NP exposure might affect the developing fetus. In the current study, female CD-1 mice were given a low, medium, or high dose (10, 50, or 100 mg/kg body mass) of NPs during organogenesis (gestation day (GD) 8, 9, or 10) in order to observe if there is a dose related effect on reproduction and to examine if fetal bioaccumulation of NPs will result in decreased fecundity or malformations in the progeny. At low dosages, no adverse effects were observed. At the highest dosage, increased resorptions were observed for the PAA NPs given on GD 8 and the PEI NPs given on GD 10. The testes and uteri of the offspring were harvested and histologically examined for abnormalities. Increased uterine and decreased seminiferous tubule epithelial linings were observed in offspring of dams given the highest dosage of NPs; no changes in fecundity were observed in any group. While no negative reproductive effects were observed at the lower dosages, exposure to a high dosage of surface charged iron oxide NPs during pregnancy may result in increased fetal death and reproductive organ abnormalities in the offspring.

Environmental exposures to endocrine disruptors (EDs) are thought to contribute to idiopathic increases in male reproductive abnormalities. Although humans are exposed to a myriad of EDs from conception through adulthood, few studies have evaluated the effects of combined exposures, while animal studies often used doses exceeding environmental levels. We hypothesized that prenatal exposure to combined low dose of the phytosterogen genistein and the plasticizer di-(2-ethylhexyl) phthalate (DEHP) might pose a greater risk to male reproduction than individual compounds. Pregnant Sprague Dawley dams were gavaged from gestational day 14 to birth with either corn oil, genistein, DEHP or their mixture at 10 mg/kg/day, a dose at which either compound does not cause conspicuous long term effects. Adult serum testosterone levels were unchanged. However, histological analysis revealed increased interstitial fibrosis in testes of ED-exposed adult offspring, suggestive of premature aging. Quantification of elongated spermatids and quantitative PCR analysis (qPCR) of germ cell markers indicated adult germ cell alterations in ED-exposed rats.

Gene expression arrays identified 83 up-regulated and 171 down-regulated genes (p<0.05) in testicular RNA from ED-treated relative to control rats, including genes with explicit ties to male reproduction, such as FOXA3, PDGFRα and HSD3B1, suggesting disrupted testis development and function. These changes were further validated by qPCR. These results show the BFR maternal exposure to a mixture of unrelated EDs at environmentally relevant doses permanently disrupt testicular gene expression profiles and histology in a manner different from individual compounds, highlighting a need for more realistic and comprehensive analysis of endocrine disrupting chemicals.
eye opening). Onset of puberty was accelerated in females (20 mg/kg); furthermore, males exhibited delayed onset of puberty (60 mg/kg). Body weight or food consumption has not differed among treatment groups to date. However, both male and female offspring had increased liver weights at PND 21 (20 and 60 mg/kg). Moreover, male fat pad weights were significantly decreased at PND 46 (20 mg/kg). PBDE exposure did not affect fasting glucose or insulin levels, and there was no evidence of impaired glucose tolerance (AUCglucose) or insulin resistance (AUCinsulin). In conclusion, perinatal BFR exposure alters reproductive development as indicated by accelerated onset of puberty in female offspring and delayed onset in males. Decreased fat pad weights in males at PND 46 indicate that BFR exposure may have metabolic effects.

1713a Reproductive and Developmental Toxicology Assessment of Oral Dietary Calcium Formate in Yucatan Miniature Swine

Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Rational: Calcium Formate (CaF) is being considered as a dietary calcium supplement. Objective: Assess the reproductive/developmental toxicity of CaF using the miniature pig model when administered orally via food consumption. Experimental Procedure: Sixty (30 male and 30 female) sexually mature Yucatan miniature swine were gender paired for breeding and randomized into 3 ggs of 10 pairs receiving untreated control, low dose (2.25% CaF), and high dose (4.5% CaF) in the daily diet. Standard reproductive and developmental variables were assessed, including clinical, gross, and microscopic pathology (parents and piglets). Results: Female fertility index/gp ranged from 80-100%; 170 offspring were recorded; viability was good. Length of gestation, birth wts and body wt change were comparable. Litter size was robust (range 5.4-7.1) for all groups. CaF supplementation was associated with decreased (dec.) food intake in both parents in the high dose gp and with dec. weight gain in both parents during the prematuring phase of the study. These between gp differences persisted through the gestational phase for the females, but there was not a statistically significant increase (inc.) in the magnitude of these differences over time. CaF supplementation was associated with inc. in serum calcium levels in both parents. Although statistically significant, the magnitudes of these differences were small, and well within the normal physiologic ranges. There were no findings of toxicity in the offspring related to maternal exposure to dietary CaF. Conclusion(s): Dec. food intake, dec. weight gain during premating phase, and inc. serum calcium were associated with oral dietary CaF administration. These findings were consistent with previous research, and/or represented expected responses to the administration of oral CaF supplementation.

1713b Effect of Vincamine on the Reproductive System of Harlan Sprague Dawley Rats and B6C3F1/N Mice

1Toxicology Branch, National Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, NC, 2Cellular & Molecular Pathology Branch, NIEHS, RTP, NC, 3Program Operations Branch, NIEHS, RTP, NC and 4Battelle, Columbus, OH.

Vincamine is an alkaloid extracted from the leaves of Vinca minor. The National Toxicology Program conducted short-term/pilot toxicity studies in Harlan Sprague Dawley rats and B6C3F1/N mice. Time-mated rats were dosed up to 1000 mg/kg from gestation day (GD) 6 through GD 21. All dams in the 1000 mg/kg groups were moribund on GD 7 and exhibited implants at necropsy. Dams dosed with ≥ 30 mg/kg did not produce pups, and the majority of undelivered dams had fetal resorptions when necropsied. Dams and pups in the 10 mg/kg dosage group did not exhibit any effects attributed to vincamine. Vincamine was subsequently administered up to 300/mg/kg to time-mated female rats from GD 17 to GD 21 (after the period of major organogenesis), then postnatal day (PND) 1 through PND 20. Pups were administered vincamine from PND 12 to PND 20. Vincamine was well tolerated by the dams; all dams survived to study termination, and there were no treatment related effects on littering index, duration of gestation or maternal behavior. On PND1 and 4, vincamine administration was associated with lower pup body weights (100 and 300 mg/kg) and smaller litter size (300 mg/kg). Mild testicular hypoplasia, and minimal ovarian hypoplasia were observed at doses levels ≥ 100 mg/kg at necropsy on ~ 21 days of age. In mice, vincamine was administered by gavage up to 1000 mg/kg for 14 days. Morbidity and mortality was observed at 500 (females) and 1000 (males and females) mg/kg. Consistent with the rat study, the tests were a target of vincamine exposure in male mice. A dose-dependent decrease was observed in testes and epididymis weights in the 500 and 1000-mg/kg groups. Testicular necrosis in the germinal epithelium of the seminiferous tubules was noted among males exposed to dose levels ≥ 250 mg/kg of vincamine. This work was supported by the NIH.

1713c Dose Addition Predicts Effects of Phthalate Mixture on Male Reproductive Tract Development and Associated Fetal Testis Gene Expression in Rats

1NTPINIEHS, RTP, NC and 2USEPA, RTP, NC.

A challenge in cumulative risk assessment of phthalate esters is incomplete data on individual chemicals. The objective of the current study was to test whether dose addition (DA) and relative potency factor (RPF), which is a type of DA that relies upon a reference compound, would be better predictors than response addition (RA) of the effects of a 5 phthalate mixture on fetal testis gene expression (star, cyp1a, and insulin-like hormone 3) and hormone-sensitive male reproductive tract development when assumptions were made for missing individual phthalate data. We administered a dose range of the mixture (100, 80, 60, 40, 20, 10, 5 or 0% of top dose consisting of 300 mg/kg per chemical of benzyl butyl (BBP), di(n) butyl (DBP), diethyl hexyl phthalate (DEHP), di-isobutyl phthalate (DIBP) and 100 mg dipentyl phthalate (DPP/kg)) via gavage to rat dams on GD18-18 (fetal gene expression study) or GD8-postnatal day 3 (in vivo study); we selected the ratio of the top dose so that each phthalate contributed equally to the reduction in fetal testosterone (T) production based on estimates of their potencies from previous studies. We compared observed mixture responses to model predictions of DA, RPF, and RA based on the logistic regression analysis of the individual phthalate data using DBP or DEHP as the reference phthalates. DA predicted the inhibition of fetal gene expression at GD18, decreases in neonatal anogenital distance and adult reproductive organ weights, and induction of juvenile areola retention and adult reproductive malformations. RPF based on fetal T production was nearly as accurate as DA, while RA was never the best model. Similar results were obtained when the observed data of the mixture were force fit to the logistic regression parameters of the models. Therefore, dose addition was a good predictor of the mixture even in the face of incomplete data on the individual phthalates. This research was partially supported by an interagency grant by the NIH, NIEHS. This abstract does not necessarily reflect USEPA policy.

1713d The Effects of Triclosan on the Male Reproductive System of the Rat

T. E. Stoker1, G. W. Louis2 and D. Hallinger.

Endocrinology Branch, US EPA, Research Triangle Park, NC.

Triclosan (TCS), a widely used antibacterial agent, has been shown to have endocrine disrupting activity in mammals. Although the majority of these studies report that TCS alters thyroid hormones, effects on the estrogenic and androgenic pathways have also been observed. These include reports indicating anti-androgenic activity of TCS in vitro and a decrease in serum testosterone (T) concentrations in vivo. In the first study, we further examined the effect of TCS on androgenic activity in the male rat using the Hershberger assay. Six-week old castrated male rats were gavaged for 10 consecutive days with 50 or 200 mg/kg of TCS or vehicle control (corn oil) to determine the presence of any potential androgenic effects. Other groups of rats were treated with testosterone propionate (TP) (0.2 mg/kg, sq) alone or in combination with 50 or 200 mg/kg TCS to evaluate possible anti-androgenic or TP potentiation by TCS. On day 10, the accessory sex tissues (glans penis, Cowper’s glands, levator ani bulbous cavernous muscle complex, seminal vesicles, and ventral prostate) were weighed. TCS alone did not alter the weight of any of the tissues. Also, TCS did not alter the weight of the tissues when given in combination with TP. As expected, TCS exposure (alone or in combination with TP) resulted in a dose-dependent decrease in serum thyroxine after a 10 day exposure to 50 and 200 mg/kg TCS. In a second in vitro study, we examined the effect of TCS on T production using the H295R cell line. Forskolin and prochloraz served as positive controls producing the expected increase and decrease in T production, respectively. TCS from 0.01 to 3.0 μM did not alter T. 10 μM of TCS induced 20% cytotoxicity. Thus, in the present study TCS did not have androgenic or anti-androgenic activity in the Hershberger assay and was without effect on steroidogenesis in the H295R cell line. Serum T4 was significantly decreased demonstrating that the doses selected were sufficient to cause a change in this hormone. This abstract does not necessarily reflect EPA policy.
Bisphenol A (BPA) is a chemical used in the manufacture of polycarbonate and epoxy resins. The molecular pathways potentially modulated by doses of BPA below those needed to activate the estrogenic pathway remain poorly characterized. We assessed the effect of BPA on the gene expression in prostates from 4-day-old rats, an age when the internal levels of aglycone BPA are relatively high due to an immature metabolic system. BPA-treated naive rats were directly dosed daily from the day after birth. Dose groups included naive and vehicle controls, seven "low" BPA doses [2.5, 8, 25, 80, 260, 840, 2,700 μg/kg body weight (bw)/day], two high BPA doses (100,000, and 300,000 μg/kg bw/day), and two doses of the reference estrogen EE2 (0.5 and 5.0 μg/kg body weight (bw)/day). Genome-wide gene expression was assessed by DNA microarray in a subset of doses, and genes of interest were validated by quantitative real-time PCR using all study doses. Principal component analysis showed that samples segregate into three sub-groups: 1) vehicle and low BPA; 2) high BPA and low EE2; and 3) high EE2. The high EE2 dose modulated the largest number of genes, followed by the low EE2 dose. Genes commonly modulated by the high BPA and EE2, which included Dclk3, Gnat2, Gzmc, Map4k5, and Pipc, were modulated in the same direction by both chemicals. Modulation of genes in the "low" BPA dose range was inconsistently observed across all doses, with no dose-response pattern. These data suggest that BPA doses ≥ 2,700 μg/kg bw/day have limited effects in the gene expression in the rat prostate under our experimental conditions. This is consistent with the lack of "low" BPA effects observed in other endpoints, including prostate histopathology, examined in 90-day-old siblings from the same study. IAG FDA 224-12-0005/NIH ES12013.
show that the dispersed crude oil significantly increases the number of apoptotic cells and diploid sperm (immature) in treated worms' gonad when compared to controls at all exposure levels (p < 0.05). Genes involved in the apoptosis pathway were up-regulated, which include cel-13, cel-3, ced-4, ced-9, cep-1, dpl-1, efl-1, efl-2, egl-1, egl-38, lin-35, pax-2, and sir-2.1. Given cep-1(1053) was activated at all dispersed oil treatments and the germ cell apoptosis was suppressed in the CEP-1 loss of function mutant, the increased apoptosis is likely CEP-1 dependent. A total of 231 microRNAs expressions were analyzed using quantitative real-time PCR; 59 miRNAs were up-regulated, while 82 were down-regulated. Heatmap clustering indicates that dispersed oil displayed a distinct miRNA expression profile compared to control, oil-alone, and dispersant-alone treatments. The gene targets and functions of miRNAs were analyzed using bioinformatics tools (TargetScan, miRanda, and KEGG). A variety of reproduction related pathways were found to be regulated by oil-dispersant affected miRNAs, including MAPK signaling pathway, Wnt signaling pathway, Hedgehog signaling pathway, and Oocyte maturation pathway, etc. This work provides mechanistic understandings of crude oil-dispersant induced reproductive toxicity.

**1713j** High-Content Screen and Mechanistic Study of Environmental Reproductive Toxins in *C. elegans*

D. A. Parodi and P. Allard, 1, 2, *ISG, UCLA, Los Angeles, CA and *EHS, UCLA, Los Angeles, CA.

Chemicals play an integral part of our everyday life despite their significant impact on human health and the environment. Global chemical production is doubling every 25 years, rapidly outpacing population growth, increasing both in volume and in the variety of the compounds released in the environment each year. Over the past two decades, a contribution of environmental exposures to the etiology of reproductive health effects of exposures has become an increasing cause for concern. However, there is tremendous difficulty in assessing safety of these chemicals due to their large number and also from the complexity of biological effects they elicit over a large range of doses. Here, I address these issues by using the genetic model system, the worm *Caenorhabditis elegans* in two ways. First, I aim to identify proreptochemicals by screening chemicals for their ability to disrupt meiosis and induce aneuploidy in *C. elegans*. For this purpose, I developed a 384-well plate high-content microscopy assay that can accurately detect the induction of aneuploidy based on the emission of GFP fluorescence in aneuploid embryos (Allard et al, 2013). This assay will be used to screen ToxCast Phase I and II environmental chemical libraries and to identify a list of compounds with high aneugenicity. Second, a molecular and cellular mechanistic follow-up analysis of hits will be performed. Preliminary work indicates that worms exposed to 100μM Maneb, Feranimol or Diazinon show a significant induction in the number of germline apoptotic nuclei (2.7, 2.6 and 3.3-fold induction, respectively, p<0.05) and an increase in reduced nuclear density (2.8, 2.6 and 2.4-fold induction, respectively, p<0.05), suggesting that these compounds are potent reproductive toxicants causing germline maintenance disruption and acute germ cell death. Together, these studies aim at developing unique methods to interrogate our chemical environment for its effect on germline maintenance and health.

**1713k** Cross-Species Evaluation of Endocrine Disrupting Effects of Lead (Pb) on Maturation and Development

E. P. Himes, L. Vinikoor-Imler and M. G. Lassiter. EMAG, NCEA, US EPA, Research Triangle Park, NC.

In a cross-species evaluation conducted in support of the review of the US EPA National Ambient Air Quality Standards (NAAQS) for Lead (Pb), findings from epidemiologic, toxicological and ecological disciplines were used in a weight of evidence approach to evaluate reproductive and developmental effects of this metal, including endpoints associated with endocrine disruption. In the process of synthesizing information on reproductive effects of Pb for the 2013 Integrated Science Assessment for Lead (ISA), we noted that Pb is associated with maturational delays (e.g. puberty onset, developmental duration, life cycle length, metamorphosis) across a wide variety of organisms. A causal association between Pb exposure and reproductive and developmental endpoints for both human health and ecological receptors were reported. Moving beyond the synthesis conducted for the Pb ISA, we have reviewed the literature on changes in timing of developmental milestones associated with exposure to Pb. Evidence from multiple species points to an underlying common mode of action of Pb on the insulin-like growth factor signaling pathway; inhibit B was also affected in vertebrate models of Pb exposure. An interdisciplinary cross-species approach provided insights into endocrine disruption by Pb and a possible mode of action of this metal. Increased time to sexual maturation or delayed development may have consequences for reproduction and development across a broad range of species.

The views expressed in this poster are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.

**1713l** Dual Role of microRNA-31 in 2, 3, 7, 8-Tetrachlorodibenzo- p-dioxin(TCDD)-Mediated Ureaplacement of CYP1A1 and Fox3 in Activated T Cells

P. Mehrotra, P. S. Nagarkatti and M. Nagarkatti. Pathology, Microbiology and Immunology, University of South Carolina School of Medicine, Columbia, SC.

TCDD, an environmental contaminant, is well known for inducing severe toxicity including immunosuppression. We examined the mechanisms by which TCDD affects T cell response to Staphylococcal enterotoxin B (SEB) and Pertussis Toxin (PTX). SEB, a superantigen, activates ~20% of T cells via Vβ8 T cell receptor and causes a robust release of pro-inflammatory cytokines. Pertussis Toxin promotes the generation of IL-17-producing CD4+ cells by inducing IL-6. We injected C57BL6 mice with either SEB or PTX, and treated them with either vehicle or TCDD. Our studies showed that TCDD treatment of SEB-activated lymphocytes led to a decrease in Vβ8+ T cells. TCDD treatment of PTX-activated lymphocytes dampened Th17 cells while promoting Fox3+ Tregs. TCDD also induced apoptosis in activated T cells, suppressed pro-inflammatory cytokines, IFN-γ, TNF-α and IL-6, and induced anti-inflammatory cytokine, IL-10. In order to determine the role of microRNA (miR) in TCDD-induced immune dysregulation, we performed high throughput miR analysis. In silico analysis demonstrated that miRs induced by TCDD regulated several pathways including induction of apoptosis, AHR signaling and Treg differentiation. Interestingly, miR-31 which was down regulated following TCDD treatment was found to be complementary to both the 3’-UTR of Fox3 and CYP1A1 genes, which was validated by RT-PCR. Furthermore, miR-455 against ARNT target gene was also down-regulated in TCDD treated groups. In addition, miR-21 which targets the pro-apoptotic factors, Fas and Fasl, was down-regulated by TCDD, which correlated with the ability of TCDD to induce apoptosis. Together, our studies demonstrate that TCDD-mediated immune regulation may be mediated by altered expression of several microRNAs (Supported by NIH grants P01AT003961, P20 RR032684, R01AT006888, R01ES019313, R01MH094755 and VA Merit Award BX001375).

**1713m** Relationship between Allergic Characteristics of Swine Husbandry Workers and Endotoxin Level in Swine Farm Dust

H. Kim, Y. Heo, K. Shin, J. Jo and K. Roque, 1Occupational Health, Catholic University of Daegu, Gyeongsan si, Republic of Korea and 2Preventive Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Animal husbandry workers could be exposed to various work hazards including toxic gases, chemicals, and endotoxin. Immunological evaluation on allergic hyporesponsiveness occurrence was undertaken for swine farm workers. Relationship between endotoxin level in dust collected from swine farms and immunological markers related with respiratory allergy was evaluated. Peripheral blood samples were collected from 10 workers at 10 swine farms in Korea. PMBCs were stimulated with PMA and ionomycin for 48 hours. The levels of cytokines at culture supernatants were determined using a ELISA kit. The concentration of particulate matter (PM10) in the indoor air of the swine farms was evaluated using a PVC membrane filter and mini volume air sampler, and endotoxin levels in the dust were measured by Limulus Amebocyte Lysate Kinetic QCL method. Levels of endotoxins in total dust were categorized into high (GM:109.35 EU/m²) and low concentrations (GM:0.95 EU/m²) for 5 swine farms, respectively. IL-4 levels were higher in the high endotoxin group than the low endotoxin group, while interferon-γ levels were lower in the high endotoxin group than the low endotoxin group. The ratio (IFNγ to IL-4) was lower in the high endotoxin group (1.15±0.60) than the low endotoxin group (3.09±2.38). The level of IL-13 was significantly higher in the high endotoxin group (1.12±0.37 ng/ml) than the low endotoxin group (0.57±0.04 ng/ml). Plasma IgE levels were five times higher in the swine farm workers than the seven control subjects not involved with animal husbandry at the same residential area as the swine farm workers. The house dust mite (Dermatophagoides farinae, D. pteronyssinus) and cockroach were the major respiratory allergens for swine farm workers. This study suggests that the immunological function of swine farm workers exposed to high level of endotoxin could be modulated toward allergic reactivities. [Supported from Korean Rural Development Agency, PJ008678]
Glucose and Insulin Mediated Alteration in Metabolic Activity of U937 Cells

A. Engin, B. Karahall and E. Coskun.

Department of Toxicology, Gazi University, Faculty of Pharmacy, Ankara, Turkey.

By 2030, it is estimated that the number of people with diabetes will be more than 82 million in developing countries and more than 48 million in developed countries. In type 2 diabetes, insulin resistance and metabolic syndrome are associated with persistent hyperglycemia and chronic inflammation due to the macrophage activation by impaired glucose retention. Enhanced reactive oxygen production, increased modification in ligands and disruption in insulin signaling pathway are the main causes in the development of diabetic complications. The aim of our study is to evaluate the alteration in the metabolic activity of U937 human monocytic cell line by glucose and insulin. U937 cells were incubated with or without insulin (10 µU/ml – 60 µU/ml) and with various glucose concentrations (50 mg/dl – 500 mg/dl) that were determined due to the blood glucose levels of International diabetes classification. Metabolic activity of U937 cells were significantly increased in hypoglycemic conditions with 60 µU/ml insulin at 48 hours. However, higher glucose in combination with high insulin concentrations significantly decreased metabolic activity of the monocytic cells at 72 hours. These results indicate that chronic exposure to high glucose due to uncontrolled diabetes may alter the immune response related to the changes in the metabolic activity of the immune system cells.

Ascorbic Acid Improves Hyperoxia-Compromised Host Defense against Pseudomonas aeruginosa Infection in Mice

V. S. Patel1, V. Sampat1, M. Espey1, H. Wang2 and L. Mantell1, 2.

1Department of Pharmaceutical Sciences, St. John’s University College of Pharmacy and Health Sciences, Jamaica, NY, 2Centers for Inflammation and Immunology, The Feinstein Institute for Medical Research, North Shore-LIJ Health Science, Manhasset, NY and 3National Institutes of Health, Bethesda, MD.

Oxygen therapy using high concentrations of oxygen (hyperoxia) is associated with compromised host defense and greater susceptibility to bacterial infections, causing ventilator-associated pneumonia (VAP). Hyperoxia-induced excessive ROS production and accumulation of extracellular HMGB1 play critical roles in impairing macrophage’s ability to phagocytose. Ascorbic acid (AA), a antioxidant, exhibits beneficial effects in various ROS-mediated diseases. The aim of this study was to determine whether AA could improve hyperoxia-compromised host defense and macrophage functions. C57BL/6 male mice were exposed to hyperoxia (≥98% O2, 48 h) followed by intratracheal inoculation with Pseudomonas aeruginosa, and simultaneously treated with different concentrations of AA. RAW 264.7 cells (a macrophage like cell line) were also exposed to different concentrations of AA prior to 95% O2 exposure, ROS levels, phagocytic activities and extracellular HMGB1 accumulation were analyzed. AA effectively improved bacterial clearance in lungs and airways of the mice. It significantly rescued the hyperoxia-compromised macrophage function of phagocytosis. Improved phagocytic activity was accompanied by reduced ROS levels as well as decreased accumulation of extracellular HMGB1.

Our study demonstrates that AA, a cost-effective dietary supplement, could provide a rewarding aid in prevention and treatment of VAP.

Sodium Methyldithiocarbamate: Potential Connections of Disparate Effects

Basic Sciences, Mississippi State University, Mississippi State, MS.

Sodium methyldithiocarbamate (SMD) is the third most abundantly used conventional pesticide in the U.S. We have previously reported that SMD has immunotoxic effects, but we have not previously reported a comprehensive description of the effect of this compound on gene expression and host resistance in a mouse model. These effects are reported here, and they indicate that oral exposure to the compound and relatively high doses (100-300 mg/kg) causes substantial decreases in innate immune and inflammatory responses to bacterial lipopolysaccharide (from Escherichia coli) or to viable bacteria. A series of SMD dosages most potently inhibited expression of genes related to interferon response and production pathways. These results suggest that the action of a strong interferon inducer might be inhibited to a greater extent than the action of a stimulus such as LPS or whole bacteria. Thus, polymeric-polyacrylicidic acid (poly IC), the major ligand for TLR3 was investigated, and SMD was found to inhibit cytokine and chemokine induction by this compound at dosages as low as 10 mg/kg, which are substantially lower than required for inhibition of these responses by LPS or whole bacteria. Although, we have previously shown that SMD decreases survival in an E. coli model of sepsis, inhalation or dermal exposure are more likely routes for human exposure to SMD. We report here that inhalation of SMD or its major breakdown product (methylisothiocyanate) did not significantly decrease survival. However, survival was decreased by oral administration of SMD. The results indicate that survival was decreased by oral administration was likely due to initial inhibition of decreased bacterial killing in phagocytic cells and decreased production of cytokines or chemokines. We now hypothesize that the effects of SMD on lethal outcome in sepsis and TLR3 responses are related and that fully understanding this will also suggest reasons for differences in effects of dosage routes.

Immunotoxicology Profile following Exposure to Silt Deposit Dust Samples from Nellis Dunes Recreational Area, Clark County, Nevada

1Microbiology, MSU, Bozeman, MT, 2Harry Reid Center for Env. Studies, UNLV, Las Vegas, NV, 3Anthropology, UNLV, Las Vegas, NV, 4Geoscience, UNLV, Las Vegas, NV and 5Pharmacology and Toxicology, ECU, Greenville, NC.

The Nellis Dunes Recreation Area (NDRA) is a popular region for off-road vehicle driving that attracts over 300,000 commercial and recreational users each year. Trace metals that could potentially affect human health have been measured in soil and airborne dust samples. Map unit CBN7 is composed of aggregated silt deposits commonly found in badlands without rock or vegetative cover. Dust samples from CBN7 with a median grain size of 4.37μm were analyzed via inductively coupled plasma mass spectrometry (ICP-MS) and contained: 293.63 ppm Mn, 248.23 ppm Sr, 49.49 ppm Cr, 26.20 ppm Pb, and 23.51 ppm As. B673CF1 female mice were exposed via oropharyngeal aspiration at doses of 0.01, 0.1, 1, 10, and 100 mg geological sample/kg/day at four intervals, each a week apart. No dose-responsive changes were observed in body or organ weights. Serum total bilirubin was dose-responsively increased beginning at 0.1 mg/kg/day. Serum creatinine levels were increased at 10 and 100 mg/kg/day whereas blood urea nitrogen was dose-responsively decreased beginning at 0.1 mg/kg/day. Blood neutrophil and lymphocyte numbers were increased at 10 and 100 mg/kg/day. Splenic CD8+ and CD4+/CD8+ T-cells were decreased; however, this was not clearly dose-responsive. No non-renal, inflammatory changes were detected. B22.2 and thymic CD4+CD8+ Igm antibody production was dose-responsively suppressed beginning at 0.1 mg/kg/day with an ED50 of 0.30 mg/kg/day. The LOAEL was 0.1 mg/kg/day whereas the NOAEL was 0.01 mg/kg/day as demonstrated by antigen-specific IgM production. Further studies will assess the potential health risks associated with recreation at this site.

Immunotoxicology Profile following Exposure to Geological Dust Samples Collected from Nellis Dunes Recreational Area

Map Unit CB2N2: Median Grain Size 4.5 μm

1Microbiology, Montana State University, Bozeman, MT, 2Harry Reid Center, University of Nevada, Las Vegas, NV, 3Anthropology, University of Nevada, Las Vegas, NV, 4Pharmacology and Toxicology, East Carolina University, Greenville, NC and 5Geoscience, University of Nevada, Las Vegas, NV.

The Nellis Dunes Recreational Area (NDRA) is a highly popular ORV area near Las Vegas, NV. Soil and airborne dust in this area are rich in naturally occurring arsenic. This presentation focuses on data from CB2N2, which is a yellow silt and clay unit mostly barren of vegetation. Dust samples with a median grain size of 4.5 μm were analyzed for total elemental composition via inductively coupled plasma mass spectrometry. The following concentrations were found: As136.82 ppm; Cr38.74 ppm; Pb:22.71 ppm; Mn: 386.28 ppm; and Sr:424.89 ppm. B6C3F1 female mice were exposed to dust via oropharyngeal aspiration at doses of 0.01, 0.1, 1, 10, and 100 mg geological sample/kg/day at four intervals, each a week apart. No dose-responsive changes were observed in body or organ weights. Serum total bilirubin was dose-responsively increased beginning at 0.1 mg/kg/day. Serum creatinine levels were increased at 10 and 100 mg/kg/day whereas blood urea nitrogen was dose-responsively decreased beginning at 0.1 mg/kg/day. Blood neutrophil and lymphocyte numbers were increased at 10 and 100 mg/kg/day. Splenic CD8+ and CD4+/CD8+ T-cells were decreased; however, this was not clearly dose-responsive. No non-renal, inflammatory changes were detected. B22.2 and thymic CD4+CD8+ Igm antibody production was dose-responsively suppressed beginning at 0.1 mg/kg/day with an ED50 of 0.30 mg/kg/day. The LOAEL was 0.1 mg/kg/day whereas the NOAEL was 0.01 mg/kg/day as demonstrated by antigen-specific IgM production. Further studies will assess the potential health risks associated with recreation at this site.
1713s Reducing Immunogenicity in a T Cell-Dependent Antibody Response (TDAR) in Cynomolgus Monkeys Leads to a Sensitive Assessment of Immunosuppression by Abatacept (CTLA4-Ig)

G. Bannish1, M. S. Perpetua1, A. J. Beavis1, B. Fraszczyk1, S. Harvey1, T. Ziegelhofer1, J. Doughty1 and L. A. Coney1. 1BioMarkers, Bioanalysis, and Clinical Sciences, Huntington Life Sciences, East Millstone, NJ. 2Biologics, Huntington Life Sciences, Huntington, Cambridgeshire, United Kingdom and 3Cardiology/Inflammation Technology, Huntington Life Sciences, East Millstone, NJ.

The TDAR response is used to evaluate drug effects on the immune system, assessing antigen presentation and T and B lymphocyte function. Cynomolgus monkeys injected subcutaneously on 5 occasions over 15 days with 1 mg Keyhole Limpet Hemocyanin (KLH) in Incomplete Freund’s Adjuvant (IFA) developed a robust IgM and IgG antibody response to KLH. Treatment of animals twice weekly with 8 mg/mL/kg Abatacept (CTLA4-Ig) by intravenous slow bolus injection did not diminish the antibody response. In a separate study, animals were injected with 100 μg KLH in the absence of adjuvant via intradermal injections. These animals developed a detectable IgM response with inverse titers of 25,000 ten days following primary immunization. IgG responses were detectable 14 days post primary injection with inverse titers of 12,000, and 7 days post secondary challenge with inverse titers of over 50,000. Treatment of a cohort of these animals with Abatacept led to an ablation of antibody responses. Antibody responses to KLH from animals were reduced but not ablated when treated with 1 mg/kg methotrexate via subcutaneous injection. Maximal mean IgM responses to KLH 10 days following primary immunization were reduced from 120,000 to 34,000. Maximal mean IgG responses to KLH were reduced from 1 x 10^6 to 0.66 x 10^6 with maximal responses delayed from 7 to 10 days post secondary KLH challenge. Combined, these data demonstrate that excessive antigenic stimulation can overcome the immunosuppressive effects of Abatacept and define an alternate immunization strategy that is susceptible to immunosuppression. Utilizing an appropriate immunization strategy in TDAR assays and including biological immunosuppressor controls, this model is optimized for safety assessment of immunomodulatory biological drug products.

1713t Sulforaphane Inhibits Vascular Inflammation in Mice and Prevents TNF-α-Induced Monocyte Adhesion to Primary Endothelial Cells through Interfering with the NF-κB Pathway

P. Nallasamy1, H. Shah1, E. Brooke1, H. Zhu1, Y. Li2 and Z. Jia1. 1University of North Carolina at Greensboro, Greensboro, NC and 2Campbell University School of Osteopathic Medicine, Buies Creek, NC.

Tumor necrosis factor alpha (TNF-α) is a critical cytokine that plays important role in regulation of the toxic effects of a variety of chemicals and toxicants. Sulforaphane, a naturally-occurring isothiocyanate present in cruciferous vegetables, has received wide attention for its potential to improve vascular function in vitro. However, its effect in vivo and the molecular mechanism of sulforaphane at physiological concentrations remain unclear. Here, we report that a sulforaphane concentration as low as 0.5 μM significantly inhibited TNF-α-induced adhesion of monocytes to human umbilical vein endothelial cells (HUVECs). Sulforaphane also significantly suppressed TNF-α-induced production of adhesion molecules. Furthermore, sulforaphane inhibited TNF-α-induced NF-κB transcriptional activity, IkBα degradation and subsequent NF-κB p65 nuclear translocation in endothelial cells, suggesting that sulforaphane can inhibit inflammation by suppressing NF-κB signaling. In an animal study, the physiologically-relevant dose of sulforaphane (300 ppm) in a mouse diet significantly abolished TNF-α-induced ex vivo monocyte adhesion and circulating adhesion molecules and chemokines in C57BL/6 mice. Histology showed that sulforaphane treatment significantly prevented the eruption of endothelial lining in the intima layer of the aorta and preserved elastic fibers’ delicate organization as shown by Verhoeff-van Gieson staining. Immunohistochemistry studies showed that sulforaphane treatment also reduced YCAM-1 and monocytes-derived F8/80-positive macrophages in the aorta of TNF-α-treated mice. In conclusion, sulforaphane at physiological concentrations protects against TNF-α-induced vascular endothelial inflammation, in both in vitro and in vivo models. This anti-inflammatory effect of sulforaphane may be, at least in part, associated with interfering with the NF-κB pathway.

1714 Regulation of Covalent Modification of 2-Tert-Butyl-1,4-Benzoquinone to Keap1 through Glutathione-Mediated S-transarylation

Y. Abiko1,2 and Y. Kumagai1. 1Graduate School of Comprehensive Human Sciences, University of Tsukuba, Ibaraki, Japan and 2Research Fellow of the Japan Society for the Promotion of Science, Tokyo, Japan.

Butylated hydroxyanisole is a phenolic antioxidant and classified class-2B carcinogen. It is readily undergoes O-dealkylation to produce 2-tert-butyl-1,4-dihydroquinone (TBHQ), which readily auto-oxidizes to the electrophilic toxic metabolite 2-tert-butyl-1,4-benzoquinone (TBQ). TBQ causes activation of transcription factor Nrf2 coupled to S-arylation of its negative regulator Keap1. The TDAR response is used to evaluate drug effects on the immune system, assessing antigen presentation and T and B lymphocyte function. Cynomolgus monkeys injected subcutaneously on 5 occasions over 15 days with 1 mg Keyhole Limpet Hemocyanin (KLH) in Incomplete Freund’s Adjuvant (IFA) developed a robust IgM antibody response to KLH. Treatment of animals twice weekly with 8 mg/mL/kg Abatacept (CTLA4-Ig) by intravenous slow bolus injection did not diminish the antibody response. In a separate study, animals were injected with 100 μg KLH in the absence of adjuvant via intradermal injections. These animals developed a detectable IgM response with inverse titers of 25,000 ten days following primary immunization. IgG responses were detectable 14 days post primary injection with inverse titers of 12,000, and 7 days post secondary challenge with inverse titers of over 50,000. Treatment of a cohort of these animals with Abatacept led to an ablation of antibody responses. Antibody responses to KLH from animals were reduced but not ablated when treated with 1 mg/kg methotrexate via subcutaneous injection. Maximal mean IgM responses to KLH 10 days following primary immunization were reduced from 120,000 to 34,000. Maximal mean IgG responses to KLH were reduced from 1 x 10^6 to 0.66 x 10^6 with maximal responses delayed from 7 to 10 days post secondary KLH challenge. Combined, these data demonstrate that excessive antigenic stimulation can overcome the immunosuppressive effects of Abatacept and define an alternate immunization strategy that is susceptible to immunosuppression. Utilizing an appropriate immunization strategy in TDAR assays and including biological immunosuppressor controls, this model is optimized for safety assessment of immunomodulatory biological drug products.

1715 An Imaging-Based RNAi Screen Identifies Novel Regulators of Nrf2 Activation

S. Hiemstra, R. Herpers, M. Niemeijer, S. Wink and B. van de Water. 1715 An Imaging-Based RNAi Screen Identifies Novel Regulators of Nrf2 Activation

S. Hiemstra, R. Herpers, M. Niemeijer, S. Wink and B. van de Water. 1Toxicology, LACDR, Leiden, Netherlands.

Reactive oxygen species (ROS) are major inducers of cellular stress and cell death. The anti-oxidant response pathway is therefore a key mechanism in protecting against ROS-mediated toxicity. The transcription factor Nrf2 is a critical regulator of the antioxidant response pathway and fundamental in cytoprotection. The activity of Nrf2 is controlled through KEAP1-mediated ubiquitination and
subsequent proteasomal degradation. Moreover, various kinases can phosphorylate Nrf2 thereby affecting its stability. Accumulated Nrf2 translocates to the nucleus targeting the expression of multitude of anti-oxidant target genes, such as Srxn1.

The entire signaling network that controls Nrf2 stability and functionality is so far unclear. To monitor the KEAP1/Nrf2/Srxn1 signaling pathway we apply live cell imaging and tagging these target genes with GFP using BAC recombining. Using high throughput confocal imaging we can quantify the dynamics of Nrf2 activation and established the concentration time course dynamics of Nrf2 activation by, amongst others, iodocacetamide and CDDO-me. In order to provide full understanding of the upstream regulators of the Nrf2 pathway, we applied a siRNA knock-down based screen using the GFP-Srxn1 reporter as a downstream target of Nrf2. We screened all individual kinases, phosphatases, ubiquitinases and transcription factors for their involvement in Nrf2 activation. After knock-down, CDDO-me was used to activate Nrf2 followed by quantification of Srxn1-GFP expression. We observed ~50 target genes that enhance Srxn1-GFP expression and ~35 targets genes that inhibit Srxn1-GFP expression, including both known and novel modulators. Pathway analysis was performed to identify the signaling networks that control Nrf2 activity. Individual hits were validated using alternative strategies to activate Nrf2 and there involvement in cytotoxicity was evaluated. This work contributes to more elaborate understanding of the signaling networks that control Nrf2 signaling in the context of xenobiotic-induced cytotoxicities.

1716 Ambient Vapor Samples Activate the Nrf2-ARE Pathway but Not an Inflammatory Response in Human Bronchial Epithelial BEAS-2B Cells

Y. Shinkai1,2, S. Nakajima1, A. Ejiguern-Fernandez, E. Stefano3, D.A. Schuetz1, J.R. Proten1, A.K. Cha1,2, and Y. Kumagai1,3. 1Faculty of Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan, 2Graduate School of Life and Environmental Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan, and 3Southern California Particle Center, University of California Los Angeles, Los Angeles, CA.

Ambient air pollutants have been reported to induce oxidative stress based inflammatory responses in humans and experimental animals. However, most of these reports describe the actions of the particulate phase of ambient and exhaust samples. We describe here results of studies investigating the actions of the vapor phase of ambient air samples collected in the midtown area of Los Angeles on human bronchial epithelial BEAS-2B cells using DNA microarray analysis. Among 26 genes whose expression increased fourfold or more, four genes were associated with detoxifying genes regulated by the transcription factor Nrf2. Consistent with these results, the vapor samples activate the Nrf2-ARE pathway, resulting in up-regulation of heme oxygenase-1 (HO-1), glutamate cysteine ligase modifier subunit, and cystine transporter (xCT) mRNAs and proteins. No appreciable increases in pro-inflammatory genes were observed. These results suggest that ambient vapor samples activate the Nrf2-ARE pathway but not an inflammatory response. Also, treatment of the vapor samples with glutathione resulted in reduction of the Nrf2 activation and HO-1 induction, suggesting that electrophiles in vapor samples contribute to Nrf2-dependent antioxidant or adaptive response. [Reference] Shinkai Y et al., Environ Toxicol, 2013, in press.

1717 Proteomics Analysis to Identify Sensor Proteins with Covalent Modification Associated with 1,4-Naphthoquinone-Induced Activation of Electrophilic Signal Transduction Pathways

R. Hirose1, T. Miura2, R. Sha2, Y. Shinkai1,2, T. Tanaka-Kagawa2, and Y. Kumagai1,2. 1Environmental Biology Lab, Faculty of Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan, 2Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan, 3Graduate School of Life Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan, 3Graduate School of Life Sciences, University of Tsukuba, Ibaraki, Japan, and 4Division of Environmental Chemistry, National Institute of Health Sciences, Tokyo, Tokyo, Japan.

While metabolic activation of naphthalene, yielding 1,2-naphthoquinone (1,2-NQ) and 1,4-NQ that can covalently bind to cellular proteins, has been recognized to be associated with its toxicity, the current consensus is that such electrophile-mediated covalent modification of sensor proteins with thiolate ions is also involved in activation of cellular signal transduction pathways for cellular protection against reactive materials. In the present study, we developed an immunchemical assay to detect cellular proteins adducted by 1,4-NQ. Dot blot analysis indicated that the antibody prepared against 1,4-NQ recognized the naphthalene moiety with the para-target genes that inhibit Srxn1-GFP expression after CDDO-me treatment, including both known and novel modulators. Pathway analysis was performed to identify the signaling networks that control Nrf2 activity. Individual hits were validated using alternative strategies to activate Nrf2 and there involvement in cytotoxicity was evaluated. This work contributes to more elaborate understanding of the signaling networks that control Nrf2 signaling in the context of xenobiotic-induced cytotoxicities.

1718 Role of Stress Response Proteins and Redox-Sensitive Transcription Factors in Chemically-Induced Liver Injury: Chemoprevention with Kolaviron and Curcumin

E. O. Fakorede1, S. Shorotiyi1,2 and Y. Suh1,2. 1Biochemistry, University of Ibadan, Ibadan, Oyo State, Nigeria and 2Research Institute of Pharmaceutical Sciences, Seoul National University, Korea, Republic of Korea.

Kolaviron, a bioflavonoid from the seeds of Garcinia kola and curcumin, present in the rhizome of Curcuma longa have been reported to possess anti-inflammatory, antioxidant, anticarcinogenic and chemopreventive activities via multiple mechanisms. Biomarkers of hepatic oxidative injury, histological and immunohistochmical techniques were used to validate the biochemical mechanisms underlying the hepatoprotection of kolaviron and curcumin. In addition, the protein expression levels of cyclooxygenase (COX-2) and inducible nitric oxide synthase (iNOS) and heme oxygenase activity (HO-1) and expression were evaluated by western blotting while DNA-binding activities of nuclear factor kappa B (NF-kB), NF-E2-related factor 2 (Nrf2) and activator protein-1 (AP-1) were determined by Electrophoretic mobility shift assay. Kolaviron reduced the Dithemyl nitrosamine (DMN)-induced markers of oxidative stress. Kolaviron inhibited the DMN-induced expression of COX-2 and iNOS. Immunohistochemical staining of rat liver verified the inhibitory effect of kolaviron on DMN-induced hepatic COX-2 expression. Furthermore, kolaviron abrogated DMN-induced binding activity of NF-kB as well as AP-1. Our data showed that curcumin increases HO-1 activity and HO-1 protein via activation of Nrf2 in rat liver. Also, Curcumin administration resulted in enhanced nuclear translocation and ARE-binding of Nrf2. Tetrathrydrocumric lacking α-β unsaturated bond elicits lower anti-inflammatory activity. Collectively, kolaviron inhibits COX-2 and iNOS expression through down regulation of NF-kB and AP-1 DNA binding activities while curcumin protects against DMN-induced hepatotoxicity through ARE-driven induction of HO-1 expression. Thus kolaviron and curcumin qualify as candidates for chemoprevention of hepatocarcinogenesis especially in regions where humans are exposed environmentally and through diet to liver toxic agents.

1719 Ozone Induces Lung Epithelial Cell Inflammation through MAP Kinase Activation without NF-κB Activation

S. D. McCullough1, K. E. Duncan2, S. M. Swanton1, L. A. Dailey1, D. Diaz-Sanchez3 and R. Devlin1. 1Clinical Research Branch, US Environmental Protection Agency, Chapel Hill, NC and 2Center for Environmental Medicine, Asthma, and Lung Biology, University of North Carolina - Chapel Hill, Chapel Hill, NC.

Ground-level ozone (O3), a ubiquitous air pollutant, is a strong oxidizing agent and potent inducer of airway inflammation via the induction of pro-inflammatory mediators such as IL-8, IL-6, and IL-1 alpha/beta. Previous attempts to characterize O3-mediated activation of these pro-inflammatory mediators have associated their up-regulation with activation of the canonical NF-κB pathway. However, these studies were conducted in transformed cell lines and thus may not accurately reflect what occurs in normal cells. With the increased availability of primary cells in recent years, we sought to test whether the previously established model of O3-dependent pro-inflammatory mediator expression applied to primary human bronchial epithelial cells (phBEC). Thus we characterized the O3-mediated activation of cellular signaling pathways in phBEC grown in air-liquid interface culture obtained from seven donors and in the bronchial epithelial cell line BEAS-2B. Despite observing activation of NF-κB signaling in the BEAS-2B cell line following O3 exposure, we were unable to detect its activation in phBEC following O3 exposure. Instead, we observed activation of the EGFR/MEK/ERK and MKK4/p38 pathways. Additionally, the inhibition of EGFR and p38 kinase activity during O3 exposure was sufficient to prevent the O3-mediated induction of pro-inflammatory mediators in phBEC. These novel findings indicate that the mechanism underlying the O3-induced expression of pro-inflammatory mediators in phBEC involves the activation of MAP kinases, not canonical NF-κB signaling. This discovery is an important step toward elucidating the molecular mechanisms associated with the adverse health effects of O3 exposure, predicting susceptible populations, and identifying strategies for therapeutic intervention.
Oxidative stress (OS) in adipose tissue (AT) causes metabolic dysfunction of fatty acid transport and dysregulation of AT expandability, which alters AT role in nutritional adaptation and glucose tolerance. Central obesity and insulin-resistance (IR) are important causative factors of metabolic syndrome directly related to AT and metabolic stress. Most notably, OS originating from obesity is considered to be a precipitating factor for obesity-induced IR in AT. In addition to nutritional excess, many chemicals of environmental concern can be deposited in AT and elicit adverse effects via inducing OS; the effects of these toxins on AT dysfunction via OS is largely unknown. The objective of the study was to understand mechanisms by which caloric restriction (CR) abolishes the antioxidant response in AT to combat OS, and the physiological outcomes of this activation. ARE, H2O2, CAT, and MnSOD were measured by ELISA kit. The data suggest that CR can reduce oxidative stress and increase the antioxidant capacity in AT. Overall, the antioxidant response is induced in WAT via Nrf2 at the transcriptional level, and Nrf2 induction results in regulation of glutathione metabolism, suggesting Nrf2 as a therapeutic drug target against OS-induced AT dysfunction.

**Benzo[a]pyrene and β-Naphthoflavone Promote Nrf2 Nuclear Translocation in HepG2 Cells**

E. C. Herrera-Cogot1, L. Ramírez-Martínez2, B. Munoz1, A. Sánchez-Flores3, F. Castrorena1, E. López-Bayghen2 and A. Albores1.

HepG2 cells, like all cancer cells, generate energy from glucose by glycolysis, with little contribution from oxidative phosphorylation (OXPHOS). However, when glucose is replaced by galactose in the growth media, these cells use OXPHOS to generate energy by utilizing glutamine and asparagine in a process called anapleurosis. Comparison of cell viability in the different media is now used routinely to screen drugs for mitochondrial toxicity. Here using a novel In-Cell Proteomics method, we have expanded the evaluation of the effect of the classical inhibitors of OXPHOS: FCCP (uncoupler), oligomycin (ATP synthase inhibitor), myxothiazol (complex III inhibitor), and rotenone (Complex I inhibitor) on mitochondrial function and cell metabolism. Cells were incubated with compounds at 100μM in either glucose or galactose for 6, 24 or 72h prior to fixation. Protein levels were quantified using specific antibodies. All 4 compounds induced cell death by 6h in galactose based on cell appearance and reduction in MCl1 and PUMA levels. In either glucose or galactose for 6, 24 or 72h prior to fixation. Protein levels were quantified using specific antibodies. All 4 compounds induced cell death by 6h in galactose based on cell appearance and reduction in MCl1 and PUMA levels.

**Heat Shock Protein A6 Expression Is Increased by AP1 and NF-kB**

H. Garside1, R. A. Capaldi2, X. Luo3, A. Capaldi3 and J. Eakins1.

HepG2 cells, like all cancer cells, generate energy from glucose by glycolysis, with little contribution from oxidative phosphorylation (OXPHOS). However, when glucose is replaced by galactose in the growth media, these cells use OXPHOS to generate energy by utilizing glutamine and asparagine in a process called anapleurosis. Comparison of cell viability in the different media is now used routinely to screen drugs for mitochondrial toxicity. Here using a novel In-Cell Proteomics method, we have expanded the evaluation of the effect of the classical inhibitors of OXPHOS: FCCP (uncoupler), oligomycin (ATP synthase inhibitor), myxothiazol (complex III inhibitor), and rotenone (Complex I inhibitor) on mitochondrial function and cell metabolism. Cells were incubated with compounds at 100μM in either glucose or galactose for 6, 24 or 72h prior to fixation. Protein levels were quantified using specific antibodies. All 4 compounds induced cell death by 6h in galactose based on cell appearance and reduction in MCl1 and PUMA levels. In parallel, there was dephosphorylation of both 4E-BP1 and the S6 ribosomal protein, indicating mTor involvement, and a strongly increased phosphorylation of eIF2α, consistent with a component of oxidative stress. In glucose there was no cell death at 6h with FCCP or oligomycin, but some apoptosis with rotenone and myxothiazol. Unlike galactose all 4 compounds induced a large increase in phos- phorylation of both p38MAPK and c-Jun kinases in glucose along with increases in both fatty acid oxidation and synthesis along with ER stress based on the increased levels of ACADM, HADHB, ACC2 and CHOP1 respectively. Our results indicate considerable effect of OXPHOS inhibitors outside mitochondria, some but not all of which can be accounted for by loss of ATP production, indicating that other fac- tors such as ROS and altered metabolic intermediates exiting this organelle provide retrograde signalling of mitochondrial stress to the rest of the cell.

**The NF-κb Family Member RelB Controls microRNA miR-146a to Suppress Cigarette Smoke-Induced COX-2 Protein Expression in Lung Fibroblasts**

Rationale: Cigarette smoke (CS) is the leading cause of preventable death worldwide. Diseases due to cigarette smoke exposure, including chronic obstructive pulmonary disease (COPD), are associated with chronic inflammation typified by the heightened expression of cyclooxygenase-2 (COX-2). RelB is an NF-κb family member that suppresses the CS-induced COX-2 protein by an unknown mechanism. The ability of RelB to regulate COX-2 protein expression in response to cigarette smoke may be due to miR-146a, a miRNA which attenuates COX-2 expression in response to inflammatory stimuli. In this study we tested the hypothesis that RelB attenuation of cigarette smoke-induced COX-2 expression is due to regulation of miR-146a.

Methods: Relbs/+ and Relb−/− mouse lung fibroblasts were exposed to 2%-5% cigarette smoke extract (CSE) for 3, 6 or 8 hours. COX-2 protein and mRNA as well as miR-146a were analyzed by WB and/or qRT-PCR. Relb−/+ cells were transfected with Relb siRNA or a miR-146a inhibitor and then exposed to 2%-5% CSE for 8h. COX-2 protein and mRNAs were then assessed by WB and qRT-PCR. Results: CSE induced a significant increase in COX-2 protein expression in Relb−/− fibroblasts compared to Relbs/+ cells. Relb siRNA in Relbs/+ cells also increased COX-2 protein. Despite increased COX-2 protein in Relb−/− fibroblasts, there was a lack of Cox-2 mRNA, suggesting transcriptional induction of Cox-2 mRNA cannot account for the heightened protein expression. There was no difference in Cox-2 mRNA stability between Relbs/+ and Relb−/− cells. Relb regulated miR-146a in response to CSE and the inhibition of miR-146a potentiated CSE-induced COX-2 protein expression.

Conclusions: RelB prevents exaggerated COX-2 expression in response to CS by controlling miR-146a expression, an event which might be crucial in dampening smoke-induced damage. Thus, the Relb/miR-146a pathway may represent a new research direction with therapeutic potential for cigarette smoke-induced lung disease such as COPD.
strates distinguishes it from chaperone family members like HSPA1A (also known as HSP70). Compared to other HSPs, less is known about the transcriptional control of A6, a potentially important characteristic as A6 expression varies greatly amongst different cell types.

Using cultured HaCaT keratinocytes (KC), we observed constitutive and heat induced expression of A6. To identify transcription factors (TF) controlling its basal expression, the A6 3kb promoter was isolated and cloned into a luciferase reporter construct (LUC). Our results from transfected 5′ promoter truncation constructs localized a positive regulatory region between -647 to -700bp. Internal promoter deletions within the -647bp LUC suggested a central fragment is crucial for the activation of the A6 promoter. Binding site specific mutants within this fragment determined AP1 plays a key role in A6 expression.

Our lab also observed reduced basal expression and halted stress inducibility of A6 due to overexpressed TNIP1, a protein involved in repressing the activation or activity of several TLR. Using a similar approach, we searched for TNIP1-regulated binding sites involved in A6 repression. Interestingly, the TNIP1-sensitive region (−647 to −700bp) lacks identified TNIP1 target TF binding sites. These results suggest that TNIP1 represses A6 through a novel TF target. Moreover, this work demonstrated A6 expression levels can be modulated to increase or decrease via activation of AP1 or TNIP1, respectively. Since HSPs protect cells from heat and chemicals and the skin is a barrier to such stressors, it is important to understand the mechanisms involved in HSP regulation in KCs.

**Role of Cytokines in Regulation of Angiotensinogen in Human Hepatocytes**

M. R. Karim, R. A. Ansari, M. A. Clark and S. A. Rizvi. *Pharmaceutical Sciences, Nova Southeastern University, Fort Lauderdale, FL.*

Increase in blood pressure and fibrotic transformation of liver is connected to the abuse of alcohol. Alcohol metabolism by the liver produces hepatic injury resulting in immune responses where the levels of cytokines, especially interleukin-1β (IL-1β), IL-6 and other cytokines are increased. IL-1β activates nuclear factor-kappaB (NF-κB) while IL-6 activates signal transducer and activator of transcription 3 (STAT3) transcription factor. IL-6 is a cell-based model, the effects of IL-1β (10ng/ml) and IL-6 (10 ng/ml) on angiotensinogen (AGT) secretion were studied by treating hepatocytes (HepG2 and Huh7) for 4hrs and 12 hrs. In addition, NF-κBmediated effects on secretion of AGT was studied by treating HepG2 and Huh7 with 50 nM phorbol 12-myristate 13-acetate (PMA) for 4 hrs. and 12 hrs. It was observed that both PMA and IL-1β increased the secretion of AGT in HepG2 cells while such an effect was not pronounced in Huh7 cells. IL-6 treatment also increased the level of AGT secretion in HepG2 compared to Huh7 cells. It is concluded that human AGT which is a class II acute phase response protein can be modulated by NF-κB activation, and HepG2 hepatocytes are sensitive to NF-κB modulation whereas Huh7 hepatocytes are not.

**Modification of Pattern Recognition Receptor Expression As a Potential Mechanism of GI Toxicity**

G. Yanosko and B. Hiraoka. *Pfizer, Inc, San Diego, CA.*

Gastrointestinal toxicity is a common adverse effect of oncology drugs. Multiple mechanisms of toxicity are likely, particularly from kinase inhibitors, and include inhibition of proliferation, and changes in cell-cell adhesion, migration or differentiation. Epithelial cells of the gastrointestinal tract interact with the resident gut microbiota via pattern recognition receptors (PRR), an interaction which helps maintain barrier integrity of the epithelial lining. Using IEC-6 cells as a model for the crypt cell population of the small intestine and IPEC-J2 cells as a model for the intestinal enterocyte population, we examined the gene expression of two PRRs, toll-like receptors (TLR) 2 and 4, after 48 or 72 hour in vitro exposure to the inflammatory cytokines (TNFα and IFNγ) or 5 kinase inhibitors.

**Role of Hypoxiainmimetics in Regulation of Angiotensinogen in Human Hepatocytes**

R. A. Ansari, M. R. Karim, S. A. Rizvi and M. A. Clark. *Pharmaceutical Sciences, Nova Southeastern University, Fort Lauderdale, FL.*

Alcohol usage is linked to increased blood pressure and fibrotic transformation of the liver. Angiotensinogen (AGT), which produces angiotensin II (Ang II), an octapeptide, is involved in blood pressure regulation and fibrotic transformation of the liver after the death of hepatocytes. Ang II is produced from its precursor, AGT, by sequential activation of renin followed by angiotensin converting enzyme (ACE). The levels of AGT are less than the Michaelis-Menten constant (Km) of renin. Therefore, an increase in blood AGT levels would result in a corresponding increase in Ang II levels that might play crucial role in blood pressure regulation and fibrogenic activity. Alcohol metabolism by the liver produces oxidative stress that activates hypoxia inducible transcription factor-1alpha (HIF-1α). In addition, alcohol-mediated hepatic injury produces immune responses resulting into increased levels of interleukin-1β and other cytokines. IL-1β activates nuclear factor-kappa B (NF-κB) transcription factor. Since hepatocytes lose the ability to metabolize alcohol after several passages, in order to mimic the alcohol mediated HIF-1α activation, hypoxia mimetics were employed to investigate the effect of HIF-1α activation on AGT secretion.

**MicroRNAs (miRNAs) regulate nearly 60% of cellular protein expression and are subject of intense research in both the therapeutic and diagnostic areas.** Circulating miRNAs associated with proteins, exosomes and vesicles are proving to be highly sensitive and transplantable biomarkers of drug-induced injury. With the advancing discovery of novel biomarkers, there is a growing need for sensitive and specific extraction and quantification methods. RT-qPCR has gained acceptance as a robust and reliable transcriptomic method to profile subtle changes in miRNA levels. For interpretation of results and to allow comparison between studies, the choice of a suitable reference miRNA to use as an internal control is a crucial factor.

To date, there has been no systematic evaluation of RT-qPCR reference genes for the study of miRNAs expression in whole blood from pre-clinical species. In this study, the expression of two housekeeping miRNAs in whole blood, miR16 and miR103, selected from the literature, has been validated using two RT-qPCR kits: miRCURY LNA (Exiqon) and miScript (QIagen). After comparison of the kits, the expression of these miRNAs was assessed in male and female animals from five pre-clinical species: rat, mouse, dog, mini-pig and primate. Differences were found between the two kits for the quantification of miRNA. The Qiagen kit was a robust method for analysis of miRNA with no inhibition from the matrix. The Exiqon kit was much more sensitive, with a quantification limit at 2 x 10-5 ng but under comparable conditions it was more prone to PCR inhibition compared to the Qiagen kit. miR16 and miR103 were quantified with highly similar Ct values ranging from 14.9-18.3 for miR16 and 16.9-22.7 for miR103 with rodents consistently expressing slightly lower levels than the other species. To investigate the suitability of each gene as a housekeeping gene, circulating miRNAs were collected from routine toxicology studies. These data demonstrate the suitability of miR-16 and miR-103 over the more commonly referenced U6 small nuclear RNA using the Exiqon kit.
The prediction of xenobiotic exposure leading to long-term adverse reactions, such as off-target toxicity, cell death, and/or carcinogenesis, has been aggressively pursued in the toxicological and pharmaceutical communities. However, the development of computational models coupled with high-throughput screening assays capable of not only predicting a toxic outcome (e.g., cell death) but also the mode(s) of action contributing to this eventual fate have yet to fulfill these advantageous expectations. Previously, we have shown that 24 hour in vitro cell death can be forecasted at significantly early time-points by exploiting the rapid, endogenous pharmacodynamic response to xenobiotic exposure. This approach utilized protein phosphorylation responses of key proteins found in cellular death and survival pathways at time points relevant to critical signaling events to forecast the eventual cellular fate, irrespective of xenobiotic mode of action(s). However, the mode(s) of action contributing to the cell's predetermined fate remains elusive. To this end, we propose a graph theoretical approach to decode the early networked phosphoprotein response of select proteins following xenobiotic insult. In this proof-of-concept study, we monitored the phosphoprotein response of HepG2 cells exposed to TDZD-8 (GSK3 inhibitor) for a short amount of time (40 minutes) and a longer period of time (10 hours). Euclidean distances of these responses were used as weighted edges (protein-protein theoretical links) to compute the graph theoretical parameter, radiality, for each node (protein) measured. Radiality-based dose-response curves were then constructed to identify proteins related to alterations in network activity following TDZD-8 exposure. From this approach, the potential mode(s) of action at critical time points related to signaling events that are responsible for the cell's predetermined fate (i.e., cell death) may be elucidated, which will greatly impact xenobiotic high-throughput risk assessment in vitro as well as pharmaceutical adverse drug reaction analyses.

**PS 1730** Regulation of Airway Mucin Gene Expression by Aspergillus

Environmental mold exposure causes or exacerbates respiratory disease and it is one of the most deleterious environmental hazards that could impact on our health. Aspergillus (ASP) is one of the most prevalent types of molds that are found indoors and outdoors. Bronchiectasis is the prominent symptom resulted from ASP exposure. Airway obstruction caused by mucus over-production and the damage to the tracheobronchial walls are the hallmark of the bronchiectasis. Since epithelial injury and abnormal repair has been linked to mucus overproduction, we test the hypothesis that ASP damages airway epithelial cells to induce growth factor secretion and the activation EGFR pathway, which in turn elevates mucin expression and mucus production. In our study, ASP activated both Reactive Oxygen Species (ROS) generation and Calcium flux through a protease-dependent but PAR-independent pathway. ROS was critical for the induction of cell death, which Calcium flux was indispensable for mucin increase via a novel PKC-ERK pathway. Interestingly, this pathway was mostly EGFR-independent. Thus, delineating this novel mechanism will lead to the development of effective diagnostic and therapeutic reagents for the pulmonary diseases resulted from environmental mold exposure.

**PS 1731** An Approach to Investigate Intracellular Protein Network Responses

A. A. Han1, H. N. Williams1, J. A. Vran1, N. Boggs1 and J. W. Boyd1.1Chemistry, West Virginia University, Morgantown, WV and 2Applied Physics Laboratory, Johns Hopkins University, Laurel, MD.

Modern toxicological evaluations have evolved to consider toxicity as a perturbation of biological pathways or networks. As such, toxicity testing approaches are shifting from common endpoint evaluations to pathway based approaches, where the degree of perturbation of select biological pathways is monitored. These new approaches are greatly increasing the data available to toxicologists, but methods of analyses to determine the inter-relationships between potentially affected pathways are needed to fully understand the consequences of exposure. An approach to construct dose-response curves that use graph theory to describe network perturbations amongst three disparate mitogen-activated protein kinase (MAPK) pathways is presented. Mitochondrial stress was induced in human hepatocytes (HepG2) by exposing cells to increasing doses of the complex I inhibitor, rotenone. The relative phosphorylation responses of proteins involved in the regulation of the stress response were measured. Graph theory was applied to the phosphorylation data to obtain parameters describing the network perturbations at each individual dose tested. The graph theory results depicted the dynamic nature of the relationship between p38, JNK, and ERK1/2 under conditions of mitochondrial stress, and revealed shifts in the balance of these MAPK pathways at low doses. The inter-relationship, or crosstalk, amongst these 3 traditionally linear MAPK cascades was further probed by co-exposing cells to rotenone plus SB202470 (JNK and p38 inhibitor) or rotenone plus SB202474 (JNK inhibitor)). The cells exposed to rotenone plus SB202474 resulted in significantly decreased viability, which could be visualized and attributed to the decrease of ERK1/2 network centrality. The approach presented here allows for the construction and visualization of dose-response curves that describe network perturbations induced by chemical stress, which provides an informative and sensitive means of assessing toxicological effects on biological systems.

**PS 1732** The microRNA Pathway in Blast-Induced Neurotrauma

D. Dobbins, J. R. Polli, E. E. Connolly and X. Pan. Biology, East Carolina University, Greenville, NC.

A complex genetic response following traumatic brain injury (TBI) is associated with lingering neurologic and cognitive problems during neuroregeneration and mild TBI recovery. miRNAs, a class of endogenous non-coding small RNAs, have been identified as a major gene regulator in most biological and metabolic processes. Abrupt expression of miRNAs is found in neurodegenerative diseases and other CNS disorders. Therefore, a dynamic miRNA network regulating TBI-induced gene expressions may represent the molecular signature of TBI pathophysiology. A mild brain injury rodent model was generated using an advanced blast simulator. As an acute response to 70 kPa over ambient pressure, the mRNA expressions of vitamin D receptor, progesterone receptor, and all selected inflammatory parameters were misregulated in blood and brain tissues. Our preliminary work has also histologically verified the mild brain injury and evaluated the memory and cognitive deficits using the Morris Water Maze. Compared to shams, intraventricular hemorrhages are common observations and blast-injured animals showed cognitive deficits and signs of depression behaviors. Twenty four miRNAs display aberrant expression in blood of blast-injured animals collected seven days post-blast. miRNA markers target various neurological, inflammatory, and endocrinological pathways.

**PS 1733** The Effect of Thiazolidinediones on Cell Metabolism

J. Eakins1, R. A. Capaldi1, X. Luo2, A. P. Capaldi3 and H. Garside1. 1Drug Safety and Metabolism, AstraZeneca, Macclesfield, United Kingdom, 2MetrProf Inc., Tucson, AZ and 3University of Arizona, Tucson, AZ. Sponsor: P. Duffy.

Several first generation thiazolidinediones used to treat diabetes have been either withdrawn (troglitazone) or have black box warnings (rosiglitazone and pioglitazone) due to toxicity. We have studied 4 thiazolidinediones: troglitazone, rosiglitazone, pioglitazone and WY14621 using a novel In-Cell Proteomics method that monitors the change in levels of, and altered post-translational modifications in, key proteins of metabolism. This method simultaneously shows the therapeutic effects of the drugs as well as adverse events likely due to toxicity. Treating HepG2 cells with 100uM of each for 6, 24 or 72h, all compounds have effects consistent with activation of PPARγ; they up-regulate both mitochondrial and peroxisomal lipid metabolizing enzymes. All but WY14621 also up-regulate levels of the enzymes of oxidative phosphorylation, Krebs cycle and pyruvate dehydrogenase consistent with PPARγ activators. Increased phosphorylation of S6 ribosomal protein (5-7 fold) over DMSO treated cells was observed, as would be expected given the enhanced protein synthesis. There were also increased levels of IFNγ, HSP90, SOD2 and catalase, but not SOD1, indicative of activation of the unfolded protein response and oxidative stress. Interestingly, troglitazone differs from the other compounds. In HepG2 cells this compound caused apoptosis with a strong reduction in the level of both MCL1 and PUMA, increases CHOP1 levels, indicative of strong oxidative stress, dephosphorylation of 4E-BP1, and up-regulation of beclin 1 at 6 but not 72h suggesting an attempted autophagy. Interestingly, when examined in cardiomyocytes, troglitazone shows all of the proposed therapeutic effects but does not induce apoptosis, and there is no increase in levels of Chop1, phospho-4E-BP1 or beclin 1, suggesting reduced cell stress compared to HepG2 cells. These results show the utility of a broad screen of metabolism by protein changes in identifying the different effects of compounds in a particular class and deciding between therapeutic versus toxic reactions.
Inhibition of toxicants such as tobacco smoke, air pollution and those from industrial processes (e.g. arsenic) can lead to respiratory dysfunction including Chronic Obstructed Pulmonary Disease (COPD). The respiratory epithelium provides the first line of defense against inhaled insults. The cells that comprise the airway epithelium coordinate innate immune defenses and initiate adaptive immune responses. Although it is well known that toxicant-induced COPD can result in part from dysfunctional airway epithelial cellular physiology, the mechanisms by which this occurs remain elusive. Traditional cellular toxicity assays represent an end point in toxicity analysis, however, diseases commonly progress with compromised cellular physiology in lieu of cell death. To better assess cell-compromising toxins, we have used the xCELLigence Real-Time Cell Analyzer (RTCA). RTCA is a high-throughput screening format (6x96-well plate) that uses impedance measurements to detect physiological changes in adherent cells. We monitored human bronchial epithelial cells for changes in response to paracrine signaling molecules critical to airway epithelial innate immunity (e.g., ATP). Responses in untreated cells were compared to responses in cells treated for 4 - 24 hrs with arsenic, nanoparticles, or tobacco product constituents. We found that these respiratory toxicants induced dose-dependent alterations of physiological responses. Importantly, this cell signaling toxicity was measured at doses much lower than required to observe cytotoxicity. Findings from the RTCA experiments were confirmed with more traditional cell signaling assays (e.g., digital imaging microscopy of Ca²⁺ signaling). In conclusion, the RTCA device offers a high-throughput approach to screening cells for toxic/toxicant-induced dysfunction independent of cell death and potentially important in toxic/toxicant-induced disease.

Forecasting Cell Death Dose-Response from Early Signal Transduction Responses In Vivo
J. W. Boyd, J. A. Vrana, H. N. Williams and A. A. Han. Chemistry, West Virginia University, Morgantown, WV.

The rapid pharmacodynamic response of cells to toxic xenobiotics is primarily coordinated by signal transduction networks, which follow a simple framework: the phosphorylation / dephosphorylation cycle mediated by kinases and phosphatases. However, the time course from initial pharmacodynamic response(s) to cell death following exposure can have a vast range. Viewing this time lag (between early signaling events and the ultimate cellular response) as an opportunity, we hypothesize that monitoring the phosphorylation of proteins related to cell death and survival pathways at key, early time-points may be used to forecast a cell’s eventual fate, provided that we can measure and accurately interpret the protein responses. In this presentation, we focus on a three-phased approach to forecast cell death exposure: 1) determine time-points relevant to important signaling events by exploiting the relationship between mitochondrial-driven energy metabolism and kinase response to estimate theoretical ATP production, 2) experimentally determine phosphorylation values for proteins related to cell death and/or survival pathways at these significant time-points, and 3) estimate the 24 hour plasma membrane degradation dose-response of cells to xenobiotic exposure from protein cluster analyses. To test this approach, we exposed HepG2 cells to two disparate treatments: a GSK3β inhibitor and a MEK inhibitor. After using our three-phased approach, we were able to accurately forecast the 24 hour HepG2 plasma membrane degradation dose-response from protein phosphorylation values as early as 20 minutes post-MEK inhibitor exposure and 40 minutes post-GSK3β exposure.

TC-PTP Inhibits UVB-Induced Keratinocyte Survival and Proliferation by Regulating Stat3 Signaling
J. W. Shin1, 2, H. Lee1, 2, L. D. Morales2, 3, J. Kim1, 2
1Pharmacology, University of Texas Health Science Center at San Antonio, San Antonio, TX and 2Edmund Medical Research Division, University of Texas Health Science Center at San Antonio, Edinburg, TX.

Ultraviolet B radiation (UVB) contributes to the development of skin cancer by creating DNA damage that can yield gene mutations which disrupt intracellular signaling mechanisms. One vital signaling mechanism is tyrosine phosphorylation signaling. We have previously shown that T-cell protein tyrosine phosphatase (TC-PTP) contributes to the rapid dephosphorylation /deactivation of Stat3 in response to UVB irradiation in keratinocytes. In the current work, we investigated the functional role of TC-PTP in keratinocyte survival and proliferation following UVB exposure. Knockdown of TC-PTP in mouse keratinocytes using siRNA significantly reduced apoptosis following UVB irradiation in comparison with control keratinocytes as evidenced by the decreased levels of activated caspase-3 and PARP cleavage. This reduction corresponded with an increased level of phosphorylated Stat3 in TC-PTP-deficient keratinocytes. Knockdown of TC-PTP in keratinocytes also significantly increased cell proliferation following UVB irradiation compared with control keratinocytes. Similar with these results, overexpression of TC-PTP in keratinocytes significantly increased apoptosis and decreased cell proliferation in response to UVB irradiation compared with control keratinocytes, which corresponded with a decreased level of phosphorylated Stat3. Treatment of TC-PTP-deficient keratinocytes with specific Stat3 inhibitor, STA21 significantly reduced cell viability, upon UVB exposure in comparison with untreated TC-PTP-deficient keratinocytes, which suggests that the effect of TC-PTP on cell viability is mediated by Stat3 dephosphorylation. Combined, our results indicated that TC-PTP plays an important role in the regulation of keratinocyte proliferation and survival after UVB irradiation. These results suggest that TC-PTP may be a novel potential target for the prevention of UVB-induced skin cancer.
activate CYP2C9 transcription in response to electrophiles. These results indicate that oxidative stress generated by exposure to electrophilic xenobiotics and metabolites induces the expression of CYP2C9, thereby altering the metabolic clearance of therapeutic drugs and xenobiotics which are substrates of CYP2C9.

**1736c Dose-Specific Nicotine-Dependent Behaviors in Caenorhabditis elegans: Regulation of Nicotinic Acetylcholine Receptors**

J. R. Polli and X. Pan, Biology, East Carolina University, Cary, NC.

Nicotine, the major psychoactive compound in tobacco, targets the nicotinic acetylcholine receptors (nAChRs) and leads to drug dependence. The nematode Caenorhabditis elegans (C. elegans) genome encodes conserved and extensive nicotinic receptor subunits, representing an excellent system to investigate nicotine-induced cholinergic signaling in the context of drug addiction. However, the in vivo expression pattern of nAChR genes under chronic low-level nicotine exposure has not been systematically investigated in C. elegans. Here, we have reported the first in vivo expression of the 28 authentic nAChRs at the mRNA level following nicotine exposure in C. elegans. Chronic (24 hour) low-level (6.17-6.7 μM) nicotine exposure has been shown to change the expression of nicotinic receptors in a dose-specific manner. Worms exposed to 6.17 and 6.7 μM nicotine displayed nicotine-dependent behaviors. Quantitative real-time PCR results showed that five genes (lev-1, acr-6, acr-7, lev-8, and acr-14) were significantly up-regulated at 61.7 μM nicotine treatment, with worms showing significant withdrawal behaviors when the nicotine supply was discontinued. However, the 19.5 μM dose worms did not exhibit the withdrawal behavior, which was accompanied by a general increase in nAChRs expressions. We have also predicted conserved microRNAs that may target these receptor genes using online algorithm tools. Quantitative real-time PCR results showed that several predicted miRNAs were co-expressed with their target nAChR genes, including let-7, mir-355, mir-70, and mir-71. This study provides useful information regarding the comprehensive in vivo expression pattern of the 28 “core” nAChRs and its relationship with addiction behaviors.

**1736d Nrf2 Protects Mitochondrial Degeneration by Oxidative Stress**

J. G. Strom1, B. Xu1, J. A. Johnson2 and Q. M. Chen1. Pharmacology, University of Arizona, Tucson, AZ and 2School of Pharmacy, University of Wisconsin-Madison, Madison, WI.

Oxidative stress plays an important role in cellular injury. Cells surviving oxidative stress often become enlarged with increased protein content. In the myocardium, enlargement of cardiomyocytes consequential to tissue injury contributes to mal-adaptive remodeling and subsequent development of heart failure. Here we address the role of mitochondria in cells surviving oxidative stress and becoming enlarged using primary cultured rat cardiomyocytes as an experimental model. These cells survive low to mild doses of H2O2 but develop hypertrophy. In control cells, mitochondria exist in elaborate and elongated networks. Within 24 hours after exposure to a mild dose of H2O2, the mitochondrial network was replaced by predominately individual, punctate mitochondria. Electron microscopy revealed H2O2-induced swelling of mitochondria with disorganized cristae and areas of condensation. Measurements of functional mitochondria showed a H2O2 dose-dependent (50 to 400 μM) decrease over a course of 5 days. At the protein and mRNA levels, H2O2 treatment resulted in a reduction of mitochondrial components, cytochrome c and cytochrome b. Nrf2 overexpression prevented H2O2 from inducing mitochondrial morphological changes and the reduction of cytochrome c and cytochrome b. Although Nrf2 is known as a transcription factor regulating antioxidant and detoxification genes, Nrf2 overexpression did not reduce the level of protein oxidation as measured by carbonyl formation. We found that Nrf2 localizes to the outer mitochondrial membrane, suggesting a direct role in mitochondrial protection. Mitochondria prepared from the myocardium of Nrf2 knockout mice are more sensitive to permeability transition. Correlating with the protective effect of Nrf2 against mitochondrial decay, Nrf2 overexpression prevented H2O2 from inducing cardiomyocyte hypertrophy. These data suggest that mitochondrial decay due to oxidative stress contributes to cardiomyocyte hypertrophy and Nrf2 protects mitochondria from oxidant injury likely through direct interaction with mitochondria membrane.

**1736e RNA-Seq Analysis of the Functional Link between Vascular Disruption and Adverse Developmental Consequences**

J. Franzosa1, R. S. Settivari2, R. Ellis-Hutchings3, N. Kleinstreuer3, R. Husek3, E. W. Carney1 and T. B. Knudsen1. 1NCCT, U.S. EPA, RTP, NC, 2The Dow Chemical Company, Midland, MI and 3IHL, In SituCETAM, NIEHS, RTP, NC.

Vasculogenesis and angiogenesis are complex processes necessary for normal development. High throughput-screening (HTS) efforts by the US EPA ToxCast program identified a diverse set of environmental chemicals that potentially disrupt biological targets associated with blood vessel formation and/or remodeling. To investigate embryonic responses to vascular disruption, gestation day 10 rat embryos were exposed in vitro to anti-angiogenic reference compounds 5HPP-33 (5, 15, 30 μM) or TNP-470 (0.25, 2.5, 25 μM) and vehicle controls. The major effects elicited after 48 h were embryo lethality (5HPP-33 ≥ 15 μM) and dysmorphogenesis (TNP-470 ≥ 0.25 μM). RNA-Seq was conducted on RNA from embryos and yolk sacs (n= 8 embryos or 4 pools of 2 yolk sacs per concentration) at 4 h post-exposure, a time point selected to identify early transcriptional responses. Patterns of differentially expressed genes (DEGs) were tissue and concentration-dependent (apical vs transcriptional responses). Unsupervised hierarchical clustering of embryonic DEGs showed that transcriptional responses at the highest concentration of 5HPP-33 were similar to TNP-470 at any concentration. Pathway analysis revealed that the most significantly enriched pathway for exposures eliciting overt phenotypes, 5HPP-33 (30 μM) and TNP-470 (0.25, 2.5 and 25 μM) was the cellular p53 response pathway. Concentration-dependent effects were observed in embryonic DEGs directly related to known vasculogenesis targets (i.e. VCAM1, TNF, CASP8, HIF1A, AHR). These data demonstrate the importance of p53 signaling in developmental angiogenesis and support the hypothesis that conserved vascular disruption pathways can lead to developmental toxicity outcomes of with diverse phenotypes. The identification of altered vascular regulatory networks perturbed by developmental toxicants supports an adverse outcome pathway associated with disruption of the embryonic vasculature. This abstract does not necessarily reflect US EPA policy.

**1737 Developmental Neurotoxicity Assessment in a 3D Organotypic Neuronal Model Using a Metabolomics Approach**

H. T. Hogberg, R. Bachinski, M. Boushild, G. Harris, A. Kleensang, S. Odwin-DeCosta, L. Farnies, L. Smirnova, L. Zhao and T. Harrung, CAAT, Johns Hopkins University, Bloomberg School of Public Health, Baltimore, MD.

The National Research Council report from 2007 “Toxicity Testing in the 21st Century: A vision and a strategy” (Tox-21c) has created an atmosphere of departure in the US. It suggests moving away from traditional animal testing to modern technologies based on pathways of toxicity. An area of toxicology where Tox-21c could have a significant impact is developmental neurotoxicity (DNT). There is concern that exposures to environmental chemicals contribute to the increasing incidence of neurodevelopmental disorders in children. However, due to lack of DNT studies only very few substances have been identified as developmental neurotoxics. Moving towards a mechanistic science can help us identify the perturbed pathways that likely lead to these adverse effects. A 3D rat primary organotypic neuronal model was exposed from day 7 up to 21 to suspected (developmental) neurotoxicants including pesticides, drugs and metals. Mass spectrometry based metabolomics measurements were performed and quantitative measurements of genes expressed in different cell types (neural precursor cells, neurons and glial cells). Mass spectrometry analysis showed differences in metabolic levels between control and treated cells in a concentration dependent manner. Signatures of changed features have been putatively identified and associated to perturbed pathways supported by gene expression data. For example metabolites involved in the biochemical pathway of the neuronal specific metabolite N-acetyl aspartate (NAA) (malate, aspartate, NAA and glutamate) were significantly decreased after exposure to lead chloride and maneb. In patients, the level of NAA has shown to be decreased in numerous neuropathological conditions such as brain injury, stroke and Alzheimers. It also indicates neuronal/zonal loss or compromised neuronal metabolism. Obtained data suggests that metabolomics could be a promising tool for developmental neurotoxicity assessment. Funded by the FDA #U01FD004230.
This work aims to develop a human 3D brain model to identify changes in transcriptome, including microRNA expression (miRNomics), and metabolome after exposure to neurotoxicants. The LUHMES cell line differentiates rapidly and homogeneously into dopaminergic neurons (DNs) in traditional monolayer cultures. Knowing the fact that 3D culture conditions better mimic the in vivo response, we developed a 3D human neuronal model using LUHMES cells and constant gyration shaking culture condition. The LUHMES cells have shown prolonged survival when cultured 3D compared to traditional monolayers. The differentiation in 3D aggregates was characterized by qRT-PCR, flow cytometry and immunocytochemistry. We observed increase of NeuN positive cells (mature neurons) and decrease Ki-67 positive cells (proliferating cells) in the course of differentiation by flow cytometry. During early stages of differentiation, 3D cultures did not contain any apoptotic cells. However, up to 30% of the cells within aggregates were apoptotic (Annexin V/caspase3 positive) at later time points (15-21 days) that could be reduced by decreasing the size of aggregates. We observed strong induction in gene expression of neuronal markers (β-III-Tubulin, DAT, synaptin 1, and TH) as well as neural-specific/enriched miRNAs (mir-124, mir-126, mir-132, mir-133b, mir-137). To demonstrate the model’s suitability for neurotoxicity testing, the aggregates were treated for 24 and 48 hours on day 6 and 12 of differentiation with dopaminergic neurotoxicants, MPP+ and rotenone. Perturbations in energy metabolism and stress response following mitochondrial complex 1 inhibition was characterized by LC-MS based metabolomics, transcriptomics, miRNA profiling and mitochondrial function assay. In conclusion, we have successfully developed a new 3D human model that can be used for (developmental) neurotoxicity testing.

**Development of Calcium Responses and Electrical Activity in Differentiating Mouse Neural Progenitor Cells In Vitro**

M. M. Dingemans, M. de Grooth and B. H. Westerink. Neurotoxicology Research Group; Institute for Risk Assessment Sciences; Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands.

In vitro methods for developmental neurotoxicity (DNT) testing have the potential to reduce animal use and increase insight into mechanisms of chemical-induced alterations in the development of functional neuronal networks. Mouse neural progenitor cells (mNPCs) have proven valuable to detect DNT using biochemical and morphological techniques. However, their neurophysiological characteristics are still largely unknown.

We have therefore investigated calcium responses and electrical activity in primary mNPCs (using the Ca2+-responsive dye Fura-2 and a multi-electrode array system, respectively) to explore their applicability for DNT testing with focus on neuronal function.

Immunocytochemistry reveals that mNPCs express neuronal, glial and progenitor markers at various differentiation durations. Stimulus-evoked changes in intracellular calcium concentration ([Ca2+]i) were investigated at 1, 7, and 14 days of differentiation. Increases in [Ca2+]i are evoked by depolarization, acetylcholine, and L-glutamic acid, dopamine, adenosine triphosphate and, to a lesser extent, by se-rotonin and gamma-aminobutyric acid. Notably, the percentage of responsive cells and response amplitudes indicate changes in the expression and functionality of related neurotransmitter receptors and calcium signaling pathways during in vitro differentiation. The development of functional intercellular signaling pathways is confirmed in mNPCs cultured on multi-electrode arrays, demonstrating that mNPCs develop spontaneous electrical activity within 1-2 weeks of differentiation. These data demonstrate that mNPCs develop functional neuronal characteristics in vitro, making it a promising model to study chemical-induced effects on the development of neuronal function.

The enzyme CYP1A2 can sequester toxics such as dioxins and coplanar PCBs. The aryl hydrocarbon receptor (AHR) bind coplanar PCBs, initiating transcription of several genes including CYP1A2, a key detoxifying enzyme. Though it is also reportedly expressed in the cortex and cerebellum of the brain, its physiologic function in the brain remains unknown. Previous work in our lab uncovered learning and memory deficits in Cyp1a2(-/-) knockout mice. Our current work compares Ahr/Cyp1a2(-/-), Ahr/Cyp1a2(-/-), and Ahr/Cyp1a2(-/-) mice exposed during gestation and lactation to PCBs or the corn oil vehicle. Pregnant dams were treated from gestational day 0 (GD0) to postnatal day 25 (PND 25). We compared the three genotypes of mice using a battery of six tests: rotarod, gait analysis, sticker removal, pole climbing, balance beam, and grip strength. There was a significant main effect of treatment on all 5 days of testing (P<0.05) and a significant genotype x treatment interaction on Day 4 of testing (P<0.05) with PCB-treated Ahr/Cyp1a2(-/-)/mice showing the greatest impairments. There was a significant main effect of genotype and treatment in gait analysis with PCB-treated animals and Ahr/Cyp1a2(-/-) mice having significantly longer stride lengths (P<0.05). There were no significant differences in the pole test. Both Cyp1a2(-/-) knockouts had significantly shorter latencies to traverse the beam (P<0.001). Further analysis will be required to determine if this indicates a difference in motor function or greater motivation to reach the safety of the darkened goal box.

1745 PFOSInducesBehavioralAlterationsCompatiblewithADHDin aZebrafishModelofDevelopmental Neurotoxicity

Background: Perfluorooctane sulfonate (PFOS) is a widely spread environmental contaminant. It accumulates in the brain and has potential neurotoxic effects. The exposure to PFOS has been associated with higher impulsivity and increased ADHD prevalence.

Objectives: We investigated the effects of developmental exposure to PFOS in zebrafish larvae, focusing on the modulation of activity by the dopaminergic system.

Methods: We exposed zebrafish embryos to 0.1 or 1 mg/L PFOS and assessed swimming activity at 6 dpf. We analyzed the structure of spontaneous activity and the acoustic startle response. In addition, we investigated the effects of D-amphetamine on the alterations in spontaneous activity and startle response in zebrafish larvae. Results: We found that zebrafish larvae exposed to 1 mg/L PFOS displayed a disorganized pattern of spontaneous activity consisting of less frequent, but more intense bouts of activity as compared with controls. In addition, the startle response is followed by persistent hyperactivity. D-amphetamine partly corrected the phenotype in zebrafish larvae exposed to 1 mg/L PFOS.

Conclusion: Developmental exposure to PFOS induces hyperactivity mediated by a dopaminergic deficit that can be corrected by D-amphetamine. Our data support the association of PFOS exposure with impulsivity and ADHD in children.

1746 Early Embryonic2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) ExposureDisruptsForebrainandCerebralVascularDevelopmentin Zebrafish

TCDD is a persistent environmental contaminant that exerts toxicity by activating the aryl hydrocarbon receptor (AHR) signaling. Using fluorescent-immunohistochemistry (F-IHC) and confocal microscopy, we examined TCDD-exposed and control zebrafish brains and found that TCDD exposure disrupts forebrain and cerebral vascular development. Within the forebrain, the olfactory bulbs (OB) and habenular nuclei were smaller and had reduced expression of activated leukocyte cell adhesion molecule, an axonal marker. F-IHC staining with a synaptic marker (synaptic vesicles) revealed disorganization within the OBs. We examined cerebral vasculature at 48, 72, 96, and 120 hours post fertilization (hpf) using a flk1:EGFP endothelial reporter line. To visualize vascular morphology, we collected a series of optical sections and generated brightest point projections using Olympus software. Cerebral vasculature malformations were identified in the fore-, mid- and hindbrains of TCDD-exposed embryos at all times examined. The presence of phenotypes at 48 hpf, prior to decreases in cardiac output, indicate that TCDD can impact vascular development independent of cardiac function. We also found that exposure to a sub-lethal level of TCDD (50 ppt) disrupts cerebral vasculature development. We blocked atrh translation using atrh1 and atrh1 morpholinos and observed fore- and midbrain vascular malformations. These phenotypes in zebrafish are consistent with AHR's role in mammalian vascular development. A common mechanism mediating TCDD-induced toxicity is downregulation of the transcription factor, sox9b. We are examining sox9b as a potential TCDD target in the developing nervous system and have found that loss of sox9b results in severe brain and vascular phenotypes. Thus, TCDD exposure disrupts brain and vascular development. Whether disrupted cerebrovascular development caused by fetal TCDD exposure in humans plays a role in neurodevelopmental disorders and cognitive impairment remains to be determined. (Supported by NIH ES012716).

New strategies are needed to address the data gap between the bioactivity of chemicals in commerce and the environmental versus existing hazard information. This data gap is especially wide when considering toxicological endpoints that are difficult to measure purely in vitro systems, such as abnormal behavior. We describe an embryonic zebrafish system where behavior can be both experimentally perturbed (6 doses of chemical and 1-second pulses of light) and measured (accompanying real-time, spontaneous movement) in a high-throughput fashion. This system is applied to characterize the behavioral response to 1060 ToxCast™ chemicals as hyperactive or suppressive to movement of 24 hours-post-fertilization (hpf) zebrafish embryos subjected to intermittent pulses of light. By dividing the experimental interval according to light pulses (Background = prior to first pulse; Excitatory = after first pulse; Refractory = after second pulse), we observe movement responses that can classify neuromodulator chemicals as eliciting light-independent movement alterations (102), light-dependent photomotor responses (231), or both (276). The chemicals can be further subdivided into a discrete number of prototype clusters based upon hypo- and/or hyperactivity patterns across light intervals. As an integrative measure of normal development, significant alterations in movement highlight neuroactive chemicals representing several modes of action. These early behavioral responses are predictive (relative risk r < 0.05) of 17 specific developmental abnormalities including notochord defects and mortality measured at 5 days-post-fertilization (dpf). Therefore, this system can provide for rapid characterization of chemical-elicited behavioral responses at an early developmental stage that are indicative of significant downstream hazard.

1747c Developmental Exposure to PCBs Differentially Alters Sensitivity to Audiogenic and Kindling-Induced Seizures in Rats
S. Bandara1, S. L. Schantz1 and M. E. Gilbert2.1University of Illinois at Urbana-Champaign, Urbana, IL and 2US EPA, Research Triangle Park, NC.
Previously we reported an increased incidence of audiogenic seizures in offspring of rats exposed to an environmental mixture of polychlorinated biphenyls (PCBs). This study compares the proconvulsant properties of PCB exposure in audiogenic and electrical kindling seizure models. Adult male and female offspring exposed to the PCB mixture throughout gestation and lactation were subjected to an audiogenic seizure paradigm (100dB, 8 kHz, 2m) and behavioral seizure response (wild running, clonus) recorded. Male littersmates were stimulated (1×1 train of 60Hz pulses, 1ms pulsewidth, 50-200mA) through indwelling electrodes in the amygdala to establish a threshold for induction of an electrographic afterdischarge (AD). Thereafter, stimulation was delivered once daily at 200μA until a fully generalized seizure (Racine Scale 1) was evoked. Electrographic and behavioral seizure characteristics were recorded in response to each stimulation. Consistent with previous findings more PCB-exposed rats than controls exhibited clonic seizures (76% vs 22%) in response to noise. In contrast to an augmented audiogenic seizure response, PCBs delayed the development of electrical kindling (16.4 vs 11.6 ADs to 1st Stage 5 seizure). This delay occurred in the early stages as significantly more sessions were required to advance rats from focal (Stage 1-2) to generalized (Stage 3-5) seizures. Groups did not differ in AD thresholds. A trend towards longer cumulative AD duration to 1st generalized seizure was also evident in the PCB-exposed group. A dissociation of responsiveness based on seizure model indicates that while developmental PCB exposure has proconvulsant effects at the level of the auditory brainstem, the same exposure slows the progression of behavioral manifestations from a focal seizure site in the forebrain. The latter may be reflective of impaired plasticity mechanisms previously reported in PCB-exposed animals. Does not reflect EPA policy; funded by ES15687.

1747b Impact of Perinatal TCDD Exposure on Neuroendocrine Stress Response System in Mice
S. L. Bennet1, T. Inoshita1, Y. Ding1, M. Kakeyama1,2 and C. Tohyama1,1Graduate School of Med., University of Tokyo, Bunkyo-Ku, Tokyo, Japan and 2Grad. Sch. Biomed. Sci, Nagasaki University, Nagasaki, Japan.
Adversities during the perinatal period can disrupt the development of the neuroendocrine stress response system, which may influence the vulnerability to psychiatric pathology later in life. The increasing trend of a prevalence of developmental and psychiatric disorders has been suspected of being induced at least partly by environmental chemical exposure during perinatal development. We have previously reported the lasting consequences of perinatal exposure to a low dose of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in cognitive, social, and emotional functions in mice. However, its effect on the development of the stress response system has not yet been defined. The current study thus aimed to examine whether an oral administration of 0, 0.6 or 3.0 μg TCDD/kg on GD 12.5 in C57BL/6 mice induces a permanent impact on the stress response system of the male offspring. A series of stress challenges was conducted when they were adults (8-10 weeks), in order to characterize the hypothalamic-pituitary-adrenal (HPA) axis function. The TCDD-exposed offspring exhibited hypoactivity of the HPA-axis as well as disruption in the central feedback regulation, and the endocrine phenotype was especially conspicuous in the higher dose, TCDD3.0 group. A significant reduction of corticotropin-releasing hormone (CRH) receptor gene expression was detected in the hippocampus of the TCDD3.0 adult mice, which was also confirmed in the TCDD3.0 neonatal hippocampus. Additionally, reductions in hippocampal ACTH receptor and glucocorticoid receptor mRNA ratio were observed at the neonatal stage. The present results suggest that developmental programming of the stress response system is susceptible to a perinatal TCDD exposure, and that a reduced gene expression level of central feedback regulating molecules may underlie their exacerbated stress response.
Embryos were observed at 24 and 120 hpf by stereomicroscope for mortality and gross malformations. At 24 hpf, no differences were observed between treatment groups. By 120 hpf, embryos treated with PCB 77 were not significantly different from vehicle controls or untreated embryos. In contrast, there were significant, concentration-related increases in gross malformations and mortality in embryos treated with either PCB 52 or PCB 95, with PCB 95 exhibiting significantly greater potency than PCB 52. These data correlate with the relative potencies of these PCB congeners on RyR activity, suggesting the feasibility of using embryonic zebrafish as a novel in vivo model to study the developmental effects of RyR-active PCBs. Supported by NIH (grant ES014901 and ES011269).

1747 e Sex-Dependent Effects of Lead and Prenatal Stress on Neonatal Stress Receptor and Adult Corticosterone Levels

S. Pelkowski1, M. Sobolewski1, H. Weston1, S. Kidd2, D. W. Anderson2, J. S. Schneider3 and D. A. Cory-Slechta1.

1Univ. of Rochester, Rochester, NY and 2Thomas Jefferson Univ., Philadelphia, PA.

Early life exposure to lead (Pb) and prenatal stress (PS) creates sex-specific alterations in CNS development, including the hypothalamic–pituitary–adrenal (HPA) axis, the major stress response system. The current study examined the potential sex-specific effects of Pb ± PS on alterations in glucocorticoid (GR:NR3C1) and mineralocorticoid (MR:NR3C2) receptors in neonatal brain and in adult corticosterone levels. C57Bl/6j mice received 0 or 100 ppm Pb water 2 mos prior to breeding through weaning. Half of these mice were exposed to restraint stress 3x/day for 30 min from GD 11–19, while the other half received no stress (NS). This yielded 4 treatment groups: sex: 0-NS, 0-PS, 100-NS and 100-PS. At PND 0 and PND 6, frontotemporal hippocampus and cerebellum were dissected, and the remaining brain used for receptor expression analysis. GR and MR levels were assessed in nuclear and cytosolic brain fractions. Both Pb and Ps significantly reduced nuclear GR levels relative to 0-NS controls in females, whereas only PS (0-PS and 100-PS) significantly reduced nuclear MR levels. Males showed the opposite pattern, wherein Pb (100-NS and 100-PS) showed significantly elevated nuclear GR levels. At PND 60, sex-specific differences were also observed in corticosterone levels. Pb-treated males exhibited blunted baseline corticosterone levels, and PS-treated males exposed to acute handling stress displayed significantly elevated corticosterone responses. In contrast, no Pb ± PS-related changes in corticosterone occurred in females. These results show that early life exposure to Pb ± PS creates sex-specific alterations in stress physiology as found for both neonatal and adult neuroendocrine profiles. Altered corticosterone homeostasis has been associated with impaired cognitive function and neurological damage. Understanding the sex-specific response of the HPA axis to early developmental lead and stress exposure may increase our understanding of gender-specific neurobehavioral diseases. ES021534-01

1748 Persistent Organic Pollutants and Different Types of Pesticides Can Interact during Brain Development to Exacerbate Behavioral and Cognitive Deficits in Mice

Environmental Toxicology, Uppsala University, Uppsala, Sweden.

In the field of toxicology the tradition has been to investigate one substance/comound at the time without any thought of possible interactive effects concerning multiple exposures. Humans are continuously exposed to persistent organic pollutants, such as methymercuric (MeHg) and the phenthraconted compound perfluorohexane sulfonate (PFHxS), and different pesticides, such as the organophosphate chlorpyrifos and the organochlorine endosulfan. There is some information present about the developmental neurotoxicity of these individual compounds and we have recently seen that they, individually can induce behavioural disturbances such as deranged spontaneous behaviour and habituation, learning and memory defects and reduced cognitive functions, together with altered function of the cholinergic system, when the exposure occurs during a critical phase of neonatal brain development (PND 10). Therefore, in the present study we investigated how a combined exposure to MeHg and chlorpyrifos as well as a combined exposure to PFHxS and endosulfan could affect behaviour and cognitive function. Adult mice, neonatally exposed to 0.4 mg MeHg/kg bw and chlorpyrifos (5 or 10 mg/kg bw), showed a disturbed spontaneous behavior to a novel home environment and reduced habituation compared to the control animals and the individual exposures. The same was seen in adult mice neonatally exposed to PFHxS (6.1 or 9.2 mg/kg bw) and endosulfan (0.05 or 0.1 mg/kg bw). Interestingly, these effects seem to be of a synergistic nature, because effects were even seen for combinations of doses where the individual doses did not induce disturbances in spontaneous behavior to a novel home environment. These results indicate that the present methods of risk assessment can underestimated the potential risk with chemicals, since combinations of chemicals potentially can shift the dose-response curve.

1749 Adult Dose-Response-Related Behavioral Effects of 4 Different Pesticides, after Neonatal Exposure

Environmental Toxicology, Uppsala University, Uppsala, Sweden.

There are several different types of pesticides globally used, all with their own characteristics and toxicological potency. In the present study we have exposed male mice neonatally to different doses of four different types of pesticides, car-baryl (carbamate) chlorpyrifos (organophosphate), cypermethrin (pyrethroid) and endosulfan (organochlorine), and tested them for spontaneous behavior in a novel home environment at adult age. The doses used were 0.5 – 20 mg carbvaryl/kg bw, 0.1 – 5.0 mg chlorpyrifos/kg bw, 0.1 – 5.0 mg cypermethrin/kg bw and 0.05 – 20 mg endosulfan/kg bw. All four pesticides induced adult disturbances in the spontaneous behavior in a novel home environment, affecting cognitive function, at 2 months of age. Carbaryl induced a dose-response related effect on spontaneous behavior from 5 mg/kg bw and up, while chlorpyrifos only induced a weak effect with the highest dose tested (5 mg/kg bw). The pyrethroid cypermethrin induced dose-response related neurotoxicity from 0.5 mg/kg bw and up. The organochlorine endosulfan also induced dose-response related neurotoxicity from 0.1 mg/kg bw and up. These disturbances also persisted when the animals were re-observed at 4 months of age, indicating that these effects are long-lasting or even irreversible. From this study we conclude that endosulfan seem to be the most potent, of these four compounds, to induce cognitive behavioral effects in the adult after neonatal exposure, while carbvaryl has the lowest potency to induce these types of neurotoxic effects.

1750 Developmental Exposure to Levels of Chlorpyrifos That Do Not Inhibit Brain Cholinesterase Increases Decreased Emotional Reactivity in Rodents

R. L. Carr, M. K. Ress and C. A. Nail. Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.

Traditionally, chlorpyrifos (CPS) mediates its toxicity through inhibition of cholinesterase (CHE). However, in recent years, the toxicological effects of developmental CPS exposure have been attributed to an unknown non-cholinergic mechanism of action. We hypothesize that the endocannabinoid system may be an important target because of its vital role in nervous system development. We have previously reported that repeated exposure to 0.5 mg/kg CPS results in the inhibition of fatty acid amide hydrolase (FAAH), the enzyme that metabolizes the endocannabinoid anandamide (AEA), without measurable inhibition of CHE. This exposure resulted in the accumulation of AEA in the forebrain of juvenile rats. Current literature indicates that FAAH activity and AEA levels play an important role in the regulation of emotional reactivity. However, it is unclear if our observed changes in these parameters results in any changes in emotional reactivity. To determine this, 10 day old rat pups were exposed daily for 7 days to either corn oil or 0.5, 0.75, or 1.0 mg/ kg CPS by oral gavage. On PND25, the rats were placed into a dark container in a novel open field and the latency to emerge from the container was measured. In this test, rats that stay in the dark for a long time are considered emotionally reactive. All CPS treated groups spent significantly less time in the dark prior to emerging as compared to control suggesting a decreased level of emotional reactivity induced by CPS exposure. Although not directly correlated, our data suggest that the alteration of endocannabinoid signaling during developmental exposure can lead to alteration of behavioral function.

1751 Zebrafish Brain Development Is Altered by Early Exposure to the Organophosphate Chlorpyrifos

H. Richendrfer and R. Creton.

MCB, Brown University, Providence, RI.

Pesticides are found ubiquitously in the environment because of their wide use in agriculture. While adults have enzymes that are able to break down pesticides, developing embryos lack the necessary enzymes for toxicant breakdown. Low doses of organophosphate pesticides during early embryonic development in animal models and humans have been documented to affect brain development and behavior. Because embryos are more vulnerable to pesticides, it is important to determine at which stages of development embryos are most affected by the exposure to organophosphate pesticides. Using zebrafish as a model system for pesticide exposure is advantageous because embryos can be exposed to organophosphates immediately after fertilization and large numbers of larvae can be used for high-throughput behavioral analysis and brain imaging. Using a high-throughput assay developed in our lab we have shown that low doses of a widely used organophosphate, chlorpyri-fos (even in very low doses), affect discrete behaviors if administered during specific developmental time periods. Current studies in our lab utilize a transgenic line of zebrafish, Tg(elavl3:Kaede) for two-photon brain imaging. Embryos from this line
The organophosphorus pesticide chlorpyrifos (CPS) primarily exerts toxicity through inhibition of acetylcholinesterase (AChE). However, several studies hypothesized that additional targets of CPS may be responsible for its developmental neurotoxic effects. Butyrylcholinesterase (BChE) is the evolutionary counterpart to AChE. Both enzymes appear early in nervous system development prior to cholinergic nerve formation, with BChE expressed before AChE. Therefore, we hypothesized that BChE may be an important target of CPS during neuronal development. To model neuronal development in vitro, we used human neural stem cells (NSCs) derived from induced pluripotent stem cells (iPSC). After four days of Brain-derived neurotrophic factor (BDNF) induced neuronal differentiation of iPSC-derived NSCs, BChE activity increased 115%, while AChE activity was unchanged. BChE mRNA expression increased greater than two-fold, whereas AChE mRNA expression was not altered. Treatment of differentiating NSCs with chlorpyrifos (10 μM) continuously during differentiation caused the inhibition of AChE and BChE activity by 82% and 97%, respectively. However, CPS exposure had no effect on cell morphology, viability or the expression of the early neuronal differentiation marker HES5. To determine the role of BChE protein, shRNA was utilized to knock down expression of BChE. Preliminary results indicate a 74% decrease in HES5 after BChE knockdown, which suggests that BChE may play a role in the differentiation of NSCs independent of, or in addition to its enzymatic activity. Support provided by: R01ES051991 and P30ES050922.

1753 Ketamine Induces Neurotoxicity in the Developing Brain

J. Liu, X. Han and S. D. Soriano. Anesthesia, Harvard Medical School, Boston, MA.

Ketamine, a non-competitive N-methyl-D-aspartate receptor (NMDA-R) antagonist, is commonly used to induce anesthesia and analgesia in infants and children undergoing surgery and painful procedures. However, little is known about how ketamine impact the developing nervous system, especially in infants and young children. In our previous studies, we found that ketamine activated aberrant cell cycle reentry and induced apoptosis by increasing expression of cyclin D1, cleaved-caspase-3 and Bim in vivo. Ketamine also activated the AKT – GSK-3β (glycogen synthase kinase 3β) pathway in the developing rat brain. Based on these, we hypothesize how ketamine affects pathological neurodegeneration the developing rat brain.

Material and Methods: Sprague-Dawley postnatal day 7 (P7) rat pups were used for this study. Doses were given through intraperitoneal doses of either saline or ket at 90 minutes intervals over 6 h. After the 6 h treatment period, the animals were deeply anesthetized with pentobarbital (100 mg/kg, IP). Parts of the brain tissues were extracted and flash frozen in liquid nitrogen for western blotting analysis. The other parts were fixed in 4% paraformaldehyde for immunohistochemical assay, apoptosis such as cleaved-caspase-3, TUNEL, and other protein expression such as Disrupted in schizophrenia-1 (DISC1) and early growth response-1 (EGR-1) were determined by immunofluorescent and western blotting assays.

Results and Conclusion: Ketamine could significant increase neuroapoptosis by increasing apoptosis and cleaved-caspase-3 expression in the rat brain tissues. Ket also significantly decreased the expression of DISC1 and EGR-1, indicating a reduction in developing neurite. These findings suggest that ketamine may induce neurodegeneration by regulating DISC1 pathway in the developing brain.
the developing brains of experimental animals. It has been speculated that the underlying mechanism involves a compensatory upregulation of NMDA receptor subunits that amplifies intracellular calcium concentrations that are beyond the buffering capacity of the mitochondria. This results in loss of mitochondrial membrane potential and disruption of electron transport, eventually leading to altered levels of reactive oxygen species and cell death. Little is known, however, about the overall changes in the mitochondrial ultrastructure that may accompany the distinct events in this cascade. The objective of this study is to utilize complementary methods of electron microscopy (EM) to study the mitochondrial ultrastructure in developing rat brains after ketamine treatment: classical transmission EM (TEM) to study single mitochondria in individual neuronal cells in 2D and serial block-face scanning EM (SBF-SEM) to study mitochondria-rich brain tissues in 3D. Postnatal day 7 rats were administered 6 injections of 20 mg/kg at 2-h intervals, a dose that was previously found to induce significant neurotoxicity in the frontal cortex. Severity grading of TEM micrographs showed a significant proportion of swollen mitochondria in the frontal cortex (p = 0.02), while 3D reconstructions of SBF-SEM data showed that mitochondrial volume was concurrently increased. Such alterations of mitochondrial ultrastructure are solid evidence indicating mitochondria play a critical role in ketamine-induced neuronal cell damage. This study demonstrates that quantitative 2D and 3D EM are valuable tools that can reveal how ultrastructure plays a critical role in understanding drug interactions.
with flow cytometry. This study signifies that PPCPs alter the expression of key synaptic proteins that potentially contribute to neurological disorders like ASD by disrupting neuronal development.

1761 Nicotine-Induced Insomnia in Larval and Juvenile Zebrafish
M. E. Welter and K. R. Svoboda. Joseph J. Zilber School of Public Health, University of Wisconsin-Milwaukee, Milwaukee, WI.

At least 13% of pregnant mothers smoke while they are pregnant and the children of those mothers often sleep less than children born from mothers who do not smoke. In addition to these developmental consequences of smoking, adult smokers often report having problems associated with disrupted sleep. It is thought that these disruptions are related to nicotine which is a potent stimulant and a key ingredient found in cigarettes. The action(s) of nicotine are mediated by activation of neuronal nicotinic acetylcholine receptors (nAChRs) distributed throughout the nervous system. The pineal gland and the retina, two structures that are important for controlling the circadian rhythm (CR) express nAChRs in zebrafish. Thus, we hypothesized that an acute nicotine exposure would disrupt the CR and potentially create an “insomnia-like” phenotype in zebrafish. We evaluated the consequences of an acute, continuous nicotine exposure on the CR in one, two, and three week old zebrafish. One week old larvae exposed to 1 μM nicotine had a disrupted CR. Two week old zebrafish exposed to 5 μM nicotine had a disrupted CR, but a 1 μM nicotine exposure had no effect on the CR. Interestingly, continuous exposure to both 1 μM and 5 μM nicotine disrupted the CR in 3 week old zebrafish. Along with the disruption in the CR, nicotine exposure consistently increased locomotor activity in the initial 6 hours of the CR. These results indicate that nicotine is capable of altering the “sleep state” of the zebrafish by creating an initial period of hyperactivity followed by a disruption in the circadian rhythm. When combined, we suggest that these phenotypes may be analogous to nicotine-induced insomnia in humans.

1762 Coexposure to Gamma-Radiation and Nicotine during a Critical Period of Neonatal Brain Development Can Exacerbate Cognitive Deficits in Adult Mice
S. Buratovic1, B. Steinerlov2, S. Sundell-Bergman1, A. Fredriksson1 and P. Eriksson1. 1Dept. Environmental Toxicology, Uppsala University, Uppsala, Sweden, 2Dept. Radiology, Oncology and Radiation Science, Uppsala University, Uppsala, Sweden and 3Dept. Soil and Environment, Swedish University of Agricultural Sciences, Uppsala, Sweden.

It is known that neonatal exposure to low doses of external γ-radiation as well as nicotine can affect cognitive functions in adult mice. The present study was carried out to investigate whether neonatal co-exposure to external γ-radiation and nicotine can exacerbate developmental neurotoxic effects, including altered susceptibility of the cholinergic system, in adult mice. Neonatal male NMRI mice were exposed to γ-radiation (60Co, 0.2 Gy, dose-rate 0.07 Gy/min) on PND10, PND10 and 11 or PND10, 11 and 12, 3) 0.2 Gy and 66 mg nicotine/kg bw s.c. twice daily on PND10, PND10 and 11 or PND10, 11 and 12, 2) 66 mg nicotine/kg bw s.c. twice daily on PND10, PND10 and 11 or PND10, 11 and 12, 3) 0.2 μg and 66 μg nicotine/kg bw on PND10, PND10 and 11 or PND10, 11 and 12. Controls were exposed to saline and sham irradiated. At an adult age of 2 months animals were observed for spontaneous behaviour in a novel home environment and the variables locomotion, rearing and total activity were registered. Neurotoxic recordings regarding altered susceptibility of the cholinergic system, animals were injected with 80 μg nicotine/kg bw sc and observed for spontaneous behaviour. Animals exposed to 3 x 0.2 Gy as well as animals co-exposed to 3 x 0.2 Gy and 3 x 66 μg nicotine/kg bw showed a deranged spontaneous behaviour at 2 months of age. When challenged to nicotine (80 μg/kg bw) previously mentioned animals showed an increased susceptibility to nicotine at an adult age. All effects were significantly more pronounced in mice co-exposed to γ-radiation and nicotine. These results indicate that external γ-radiation and nicotine can interact to enhance behavioural defects at an adult age if the exposure occurs during a critical period of neonatal brain development. The increased susceptibility to nicotine and altered cognitive function suggests that the cholinergic system is a target system for this type of neurotoxic effects.

1763 Integrating Kinetics and Dynamics for Domoic Acid: Lessons Learned from a Mouse Neurodevelopmental Study
J. Park1, M. Shiotani1, S. Hong2, D. Wittington2, T. B. Cole3, W. C. Griffith1, T. M. Burbacher1, L. G. Costa1 and E. M. Faustman1, 2, 3Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, 2Medical Chemistry, University of Washington, Seattle, WA and 3Institute for Risk Analysis and Risk Communication, University of Washington, Seattle, WA.

Although human public health guidelines have been implemented to limit domoic acid (DA) ingestion from shellfish, consumption of DA contaminated seafood by pregnant women remains a concern as DA produced by harmful algal blooms of Pseudo Nitzschia could alter neurodevelopment of fetuses. To assess the effects of repeated, low-level DA exposures on early neurodevelopment, we conducted toxicokinetic and neurobehavioral studies on pregnant C57BL/6 mice and their offspring. Maternal non-symptomatic human-relevant doses of 0, 1, or 3 μg/kg of DA were administered orally in pregnant mice from gestational days (GD) 10 to 17. The toxicokinetics study showed significant DA accumulations in fetal brain and amniotic fluid over time. Maternal and fetal blood peaked at 1.2 and 3.4 hours after the last dose on GD17, respectively, suggesting that fetuses have delayed exposures to DA. Maternal and non-pregnant mice plasma clearance rates (95% CI) were 0.18 (0.16, 0.21) per hour, where up to 38% of DA in maternal blood was going into fetuses. The neurobehavioral tests revealed that offspring from DA exposed dams demonstrated significant dose and sex specific neurobehavioral effects in some of post weaning measurements, such as anxiety in elevated plus maze, walking patterns in CatWalk, home-cage behaviors, and memory in Morris water maze. Integration of kinetics and dynamics of DA were done by correlating areas under the curve and peak concentrations with neurobehavioral outcomes. Results from our studies add significant new information to the literature on kinetics and dynamics of DA with human-relevant exposure patterns, pathways, and levels. This work has been supported by the Pacific Northwest Center for Human Health and Ocean Studies (NIH: P50 ES012762 and NSF: OCE-0434087, OCE-0910624, and 1128883).

1764 Neurohistopathological Postnatal IP Dose of MK-801 in Juvenile Rats
R. M. Parker1, D. C. Thake2 and R. C. Switzer1. 1DART, Huntington Life Sciences, East Millstone, NJ, 2MW ToxPath Sciences LLC, Chesterfield, MO and 3NeuroScience Associates, Inc, Knoxville, TN.

Characterization of low occurrence of isolated minimal or mild degeneration (DEG) and apoptosis (APO) in control brains is imperative to determine the difference between relationship of normal changes and the effects of a test article. The effects of MK-801 (a non-competitive NMDA antagonist with known neurotoxic properties) on the development of juvenile Sprague-Dawley rat brains were characterized. The MK-801 group received a single dose (3 mg/kg, IP) on PNDs 2, 7, 8, 9, 11, 13, 16, 23, 29, 59, 69 or 111. The control article (distilled water, 3 μL/ Kg, oral gavage) was dosed daily from PND 7 until the day prior to termination. Thirty or twenty rats per sex per time-point had brains perfused/harvested on PNDs 8, 9, 10 and 12, or on PNDs 14, 17, 24, 40, 71 and 113, respectively. The brains were embedded, coronally sectioned at 40μm (through the entire brain length), and stained with amino cupric silver (DEG changes) and caspase 9 stain (APO). Neurohistopathological evaluation of the entire brain for DEG and APO was performed. APO and DEG was prevalent in numerous brain regions of younger control animals (primarily from PND 8 through PND 24). Therefore DEG and APO treatment effects are changes present in a given brain area, specific for each PND, that were greater in incidence or severity than control values. Increased DEG and APO were present in MK-801 animals at all time-points. Increased DEG and APO in MK-801 rats were present in a large number of brain sites in the earlier PNDs with severities ranging from minimal to marked while these changes at later PNDs were substantially diminished. Females generally had more brain sites involved than did males especially at the later PNDs. By PND 40, males typically had only 3 or 4 sites at which DEG was observed. APO that was present in MK-801 rats was generally distinct and unequivocal when compared with the control animals. Based on this data, isolated minimal or mild occurrences of DEG and APO should not be considered treatment related events in juvenile Sprague-Dawley rats.
Comparing the Neurotoxic Effects of Propofol and Ketamine in Rat Embryonic Neural Stem Cells

F. Liu1, N. V. Sadovova2, C. M. Fogle1, T. A. Patterson1, M. G. Paule1, W. Slikker1 and C. Wang1, 1National Center for Toxicological Research, Jefferson, AR and 2Toxicologic Pathology Associates, Jefferson, AR.

Propofol and ketamine are widely used in pediatric anesthesia and analgesia. To evaluate their developmental neurotoxicity and examine underlying mechanisms, embryonic neural stem cells (NSCs) were used. NSCs were harvested from gestational day 14 rat fetuses and exposed on day 7 in culture to propofol at concentrations of 10, 50, 100, and 600 μM, or ketamine at 1, 10, 100, and 500 μM ketamine in growth medium (GM) for 24 hr or to 10 μM propofol or 10 μM ketamine in differentiation medium (DM). In GM propofol caused a dose-dependent reduction in NSC viability; while ketamine did not have this effect at the high concentration of 500 μM. At clinically-relevant concentrations in GM, propofol produced a dramatic increase in ROS generation and enhanced apoptosis as evidenced by an increase in Bax and in TUNEL-positive cells. Similar apoptotic effects were not observed at clinically-relevant dose of ketamine. No significant intracellular Ca2+ influx was detected when NSCs were stimulated with 50 μM NMDA in GM, suggesting there were no functional NMDA receptors expressed on NSCs in GM. In DM, most of the NSCs differentiated into neurons or glial cells. Differentiated neurons were identified using immuno staining with PSA-NCAM (a neuron-specific marker) and calcium influx stimulated with 50 μM NMDA suggested the existence of functional NMDA receptors. Propofol and ketamine significantly increased NSC ROS generation in GM. Propofol and ketamine caused neuronal damage but did not significantly affect glial cells. These observations suggest that ROS plays a key role in propofol and ketamine-induced neurotoxicity and that Ca2+ imaging and gene and protein arrays will be critical for defining associated mechanisms. In summary, an excitatory action of glutamate neurotransmission can be closely related to anesthetic-induced toxicity during development.

Evaluating Neural Progenitor Cell Expansion following Sevoflurane Exposure in Developing Rat Brain Using Micro positron Emission Tomography of [18F] Fluoro-L-Thymidine

S. Liu1, M. G. Paule1, X. Zhang1, G. Newport1, S. Apana2, M. Berriage2, W. Slikker2 and C. Wang1, 1Neurotoxicology, National Center for Toxicological Research, Jefferson, AR and 23D Imaging, LLC, Little Rock, AR.

Neutral progenitor cell expansion is critical for normal brain development. During the brain growth spurt, exposures to general anesthetics which either block the N-methyl D-aspartate receptor (NMDAR) or enhance the γ-aminobutyric acid (GABA) receptor type A (GABA_R) can disturb the neuronal transduction. Few reports on the effects of anesthetic exposure on neural progenitor cell expansion in vivo had been published up to date. Here, minimally invasive micro positron emission tomography (microPET) coupled with 3'-deoxy-3'-[18F]fluoro-L-thymidine ([18F]FLT) was utilized to detect the effects of sevoflurane exposure on neural progenitor cell proliferation. FLT, a thymidine analog, is taken up by cells and phosphorylated in the cytoplasm, leading to its intracell lar trapping. The uptake and phosphorylation of FLT correlate highly with cellular proliferation. Intracellular retention of [18F]FLT, thus, represents an observable in vivo marker of cell proliferation. Postnatal day (PND) 7 rats (n=10) were exposed to 2.5% sevoflurane mixed with O2 for 9 hr. One wk post-exposure, the standard uptake values (SUVs) for [18F]FLT in the hippocampal formation were significantly attenuated in the sevoflurane-exposed rats in comparison with control ones (t test, p < 0.05), suggesting decreased uptake and retention (proliferation) in these regions. Two and four wk post-exposure SUVs for [18F]FLT were comparable in the sevo-exposed rats and control ones. Co-administration of 7-nitroindazole (7NI, 30 mg/kg, n=5), a selective inhibitor of neuronal nitric oxide synthase, moderately (around 15%) attenuated the sevo-induced decrease in [18F]FLT SUVs. These findings suggested that neural progenitor cell proliferation is significantly decreased following sevoflurane exposure in the developing rat brain.

Vigabatrin-Induced Effects on the CNS of Juvenile Rats: Further Characterization of Histological Findings

A. D. Rasmussen1, K. M. Wegener1, P. Mullins2, E. Richardson2 and N. Downes2, 1Regulatory Toxicology & Safety Assessment, H. Lundbeck AS, Valley, Denmark and 2Sequenti Ltd, Ledbury, Herefordshire, United Kingdom.

Vigabatrin is an oral antiepileptic drug (AED) marketed under the trade name Sabril as adjunct therapy for adults with refractory complex partial seizures and as a mono therapy for children aged 1 month to 2 years with infantile spasms. Vigabatrin causes irreversible inhibition of gamma-aminobutyric acid transaminase (GABA-T), the enzyme responsible for the catalysis of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA), and oral treatment with this compound results in increased level of GABA in the cerebrospinal fluid and brain. In the study presented here, administration of vigabatrin to juvenile rats during discrete periods of time (starting from day 4 of age) resulted in histopathological changes in the brain in terms of neuropil microvacuolation, as well as effects on myelination and on the oligodendrocytes. The variation in the location of the lesions appears to be consistent with the process of myelination previously reported in rats; in the youngest animals, myelination occurred mainly in the hind brain (medulla oblongata and pons) and there was no appreciable myelination in the
thalamus which showed minimal myelination on Day 7 and appreciable myelination by Day 10. It seems likely that the swollen oligodendrocytes seen after as the initial change in the thalamus represented an early stage in the development of the myelin lesion which was seen later as neuropil vacuolation.

The data presented here provide evidence that the histopathological findings reported in the developing nervous system of rats when exposed to Vigabatrin. A full account of the study data is pending publication during 2014.

**R 1765 Hydraulic Fracturing: Are There Worker Health Issues?**

D. Kaden¹, R. O. McClellan¹, J. E. Snowler², R. A. Nocco², M. Finn¹ and Z. Naufal².

Use of horizontal drilling and hydraulic fracturing in the US oil and gas (O&G) industry has expanded, with >500,000 workers in this industry in 2013. As with any industry, the workforce has the greatest potential for exposure to contaminants. Furthermore, due to the rapid expansion and need to work at multiple locations, many workers remain transient and work at different sites, often owned by different operators, which can lead to additional complexities when assessing exposures. O&G exploration using hydraulic fracturing has constantly evolved to increase efficiency in recovering oil and gas, which have market value, and further minimize any environmental and health hazards to workers and nearby residents. The highly sophisticated process holds potential hazards as high pressures are used transferring large volumes of water, sand (silica), and small quantities of specific chemicals from the surface to specific geologic structures. Extensive use is made of diesel-powered equipment. Current practices seek to recover and reuse injected fluids to minimize water consumption and the disposal of hazardous waste, including trace elements and naturally-occurring radioactive material. Toxicology and epidemiology have been used to guide improvements in technology (e.g., advanced diesel engines, fuels, and exhaust after-treatment to reduce diesel emissions of PM and NOx) and replace proppants/additives with more environmentally-friendly alternatives. Concern for occupational hazards, including minimizing exposure to noxious agents that may have immediate or long-term impact, is key to planning hydraulic fracturing operations.

**IS 1766 Understanding the Implications of Breastfed Infant Exposures to POPs: How Can We Do Better?**

G. M. Lehmann¹, D. G. Farrer¹, J. S. LaKind², M. Poulsen³, H. A. El-Masri¹, D. D. McLanahan¹ and S. Haddad¹.

Persistent organic pollutants (POPs), such as polychlorinated biphenyls (PCBs), may accumulate within a woman’s adipose tissue over many years prior to pregnancy and may subsequently partition into human milk upon breastfeeding. As a result, infant POP intake from breastfeeding may be much greater than average daily maternal POP doses. The developmental period is critical because it sets the stage for lifelong health. Humans continue to develop postpartum, and effects of daily maternal POP doses. The developmental period is critical because it sets the stage for lifelong health. Humans continue to develop postpartum, and effects of daily maternal POP doses.

The training and continuing education of toxicologists is a priority for the SOT membership as demonstrated by the SOT Professional Needs Assessment Task Force (PNATF) and the Education Summit. But what defines a well-trained toxicologist or the “Total Toxicologist”? Does the definition vary depending on the employment sector? Do current graduate programs and continuing education programs provide the necessary and sufficient training for toxicologists? To initiate a discussion regarding these questions, SOT and the National Institute of Environmental Health Sciences sponsored the 2011 Toxicology Educational Summit, which brought participants from academia, industry, and government together to better define the necessary skill sets for the Total Toxicologist (Tox Sci 127:331, 2012). Conclusions from the Summit underscored a deficiency in critical thinking, communication skills, and practical application of laboratory data to drug development and risk assessment as well as a need for improved educational opportunities for mid-career toxicologists. Sustaining a career in the current and future global environment, with the ever-changing and rapid advances in technology, requires partnerships between academia, industry, and government to train and re-train the Total Toxicologist. The goal of this session is to offer multi-faceted perspectives on the skill sets (both hard and soft) required for a successful career as a Total Toxicologist and will include talks from early-, mid-, or late-career toxicologists currently employed in academia, industry (pharmaceutical and agricultural/chemical), or government. The session will also provide a brief summary of the results from the PNATF survey to offer a perspective from the SOT membership regarding their perceived training needs. This session should be of interest to students, postdocs, and early- and mid-career toxicologists and is consistent with SOT’s goals to continue educational awareness and advancements for all toxicologists.

The in vitro effect of selenium (Se) and a combination of vitamin E and vitamin C on some pesticides, viz atrazine, dimethoate, or endosulfan at three different levels of 10, 20, and 30 mM to induced biochemical alterations in rat erythrocytes and hepatocytes of rats was investigated by determining the levels of lipid peroxidation (nmoles MDA/mg protein), glutathione (mole GSH/mg protein) and glutathione peroxidase activity, enhanced the glutathione contents. Treatment with pesticides stimulated thiobarbituric acid reactive substances (TBARS) activity and glutathione peroxidase activity, enhanced the glutathione contents. Treatment with selenium and a combination of vitamin E and/or vitamin C potentially reduced the free radicals in erythrocytes or hepatocytes and ameliorated the oxidative stress induced by such pesticides. The results suggested that pesticides treatment increases in vitro lipid peroxidation, glutathione peroxidase level and glutathione content by increasing oxidative stress in erythrocytes and hepatocytes of rats and selenium and a combination of vitamin E and vitamin C can reduce this lipoperoxidative effect.

Nonsteroidal anti-inflammatory drugs (NSAIDs) have been reported to induce cytotoxicity in cancer and non-cancerous cells. Overdose of acetaminophen (APAP) has been known to cause liver injury in humans and experimental animals. Their precise molecular mechanisms, however, are not clearly understood. Our previous studies using HepG2 cells treated with aspirin and mouse macrophage J774.2 cells treated with APAP strongly suggest cell cycle arrest and induction of apoptosis associated with mitochondrial dysfunction and oxidative stress. Macrophages are known to play a critical role in toxicity as well as protection of target tissues against the toxicity induced by NSAIDs. In the present study, we have further demonstrated that macrophages are a more sensitive target for aspirin–induced toxicity than HepG2 cells in lipopolysaccharide (LPS)–treated – macrophage J774.2 and hepatoma HepG2 cells. A marked and differential alteration in oxidative stress, apoptosis, glutathione redox homeostasis and mitochondrial functions were ob-
served in these cells. Pre-treatment of the above cells with N-acetylcysteine, a known antioxidant, has also exhibited selective cytoprotective effects. Our results have suggested that altered glutathione (GSH)-redox metabolism, oxidative stress and mitochondrial function in macrophages and hepatoma cells play a critical role in LPS/NSAIDs-induced cytotoxicity. These results may help in better understanding the pharmacological, toxicological and chemopreventive properties of NSAIDs in cancer and non-cancerous cellular systems. (Supported by Sheikh Hamdan Medical Research Grant and Terry Fox Cancer Research Funds and a fund from CMH5 Research Committee).

1770 Brominated Diphenyl Ether-47 Induces Oxidative Stress and Inflammatory Pathways in Human Placental Cells In Vitro

H. Park and R. Loch-Caruso, University of Michigan, Ann Arbor, MI.

Polybrominated diphenyl ethers (PBDEs) are widely used flame retardant compounds. Brominated diphenyl ether (BDE)-47 is one of the most prevalent PBDE congeners found in human breast milk, serum and placenta. Exposure to BDE-47 has been linked to adverse pregnancy outcomes in humans including preterm birth, low birth weight and stillbirth. Although the underlying mechanisms of adverse birth outcomes are poorly understood, critical roles of oxidative stress and inflammation are implicated. The present study investigated BDE-47-induced oxidative stress and proinflammatory (PG) production in a human extravillous trophoblast cell line, HTR-8/SVneo. After 4, 12 or 24 h exposure of HTR-8 cells to BDE-47, intracellular glutathione (GSH) concentration, PGE2 release, and expression of 84 redox-regulated genes were assayed. Treatment of HTR-8 cells with 20 µM BDE-47 for 24 h resulted in differential expression of redox-sensitive genes compared to solvent control. BDE-47 was assayed with commercial Oxidative Stress PCR Array. Treatment of HTR-8 cells with 5, 10, 15, and 20 µM BDE-47 for 24 h increases intracellular GSH levels compared to solvent control, consistent with increased mRNA expression of genes related to GSH synthesis. At 24 h, 20 µM BDE-47 induced significant increases in PGE2 release into the culture medium. The PGE2 increases were accompanied by significant 5.3, 4.4 and 4.7-fold increases in mRNA expression of the proinflammatory cytokine and lipid mediator genes. Increases were also observed for Mrp1, a multidrug efflux protein believed to contribute to BDE-47 efflux from cells. These results suggest that BDE-47 mediates an oxidative stress inflammatory response in human placental cells.

1771 Radical Acylation of L-Lysine-Containing Peptides and Sorbarmine by Peroxynitrite-Treated Diacetyl and Methylglyoxal

F. J. Bechara1, 2, R. Tokikawa2, M. Machini2, M. Uemi2, N. A. Assunção1 and A. A. Alves1.

Highly reactive α-dicarbonyl compounds such as diacetyl, methylglyoxal, 4,5-dioxyvaleric acid, and 3-deoxyglucosone have been characterized as secondary catabolites that can aggregate proteins and form DNA nucleobase adducts in several human maladies. In vitro, diacetyl (DA) and methylglyoxal (MG) have also been shown to rapidly add up the peroxynitrite anion (k2 > 10xp4 to 10xp5 M-1s-1), a potent biological nucleophile, oxidant and nitrating agent, followed by carbon chain cleavage to carboxylic acids from acryl radical intermediate that can attach to amino acids added to the reaction mixtures. Here, using HPLC or CE coupled to ESI or MALDI-TOF/MS techniques, we show that the DA or MG/peroxynitrite systems are capable of acetylating the α-lysyl residues of synthetic KALA-OH, Ac-KALA-OH, K(Boc)ALA-OH, and Ac-A-E-F-K-F-A-L-NH2 as well as amino acid residues of bovine sorbarmine in phosphate buffer pH 7.4. The pH profiles (6.2-8.2) of the reactions traced for the tetrapeptides are bell-shaped, peaking at approximately 7.5, therefore near the pKa values of both ONOOH and H2PO4- anion, which is in accordance with the pH dependency of the reaction products. CE or HPLC and MS analyses of reaction products confirmed αN- and αε-acylation of Lys derivatives by DA as well as acetylation and formylation by MG. Moreover, the EPR MNP-CH3CO radical adduct signal was found to be quenched upon addition of L-His. These data raise the hypothesis of contributing radical acylation of peptides in epigenetic processes, where their enzymatic acetylation is a well-documented event, recently reported to be as critical to the cell cycle as phosphorylation. Also noteworthy is the observed formation of L-Lys containing peptides by MG never reported to occur in proteins. Financial support: FAPESP, CNPq, INCT Redoxoma.
The coexistence of aflatoxicosis and protein malnutrition in children is a major health burden in developing countries especially in sub-Saharan Africa. Hence, this study investigated the effects of the coexistence of Aflatoxin B1 (AFB1) poisoning and protein malnutrition on renal and hepatic antioxidant status and the integrity of genomic DNA in weanling rats. Eight groups of animals were used in this study; groups 1 and 2 were male and female animals fed normal protein diet (20% protein), groups 3 and 4 were male and female animals fed low protein diet (5%), groups 5 and 6 were male and female animals fed normal protein (20%) + 40ppb AFB1 and groups 7 and 8 were male and female animals fed low protein (5%) + 40ppb AFB1 respectively. At the end of eight weeks, rats were sacrificed after an overnight fast and liver and kidney were excised. Glutathione, glutathione transferase, superoxide dismutase, catalase and glucose-6-phosphate dehydrogenase were determined spectrophotometrically while genomic DNA fragmentation was determined by agarose gel electrophoresis after extraction of DNA from the tissues. Results showed that the coexistence significantly (p<0.05) decreased glutathione, glutathione transferase, and superoxide dismutase while it increased peroxidase in the kidney and liver. It significantly (p<0.05) increased catalase in different tissues. Results showed that the coexistence significantly (p<0.05) decreased glutathione, glutathione transferase, and superoxide dismutase while it increased peroxidase in the kidney and liver. It significantly (p<0.05) increased catalase in the liver while a decrease was observed in the kidney. Furthermore, a decrease in glucose-6-phosphate dehydrogenase was observed in the liver while no significant (p>0.05) difference was observed in the kidney. Agarose gel electrophoresis showed DNA damage in the kidney of the rats while no difference in pattern was observed in the liver. Our results suggest that sub-chronic coexistence of AFB1 poisoning and protein malnutrition resulted in oxidative stress with a concomitant DNA damage in the kidney of weanling rats.

MALDI-Mass Spectrometry-Based Biochemical Microscopy of Cardiolipin Molecular Species in Brain Tissue

A. Amoscato1, L. J. Sparvero1, R. He3, B. Pitt1, H. Bayir2, 1 and V. E. Kagan1,
1Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, 2Pharmacy College, Jinan University, Guangzhou, China.

Existing protocols associated with MALDI imaging mass spectrometry (MALDI-IMS) in the mapping of lipids on tissue sections fail to detect the mitochondria-unique phospholipid cardiolipin (CL), known to be essential for cell and mitochondrial physiology. We developed a new protocol enabling the “biochemical microscopy” of diversified individual molecular CL species. This has been achieved by the employment of: i) phospholipase C to reduce highly abundant phosphatidylincholine (PC) signals, ii) chemical crosslinking with 1-ethyl-3-[3-dimethylaminopropyl] carbodiimide hydrochloride (EDC) to block ion suppressive effects from carboxyl containing molecular species, iii) modified matrix application methods and ammonium acetate washes to enhance CL signal in negative ion mode. Using these treatments, we were able to visualize and map CL in rat brain tissue. We documented a spatial distribution for CL in the rat brain. The relative intensities of CL species m/z 1448 and 1450 were highest in the hippocampal area and decreased in intensity as one transitions from the hippocampus toward the white matter and cortex areas. Higher mass CL species displayed similar or increased intensities in the hippocampus and cortex areas. We therefore investigated the role of zinc exposure on the mitochondrial redox status by measuring the EGSH in mitochondria. Cultures of the human bronchial epithelial cell line BEAS 2B were transduced using lentiviral
The transcription factor Nrf2 has revealed as the master regulator of intracellular redox homeostasis. As an adaptive response to oxidative stress, Nrf2 activates transcription of a battery of genes encoding antioxidant protein, detoxification enzymes and xenobiotic transporters by binding to the cis-antioxidant response elements in the promoter region of these genes. Previous work by our lab and others demonstrated that Nrf2 is subject to poly-ubiquitin-mediated proteasomal degradation in a Keap1-dependent manner. Here we report a potential functional connection between protein quality control and Nrf2 activation. Genetic knockdown or pharmacological inhibition of p97, an AAA-ATPase governing critical steps in ubiquitin-dependent protein quality control and intracellular signaling pathways, resulted in an increase in Nrf2 protein level as well as increase Nrf2 target gene expression. We also demonstrated that p97 is in complex with Nrf2 and with Cul3-Keap1-Rbx1 E3 ligase complex using biochemical and proteomics analysis. Furthermore, indirect immunofluorescent staining reveals both inhibited p97 function and treatment with arsenite lead to increased autophagosomal formation, implying the possible link between arsenic, p97, autophagy, Nrf2 upregulation and cellular toxicity. These findings not only suggest new regulatory mechanism of Nrf2-Keap1 pathway, but also offer a potential mechanism by which arsenic activates the Nrf2 pathway.

**1780 Microtubule-Associated Protein 1s (MAP1s) Is a Novel Component of the Noncanonical p62-Dependent Mechanism of Nrf2 Regulation**

Microtubule Associated Protein 1s (MAP1s) is a short and ubiquitously expressed member of the microtubule-associated protein (MAP) 1 family. Recent studies have identified a cytoskeletal role for MAP1s in neurodegeneration. MAP1s eliminates genome instability and protein aggregates, and protects against chemically-induced hepatocarcinogenesis. The interaction of MAP1s with several cellular components such as tubulin, actin, RASSF1A, LRPPCR and the autophagy protein LC3 has already been characterized. Here we identified that MAP1s and Keap1 are contained in the same protein complex through their interactions with p62, rather than through direct, ETGE motif-dependent MAP1s-Keap1 interaction. Moreover, MAP1s and Keap1 colocalized with p62 and LC3 in a punctate pattern that suggests that they all form part of an autophagic complex. Overexpression of MAP1s resulted in decreased protein levels of coexpressed Keap1, and treatment with the proteasome inhibitor MG132 resulted in a more dramatic decrease in Keap1 protein levels. On the other hand, treatment with diverse autophagy inhibitors prevented further Keap1 degradation. Additionally, MAP1s knockdown resulted in increased protein levels of Keap1 and p62, with a concomitant decrease in Nrf2 signaling. In vivo, we saw that acute treatment of nude mice with the hepatic carcinogen diethylnitrosamine (DEN) resulted in MAP1s induction in liver. This induction of MAP1s also resulted in increased protein levels of p62, Nrf2, NQO1, and decreased protein levels of Keap1. Interaction between p62 and Keap1 was previously been shown to impede Nrf2 degradation, thereby favoring its stabilization and induction of downstream genes. Taken together, all these results suggest that MAP1s is a novel component of the non-canonical pathway of Nrf2 activation mediated by p62.
for 3 h and then incubated for 1 h with: 1) medium alone, 2) 25 μM MDA, 3) 0.2% Intralipid (emulsion of egg yolk and soybean triglycerides), 4) MDA plus Intralipid, 5) 10 μM Sp600125 (JNK inhibitor), and 6) MDA plus Intralipid plus Sp600125. Cells were then incubated with bodipy green, TMRM and propidium iodide (PI) to visualize neutral lipids, polarized mitochondria and non-viable cells, respectively, by confocal microscopy. After medium alone, hepatocytes displayed few lipid droplets. MDA alone did not increase lipid droplet accumulation but caused a decrease of mitochondrial membrane potential (ΔΨ) assessed by TMRM. Intralipid alone caused neither accumulation of lipid droplets nor a decrease of ΔΨ. However, MDA combined with Intralipid led to substantial increases of size and quantity of lipid droplets together with a decrease of ΔΨ. JNK inhibition with Sp600125 blocked lipid accumulation and the decrease ΔΨ after MDA plus Intralipid. No treatments induced PI staining. These results are consistent with our previous hypothesis that aldehydes like MDA inhibit mitochondrial voltage dependent anion channels (VDAC) with consequent inhibition of β-oxidation of fatty acids and mitochondrial ΔΨ formation (JBC 2012;287:7692-7700). However, since our expectation was to develop a source of lipid was present. Interestingly, JNK inhibition abrogated reactivity induced by MDA plus Intralipid, suggesting that aldehyde dependent VDAC closure occurs via a JNK-dependent pathway.

1784 Development of a Novel Lumogenic Assay for H2O2 Detection

H2O2 is a reactive oxygen species (ROS) that is convenient to measure because of a relatively long half-life and it is also useful as a general marker of oxidative stress. Commercial H2O2 reporters include fluorogenic probes that react directly and selectively with H2O2 or via catalysis by horseradish peroxidase (HRP). The direct probes are convenient for imaging ROS inductions, but tend to be non-selective among the various ROS and they deliver small assay windows in homogenous formats. While HRP-dependent probes are sensitive and selective, they are prone to high false hit rates in screens and perform poorly in cell based assays. To overcome these shortcomings we synthesize a cyanobenzothiazole derivative containing a borate ester and self-cleaving linker (2-ethyl-6-(4-(4,4,5,5-tetramethyl-1,3-dioxaborolan-2-yl)benzoyloxy)benz[d]thiazole) to use as a lumogenic probe. The borate reacts directly and selectively with H2O2 to expose the linker and eliminate a free cyanobenzothiazole. The latter moiety reacts rapidly with D-cysteine to form luciferin, which in turn generates light with luciferase. Based on well-known characteristics of luciferase assays we expected low background, wide dynamic range, and low false hit rates. In a homogenous format cells were where exposed to test articles (e.g. ROS inducers) and probe, and then to a luciferase formulation containing D-cysteine. The luciferase produced light read by a luminometer in proportion to the H2O2 concentration of the sample. Prototypical ROS inductions were detected with high sensitivity and a wide dynamic range in a multwell format. To test high throughput performance, we screened the 1280 compound LOPAC library against HepG2 cells. Cells in medium were compared to medium alone to select H2O2 modulators and to discriminate between cell-based and abiotic effects. LOPAC screens revealed a low false hit rate (0.5%) compared to an HRP based method (7.1%). These results indicate the assay obviates certain limitations of fluorometric methods and that it should prove effective for small scale and high throughput applications.

1785 Nrf2 but Not NF-kB Is Activated by African Dust Organic Extract in BEAS-2B

Every year, African dust storms cross the Atlantic Ocean impacting the Caribbean region. Airborne particulate matter (PM) falls out along its path. This matter contributes to the oxidative atmospheric potential of the environments and in organisms. The impact of this global phenomenon on the health of the Puerto Rican community continues to be evaluated. We previously reported the induction of IL-6 and IL-8 by African dust (ADE) in human bronchial epithelial cells (BEAS-2B). Here we expand our research to assess the activation of two trans factors 1) the nuclear erythroid 2-related factor 2 (Nrf2) and 2) the nuclear factor κB (NF-κB). The role of heavy metals and oxidant capacity were evaluated using 1) the nuclear erythroid 2-related factor 2 (Nrf2) and 2) the nuclear factor κB (NF-κB). For example, deferoxamine mesylate (DF) and N-acetyl-L-cysteine (NAC), in cells treated with PM organic extracts (50μg/ml). Protein extracts were obtained using the Nuclear Extract Kit (Active Motif) according to the manufacturer and quantified by the Bradford assay. Activation of Nrf2 and NF-κB were determined by an ELISA base assay (Active Motif). Nuclear extracts including the activated transcription factors were added to a plate coated with the specific oligonucleotide containing a consensus-binding site for Nrf2 or NF-κB. Both ADE and Non-ADE extracts induce the activation of Nrf2 after 1 h. This response is partly due to the oxidative capacity of ADE (not significant for Non-ADE) extract since it was significantly reduced by NAC. ADE and Non-ADE extracts triggered the activation of Nrf2 however; the magnitude of this activation was significantly increased for ADE. To our surprise we were unable to find any evidence for NF-κB activation after 1 or 4 hrs. This research demonstrates that African dust arriving Puerto Rico has an oxidative capacity capable of activating antioxidant defenses in lung cells. The activated molecules are good candidates for testing biomarkers of exposure to cellular stress during seasonal respiratory outcome. Support provided by MBRs-RISE Grant R25GM061838.

1786 Perfluorooctanoic Acid (PFOA) Causes Oxidative Stress in the Mouse Pancreas

L. M. Kamendulis1, Q. Wu and B. A. Hocevar. Environmental Health, Indiana University School of Public Health, Bloomington, IN.

Perfluoralkyl chemicals (PFCs) such as perfluorooctanoic acid (PFOA) are widely used in industrial and commercial applications and are environmentally and biologically persistent. In rodents, PFC exposure has been shown to lead to reduced body weight, liver hypertrophy, and decreased cholesterol levels. In addition, chronic exposure to PFCs induce liver, Leydig and pancreatic acinar cell tumors (PACTs) in rodents. Epidemiologic studies have also linked exposure to PFC compounds to adverse health effects in humans, several of which identified an association between PFC exposure and pancreatic disease. To address the effects of PFCs on the pancreas, we treated 8 wk old C57Bl/6 mice with vehicle or PFOA by gavage at doses of 0.5, 2.5 or 5.0 mg/kg BW/day for 7 days. In addition, a group of mice were treated with omeprazole, which induces mild pancreatitis and produces an oxidative stress in the pancreas. Our results demonstrate that exposure to PFOA results in pancreatic toxicity, evidenced by increased serum levels of amylase and lipase in the PFOA treatment groups. PFOA accumulated in serum, liver and pancreas in a dose-dependent manner. Increased levels of the lipid peroxidation product F2-isoprostane were observed in both the pancreas and liver (2.5-fold and 1.5 fold, respectively) indicating that PFOA induced oxidative stress in these tissues. In the pancreas and liver, F2-isoprostane levels were strongly correlated with PFOA content (r² = 0.86, and 0.90, respectively). The mRNA expression of the cystosolic and mitochondrial forms of superoxide dismutase, (SOD1 and SOD2) was increased by 1.5 fold in the pancreas of PFOA treated mice, which was accompanied by an increase (24%) in the enzymatic activity of SOD. While the levels of GSH in the pancreas were not altered, the ratio of GSH:GSSG was significantly decreased by PFOA exposure. In contrast, PFOA increased GSH levels and the GSH:GSSG ratio in the liver. Collectively, these results suggest that PFOA exposure results in oxidative stress in the pancreas.

1787 Investigating the Bioenergetic and Oxidative Impacts of Rapid Altitude Adjustment

M. K. Makley1, R. R. Chapleau2, A. G. Ntamack3, R. A. James3, L. M. Gearhart1, D. A. Mahle4, H. M. Jackson Foundation, Wright Patterson ABF, OH, 2NAMRU-D, Wright Patterson ABF, OH, 3Camrus International, Wright Patterson ABF, OH and 4USAF 711HPWR/HDJ, Wright Patterson ABF, OH.

Rapid ascent to high altitudes commonly results in a severe decrease in exercise performance and cognitive abilities. Many situations, in which rapid altitude changes are required, such as mountain rescues and flight, necessitate transport in aircraft or high-performance vehicles. Sprague-Dawley rats were elevated to three simulated altitudes for one hour (1,000, 10,000, or 20,000 feet) under constant oxygen levels. Liver, heart, and brain mitochondria were immediately isolated following exposure for evaluation of State 3, State 4, and uncoupler-stimulated respiration in a Seahorse XF Bioanalyzer. In addition to evaluating ATP production, spare capacity, and proton leak with the XF Bioanalyzer, measurements of the oxidative stress markers cytochrome c and thiobarbituric acid reactive substances (TBARS) were taken. Our results from heart tissue show that in addition to reduced oxygen delivery to organs, altitude affects the basic bioenergetics of the cell by reducing the oxidative capacity of the mitochondria. Although ATP production is maintained at a relatively constant level (0.25 pmoles/min), the mitochondrial membrane is weakened as indicated by an increase in proton leakage (42%). Furthermore, the levels of TBARS in the blood increase 28% with the raise in altitude to 20,000 feet, supporting our physiological observations. The decrease in spare respiratory capacity corresponding to a weakened membrane and the presence of oxidative stress markers suggests that additional stressors at altitude could have catastrophic outcomes. Future work will investigate the impact on mitochondrial function in unique brain regions as well as skeletal muscle effects.
Studying Nrf2-Mediated Oxidative Stress Response in Human Keratinocytes Exposed to Two Plant Polyphenols—Quercetin and Curcumin

P. Xue1, B. Sun1, J. Dong1, Y. Adelvey2, P. L. Carmichael1, A. White2, M. E. Andersen1, R. A. Clewell1 and J. Pi1, 1Department of Biology, University of North Carolina at Greensboro, Greensboro, NC, 2Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD and 3Department of Pharmacology, Campbell University School of Osteopathic Medicine, Buies Creek, NC.

Methionine sulfoxide reductase A (Msra) is an oxidoreductase repair enzyme responsible for catalyzing the stereospecific reduction of methionine-S-sulfoxide to methionine. Previous studies have shown that reactive oxygen species (ROS) can lead to the oxidation of methione, thereby rendering proteins functionless. Reversal of this process by Msra has been shown to restore protein function, and has been implicated in cellular senescence, the aging process, neurodegenerative diseases, and glucose homeostasis. The antioxidant response of Msra is established, but the transcriptional regulation remains uncertain. Nrf2, a key regulator of the antioxidant response, is a transcription factor that is responsible for altering gene expression upon insult triggered by ROS. We predicted Msra to be a novel target gene of Nrf2 based on 2putative AREs contained within the promoter region. Preliminary data, through induction of Nrf2, identified that Msra protein expression acts just as other well-established Nrf2 target genes. Subsequent knockdown of Msra in HaCaT cells showed reduced protein level of Msra. Taken together, our data indicate that Msra is a novel target gene of Nrf2. The regulation of Msra and its functional contribution to the Nrf2-mediated defensive response are currently under investigation.

Production of Reactive Oxygen Species by the Redox Cycling of 9,10-Phenanthraquinone in Human Monocyte THP-1 Cells: Role of the Mitochondrial Electron Transport Chain

Z. Ia1, H. Zhu1, M. A. Trush2 and Y. Li1, 1Department of Biological Chemistry, University of North Carolina at Greensboro, Greensboro, NC, 2Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD and 3Department of Pharmacology, Campbell University School of Osteopathic Medicine, Buies Creek, NC.

Exposures to environmental pollution remains a major problem and poses continuing risks to human health. Airborne particulate matter (APM) contains large amounts of quinoid compounds and it has been shown that 9,10-phenanthraquinone alone compromises about 6% of the total organic extract of diesel exhaust particles. However, the potential involvement of 9,10-phenanthraquinone in APM-induced adverse effects remains unclear. In this study, we determined whether 9,10-phenanthraquinone could undergo redox cycling in human monocyte THP-1 cells. Incubation of THP-1 cells with 9,10-phenanthraquinone at 0.1-1 μM resulted in a significant stimulation of potassium cyanide (KCN)-resistant oxygen consumption, indicating that 9,10-phenanthraquinone could undergo redox cycling in cells. Redox cycling of 9,10-phenanthraquinone to produce ROS in support of this process, incubation of 9,10-phenanthraquinone with mitochondria isolated from the THP-1 cells also stimulated ROS production. In summary, this study demonstrated that 9,10-phenanthraquinone produces ROS in THP-1 cells and METC is a CDDO-Im via Glutathione-Mediated Mechanism

H. Shah1, C. Saunders1, A. Spenn1, E. Brooke1, P. Nallamsamy1, H. Zhu2, Y. Li1 and Z. Ia1, 1Department of Biology, University of North Carolina at Greensboro, Greensboro, NC, and 2Department of Pharmacology, Campbell University School of Osteopathic Medicine, Greensboro, NC.

Acrolein is an environmental toxin, mainly found in smoke released from incomplete combustion of organic matter. The compound is ubiquitously found in endogenous as well as exogenous environment. Several studies showed that exposure to acrolein can lead to liver damage. The mechanisms involved in acrolein-induced hepatocellular toxicity, however, are not completely understood. This study examines the toxic effects and cytotoxic mechanisms of acrolein on HepG2 cells. Acrolein at pathophysiological concentrations was shown to cause a concentration-dependent decrease in cell viability. Acrolein treatment was also found to cause apoptotic cell death and an increase in levels of protein carbonyl and TBARS (thiobarbituric reactive acid substances), markers of protein damage and lipid peroxidation, respectively, in HepG2 cells. Acrolein also rapidly depleted intracellular glutathione (GSH), phase II enzyme GSH-conjugation transfers (GST) and aldose reductase (AR), three critical cellular defenses that detoxify reactive aldehydes. Results further showed that depletion of cellular GSH by acrolein preceded the loss of cell viability, which suggests that cellular GSH depletion may be an important event in acrolein-induced cytotoxicity. To further determine the role of cellular GSH in protecting against acrolein-mediated cytotoxicity, buthionine sulfoximine (BSO) was used to inhibit cellular GSH biosynthesis. It was observed that depletion of cellular GSH by BSO led to a marked potentiation of acrolein-in-mediated cytotoxicity in HepG2 cells. Furthermore, induction of GSH levels by CDDO-Im, a triterpenoid compound, afforded protection against acrolein toxicity in a concentration-dependent manner via induction of GSH mechanism. This study may provide understanding on the molecular action of acrolein which may be important to develop novel strategies for the prevention of acrolein-mediated toxicity.

Protection of HepG2 Cells from Acrolein Toxicity by CDDO-Im via Glutathione-Mediated Mechanism

H. Shah1, C. Saunders1, A. Spenn1, E. Brooke1, P. Nallamsamy1, H. Zhu2, Y. Li1 and Z. Ia1, 1Department of Biology, University of North Carolina at Greensboro, Greensboro, NC, and 2Department of Pharmacology, Campbell University School of Osteopathic Medicine, Greensboro, NC.

Acrolein is an environmental toxicant, mainly found in smoke released from incomplete combustion of organic matter. The compound is ubiquitously found in endogenous as well as exogenous environment. Several studies showed that...

Using intermittent hyperoxia can significantly ameliorate the toxic effects of hyperoxic exposure. Thus, either giving sufficient time to recover or upon the duration of both hyperoxic and normoxic exposure. Macrophages that were compromised by 24 hours of continuous hypreoxiacan was reversed upon subsequent exposure to normoxia. We tested two exposure paradigms to address the effects of hyperoxia on macrophages. We tested two exposure paradigms to address whether: 1. the adverse effects of hyperoxia on macrophages are reversible. 2. Intermittent exposure to hyperoxia is less deleterious than continuous exposure in compromising phagocytic function. Here, we report that phagocytic function compromised by 24 hours of continuous hyperoxia was reversed upon subsequent exposure to room air for 24 or 48 hours. The extent of recovery is dependent upon the duration of both hyperoxic and normoxic exposure. Macrophages that were subjected to intermittent exposure to hyperoxia (2 hours break after 12 hours exposure) exhibited significantly higher phagocytic activity compared to those with continuous 24 hour exposure. Thus, either giving sufficient time to recover or using intermittent hyperoxia can significantly ameliorate the toxic effects of hyperoxia on macrophage function.

Identification of Novel Chemical Inhibitors of Nrf2-ARE Activity and Their Application in Sensitizing Human Acute Monocytic Leukemia Cells to Chemotherapy

H. Peng², P. Xue², Y. Hou², H. Zhang², W. Sun², Y. Dong², Y. Zhou², W. Qin², S. Peng³, B. Nelson², R. A. Clewell³, Q. Zhang², M. E. Andersen², and J. Pi². School of Public Health, China Medical University, Shenyang, Liaoning, China. *The Hammer Institute for Health Sciences, RIT, NC, ‡Academy of Military Medical Sciences, Beijing, China and ÍFudan University, Shanghai, China.

Nuclear factor E2-related factor 2 (Nrf2) is a master regulator of the antioxidant response element (ARE)-dependent transcription and plays a pivotal role in chemical detoxification in both normal and tumor cells. In keeping with previous findings that Nrf2-ARE plays a critical role in chemotherapeutic resistance of cancer cells, stable knockdown of Nrf2 by lentiviral shRNA in human acute monocytic leukemia THP-1 cells resulted in sensitization to cytotoxicity induced by multiple chemotherapeutic agents, including arsenic trioxide (As2O3), etoposide and doxorubicin. We screened a panel of chemicals using a variety of human and mouse cell lines expressing an ARE-luciferase reporter, and found that a group of widely used anti-tubercular drugs, including ethionamide (ETH) and isoniazid (INH), displayed substantial inhibitory property against Nrf2-ARE activity. This inhibitory property was further validated by significant reduction in mRNA expression of multiple ARE-driven genes under basal and oxidative stress conditions. Suppression of Nrf2-ARE by ETH or INH significantly enhanced the sensitivity of THP-1 and several other cancer cells, such as human histioctye lymphoma U937 cells, to As2O3-induced cytotoxicity as determined by cell viability assays, ATP production, cell cycle and apoptosis analysis. In THP-1 cells, the sensitization effect of ETH to As2O3-induced cytotoxicity is Nrf2 dependent, suggesting that Nrf2 is a potential target of the chemotherapeutics. To our knowledge, our study is the first to demonstrate that ETH and INH suppress Nrf2-ARE signaling and disrupt the transcriptional network of the antioxidant response, leading to sensitization of cancer cells to chemotherapeutic agents.

Altered Mitochondrial Bioenergetics in Response to Arsenic Exposure: New Outlook on Arsenic-Induced Toxicity

H. D. Chavan, K. Mickey and P. Krishnamurthy. Pharmacology, Toxicology & Therapeutics, Kansas University Medical Center, Kansas City, KS.

Arsenic is a human carcinogen that is ubiquitously present in the environment. Arsenic mediated toxicity is suggested to be due to the induction of reactive oxygen species. However, the origins of these radicals are not clearly understood. Here we show that arsenic exposure, at environmentally relevant concentrations, uncouples...
oxygen consumption from ATP production in mammalian cells leading to increased electron leakage, decreased ATP production and reduced spare respiratory capacity. Analysis of the mitochondrial respiratory complex provides evidence implicating a dose-dependent deregulation in respiratory complex activity in response to arsenic exposure, suggesting that mitochondrial dysfunction might contribute to arsenic-mediated induction of reactive oxygen species. These data illustrate that mitochondria might be a primary target in arsenic-induced oxidative stress and understanding the mechanism by which arsenic deregulates mitochondrial respiratory complex activity and uncouples oxygen consumption from ATP production might provide an important cellular target in interventional remedy for arsenic-induced toxicity.

1798 Keap1 Redox-Dependent Regulation of Doxorubicin-Induced Oxidative Stress Response in Cardiac Myoblasts

K. B. Wallace and K. K. Nordgren, Biomedical Science, University of Minnesota Medical School, Duluth, MN.

Doxorubicin (DOX) is a widely prescribed treatment for a broad scope of cancers, but clinical utility is limited by the cumulative, dose-dependent cardiomyopathy that occurs with repeated administration. DOX-induced cardiotoxicity is associated with the production of reactive oxygen species (ROS) and oxidation of lipids, DNA, and proteins. A major cellular defense mechanism against such oxidative stress is activation of the Keap1/Nrf2-antioxidant response element (ARE) signaling pathway, which transcriptionally regulates expression of antioxidant genes such as Nq o1 and Gap1. In the present study, we address the hypothesis that an initial event associated with DOX-induced oxidative stress is activation of the Keap1/Nrf2-dependent expression of antioxidant genes and that this is regulated through drug-induced changes in redox status. Keap1 protein incubation of H9c2 rat cardiac myoblasts with DOX resulted in a time- and dose-dependent decrease in non-protein sulphydryl groups. Associated with this was a near 2-fold increase in Nrf2 protein content and enhanced transcription of several of the Nrf2-regulated downstream genes, including Gap1, Ugtal, and Nq o1; the expression of Nf22 (Nrf2) itself was unaltered. Furthermore, both the redox status and the total amount of Keap1 protein were significantly decreased by DOX, with the loss of Keap1 being due to both inhibited gene expression and increased autophagic, but not proteasomal, degradation. These findings identify the Keap1/Nrf2 pathway as a potentially important initial response to acute DOX-induced oxidative injury, with the primary regulatory events being the oxidation and autophagic degradation of the redox sensor Keap1 protein. (Supported-in-part by grants from the 3M Company and Whiteside Institute.)

1799 Retinoic Acid Receptor-Dependent Interactions Contribute to the Selective Cytoprotection Afforded by All-Trans-Retinoic Acid against Renal Injury

J. Sapir, R. T. Miller, R. D. Canatsey, A. B. Romans, T. J. Monks and S. S. Lau, SWEHSC, Pharmacology and Toxicology, University of Arizona, Tucson, AZ.

Chemical-induced nephrotoxicity is a major cause of acute kidney injury. Pretreatment of LLC-PK1 cells with all-trans-retinoic acid (ATRA, 25 μM, 2 hr) affords cytoprotection against chemical nephrotoxicants such as p-aminohippocresol (PAP, 150 μM, 3 hr), iodoacetamide (IDAM, 25 μM, 2 hr) and 2-(glutathionyl-S-v)hydroquinone (MGHQ 300 μM, 2 hr) as assessed by the Neutral Red assay. In contrast, pretreatment of cells with ATRA provides no protection against cisplatin (25 μM, 24 hr) -induced apoptosis, suggesting that ATRA selectively protects against toxicity that induce necrosis and not apoptosis. The biological effects of retinoids are typically mediated through interaction with the nuclear retinoic acid receptors (RAR) and retinoid X receptors (RXR). While western blot analyses of nuclear lysate from LLC-PK1 cells, revealed the presence of both RAR and RXR, ATRA only induced the RAR isoforms. Since ATRA binds to the RAR agonist 4-[(E)-2-(5,6,7,8-tetrahydro-5,5,8,8-tetramethyl-2-naphthalenyl)-1-propenyl]-benzoic acid (TTNPB) (25 μM, 24 hr) protected against PAP (125 μM, 3 hr) and IDAM (20 μM, 2 hr) -induced nephrotoxicity. Pretreatment of LLC-PK1 cells, with the pan-RXR agonist methylclofenamate (25 μM, 24 hr), afforded minor protection against PAP (125 μM, 3 hr) but not IDAM (25 μM, 2 hr). The results are consistent with the view that ATRA-mediated cytoprotection involves interaction with the RAR receptor. During ATRA-mediated cytoprotection, the endoplasmic reticulum chaperone Grp78 is induced in a similar time-dependent manner in LLC-PK1 cells. Thus, ATRA and Grp78 may serve as an effective therapeutic intervention prior to kidney transplantation, which causes ischemic-reperfusion renal injury (ES016578, ES066694, ES007091).

1800 Administration of Sulindac, an NSAID, and Qurectin, an Antioxidant, in Combination Attenuates Bleomycin-Induced Lung Fibrosis in Wistar Rats

R. Verma1, M. V. Patel2, V. J. Piccirillo1, P. Mehta3, D. Gohel2, T. Marvania2 and S. Balakrishnan1, 1VJP Consulting, Inc., Ashburn, VA, 2Department of Toxicology, Jai Research Foundation, Vadodara, Gujarat, India and 3Department of Zoology, The M.S. University of Baroda, Vadodara, Gujarat, India.

Idiopathic pulmonary fibrosis is the most prevalent chronic lung disease. Inflammation and oxidative stress are considered major mechanisms that induce lung tissue inflammation and fibrosis. Studies have suggested that reactive oxygen species such as superoxide anion, hydrogen peroxide and hydroxyl radical are major mediators of lung inflammatory processes. The present study was conducted to evaluate the ameliorative effects of qurectin (a dietary flavonoid having strong antioxidant activity) alone and in combination with sulindac (non-steroidal anti-inflammatory drug) on lung injury induced by bleomycin. Following single intra-tracheal instillation bleomycin rats were treated by oral administration of either qurectin (100 mg/kg/day) or sulindac (20 mg/kg/day) for 20 days reduced the severity of bleomycin induced effects on relative lung weights, lung hydroxyproline contents and plasma TNF-α levels. However, suble effects of toxicity persisted in the qurectin and sulindac treated groups. The combination of qurectin (50 mg/ kg/day) and sulindac (10 mg/kg/day) was more effective in reducing bleomycin induced lung toxicity than the higher doses of each agent separately. Therefore, these results suggest that the concurrent administration of qurectin and sulindac in low doses are synergistic in protection of the lung from oxidative stress induced effects.

1801 Dietary Flavonoid Quercetin Attenuates Bleomycin-Induced Pulmonary Fibrosis in Rats by Improving Lung Antioxidant Status

D. Gohel2, V. J. Piccirillo1, M. V. Patel2, R. Verma1, P. Mehta3, T. Marvania2 and S. Balakrishnan1, 1VJP Consulting, Inc., Ashburn, VA, 2Department of Toxicology, Jai Research Foundation, Vadodara, Gujarat, India and 3Department of Zoology, The M.S. University of Baroda, Vadodara, Gujarat, India.

Lung fibrosis is a frequent side effect of the chemotherapeutic agent bleomycin. Reports suggest that reactive oxygen species may play a key role in the development of lung fibrosis from this agent. The present study examined the protective role, if any, of the dietary flavonoid, quercetin, against bleomycin induced lung fibrosis in rats. Animals were divided into a control group (0.5% carboxymethylcellulose orally for twenty days post sham intra-tracheal instillation of saline on day 0), a bleomycin group (6.5 U/kg body weight via single intra-tracheal instillation on day 0 followed by oral administration of 0.5% carboxymethylcellulose for twenty days) and a bleomycin plus quercetin group (single 6.5 U/kg intra-tracheal bleomycin instillation followed by oral administration of quercetin for twenty days). Our results show that bleomycin administration increased lipid peroxidation resulting in prolonged state of local tissue inflammation characterized by elevated levels of TNF-α even after twenty days of drug treatment. The prolonged oxidative stress resulted in excessive collagen deposition in the peribronchial and perilveolar region of lung culminating in lung fibrosis. Twenty days of quercetin treatment following bleomycin administration stabilized tissue antioxidant capacity at normal levels with recovery from lung inflammatory changes. Trichrome stained lung tissue from the rats receiving repeated doses of this flavonoid revealed only basal levels of collagen deposition as confirmed by normal levels of hydroxyproline. The results of the present study strongly suggest that quercetin may be an effective protective agent against bleomycin induced pulmonary fibrosis.

1802 Nrf2 Activation by the First-in-Class Direct Keap1-Nrf2 Interaction Inhibitor LH601A in Human Kidney Cells

G. Thorne1, X. Wen1, M. S. Joy4, L. Hu1 and L. M. Aleskuncic1, 1Dept of Pharmacy and Health Professions, Elizabeth City State University, Elizabeth City, NC, 2Dept of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ, 3Dept of Medicinal Chemistry, Rutgers University, Piscataway, NJ, 4Dept of Pharmaceutical Sciences, University of Colorado, Aurora, CO and 5Environmental and Occupational Health Sciences Institute, Piscataway, NJ.

Under basal conditions, the antioxidant transcription factor, Nuclear factor (erythroid-derived 2)-like 2 (Nrf2), is bound to the Keap1 (Kelch-like erythroid-cell-derived protein 1) protein and targeted for proteosomal degradation in the cytoplasm. In response to cellular injury or chemical treatment, Nrf2 activates the transcription of antioxidant, cell stress, metabolism and other protective genes and defends against kidney injury. LH601A is a first-in-class direct inhibitor of the Keap1-Nrf2 protein-protein interaction. We hypothesize that LH601A will activate Nrf2 signaling in human cultured kidney cells and protect against chemical-induced kidney
In the present study, we sought to determine whether cells (rodent and human) expressing a TSC signaling node (TSC1, TSC2, and Rheb) localizes to peroxisomal membranes, where we have recently reported that the Tuberous Sclerosis Complex (TSC) signaling node resident at the peroxisome to suppress mTORC1 and induce autophagy/pexophagy, providing a mechanism by which cells can restore peroxisomal homeostasis in response to treatment with PPAR ligands.

1804a Distinct Roles of Basal and Inducible Nrf2-Mediated Antioxidant Response against Cobalt Chloride-Induced Cytotoxicity in Human Keratinocytes
R. Zhao1, L. Wang1, M. Zhang1, S. Jiang1, J. Fu2, J. Chen2, B. Yang3, X. Liang3, D. Guan1 and J. Pi2. 1School of Forensic Medicine, China Medical University, Shenyang, China, 2School of Public Health, China Medical University, Shenyang, China and 3China Medical University, Shenyang, China.

Hypoxia is an important physiological process that is involved in many cutaneous diseases and injuries. Nuclear factor E2-related factor 2 (Nrf2) is a master regulator of the antioxidant response element (ARE)-dependent transcription and plays a pivotal role in chemical detoxification in a variety of cells, including keratinocytes. This study was conducted to illustrate the role of Nrf2-mediated antioxidant response against chemical hypoxia-induced cell injury by cobalt chloride (CoCl2), in human keratinocytes. In HaCaT cells, acute CoCl2 exposure significantly increased the levels of intracellular reactive oxygen species (ROS) and the expression of Nrf2 and multiple ARE-regulated antioxidant genes in concentration- and time-dependent manners, showing that CoCl2 causes oxidative stress in the cells. Selective knockdown (KD) of Nrf2 by lentiviral shRNA dramatically reduced the basal and inducible expression of many antioxidant enzymes and sensitized the cells to acute cytotoxicity of CoCl2. In contrast, pretreatment of HaCaT cells with a well-known Nrf2 activator tert-butylnhydroquinone protected the cells from CoCl2-induced cell injury in a Nrf2-dependent fashion. In addition, silencing of kelch-like ECH-associated protein 1 (Keap1), a Cul3-adapter protein that allows for Nrf2 to be ubiquinated and degraded by the proteasome complex, led to a dramatic resistance to CoCl2-induced cytotoxicity and apoptosis. Interestingly, knockdown of Keap1 markedly enhanced the basal activity of Nrf2, but reduced the induction of ARE-dependent genes by CoCl2, suggesting that basal activity of Nrf2 is more important than inductive expression of ARE-dependent genes in determining cellular sensitivity to the cytotoxicity of CoCl2. Taken together, our studies suggest that basal and inducible Nrf2-mediated antioxidant response may play distinct roles in human keratinocytes against CoCl2-induced cytotoxicity.

1804b A Dilution Effect in the Malondialdehyde Measurement in Serum with High-Performance Liquid Chromatography-Tandem Mass Spectrometry
Q. Wu, L. M. Kamendulis and B. A. Hocevar. Department of Environmental Health, Indiana University School of Public Health, Bloomington, IN.

Oxidative stress is caused by an imbalance between free radicals and antioxidants defenses in the body, which is a prominent feature of many diseases. The overwhelming redox state can lead to damages to biomolecules including proteins, lipids, and DNA. Malondialdehyde (MDA) is one of the major secondary decomposition products of peroxidized polyunsaturated fatty acid and is one of most used biomarkers in oxidative stress studies. We developed and validated a sensitive method for the quantitation of MDA in mouse serum after derivatization with 2,4-dinitrophenylhydrazine (DNPH) by high-performance liquid chromatography with positive electrospray ionization coupled with tandem mass spectrometry (HPLC-ESI-MS/MS). In spite of the promising instrument measurement, a significant sample dilution effect in sample preparation was observed for the quantitative analysis of MDA for the same mouse serum. The measured MDA levels were 74.7, 20.6, and 3.4 μM for 5%, 40%, and 100% of serum samples, respectively. The possible reason for this phenomenon is a better hydrolysis of serum samples in a more diluted serum mixture, which released relatively more low-molecular mass aldehydes and competently derivatized with DNPH in the reaction. A decreased recovery of MDA was also demonstrated for the same serum spiked with acetone, formaldehyde, or 4-hydroxynonenal. Therefore, a cautionary note on sample dilution should be made before any conclusions are drawn for MDA measurements. And other more reliable biomarkers for oxidative stress such as 8-iso-PGF2α are also highly needed for oxidative stress studies.
Oxidative stress has been implicated in the pathogenesis of lung disorders including pulmonary fibrosis. NT2 has a protective role in these disorders via transcriptional induction of cytotoxic protective genes including thioredoxin, and THP-1. Glutathione is the most abundant cellular thiol and is essential in antioxidant defense. Solute carrier family 7 (cationic amino acid transporter, y+ system), member 11 (Slc7a11, xCT) is an NT2 effector, and encodes a cystine/glutamate transporter that mediates entry of cystine into the cell coupling with efflux of glutamate to produce glutathione. We hypothesized that Slc7a11 is important to protection against pulmonary fibrosis. To test this hypothesis, bleomycin (0.5 U/ Kg body weight) or vehicle was instilled in wild-type (WT) and mice with spontaneous mutation in Slc7a11 (C3H/HeSnJ-Slc7a11+/J, Slc7a11+/-). Pulmonary injury responses were determined at 3, 7, 14, and 21 d after treatment. Bleomycin-induced influx of macrophages, neutrophils, eosinophils, monocytes, and lymphocytes in bronchoalveolar lavage fluids (BALF) were significantly higher in Slc7a11+/- mice than in WT mice (5-7 days). Pulmonary hemorrhage and appearance of uncommon inflammatory cells (e.g., atypical lymphocytes, basophils, megakaryocytes) in the BALF were enhanced in Slc7a11+/- than in WT after bleomycin. We found more lymphocytic nodules and diffused fibrotic lesions in Slc7a11+/- mice compared to WT mice 14-21 d post-bleomycin. Concurrently, gene expression and accumulation of lung collagen was significantly higher in Slc7a11+/- than in WT mice. Bleomycin also increased mRNA and protein levels of Slc7a11 in WT mice (3-21 days). Moreover, lung glutathione and its biosynthesis enzyme (glutamate-cysteine ligase) levels were increased post-bleomycin in WT mice while these changes were marginal in Slc7a11+/- mice. Results demonstrated that is Slc7a11 involved in protection against bleomycin-induced lung inflammation and fibrosis in the mouse.

Animal models do not exactly replicate human psychiatric disorders; however, these models have been used to investigate whether the behaviors associated with certain exposures in animals parallel those observed in autism. According to the most current version of the Diagnostic and Statistical Manual of Mental Disorders (DSM-V), autism is diagnosed based on (1) persistent deficits in social communication and social interaction and (2) the presence of restricted, repetitive patterns of behavior, interests and activities. To address whether developmental chlorpyrifos (CYP) exposure was associated with autistic behaviors, a literature search was conducted to identify studies in rats and mice involving gestational or early postnatal exposure to CYP or CYP oxon (the active metabolite) and subsequent behavioral testing to assess social interactions and communication, stereotypic behaviors and other behaviors associated with novelty-seeking/anxiety. A total of 13 studies conducted in 6 different laboratories were identified. Analysis of these studies found that perinatal CYP exposure was generally associated with (1) no effect, increased social communications or conflicting findings in 6 of 7 studies; (2) no effect or increased social encounters in 4 of 4 studies; (3) no effect, reduced stereotypes or conflicting findings related to stereotypic behaviors in 9 of 9 studies; and (4) no effect or increased preference for novelty and reduced anxiety in novel environments in 5 of 7 studies. When a difference from control was observed, it was often in the opposite direction of what one would expect in autism. Based on these results, perinatal CYP exposure is not associated with the development of autism-like behaviors in rats and mice.

BBP is a high-production chemical that is primarily used as a plasticizer in polyvinyl chloride products such as flooring materials. Its urinary monobenzyl phthalate metabolite is detected in biomonitoring studies indicating widespread human exposure. The chemical’s carcinogenicity was reviewed to support a decision by a qualified panel of experts on whether or not it should be added to the Proposition 65 list of chemicals known to the state to cause cancer. OEHHA conducted a search of the scientific literature for information relevant to the carcinogenicity of BBP, up through October 4, 2013. 241 papers were identified, analyzed and summarized, as follows. BBP statistically significant increased the incidence of pancreatic acinar cell tumor, mononuclear cell leukemia, and adrenal medulla tumors in rats. In addition, rare tumors of the urinary bladder transitional epithelium were identified in treated female rats, accompanied by treatment-related increases in hyperplasia. While negative in Salmonella reverse mutation assays, BBP has tested positive in multiple other genotoxicity studies. In vitro findings include DNA base lesions in mouse bone cells, DNA single strand breaks in HepG2 cells and DNA-protein crosslinks (DPC) in rat liver cells. In vivo findings include DPC in mouse liver and sister chromatid exchanges and chromosomal aberrations in mouse bone marrow cells. Microarray and proteomic studies revealed BBP induced expression of several cancer pathway-related genes and proteins (e.g. VEGF, MYC and DEK). In human breast cells (HBC) in vitro and in rat breast cells in vivo, BBP increased markers of cell proliferation, angiogenesis, epithelial-mesenchymal transition, mi-

Formaldehyde is a high production volume chemical with a multitude of industrial uses. Due to its high reactivity, the majority of inhaled formaldehyde is deposited in the upper respiratory tract. Formaldehyde exposure has been reported to cause a number of noncancer health effects, primarily at the portal-of-entry, including sensory irritation, impaired pulmonary function, asthma and immune effects, and respiratory tract pathology. This analysis attempts to cohesively and succinctly describe the mechanistic data related to these effects. Mode-of-action (MOA) data is typically described within a given health domain (e.g., supporting sensory irritation), and is most commonly used to inform biological relevance to humans. By evaluating the plausibility of the evidence, based on the chemical properties of formaldehyde and study design characteristics (e.g., route, duration, and levels of exposure), we identify and describe the potential mechanistic inter-dependencies across health effects. For example, stimulation of sensory nerve endings in the nasal mucosa can elicit an irritant sensation, but this stimulation may also initiate a release of tachykinins, eventually resulting in airway inflammation. Similarly, formaldehyde can initiate mucociliary changes that result in epithelial damage and cell proliferation, leading to lesions in the upper respiratory tract; however, thickened mucus and increased epithelial cell proliferation may also lead to pulmonary dysfunction. Detailing the plausibility of these mechanistic linkages and presenting this information schematically provides continuity and added clarity to MOA descriptions across health domains. This analysis allows for an effective evaluation of the potential biologic mechanisms that are most likely to be operative following formaldehyde exposure. Finally, this presentation facilitates a more integrated discussion of the potential relationship(s) between noncancer health effects and carcinogenicity. Disclaimer: The views expressed are those of the authors and they do not represent U.S. EPA policy or guidance.

1810 Weight-of-Evidence Evaluation of Short-Term Ozone Exposure and Cardiovascular Effects

There is a large body of research on the potential cardiovascular (CV) effects associated with ozone exposure, including epidemiology, toxicology, and controlled human exposure studies. US EPA is reviewing these data in its consideration of a revision to the ozone National Ambient Air Quality Standards (NAAQS). We conducted a weight-of-evidence (WoE) analysis to determine if there is an association between CV effects and short-term ozone exposure at levels below the current primary ozone NAAQS of 75 parts per billion (ppb). We utilized a novel WoE framework based on US EPA’s NAAQS causality framework to critically evaluate and synthesize the relevant epidemiology, controlled human exposure, animal toxicology, and mechanistic data. We concluded that the epidemiology evidence of CV morbidity and mortality is inconsistent and lacks coherence across specific CV endpoints. Specifically, the lack of epidemiology evidence of morbidity effects is not coherent with reported mortality estimates. Toxicology studies, although somewhat more consistent, are of limited relevance because they are conducted at high exposure levels, well above the current NAAQS, and there is insufficient information on dose-response relationships. Furthermore, there is a lack of coherence between reported results from epidemiology studies (suggesting no effects) and results from animal studies (suggesting small effects at high exposure levels). Similarly, controlled human exposure studies report inconsistent effects after exposure to ozone levels above the current NAAQS. Studies that aim to identify potential mechanisms for CV effects of ozone by measuring various CV-related biomarkers also report inconsistent results with uncertain clinical significance, indicating that there is no clear biological mechanism for CV effects from ozone exposure. Overall, our WoE analysis does not support that CV effects are associated with short-term ozone exposure below the current NAAQS.

1811 Do Asbestos-Induced Pleural Plaques Cause Lung Function Deficits?

J. E. Kerper1, H. N. Lynch1, L. C. Mohr2 and J. E. Goodman1. Gravident, Cambridge, MA and Medical University of South Carolina, Charleston, SC.

While there is general agreement that pleural plaques are biomarkers of asbestos exposure, there is debate in the scientific community over whether pleural plaques cause lung function deficits. Many of the studies that addressed this issue were subject to certain limitations. In most studies, pleural plaques were diagnosed by radiography, which is less accurate than high resolution computed tomography (HRCT) and can lead to misdiagnoses. Some studies reported lung function changes in subjects that had lung abnormalities in addition to pleural plaques, so that the contribution of pleural plaques to deficits was unknown. To eliminate these sources of uncertainty, we conducted the first comprehensive analysis of the associations between pleural plaques and lung function based on epidemiology studies in which 1) pleural plaques were diagnosed by HRCT and 2) individuals were identified with pleural plaques and no other lung abnormalities. We identified and analyzed 16 relevant studies. We looked for patterns within and across studies and examined whether associations were reproducible. Only three of the 16 studies reported statistically significant associations between pleural plaques and some measure of lung function. Among these three studies, the lung function parameters were not consistent, suggesting that the associations were not likely causal. In addition, mean asbestos exposures in all three studies were higher in the subjects with pleural plaques than in the subjects without. This suggests that if the effects were not due to chance, the asbestos exposure itself, rather than pleural plaques, may have been responsible for observed lung function deficits. Taken as a whole, the direction of effect (i.e., lung function deficit vs. improvement) varied among studies, indicating the absence of even subtle effects and that the lack of effect noted in the majority of studies was not a result of low statistical power. We conclude that there is no reliable association between the presence of pleural plaques in asbestos-exposed populations and lung function deficits.

1812 Firefighters’ Inhalation Exposures and the Risk of Developing Multiple Myeloma

M. Peterson and P. A. Valberg. Gravident, Seattle, WA.

Firefighters encounter a complex mixture of chemicals under unique exposure conditions. The complexity in evaluating whether these exposures lead to occupational diseases has led states to pass “presumptive causation” legislation, which assume all cancers that occur among firefighters are a result of on-the-job exposures. While such laws may be well intentioned, their scientific basis is dubious at best. Because a meta-analysis of firefighter data suggests these workers have a relative risk of 1.5 for multiple myeloma (MM), a cancer of cells in the hematopoietic system that can affect multiple sites in the body, including the bone, bone marrow, and kidney, we conducted a weight-of-evidence analysis to evaluate whether exposure to airborne chemicals typically identified in firefighting environments could be causally linked to increased MM risks. We examined a variety of factors in exposure, toxicological, and epidemiological studies, including study design, power, corroboration, relevance, and coherence within and among studies. Firefighters may inhale a variety of combustion products (including IARC Group 1 carcinogens) in both acute and more chronic scenarios (e.g., diesel exhaust). We found that for the well-studied IARC Group 1 chemicals, there was insufficient evidence that MM risk was increased with exposure. Many studies have sought to identify MM risk factors, but the results are inconsistent. Reviews and meta-analyses of MM among firefighters have reported modestly increased, but unstable, MM risks. Significant methodological issues cloud the interpretation of these meta-analyses. For example, only a few of the studies reported a statistically significant increase in MM in firefighter populations, and exposure information was often lacking. Because of a lack of concordance among the studies as to exposure and outcome, our evaluation found that airborne occupational exposures in firefighters are not causally associated with an increased risk of MM. Little is known about the etiology of MM, and job-related “presumptive causation” in the case of MM in firefighters is not supported by available scientific evidence.

1813 Toxicological Review of Biocides Used in Hydraulic Fracturing

A. Pawlits and A. L. Lebeau. CRA, Dallas, TX.

The use of hydraulic fracturing to extract gas and oil from shale formations has maintained its exponential growth in US and worldwide. Hydraulic fracturing consists of injecting water, friction reducers, proppants, disinfectants, surfactants, thickeners, scale inhibitors, corrosion inhibitors, and acids to promote flow of hydrocarbons otherwise bound in impermeable matrices. The rapid explosion of

1809 Integrated Mechanistic Evidence on Noncancer, Portal-of-Entry Effects following Formaldehyde Inhalation

While there is general agreement that pleural plaques are biomarkers of asbestos exposure, there is debate in the scientific community over whether pleural plaques cause lung function deficits. Many of the studies that addressed this issue were subject to certain limitations. In most studies, pleural plaques were diagnosed by radiography, which is less accurate than high resolution computed tomography (HRCT) and can lead to misdiagnoses. Some studies reported lung function changes in subjects that had lung abnormalities in addition to pleural plaques, so that the contribution of pleural plaques to deficits was unknown. To eliminate these sources of uncertainty, we conducted the first comprehensive analysis of the associations between pleural plaques and lung function based on epidemiology studies in which 1) pleural plaques were diagnosed by HRCT and 2) individuals were identified with pleural plaques and no other lung abnormalities. We identified and analyzed 16 relevant studies. We looked for patterns within and across studies and examined whether associations were reproducible. Only three of the 16 studies reported statistically significant associations between pleural plaques and some measure of lung function. Among these three studies, the lung function parameters were not consistent, suggesting that the associations were not likely causal. In addition, mean asbestos exposures in all three studies were higher in the subjects with pleural plaques than in the subjects without. This suggests that if the effects were not due to chance, the asbestos exposure itself, rather than pleural plaques, may have been responsible for observed lung function deficits. Taken as a whole, the direction of effect (i.e., lung function deficit vs. improvement) varied among studies, indicating the absence of even subtle effects and that the lack of effect noted in the majority of studies was not a result of low statistical power. We conclude that there is no reliable association between the presence of pleural plaques in asbestos-exposed populations and lung function deficits.
volume and extent of fracking exploration has led to community, regulator, and health practitioner concerns over the potential health effects associated with exposure to fracking fluid constituents. Many of the disclosed ingredients are cited as harmless. However, there are certain chemical groups, such as antimicrobials, that have specific (by design) adverse biological activity. This presentation focuses on the identity and toxicity of fracking fluid constituents listed as having a disinfectant function. The methodology consisted of querying publicly-available databases used by the oil and gas industry to disclose chemical information. Data fields associated with chemical name, CAS number, additive concentration, and fracking fluid concentration were extracted from each disclosed chemical. Next, retrieved chemicals were matched with toxicity data from open literature. The information on the stock as well as the formulated fluid concentrations, in concert with toxicity thresholds, was used to calculate Potential for Exposure Quotients (PEQs) under an accidental release scenario. Results for 2013 show that nearly 100 hydraulic fracture fluid additives are categorized as a biocide or an antimicrobial agent. Some of the more commonly listed disinfectants are glutaraldehyde, naphthalene, ethoxylated nonylphenol, and tetrakis hydroxymethyl-phosphonium sulfate. Aldehydes were found to be the most common (N=1,678) toxic (lowest RfC of 8.0E-05 mg/m³) fluid ingredients with the highest PEQs (average fracking fluid concentration of 2.5%). For the purpose of this presentation, all findings are presented as summary tables for ease of reference and sharing of information.

1814 Acute Effects of Acrrolein in Human Volunteers during Controlled Exposure

Acrrolein (ACR) is a reactive ω,β-unsaturated aldehyde formed by burning wood, plastic, diesel fuel, paraffin wax, smoking and cooking. It is a common constituent of indoor air. There are limited toxicological data available, however, as ACR is highly irritating to the eyes and respiratory tract, irritation is considered to be the critical effect. The aim of the study was to determine thresholds for acute irritation and inflammation for ACR and thus improve the scientific basis for setting exposure limits. Nine healthy volunteers of each sex were exposed at six occasions for 2 h at rest to: clean air, clean air + ethyl acetate (EA), 0.05 ppm ACR, 0.05 ppm ACR + 15 ppm EA, 0.1 ppm ACR, and 0.1 ppm ACR + 15 ppm EA. The exposure conditions were carried out in a balanced order and were blinded to the volunteers. Symptoms were extracted for each disclosed biocide. Next, retrieved records were rated on Visual Analogue Scales. EA was used to mask the potential influence of odor on the symptom ratings. The ratings of eye irritation increased during exposure to ACR in a dose dependent manner (median values 0 mm, 1.5 mm and 8 mm for control, 0.05 ppm and 0.1 ppm of ACR respectively, p < 0.001, Friedman test) with no influence by co-exposure to EA. No significant exposure related effects on pulmonary function or nasal swelling were found. Furthermore, no effects were seen on markers of inflammation and coagulation in blood (C-reactive protein, IL-6, serum amyloid A, fibrinogen factor VIII, von Willebrand factor and Clara cell protein) and induced spumon (cell count, differential cell count, IL-6 and IL-8). Blink frequency, recorded by electromyography, showed a dose-dependent increase (p=0.049) for exposure to ACR alone. However, this effect was not seen for combined exposure to ACR and EA. In conclusion, our study suggests that short-term exposure to 0.1 ppm ACR is mildly irritating to the eyes.

1815 At the Intersection of Occupational Toxicology and Product Quality: Harmonization of Risk-Based Values in the Pharmaceutical Sector
P. Weideman1, A. Majer1, A. Willis1, S. Sandhu1 and S. Gomez1, 1Safety Assessment, Genentech, Inc., South San Francisco, CA, 2Dept. of Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH and 3Toxicology Excellence for Risk Assessment, Cincinnati, OH.

Decisions based on health risk assessment are an integral part of pharmaceutical manufacturing. Occupational exposure limits (OELs) are a key tool for protection of workers. Acceptable daily exposures (ADEs) address residual carryover of active ingredients, as well as impurities. OELs and ADEs share a common risk method (e.g., OELs vs. ADEs). The result is improved consistency in risk values in traditional occupational risk assessments that should be considered for more rigorous CRA. Overall, we found that the absence of a decision support tool yielded inconsistent consideration of CRA in occupational assessments. The evaluation also provided insights on data gaps that preclude conduction of high confidence CRAs for current occupational scenarios. Despite these gaps we demonstrated how a systematic decision tool can serve as a pragmatic solution for improving consistency in conducting occupational CRAs.

1816 Cumulative Risks in Occupational Settings: A Checklist Tool to Support Decision Making
R. C. Lee1, P. Nance2, A. Lamb1 and A. Majer1, 1Neptune and Company, Inc., Albuquerque, NM, 2Toxicology Excellence for Risk Assessment, Cincinnati, OH, 3US Environmental Protection Agency, Washington, DC and 4University of Cincinnati, Cincinnati, OH.

Cumulative risk assessments (CRAs) evaluate the likelihood of adverse health effects resulting from all routes of exposure to multiple stressors. Applicable attention has focused on improving risk science methods in this area. For example, approaches have been published for addressing environmental exposures to mixtures of chemicals with a unifying mode of action or for assessing community level health impacts arising from diverse exposures. However, guidance for conducting CRAs for occupational scenarios is lacking. To address this gap, we conducted a critical analysis of current CRA frameworks to identify a set of techniques suitable for translation to occupational risk assessment. Consistent with elements of existing methods, we developed a refined CRA checklist tool with several features customized for consideration of the occupational environment. Key elements include provisions for incorporating exposures by oral, inhalation and dermal routes (reflecting occupational plus non-occupational exposures); specific guidance for chemical stressors with a process for modifying the CRA based on presence of multiple stressors; and, a tiered risk system to select assessment needs and provide flexibility in applying any of several alternative validated models. The CRA checklist tool was also applied to published occupational exposure scenarios to identify areas in traditional occupational risk assessments that should be considered for more rigorous CRA. Overall, we found that the absence of a decision support tool yielded inconsistent consideration of CRA in occupational assessments. The evaluation also provided insights on data gaps that preclude conduction of high confidence CRAs for current occupational scenarios. Despite these gaps we demonstrated how a systematic decision tool can serve as a pragmatic solution for improving consistency in conducting occupational CRAs.

1817 Improper Use of Haber’s Law Results in Erroneous Fatality Estimation from Predictive Models
H. Salem1, 2, J. Moyer2, 3 and D. R. Sommerville1, 1U.S. Army Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD, 2Chemical Security Analysis Center, Department of Homeland Security, Compounder (APG-EA), MD and 3Ballute Memorial Institute, Columbus, OH.

There are two common measures for inhalation exposure to a vapor/gas toxicant: the dosage (defined as the product of concentration and time [Ct]) and the toxic load (defined as Cnt, with n being the toxic load exponent). The historical and most-often used estimator is Ct (Haber’s Law) which was developed in the early 1920s. However, it was soon determined that Ct was inadequate to account for changes in toxicity as a function of exposure duration. Thus, the toxic load was introduced (and subsequently popularized in the 1980s) as an empirical solution to the shortcomings of the Ct measure. The differences in lethality predictions between dosage and toxic load approaches were investigated via simulation for a target population of rats exposed to sarin. An n of 1.6 was used for the toxic load based on the rat study of Mioduszewski et al. (2002). The Haber (n = 1) and toxic load models were compared by modeling release of sarin from a fixed point over a spatially uniform population of rats in three different scenarios. In all three scenarios, the Haber model gave slight underestimates of fatalities until approximately 3-5 minutes following release, after which fatality estimates were at least 125% higher than those of the toxic load model. This demonstrates that unequal exposure over time within a population affects differences in fatality estimation between Haber and toxic load models. When n does not equal one, fatalities are erroneously estimated when using Haber’s Law because time is unrealistically weighted against concentration. For chemicals with n greater than one, the Haber model can overestimate fatalities at low concentrations or long durations and underestimate fatalities at high concentrations or low durations. This relationship reverses for those chemicals with n less than one.
1818  Impact of Nonconstant Concentration Exposure on Lethality of Inhaled Hydrogen Cyanide in the Rat: A Case Study for Assessing the Validity of Toxic Load Models

I. M. Sweeney1, D. R. Sommerville2, S. B. Channel4, N. M. Gargas2 and R. C. Shatzki2.

1NAAMRU Dayton, Henry M. Jackson Foundation, WPAFB, OH, 2NAAMRU Dayton, CAMRIS, WPAFB, OH, 3Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD and 4Leidos, Linton, IN.

The toxic load model (TLM) is an empirical approach in hazard assessment modeling for estimating the relationship between the inhalation toxicity of a chemical and the exposure duration. The toxic load (TLM) is normally expressed as a function of vapor concentration (C) and duration (t), with TLM equaling C x t being a typical form. Hypothetically, any combination of concentration and time that yields the same "toxic load" (cumulative exposure) will give a constant biological response. These formulas have been developed and tested using controlled, constant concentration animal studies, but the validity of applying these assumptions to time varying concentration profiles has not been tested. Experiments were designed to test the validity of the TLM under conditions of non-constant acute exposure. Male Sprague-Dawley rats inhale constant or pulsed concentrations of hydrogen cyanide (HCN) generated in a nose-only exposure system for 5, 15, or 30 minutes. The observed lethality of HCN for the 11 different C vs. t profiles was used to evaluate the ability of the TLM to adequately describe the lethality of HCN under the conditions of non-constant inhalation exposure. The TLM was found to be applicable under the tested conditions, with the exception of the median lethality of very brief, high concentration, discontinuous exposures.

1819  A Framework for Risk Assessment for Less-Than-Chronic and Intermittent Exposures to Chemicals (Noncancer Endpoints)

L. T. Haber1, B. Meek3, A. Li-Muller2, M. Yole3, A. K. Mohapatra2 and S. Petrovic3.

1Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH, 2University of Ottawa, Ottawa, ON, Canada and 3Health Canada, Ottawa, ON, Canada.

Exposure to chemicals at contaminated sites, whether single, repeated or intermittent, may last for shorter periods of time than those upon which most guidance values are normally based. Because it is presently not feasible to conduct toxicity studies or develop Toxicity Reference Values (TRVs) specific to each scenario of interest, methods are needed to address this variety of scenarios, drawing as much as possible on existing guidance values. A working framework was developed to address non-cancer effects resulting from short-term and intermittent exposures to chemicals. The framework identifies key parameters relevant to the implications of duration and intermittency of exposure, and provides an integrated, tiered approach for applying increasing levels of toxicological understanding and expertise to exposure scenarios of interest, including consideration of both toxicokinetic (half-life) and toxicodynamic (persistence of effect) implications of intermittent exposures. It incorporates the use of TRVs based on exposure periods as similar as possible to the actual exposure periods and the use of dose averaging under limited, specified conditions. Key data and information sources supporting consideration of less-than-chronic exposures are also documented, including (1) references for a broad range of TRVs for less-than-chronic exposures from a variety of organizations, criteria for selection, and a description of their bases and applicability; (2) grouping of chemicals based on their half-lives and appropriate reference data sources, and (3) grouping of chemicals based on persistence of their effects. This framework will aid in improving the scientific basis for the evaluation of less-than-chronic and intermittent exposures in a variety of settings.

1820  Use of a Single-Pass, Nose-Only Exposure System to Simulate High Altitudes

The military has experienced a number of known or suspected hypoxia-related in-flight events in its pilots of high performance aircraft. Some contaminants, identified in breathing air supplied to pilots, are being investigated as a possible link to the hypoxia-related events. In order to evaluate possible hypoxia-related hypotheses in an animal model, a nose-only exposure system was adapted to expose rats to controlled levels of toluene under low pressure (high altitude) conditions. A 52-position nose-only exposure system (Lab Products, Seaford, DE) with closed animal compartments was used to demonstrate the capability for an air flow of 5.0 L/min while adjusting exhaust flow to maintain an internal pressure to simulate altitudes of 10,000 or 20,000 feet above sea level. Toluene was mixed into the test atmosphere using either a gas cylinder containing a toluene-air mixture, or toluene vapor from a pressure vessel and maintained at 100 or 200 ppm in the test atmosphere. Oxygen was incorporated into the inlet stream at the higher altitude settings to maintain a partial pressure approximately equivalent to ambient. Portable port valves were used to allow rat exposures to be staggered under simulated high altitude conditions for pharmacokinetic studies. An initial study was conducted in which adult male and female S-D rats were exposed to 200 ppm toluene for 1 hr using the single pass, nose-only exposure system at simulated altitudes of 940 (ambient), 10,000 or 20,000 feet above sea level. The post-toluene tissue uptake results are presented in a separate poster by Mahle et al. 2014.

1821  Comparison of Liver Toxicity Potencies of Three Dinitrotoluene Compounds

Z. Yan1 and J. Zhao2.

1NCEA/ORD, US Environmental Protection Agency, Washington, DC and 2National Center for Environmental Assessment, US EPA, Cincinnati, OH.

Dinitrotoluenes (DNTs) and chlorinated dibenzo-p-dioxins (PCDDs) are among the most toxic compounds. Exposures to these contaminants are widespread and can result in adverse health effects. Several studies have reported that the degree of liver toxicity of DNTs is dependent upon the isomer of the DNT. In order to understand the potential health effects associated with DNT exposure, a study was performed to compare the liver toxicity potencies of the three major isomers of DNT, 2,4-, 2,6- and 2,4,6-DNT. Potential points of departure for liver effects were identified and used to compare their toxicity potencies. We then examined the potential mechanisms that could account for the differences in hepatotoxicity. Our results indicated that similar pathologic liver lesions were induced after chronic-duration exposure to the three DNTs and their progression can be summarized in four stages: liver degenerative effects and/or cell death, hyperplastic/regenerative effects, neoplastic nodules, and hepatocellular carcinoma. Based on available biotransformation, toxicogenomic and genotoxicity information, imbalanced detoxification due to covalent binding with proteins and DNA, production of reactive oxygen species, and inhibition of oxygen supply may all contribute to DNT-induced non-cancer liver toxicity and carcinogenesis. While their potencies of noncancer liver toxicity are not significantly different, 2,6-DNT is the most potent liver carcinogen followed by 2,4-DNT; 2,4,6-DNT is the least potent. The differences of liver cancer potencies are consistent with their potencies of DNT-induced hepatocyte genotoxicity. The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. Environmental Protection Agency.

1822  Methymercury Inhibition of Serum Paraoxonase 1 Activity and the Risk of Cardiovascular Disease

B. R. Sonawane1, R. Nath1, P. Lewandowski2 and G. L. Ginsberg1.

1NCEA/ORD, US Environmental Protection Agency, Washington, DC, 2School of Medicine, Duke University, Geelong, VIC, Australia and 3Connecticut Department of Public Health, Hartford, CT.

Paraoxonase-1 (PON1) is an antioxidant enzyme present on high density lipoproteins and is known to be protective against atherosclerosis. PON1 has become a useful disease biomarker since low serum activity of this enzyme is associated with increased cardiovascular risk. PON1 also catalyzes the detoxification of organophosphates. Therefore, serum PON1 is essential for the prevention of two distinct adverse outcomes. The single sulfhydryl moiety on PON1 is believed to be the molecular target. Epidemiological and in vitro studies show that exposure to methyl mercury has been associated with a decline in PON1 activity. Based upon data from a native fish-eating population, methyl mercury exposure in the 0.1 to 0.3 μg/kg/day range is associated with substantial loss of serum PON1 activity. Using these data, we explored PON1 as a potential disease biomarker to estimate the cardiovascular risk from methyl mercury ingestion in the general population. The simulated shift in the population distribution of PON1 towards lower levels increases the percent of the population at risk for acute cardiovascular outcomes. This approach of evaluating mercury toxicity follows recommendations made in the National Academy of Sciences report “Science and Decisions” to explore the interaction between chemical toxicity and background disease. This example points out the emerging importance of disease biomarkers in chemical risk evaluation.

SOT 2014 Annual Meeting 477
currently, sustainable food production, including alternative protein sources, is receiving much attention and exploration of these sources is widely supported by international organizations. these alternative proteins sources should have the lowest allergy risk possible. until now, accurate pre-marketing assessment of the allergenicity of new proteins is impossible. moreover, existing guidance documents are restricted to qualitative, assessment, low predictive value and result often in an oversimplification in terms of hazard assessment. to overcome those limitations, we developed a two-dimensional scale for expressing allergenicity that allows a quantitative hazard characterization of new proteins. the two dimensions of the scale were defined as 1) the prevalence expressed as the percentage of the general population that has the allergy and 2) the potency of the protein expressed as the ed50 in mg-protein of the allergen (the dose that provokes objective allergic responses in 50% of the allergic persons). in terms of hazard characterization, severity of symptoms was not included, since this is a result of the nature of the exposure and the potency of the individual rather than an inherent and independent attribute of the allergen.

the scale was developed by ranking 11 allergenic products based on potency data from individual food challenges and 22 scientific papers on prevalence, selected after a critical review. the resulting 2-dimensional scale can be used to project a new protein on the scale and assess its potential hazard relative to the known allergens. in a next step, we aim to develop a model that predicts the position of a new protein on the scale using its physical, chemical and biological characteristics.

1823 determination of the relative allergenicity of food products for quantitative hazard assessment

1imperial college london, london, united kingdom; 2syngenta ltd., greensboro, nc; 3exxonmobil biomedical sciences, inc., annandale, nj; 4university of nebraska medical center, omaha, ne; 5national institute of child health and human development, Bethesda, md; 6uk chemicals regulation directorate, york, united kingdom; 7parker doe partnership llp, cheshire, united kingdom; 8ilsi health and environmental sciences institute, washington, dc; 9university of milan, milan, Italy and 10the dow chemical company, midland, MI.

the ilsi health and environmental sciences institute (HESi) risk assessment in the 21st century (RISK21) project was initiated to develop a scientific, transparent, and efficient approach to the evolving world of human health risk assessment. RISK21 developed a framework that reconsidered in the way chemical risk assessment information is obtained and used. it is a problem formulation-based, exposure driven, tiered data acquisition approach that allows an informed decision on human health safety to be made when sufficient evidence is available. this consistent approach maximizes the ability to inform decisions and optimize resource usage. two case studies were developed to illustrate these principles. the first example identified testing needs for a new mhb in class pesticide to be used in mosquito netting, and illustrated how existing information from other pesticides in the same chemical class and knowledge of use patterns can inform data needs and decision making. the second example evaluated a large number of chemicals which might be present in drinking water, to prioritize which are of highest potential concern for human health risk assessment. both case studies also identified key issues and possible approaches to address cumulative risk. the overall goal of these examples was not to make definitive risk assessment determinations but to establish the utility of the RISK21 framework in assessing the value of available information and making decisions about what, if any, additional information is needed to inform a decision.

1825 poor pregnancy outcome and small for gestational age associated with blood cadmium among mothers in Malaysia

M. Iaaf6, r. sarimina, a. ismaila and N. Ashikina. a. department of community health, national university of malayla, cheran, Kuala Lumpur, Malaysia and b. toxicology and pharmacology unit, institute of medical research, Kuala Lumpur, Malaysia.

Cadmium is a known heavy metal that contaminate environment and causes health problems like Iiai-Iiai disease. However, not many studies have been carried out to determine its pregnancy outcome. this cross-sectional study was conducted among pregnant mothers in the state of Selangor, Malaysia. the objectives were to determine blood cadmium concentrations and its impact on the pregnancy outcome. a total of 280 third trimester pregnant mothers were involved in the study using a universal sampling method at selected health clinics from July to September 2007. a face to face interview using structured questionnaires was used. pregnancy and delivery history were obtained from the antenatal record book. blood samples were analysed for cadmium using gfaas at 1MR laboratory. mean of blood cadmium concentration was 1.47g/11g/ml with minimum and maximum value of 0.12g/11g/ml and 2.86g/11g/ml, respectively. mean age of respondents was 28.3±4.4 year-old. the factors that significantly associated with blood cadmium concentration were household income per month (p<0.05), spouse type of work (p<0.05), and current haemoglobin level (p<0.05). Using the multivariate analysis, haemoglobin level was significantly associated with blood cadmium (adjusted R2 = 0.152; p<0.01). Every incremental of 1g/dl of haemoglobin will reduce 0.13g/l of blood cadmium level. the study also revealed an association between higher blood cadmium mothers with poor pregnancy outcomes (p<0.01) and small for gestational age (SGA) (p<0.01). even though the mean blood cadmium level in the study population was low compared to the reference value (10g/11g/ml), it showed that the environmental exposure to cadmium is real among pregnant mothers in this country. Proper education of public about the importance of avoiding exposure and emphasis on having an effective environmental management in maintaining a cadmium-free condition wherever possible are the ultimate aims of minimizing health impacts.

1826 lung overload: conclusions of an ECETOC task force

chronic exposures to high concentrations of poorly soluble, low toxicity particles (PSP) cause various toxicological effects in the lung. Lung overload is typified by impairment in alveolar macrophage (AM) mediated particle clearance and loss of AM mobility, suggesting a threshold mediated mode of action. the task force examined the current scientific understanding of the ‘lung overload’ hypothesis and concludes: 1) inhalation exposure to high concentrations of PSP, irrespective of particle size, are eliciting comparable localized pulmonary toxicity via processes that are pro-inflammatory in nature, causing oxidative stress and an persistent pulmonary inflammatory response 2) the mechanisms of the described effects are clearly threshold related 3) adverse outcome pathway is largely common within all species and is applicable for nano and microscale particles 4) rats are the most sensitive species with regard to non-neoplastic and unique for neoplastic responses 5) epidemiological studies have not been able to detect an association between occupational exposures to PSP and an increased risk for lung cancer 6) differences of particle retention, distribution, clearance patterns and defense systems in the lungs of exposed rats vs. primates or humans, may account for both the greater sensitivity in rats and corresponding differences in pulmonary pathological responses to long-term particle exposures 7) differences in the biosolubility of deposited particles may accelerate or slow down the process of lung overload development

the derivation of health based Occupational Exposure Limits, a Derived No Effect Level, for PSP is justified. Because rats are more sensitive than humans and based on comparable biokinetics, an overall assessment factor of 1 for intra- and inter-species differences is sufficient. DNELs based on NOAELs/NOAECs from animal inhalation studies, adjusted for human equivalent concentrations by appropriate dosimetry modeling, is recommended.
1827 A Decision Tree to Optimize Literature Identification for Pharmaceutical Risk Assessment

D. Lee1, B. K. Gadagbui1, J. F. Reichard1, A. Willis2, A. Maier1 and R. Sandhu1. 1Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH and 2National Institute of Environmental Health Sciences, NIH, Research Triangle Park, NC.

Risk assessment needs are complex for pharmaceuticals, including occupational health, patient safety, product quality and environmental impact. Assessments cover a range of substances including actives, intermediates, process reagents, excipients, degraders, contaminants and leachates. Optimizing literature identification ensures that key information is not missed and that time is not spent on unproductive database searches. Because of the diversity of scenarios and substances involved, a one-size-fits-all approach to literature identification is not efficient. We developed a decision tree for literature identification for pharmaceutical risk assessment. The decision tree starts with the identification of integrated scientific reviews or external risk assessments followed by a binning strategy depending on the use or type of substance (e.g., active, food contact material, excipient, industrial chemical, endogenous substance). Criteria used for prioritization of search sites and databases within a bin included update frequency, level of peer review, completeness of data presentation, breadth of coverage for substances of interest, ease of data access, and level of regulatory recognition. If the literature does not identify sufficient high quality data, the focus shifts to a targeted determination of tools for addressing data gaps (e.g., in silico methods and the threshold of toxicological concern). This decision tree was tested on different types of substances and reduced the overall time spent in conducting the risk assessment. The difference between fee-based pharmaceutical literature resources was also compared to freely available resources using the decision tree, and the biggest impact of the paid resources appeared to be in the reduction in time needed to sort through data from multiple sources. The decision-tree approach is an important problem formulation tool ensuring that resources used are well aligned with the intended use of the risk assessment.

1828 Use of Cluster Groups in Systematic Review of Literature

Systematic review of the literature for risk assessment purposes can result in >10,000 references, which can be time and cost intensive to review in a traditional linear manner. Commercially available, visual analytics software enables clustering of similar references based on automated text analysis. References are clustered around key concepts that distinguish papers from the full set of results and can be prioritized for review by concept. We tested the efficacy of prioritizing references for review with this software using results from a comprehensive search of CVL literature. Our initial search strategy resulted in approximately 9,000 references. We eliminated approximately 3,500 references electronically using additional key word searches and identified a batch of over 300 highly relevant ’seed’ references. The remaining references along with seeds were clustered and about 1,600 references were found in clusters containing at least one seed reference. This group of references was prioritized for review and evaluated by multiple screeners. The remaining references underwent a traditional title and abstract review by a single subject matter expert. Ultimately, we found approximately 85% of the relevant animal and 70% of the relevant human hazard identification studies in the health effects cluster. Depending on the circumstances and size of clusters, references in clusters not identified as relevant can be handled in several ways: discard without review (not recommended), apply additional key word searches to prioritize further, or screen by a single (rather than multiple) reviewer. Based on our results, clustering references is an effective way to streamline review of large literature datasets as the bulk of the relevant literature was found within the health effects cluster. We conclude that clustering approaches have promise, but must be carefully tailored to individual needs. Additional comparisons of this type are warranted. The views expressed are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.

1829 Evaluating Study Quality: A Comparison of the TOXR Tool and OHAT Approaches

R. Blain1, A. S. Bale2, A. L. Boyles2, A. A. Rooney1, D. Segal2, C. Skuce1 and M. Selgrade1. 1ICF International, Durham, NC, 2EPA, Office of Research and Development, NCEA, Washington, DC and 3NTP, National Institute of Environmental Health Sciences, Durham, NC.

Standardization and documentation of criteria used to evaluate the quality of studies used in risk assessment is a recognized need in the environmental health sciences. The NTP Office of Health Assessment and Translation (OHAT) developed a method of evaluating animal and human studies for risk of bias based on criteria used in systematic reviews. The European Commission developed the ToxR tool to assess the reliability of toxicological data from in vitro and in vivo studies. Both methods are intended to evaluate studies in a systematic and transparent manner, but the approaches differ. The ToxR tool applies points based on a yes/no to a series of questions that leads to the assignment of Klimisch categories ranging from insufficient documentation to reliable without restrictions. The OHAT approach also has a series of questions with project-specific criteria for 4 possible ratings reflecting the potential for bias in the study, but no overall score is assigned. Seven reviewers independently used the OHAT method to evaluate 11 in vivo animal studies and 7 in vitro skin permeation studies previously evaluated using the ToxR tool. The purpose was to evaluate the OHAT tool for consistency among different reviewers and compare and contrast the strengths and weaknesses of the two tools. For both methods, we found that some questions were too vague, resulting in different interpretations. For the OHAT method, this could be due to our failure to tailor criteria rating for this specific project as required. The ToxR Tool would also benefit from such tailoring. With both tools, high quality studies generally had the most similarity between the reviewers, while lower quality studies varied. Strengths and weaknesses were noted for both tools and opportunities for each to incorporate changes were suggested by the current comparison. This abstract does not reflect EPA policy.

1830 Systematic Evaluation of Inhalation Studies for Exposure Quality: A Case Study with Formaldehyde

Misusing can occur by any route of exposure, but it is a particular challenge for inhalation studies because of the inherent complexity of generating and characterizing consistent test atmospheres. There is an expectation that human and animal test subjects in a chamber study will be exposed under conditions that are carefully regulated, frequently measured, and clearly reported. Poor study design, human error, and problems with mechanical and electronic equipment can impair an inhalation exposure and undermine the validity of a study. A systematic approach to evaluating studies, when selecting inhalation studies for a chemical assessment, involves a toxicologist familiar with chamber operations evaluating each study for seven key elements of exposure quality: 1) test article characterization, 2) generation method, 3) analytical method, 4) analytical concentrations, 5) particle size characteristics, 6) chamber type, and 7) controls. Any deficiencies are recorded in a table and the study is ranked for its exposure quality and documentation. These rankings may determine whether a study is considered for hazard evaluation and/or dose-response analysis. The exposure quality evaluation of approximately 200 formaldehyde chamber studies is presented as an example. Nearly half of these studies are considered inadequate for hazard evaluation and/or dose-response analysis.

The views expressed are those of the authors, and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.

1831 Development of a Database Tool to Track the Study Selection Process for Hazard Identification: Naphthalene Case Study

C. Keshava1, K. Zaccaria1, P. McClure1, J. A. Stickney1 and W. A. Chiu2. 1SRC, Inc., East Syracuse, NY and 2National Center for Environmental Assessment, US EPA, Washington, DC.

When developing a systematic review process for identifying relevant health effects literature for evaluation of chemical health hazards, transparency in the study selection process is imperative. Using naphthalene as a case study, a database tool was developed to organize and summarize the toxicological literature for this chemical and to communicate evaluation and selection of studies for hazard identification. The moderately-sized database for naphthalene consists of human case reports and epidemiology studies; chronic, subchronic, and acute animal toxicity studies; and mechanistic and genotoxicity studies. The database tool tracks study selection, evidence table and exposure-response array development, and quality-control review processes. Major features of the database tool are: 1) inclusion of all human and animal toxicity studies selected for full-text review from the systematic literature search, with brief study details and identification of all endpoints evaluated; 2) rationale for inclusion/exclusion of the study in evidence tables/exposure-response arrays; and 3) identification of endpoints with statistically significant findings. This case study of naphthalene demonstrates a database tool that organizes and tracks hazard identification activities, identifies potential data gaps, and reduces potential study-selection bias by transparently presenting pertinent information for all.
potentially relevant studies. Additionally, this database tool effectively conveys the database’s size and coverage of endpoints while communicating study-specific decisions in the hazard identification process.

1831a Scientists’ Attitudes toward Regulatory Risk Assessment

S. Lichter and J. M. DeSesso. 1Exponent, Alexandria, VA; 2George Mason University, Arlington, VA.

Public debate over the scientific quality and accuracy of chemical risk assessments developed by federal programs is growing. This debate can be informed by accurate knowledge of expert opinion on these issues. Therefore, we conducted a survey on regulatory risk assessment (RRA) among scientists with knowledge and experience in this field. Members of Risk Assessment Specialty Section of SOT; Dose Response Section of the Society for Risk Analysis, and International Society for Regulatory Toxicology and Pharmacology were surveyed in February 2013 about problem formulation and analysis plans, the acquisition and evaluation of data, weight of evidence methodology, peer review, and the use of scientific risk evaluation in risk management decisions.

The 186 respondents largely agreed on proper procedures for conducting RRAs while disagreeing on whether these procedures are properly implemented in practice. Thus, 68% regard problem formulations and analysis plans as very important, but only 30% say they are usually conducted. Similarly, 69% find it very important for assessors to have access to raw data of critical studies, but 31% say it is usually made available. Over 90% emphasize the use of clear criteria for selecting and evaluating studies, but only 24% report that standardized protocols are usually implemented. Most (82%) believe the same evaluation criteria should be used for evaluating all studies regardless of their institutional origin. Eighty-nine percent believe weight of evidence methodology should be used but only 45% say WOE methods are usually applied, and 24% describe its use as consistent or transparent. Only 41% think risk management decisions are based on current knowledge of biology and toxicology. Finally, they believe risk managers give too much weight to politics, the media, and environmental groups, and too little weight to scientific factors and economic costs and benefits. These results suggest that scientific concerns need to be addressed by federal officials in order to improve the use of risk assessments in the regulatory process.

1831b US EPA’s Framework for Human Health Risk Assessment to Inform Decision Making

The Framework for Human Health Risk Assessment to Inform Decision Making was developed by EPA’s Risk Assessment Forum to be responsive to the decision making needs of the Agency. It addresses the recommendations presented in the National Research Council’s (NRC’s) Science and Decisions (2009) on the design of risk assessments, including planning, scoping, and problem formulation. The Agency’s Risk Assessment Forum held broad-based internal discussions prior to assembling a Technical Panel of senior risk assessors and risk managers from across the Agency to develop the Framework. Prior to releasing the final Framework, the Framework received extensive Agency review along with inter-agency and external peer reviews. In developing the final Framework the input from the review process along those received from the public were considered. In addition to the focus on planning, scoping and problem formulation, the Framework presents the concept of risk assessment that are “fit for purpose” and details that this is accomplished with an increased dialogue between risk assessors and risk managers to ensure that the risk assessment will inform the risk management options. The problem formulation phase described in the Framework emphasizes the development of a conceptual model that follows the source to outcome continuum for the risk assessment as a key input into the development of the analysis plan. In accordance with longstanding agency policy, it also emphasizes the importance of scientific review and public, stakeholder and community involvement and links the reader to agency resources on these topics. This Framework will be instrumental in facilitating the implementation of existing and future EPA guidance for conducting human health risk assessments and in improving the utility of risk assessments that inform risk management decision-making processes. This presentation will discuss details of the Framework and associated implementation plans by the Agency.

1831c When Does Exogenous Exposure to Endogenously Produced Chemicals and Essential Elements Become a Problem?

The U.S. Environmental Protection Agency’s (EPA’s) National Center for Environmental Assessment (NCEA) evaluates hazard and dose–response relationships for certain substances found in the environment in order to support EPA’s risk assessment and risk management activities. Although chemical pollution is commonly considered to result from the release of anthropogenic contaminants to the environment, a number of these “contaminants” are produced either endogenously in healthy organisms or are required for normal metabolism. Some chemicals on EPA’s chemical priority list (e.g., HAPs, CCL, NAAQS), in addition to arising from human economic activities, are also produced endogenously in mammalian cells (e.g., methanol, formaldehyde, CO) or are essential elements (e.g., Zn, Mn, Cu). Chemicals that are endogenously produced or that are required for normal metabolism present unique challenges in evaluating hazards from their exogenous exposure. For instance, is there some level of change above normal internal concentrations that is needed to induce adverse effects? Are natural levels of endogenous chemicals harmless? How do exogenous exposures impact endogenous chemical levels? The purpose of this presentation is to articulate issues to consider in characterizing the toxicity of exogenous exposure to endogenous chemicals. To build more common understanding and consider issues specific to endogenous chemical health assessment, NCEA will be hosting a public workshop in 2014 on this evolving area of science. Disclaimer: The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the EPA.

1831d Environmental Epigenetics: Potential Application in Human Health Risk Assessment

Although previous studies have shown a significant involvement of epigenetic dys-regulation in human diseases, the applicability of epigenetic data in the current human health risk assessment paradigm is unclear. The goals of this study are to compare the relative sensitivities of epigenetic alterations (DNA methylation) with tumor incidence data and to explore the possibility of incorporating epigenetic data into the hazard identification step of human health assessments. DNA methylation alterations and tumor incidences in laboratory animal studies were analyzed from various toxicological databases for the following chemicals: di(2-ethylhexyl) phthalate, bromodichloromethane, dibromochloromethane, chloroform, hydrazine, trichloroethylene, benzidine, and trichloroacetic acid. All analyses involved conversion of animal doses to human equivalent doses. Benchmark dose values for tumour incidences were compared to no-observed-adverse-effect levels (NOAELs) for DNA methylation changes. In the absence of a NOAEL, a 10-fold uncertainty factor was applied to the lowest-observed-adverse-effect level (LOAEL) to approximate a NOAEL. This analysis revealed that DNA methylation is 1.2- to 25-fold more sensitive than the corresponding tumor incidence for all chemicals, except for trichloroacetic acid, where there is no difference in sensitivity. The predominant DNA methylation alteration was hypomethylation of either whole DNA or the promoter region of various oncogenes, and the exposure duration of epigenetic studies was shorter compared to a 2-year carcinogenicity study. This study shows that DNA methylation changes are more sensitive than tumor incidences and could potentially be considered as an alternative point of departure in human health assessments of suspected carcinogens. However, more research is needed to ascertain how epigenetic data can be applied in human health risk assessment. (The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA)

1831e New Concepts for Risk and Safety Assessment of Plant Food Supplements (PFS)

S. van den Berg and J. Rijers. Toxicology, Wageningen University, Wageningen, Netherlands.

To adequately support the safe use of plant food supplements (PFS), uniform and well accepted procedures for risk and safety assessment are essential. While many consumers equal ‘natural’ with ‘safe’, PFS may contain compounds that are of concern for human health. A major bottleneck in the safety assessment of botanicals and botanical ingredients and thus also for PFS is the fact that some botanicals may...
contain compounds that are both genotoxic and carcinogenic. Risk assessment of such compounds is complicated and an international scientific agreement on the best approach is currently lacking (EFSAS, 2005). Therefore, new concepts were tested that could be of use for risk and safety assessment of PFS focusing on finding adequate ways to judge the risk or safety of PFS that may contain genotoxic carcinogens. This should ultimately give a better idea on when risk management actions would be needed, but also for which PFS there is no reason for concern even though they do contain limited amounts of genotoxic carcinogens. The new concepts tested include the margin of exposure (MOE) approach, a mode of action (MOA) based approach and a matrix effect approach. The MOE was found to be a valuable approach in risk and safety assessment of PFS that can be used to set priorities for risk management. Moreover, the integrated approach of in vitro and MOA based physiologically based kinetic (PBK) modeling was found to be a very useful addition to risk and safety assessment of PFS based on the MOE approach since it facilitates read-across and also provides a way to take matrix effects into account. Furthermore, the new concepts tested may prove a way forward to markedly reduce the number of experimental animals used for safety testing of PFS.

The research leading to these results has received funding from the European Community’s Seventh Framework Programme (FP7/2007-2013) under grant agreement n° 245199. 1831f Probabilistic Environmental Hazard Assessments of ToxCast Phase I and II In Vitro Datasets

L. A. Kristofol1, D. A. Dreier1, E. S. Williams1, J. Correia2, E. P. Gallagher2, T. Kavanagh3, A. Voutchkova2, J. B. Zimmerman2, P. Anastas4 and B. W. Brooks1, 1Environmental Science, Baylor University, Waco, TX, 2University of Washington, Seattle, WA, 3George Washington University, Washington, DC and 4Yale University, New Haven, CT.

Little toxicology data exists for the majority of industrial chemicals. Our research group has examined approaches to utilize known toxicological data to predict thresholds of untested chemicals, and to select assays for assessing toxicity when multiple model systems exist. Here we employed chemical toxicity distributions (CTDs) to perform probabilistic hazard assessments (PHAs) using data from the U.S. EPA’s ToxCast program. PHAs may predict toxicological potencies of similar chemicals, prioritize chemicals for additional toxicity testing, support read-across for regulatory purposes, and identify characteristics for sustainable molecular design. An initial PHA examined the comparative sensitivity of three in vitro assays for estrogenicity representing a diverse group of industrial chemicals and pesticides from ToxCast Phase I. CTDs were compared at 5th centiles for all compounds, common compounds, and organophosphates tested. When all available data were compared, a NCGC assay was most sensitive for estrogenicity as there was a 5% probability of detecting a compound that will elicit an estrogenic response at or below 0.089 mg/L. When only common compounds and organophosphates were considered, an Attagene assay was most sensitive assay with centiles of 0.13 mg/L probability of detecting a compound that will elicit an estrogenic response at or below those potentially relevant to maximum worker exposures, was not increased compared to oral absorption (14-23%), even with guideline sized particles (1-3 μm MMAD). The portal of entry toxicity of irritant aerosols generally limits the achievable exposure concentrations such that exposures typically cannot be high enough to produce expected systemic toxicity. Test guideline size particles had greater deposition and increased surface area than predominantly larger sized aerosols produced in the field, lowering the accuracy of human hazard prediction, especially for chemical irritants. These data support the use of an evidence-based approach in determining the need for repeat inhalation studies for the assessment of human health risk assessment from inhalation.

1831h Comparison of Developmental and Neurotoxic Endpoints Observed in Experimental Animal Studies following Inhalation Exposure to n-Butanol and n-Butyl Acetate

J. Weaver1, T. Blessinger1, A. F. Sasso1, S. L. Maki1 and S. A. Bale2, 1National Center for Environmental Assessment, US-EPA, Washington, DC and 2Drug and Chemical Evaluation Section, DEA, Washington, DC.

Several studies have suggested that toxicity associated with n-butyl acetate may be informative of toxicity associated with n-butanol and vice versa. N-butyl acetate rapidly metabolizes to n-butanol; therefore, it is anticipated that the toxic effects observed following exposure to n-butyl acetate and n-butanol would be similar. A literature search was conducted to identify peer-reviewed studies that evaluated toxic health effects resulting from n-butanol or n-butyl acetate exposure. Most of these studies evaluated primarily neurotoxic and developmental toxicity endpoints. Toxicity endpoints from all of the studies were reviewed and toxicity effect levels were determined. To facilitate study comparisons, internal n-butanol blood levels were estimated by using a previously developed PBPK model (Teegarden et. al 2005). Studies investigating developmental effects of n-butyl acetate and n-butanol demonstrated similar dose related trends including decreased food consumption in dams and decreased fetal body weight. Endpoints consistent with neurotoxicity were not directly comparable between n-butanol (e.g., altered motor function) and n-butyl acetate (e.g., decreased absolute brain weight). In this case study, similar trends were observed with genotoxicity outcomes between n-butyl acetate and n-butanol in some developmental endpoints, suggesting that toxic effects identified following exposure to n-butyl acetate may be predictive of toxic effects observed as a result from exposure n-butanol.

1831i Relative Oral Bioavailability of Benzo(a)pyrene from Soils at Environmentally-Relevant Concentrations

J. W. Munson1, Y. W. Lowney2, M. Ruby3 and S. M. Roberts1, 1University of Florida, Gainesville, FL, 2Exponent, Boulder, CO and 3Integral Consulting, Louisville, CO.

Several reports in the literature suggest that interactions between PAHs and soil diminish PAH bioavailability and thus reduce risk from incidental ingestion of PAH-contaminated soil. Various animal models and approaches have been used to estimate PAH bioavailability from soil. To facilitate PAH measurement, most of these studies were conducted using PAH concentrations that only occur at heavily contaminated sites. The objective of this study was to explore the influence of soil composition, PAH concentration, and source material type on PAH bioavailability using an approach capable of measuring uptake at low, environmentally-relevant PAH concentrations (down to 1 ppm or less). Contaminated soil samples were constructed using PAHs from three source materials (PAHs in solvent, soot, and fuel oil) to which 3H benzo(a)pyrene (3H-BaP; total BaP concentrations of 1, 10, and 100 ppm) was added and weathered for eight weeks. Each soil was administered as a single dose to rats, and blood samples were taken over six days. Relative bioavailability (RBA) of the BaP from soil was estimated by comparing the area under the curve (AUC) for 3H concentration versus time in blood with the AUC observed from the same material dosed in a food matrix for comparison. Food was used for comparison because the cancer slope factor for BaP is derived from studies in rats in which the exposure medium is diet. The extent to which BaP RBA was diminished in soil versus food varied among the source materials. Differences were also observed among soils of different composition, suggesting that the nature of the soil as well as the source of PAH contamination can influence bioavailability. These data will be informative both in understanding soil-PAH interactions that affect bioavailability and form a basis for the development of in vitro approaches for PAH bioavailability estimation. Supported in part by a grant from SERDP.

1831g Developing an Evidence-Based Rationale for Determining the Necessity of Repeat Inhalation Studies of Agrochemical Aerosols with Irritant Properties

P. Singh1, P. M. Hinderliter1, R. Champana2, J. Wright1, P. Whalley1, A. Stevens1, J. D. McDonald2, P. J. Kuehl2, M. Doyle-Eisele2, C. Garner2 and R. W. Lewis1, 1Syngenta, Greensboro, NC and 2Lovelace Respiratory Research Institute, Albuquerque, NM.

An evidence-based approach was used to determine whether repeat inhalation toxicity studies for two fungicide formulations, with varying potential to produce irritation, would provide new information of use in human health risk assessment. After considering the available acute inhalation and irritation toxicity data, a 2- or 4-week repeat exposure study was conducted with formulations of chlorothalonil and azoxystrobin, respectively, including histopathology of the respiratory tract. In addition, as part of the testing strategy for chlorothalonil, pharmacokinetic data from inhalation administration in rats was generated for route to route extrapolation of systemic availability. At the end of the repeat exposure studies, concentration-related squamous metaplasia was noted in the ventralateral latyns and/or the nasal epithelium, consistent with changes commonly reported in rats following nose-only inhalation exposures to irritant chemicals. At minimal to mild grades of severity, these findings are non-adverse, and potentially reversible. Systemic absorption of chlorothalonil, following 6 hours of inhalation exposure to a concentration (0.004 mg/L) above those potentially relevant to maximum worker exposures, was not increased compared to oral absorption (14-23%), even with guideline sized particles (1-3 μm MMAD). The portal of entry toxicity of irritant aerosols generally limits the achievable exposure concentrations such that exposures typically cannot be high enough to produce expected systemic toxicity. Test guideline size particles had greater deposition and increased surface area than predominantly larger sized aerosols produced in the field, lowering the accuracy of human hazard prediction, especially for chemical irritants. These data support the use of an evidence-based approach in determining the need for repeat inhalation studies for the assessment of human health risk assessment from inhalation.
effect, is given to the mould prevalence and its health impacts in non-damp or "normal" indoor residential environments. In this study, we have performed visual inspection of residential homes in the Northern California to assess whether mold or conditions indicating mold are present in the indoor air environments. We also collected air samples in order to: (1) capture and quantify a broad spectrum of fungal/mold spores present in the air, and (2) assess whether the levels suggest a fungal/mold problem in the indoor locations. Between 2006 and 2013, we collected and analyzed more than 900 samples (> 600 outdoor air samples; 300 indoor air samples). The results showed that: (1) molds are normally found in indoor air in particularly large numbers, 100 – 8,500 spores per cubic meter of indoor air (residential homes with no visual/known dampness); (2) the range of outdoor mold was 500 – 38,000 spores per cubic meter, with four peaks in January, May, October, and November; (3) the four dominant airborne fungi were, yeast, Cladosporium, Penicillium, and Aspergillus; (4) individual homes complaining about asthma and other respiratory effects were not well correlated with indoor environments with high spore counts. Our findings suggest that: (1) the ratio, not absolute spore counts, of indoor air spores to outdoor air spores in a given residence should be used as an accurate indicator of a mold problem in a residence, and (2) special emphasis should be given when conducting mold risk assessment with individuals who might be more susceptible to health problems from mold exposure (individuals with respiratory sensitivities and a compromised immune system).

1831m Prevalence of Molds in Residential Indoor and Outdoor Environments in Northern California and Its Implication in Health Risk Assessment
I. Arnould and S. Kim. Toxicology, Bangor, CA.
Increasingly, airborne mold in home environments has been linked with asthma exacerbation and other respiratory diseases. The majority of these adverse health risk assessments due to mold exposure have been conducted with data from residential homes or buildings associated with dampness. While controlling indoor moisture and mold can help solve mold contamination problems and adverse health effects, very little attention is given to the mold prevalence and its health impacts in non-damp or "normal" indoor residential environments. In this study, we have performed visual inspection of residential homes in the Northern California to assess whether mold or conditions indicating mold are present in the indoor air environments. We also collected air samples in order to: (1) capture and quantify a broad spectrum of fungal/mold spores present in the air, and (2) assess whether the levels suggest a fungal/mold problem in the indoor locations. Between 2006 and 2013, we collected and analyzed more than 900 samples (> 600 outdoor air samples; 300 indoor air samples). The results showed that: (1) molds are normally found in indoor air in particularly large numbers, 100 – 8,500 spores per cubic meter of indoor air (residential homes with no visual/known dampness); (2) the range of outdoor mold was 500 – 38,000 spores per cubic meter, with four peaks in January, May, October, and November; (3) the four dominant airborne fungi were, yeast, Cladosporium, Penicillium, and Aspergillus; (4) individuals complaining about asthma and other respiratory effects were not well correlated with indoor environments with high spore counts. Our findings suggest that: (1) the ratio, not absolute spore counts, of indoor air spores to outdoor air spores in a given residence should be used as an accurate indicator of a mold problem in a residence, and (2) special emphasis should be given when conducting mold risk assessment with individuals who might be more susceptible to health problems from mold exposure (individuals with respiratory sensitivities and a compromised immune system).
of ATP levels by luminescent assay showed that mitochondrial complex-I inhibitors caused a significant reduction in ATP levels. Functional studies using the mitotracker green assay on N27 cells showed that exposure to complex I inhibitors caused significant damage in mitochondria. These results were also confirmed by measurements of pimonidazole. Interestingly, pretreatment with the HAT inhibitor anacardic acid (8.5μM) protected against tebufenpyrad and pyridaben–induced ATP reduction, H3 and H4 acetylation and cytotoxic cell death. Collectively, exposure to tebufenpyrad and pyridaben induced histone acetylation via mitochondrial dysfunction, which together may play a key role in dopaminergic neuronal degeneration (supported by NIH grant ES10586).

1833 Comparison of In Vitro Cell Models for Assessment of Pesticide-Induced Dopaminergic Neurodegeneration

Current biomedical and (neuro)toxicity research on (neuro)degenerative diseases relies strongly on animal models. For both ethical and technical reasons this use of laboratory animals is often undesirable. Current in vitro research largely relies on tumor derived- or immortalized cell lines. However, the suitability of cell lines for studying neurodegeneration is determined by their intrinsic properties.

We therefore characterized four different neuronal cell models (PC12, SH-SYSY, MES23.5 and N27 cells) with respect to the presence of functional membrane ion channels and receptors. Furthermore, we assessed the effects of five known neurotoxic pesticides (rotenone, lindane, dieldrin, imazalil and dinoseb) on cytotoxicity, oxidative stress and parameters of intracellular calcium homeostasis using a combined αB/CFDA assay, a H2DCFDA assay and single cell fluorescent (Fura-2) calcium imaging, respectively.

Our results demonstrate considerable differences in intrinsic properties and pesticide-induced effects on cytotoxicity and oxidative stress, as well as on intracellular calcium homeostasis between the cell lines. The results thus indicate that care should be taken when interpreting (neuro)toxicity data as the chosen cell model may greatly influence the outcome.

This work was funded by the European Union-funded project ACROPOLIS (Grant Agreement KBBE-245163) and by the Faculty of Veterinary Medicine (Utrecht University).

1834 Low Concentrations of Insecticides Induce Acute and Concentration-Dependent Effects on Calcium Homeostasis in PC12 Cells

Insecticides are widely used and are well known neurotoxic chemicals. There are different classes of insecticides based on their reported primary mode of action. Since calcium plays a critical role in neuronal development, we tested whether selected organophosphates, organophosphates, neonicotinoids, carbamates and pyrethroids can disturb calcium homeostasis in PC12 cells.

Effects on basal calcium homeostasis were investigated using single cell fluorescence (Fura-2) microscopy. By depolarizing cells with high K+–containing saline, effects on the depolarization-evoked increase in intracellular calcium ([Ca2+]i) through voltage-gated calcium channels (VGCCs) were also investigated.

The data demonstrate that endosulfan, chlorpyrifos and chlorpyrifos-oxon at 10 μM induce an acute but modest increase in basal [Ca2+]i. More importantly, most of the tested insecticides concentration-dependently inhibited the depolarization-evoked [Ca2+]i, with cypemethrin being the most potent compound with an IC50 of 0.009 μM. α-cypemethrin inhibited the depolarization-evoked [Ca2+]i with 20% at 0.03 μM, chlorpyrifos at 0.08 μM, endosulfan at 0.1 μM, chlorpyrifos-oxon at 1 μM and parathion at 2.56 μM. Carbaryl, imidacloprid, paraoxon-ethyl and paraaxon-methyl did not inhibit the depolarization-evoked [Ca2+]i.

In conclusion, our data demonstrate that 1) insecticides concentration-dependently inhibit depolarization-evoked [Ca2+]i, and that 2) oxon metabolites are less potent compared to their parent compounds in inhibiting depolarization-evoked [Ca2+]i. This acute disturbance of calcium homeostasis may partly underlie insecticide-induced neurotoxicity.

1835 Azole Fungicides Disturb Intracellular Ca2+ in an Additive Manner in Dopaminergic PC12 Cells

Humans are exposed to complex mixtures of pesticides and other compounds, mainly via food. Azole fungicides are broad spectrum antifungal compounds, widely used in agriculture as well as in human and veterinary medicine. The mechanism of antifungal action relies largely on inhibition of CYP51 inhibiting fungal cell growth and known adverse health effects ofazole fungicides are thus linked to CYP inhibition. Additionally, azole fungicide-induced neurotoxicity has been reported, though the underlying mechanism(s) are largely unknown.

We therefore investigated the effects of a group of 6 azole fungicides (mizalizal, flusilazole, fluclozate, tebuconazole, triadimenol and cyproconazole) on cell viability and on oxidative stress in dopaminergic PC12 cells using a combined alamarBlue/CFDA-AM and H2DCFDA assay, respectively. As calcium plays a pivotal role in neuronal survival and functioning, effects of these 6 azole fungicides as well as binary and quaternary mixtures of azole fungicides on the intracellular calcium concentration ([Ca2+]i) were investigated using single-cell fluorescence microscopy in PC12 cells loaded with the calcium-sensitive fluorescent dye Fura-2.

Only modest changes in cell viability and ROS production were observed. However, 5 out of 6 azole fungicides induced an non-specific inhibition of voltage-gated calcium channels (VGCCs), though with varying potency. Experiments using binary IC50 and quaternary IC50 mixture indicated that the inhibitory effects on VGCCs are additive. The combined findings demonstrate modulation of intracellular Ca2+ via inhibition of VGCCs as a novel mode of action of azole fungicides. Furthermore, mixtures of azole fungicides display additivity, illustrating the need to take mixture effects into account in human risk assessment.

This work was funded by the European Union-funded project ACROPOLIS (Grant Agreement KBBE-245163) and by the Faculty of Veterinary Medicine (Utrecht University).

1836 Atrazine Alters Neuronal Redox Status but Does Not Activate Nrf2

I. Roedel1,3, D. J. Walker2,3 and J. M. Hansen1. 1Pharmaceutical Sciences, University of Colorado, Aurora, CO, 2Civil and Environmental Engineering, Tufts University, Medford, MA and 3Medicine, Emory University, Atlanta, GA.

Atrazine (ATZ) is the second most commonly used herbicide in the United States and is widely applied to grain crops, such as corn, wheat, and sorghum. Because of its wide use, ATZ is the most commonly detected pesticide in ground water. ATZ can act as an endocrine disruptor as well as cause dopaminergic neuron death and behavioral phenotypes. The aim of this study was to characterize how subtoxic concentrations of ATZ and its metabolites alter neuronal redox status. SH-SYSY neuroblastoma cells were treated with subtoxic concentrations of ATZ and its metabolites and alterations in cytoplasmic and mitochondrial peroxidase (Prx) redox status as well as cellular GSH, GSSG and redox potentials (EhGSSG) were measured. Redox western blots showed that neither ATZ nor its metabolites, desethylatrazine (DEA), desisopropylatrazine (DIA), diaminochlorotriazine (DACT), altered cytoplasmic Prx1 redox status; however, acute exposure (4h) to DEA, DIA, or DACT resulted in slight oxidation of mitochondrial Prx3, which this effect normalized by 24h. Analysis of intracellular GSH, GSSG and EhGSSG showed that both ATZ and DIA significantly deplete GSH resulting in considerable oxidation of EhGSSG. Due to the ATZ-mediated decrease in intracellular GSH, we investigated if Nrf2 was activated by ATZ or its metabolites. Western blots of nuclear fractions showed a slight increase in Nrf2 nuclear translocation in DEA treated cells and a large increase following DACT treatment, but no increase in ATZ treated cells. Analysis of Nrf2-controlled genes (GCLC, NQO1, HO-1, Prx1) showed slight activation by DACT. GCLC expression was increased by ATZ, but it can be concluded that this mechanism may not be Nrf2-mediated. In conclusion, our results demonstrate that ATZ alters intracellular GSH redox status, but does not alter Prx redox or cause an increase in Nrf2 nuclear translocation or transcription.
Gestational and Lactational Drinking Water Exposure to Atrazine Causes Specific Behavioral Deficits and Selectively Alters Monoaminergic Systems in C57BL/6 Mouse Dams, Juvenile, and Adult Offspring

Z. Lin1, 2, N. M. Filipe2, 3 and C. A. Dodds1, 3 1Physiology and Pharmacology, Univ. of Georgia, Athens, GA, 2Interdisciplinary Toxicology Program, Univ. of Georgia, Athens, GA and 3Biology, Fort Valley State University, Fort Valley, GA.

Atrazine (ATR) is one of the most frequently detected pesticides in the U.S. water supply and limited evidence suggests that it may be a developmental neurotoxicant. The present study focused on behavioral and neurochemical (monoamine) alterations in C57BL6 mouse offspring and dams exposed to low dose of ATR (3 mg/L) via the drinking water (DW) from gestational day 6 to postnatal day (PND) 23. Behavioral tests included open field, pole, grip strength, novel object recognition (NOR), forced swim (FS), and marble burying. Maternal and offspring (PND21, 35, and 70) body and brain weights were not affected by ATR. However, ATR exposure caused: (i) hyperactivity and decreased performance in the NOR in the dams; (ii) hyperactivity (males and females), increased immobile time in the FS (males), decreased performance in the pole test (females), and increased number of buried marbles (females) in the juvenile offspring (PND35); (iii) decreased performance in the NOR by females in the adult offspring (PND70). ATR exposure also increased striatal dopamine (DA) in the dam and juvenile offspring (males and females), but not in the adult offspring, and it decreased serotonin in the perinatal cortex of female, but not male, adult offspring. These results suggest that perinatal exposure to environmentally-relevant DW levels of ATR targets the nigrostriatal DA pathway in the dam and offspring, alters motor and cognitive functions of the dam, induces a variety of sex-selective behavioral abnormalities involving motor and emotional functions in the juvenile offspring, and decreases cognitive function of female adult offspring, an effect that may be due to altered serotonin homeostasis in the perinichal cortex.

N-Methyl-D-aspartate Receptor Activation May Contribute to Glufosinate Neurotoxicity

S. R. Lantz1, 3, C. M. Mack1, K. A. Wallace2, E. F. Key1, T. J. Shafer2 and J. E. Cauda1 1Dept. of Nutritional Sciences and Toxicology, University of California, Berkeley, CA, 2Integrated Systems Toxicology Division, NHEERL, ORD, U.S. Environmental Protection Agency, Research Triangle Park, NC and 3Marquette Biological Station, U.S. Fish and Wildlife Service, Marquette, MI.

Glufosinate (GLF) at high levels in mammals causes convulsions through a mechanism that is not completely understood. The structural similarity of GLF to glutamate (GLU) implicates the glutamatergic system as a target for GLF neurotoxicity. The current work examined GLF interaction with N-methyl-D-aspartate subtype GLU receptors (NMDAR) and GLT-1 transporters via [3H]CGP39653 binding. The current work examined GLF interaction with D-aspartate subtype GLU receptors (NMDAR) and GLT-1 transporters via [3H]CGP39653 binding.

Paraquat and MPTP Induce Alterations in the Expression Profiles of microRNA in Neuro-2A Cells

Recent evidence indicates that microRNAs (miRNAs) play a key role in neurodegenerative diseases. However, little is known about how these miRNAs contribute to dopaminergic neuronal damage by paraquat (PQ) and 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). Here we used microarray analysis to show that PQ and MPTP induce alteration of miRNA expression in a cell model of Parkinson’s disease. The results reveal that treatment with 300 μM PQ caused miRNA deregulation in which 60 miRNAs were up-regulated and 228 miRNAs were down-regulated. Among the 288 miRNAs identified, the levels of six miRNAs (miR-297b-5p, miR-497-5p, miR-503-5p, miR-374-5p, miR-155-5p, and miR-600a-3p) were charged more than 1.2-fold. Upon treatment with MPTP at 300 μM PQ, a total of 576 miRNAs were deregulated; 506 miRNAs were up-regulated and 70 miRNAs down-regulated. Among the 576 miRNAs, miR-93-5p and miR-425-5p had changes above 1.2-fold. These findings showed that both PQ and MPTP alter the miRNA expression, but each affects a different set of miRNA targets. Alterations in the expressions of miR-17-5p, miR-93-5p, miR-21-3p, miR-374-5p, miR-503-5p, and miR-425-5p were verified by real-time quantitative reverse transcriptase polymerase chain reaction. Bioinformatics analysis indicated that aberrant expression of miR-17-5p potentially contributes to PQ-induced neurotoxicity. Taken together, our study demonstrates, for the first time, that characteristic changes in miRNA expression profiles occur after PQ and MPTP treatment, which suggests miRNA may be involved in the development of PQ and MPTP induced neurodegeneration as a molecular mechanism.

This work was supported by the National Natural Science Foundation in China (Grant 81172715, 30800936), Fujian Province Funds for Distinguished Young Scientists (2012J06018) and Program for New Century Excellent Talents in Fujian Province University (NCET-11-0163).

DDT and DDE Enhance the Toxicity of Amyloid Beta Peptides in Drosophila

L. DeRespi1, 3, K. Carney2, M. Konsolaki2, K. R. Reuhl1 and J. Richardson1 1RWJMS, Piscataway, NJ, 2Genetics, Rutgers University, Piscataway, NJ and 3Pharmacology and Toxicology, Rutgers University, Piscataway, NJ.

Environmental factors, such as pesticides are thought to play a significant role in the pathogenesis of diseases of the nervous system. DDT (dichlorodiphenyltrichloroethane) is a persistent synthetic organochlorine insecticide used to control ma-
Zhihong Cao, Yao Cui, Huy-Man Nguyen, David P. Jenkins, Helmar Wulff, and Ira N. Pessah investigate the impacts on activity driven neuronal plasticity. However, selected antioxidants exerted different protective actions. Compared to α-lipoic acid (MDA) were significantly increased after bifenthrin. Levels of both nitric oxide (NO) and lipid peroxides measured as malondialdehyde (MDA) were significantly increased after bifenthrin exposure, whereas 50% of control flies lived to 30 days. Interestingly, DDE did not compromise viability at concentrations up to 1μM. In a developmental model, both pesticides caused developmental delays at concentrations as low as 10μM, a concentration that caused no lethality in adult flies. Based on these results, we treated Aβ-expressing Drosophila with 1μM DDT or DDE and measured changes in their lifespan. At 15 days of exposure, lifespan of DDT-treated males was 2% lower compared to controls, whereas DDE-treated males had 18% lower viability. No changes in viability were observed in treated female flies. Our work suggests that sub-toxic levels of DDT and DDE may exacerbate the effects of Aβ in a Drosophila model of Alzheimer's and that these effects appear to be sex-specific. Supported by the SOT Intern Program and NIH grants P30ES005022 and R25ES020721.

**1842 Nanomolar Bifenthrin Alters Synchronous Ca2+-Oscillations and Cortical Neuron Development Independent of Sodium Channel Activity**

Zi Ca, Ying Cui, Huy Man Nguyen, D. P. Jenkins, and I. N. Pessah.

Bifenthrin is a relatively stable type I pyrethroid with broad agricultural and domestic uses that causes tremors and impairs motor activity in rodents. In this study, we investigated the influence of nanomolar concentrations of bifenthrin on the synchronous Ca2+ oscillations (SCO) necessary for activity dependent dendritic development. Primary mouse cortical neurons were cultured 8-9 days in vitro (DIV) loaded with the Ca2+ indicator Fluo-4, and imaged using FLIPR Tetra. Acute exposure to bifenthrin rapidly increased the frequency of SCO 2.7-fold (EC50 = 58 nM) and decreased SCO amplitude by 36%. Changes in SCO properties were independent of modifications in voltage-gated sodium channels since 100 nM bifenthrin had no effect on the whole-cell Na+ current, nor influenced neuronal Erev of cortical neurons. Moreover, the L-type Ca2+ channel blocker nifedipine failed to ameliorate bifenthrin-triggered SCO activity, and were not mediated by ryanodine receptor channel modification. By contrast, the mGlur 5 antagonist MPEP normalized the bifenthrin-triggered increase in SCO frequency without altering baseline SCO activity, indicating that bifenthrin amplifies mGlur 5 signaling independent of Na+ channel modification. Competitive (AP-5) and noncompetitive (MK801) NMDAR antagonists partially decreased bifenthrin-triggered SCO frequency increase. Bifenthrin-modified SCO rapidly enhanced the phosphorylation of AMP response element-binding protein (CREB). Sub-acute (48h) exposure to bifenthrin commencing 2 DIV enhanced neurite outgrowth and persistently increased SCO frequency and reduced SCO amplitude. Collectively, these data identify a new mechanism by which bifenthrin potently alters Ca2+ dynamics and Ca2+-dependent signaling in cortical neurons that have long term impacts on activity driven neuronal plasticity.

**1843 Protective Role of Melatonin against Alpha-Cypermethrin-Induced Oxidative Stress in Human Neuroblastoma Cell Line SH-SY5Y**

α-Cypermethrin, alpha-cyano pyrethroid insecticide, is a relatively potent neurotoxic associated with human health risks. In the present study, we aimed to investigate in an in vitro model the neuroprotective role of three well-known antioxidants, melatonin (MEL), Trolax and N-Acetylcysteine against α-cypermethrin induced neurotoxicity and on the other hand, to examine, by PCR array, the cell death pathway expression patterns in neuroblastoma cell line SH-SY5Y after pyrethroid exposure and the potential neuroprotective role of melatonin. Levels of both nitric oxide (NO) and lipid peroxides measured as malondialdehyde (MDA) were significantly increased after α-cypermethrin exposure, however selected antioxidants exerted different protective actions. Compared to other antioxidants, 1 μM MEL treatment showed the most effective protection against pyrethroid-induced lipid peroxidation and increased NO levels. We evaluated multiple cell death regulation genes after α-cypermethrin and α-cypermethrin plus MEL-treated cells, most of genes altered by the pyrethroid were partially or completely reverted by MEL treatment, among them, ATG16L1, BIRC3, FOX11, IFG1, INS, IRGM, KCNIP1, MAG, RAB23, SCNA, S100A7A, SQSTM1, TNFRSF1A, TNFRSF1B and TNFRSF1A. These results suggest that oxidative stress is a key element in the neurotoxicity process induced by α-cypermethrin and a multitasking indolamine as MEL might be beneficial to prevent toxicity caused by α-cypermethrin or even other pyrethroids with similar action mechanism. This work was supported by projects Ref. BSCGH/S85/08 (UCM), Ref. No. S2009/AGR-14639/CAM and Consolider-Ingenio 2010 Net.CSDE2007-063 (MEC), Spain.

**1844 Pyrethroid Pesticides Directly Activate Microglia through Voltage-Gated Sodium Channels Leading to Increased TNF-α Release**

J. Liu, M. M. Hossain, and J. Richardson, 1. Ernest Mario School of Pharmacy, Rutgers University, Piscataway, NJ and 2. Department of Environmental & Occupational Medicine, Rutgers Robert Wood Johnson Medical School, Piscataway, NJ.

Microglia are considered to be the resident immune cells of the central nervous system and contribute significantly to ongoing neuroinflammation in a variety of neurodegenerative diseases. Recently, we identified that voltage-gated sodium channels (VGSC) are present on microglia cells and contribute to the release of the pro-inflammatory cytokine tumor necrosis factor alpha (TNFα) (Hossain and Richardson, 2013). Based on this finding and the fact that pyrethroid pesticides act on VGSC, we hypothesized that exposure of microglia to the pyrethroid pesticides, permethrin and deltamethrin, would activate microglia and increase release of TNFα. BV2 mouse microglial cells were seeded into a 96-well plate and treated with 0-100 μM deltamethrin or permethrin for 24 or 48 hrs and cell viability was assayed using Alamar blue. Cell viability decreased in a dose and time dependent manner for concentrations of deltamethrin and permethrin above 10 μM. Next, BV-2 cells were treated with vehicle, the VGSC blocker tetrodotoxin (TTX), or 0.5-5 μM deltamethrin or permethrin in the presence and absence of TTX for 24-48 hours. Media was removed and the concentration of TNFα was assayed using ELISA. TNFα release increased significantly in a dose and time-dependent manner for both deltamethrin and permethrin. TTX significantly reduced the pyrethroid-induced TNFα release, indicating that interaction with VGSC significantly contributed to release. From these data, we conclude that pyrethroid pesticides directly activate microglial cells through interaction with microglial VGSC. Because neuroinflammation plays a key role in many neurodegenerative diseases, these data provide an additional mechanism by which exposure to pyrethroids may contribute to neurodegeneration.

**1845 Repeated Pesticide Exposure Causes Hippocampal ER Stress, Neuroinflammation, and Cognitive Deficits in Mice**

Endoplasmic reticulum (ER) stress and neuroinflammation are implicated as significant contributors to neurodegeneration. Previously, we demonstrated that the widely used pyrethroid pesticide deltamethrin causes ER stress-mediated apoptosis in SK-N-AS neuroblastoma cells. However, whether this occurs in vivo remains unknown. Here, we investigated the effects of repeated deltamethrin exposure (3 mg/kg every 3 days for 60 days) on hippocampal ER stress, neuroinflammation, and cognitive function in adult mice. Repeated exposure to low dose deltamethrin caused ER stress in the hippocampus, as indicated by increased CHOP (131%) and GRP78 (96%) levels. This was accompanied by increased levels of caspase-12 (110%) and activated caspase-3 (50%) in the hippocampus. Deltamethrin also induced microglial activation, as indicated by Iba-1 staining, and increased TNF-α mRNA expression (121%) and protein (465%) levels. To determine whether these effects lead to cognitive dysfunction, hippocampal-dependent learning and memory was evaluated with a spatial navigation task. Deltamethrin-treated animals exhibited profound deficits in the acquisition phase and in short-term and long-term memory. Additionally, deltamethrin exposure caused decreased BrdU-positive cells (36.54%) in the dentate gyrus (DG) of the hippocampus, suggesting impairment of hippocampal neurogenesis. Collectively, these results demonstrate that repeated deltamethrin exposure leads to high stress, neuroinflammation, and apoptotic cell death in the hippocampus. Furthermore, impaired hippocampal neurogenesis may contribute to deficits in learning and memory by deltamethrin. Supported by NIH P30ES005022 and R01ES015991.
The purpose of these studies was to determine if exposure of *Caenorhabditis elegans* to glyphosate or Mn/Zn ethylene-bis-dithiocarbamate-containing pesticides leads to mitochondrial dysfunction in *Caenorhabditis elegans*. E. C. Toft, R. Negga, S. K. Jada, D. C. Bailey and V. A. Fitisankis, *Biolog*, King College, Bristol, TN.

Epidemiological studies indicate that pesticide usage positively correlates with neurodegenerative disorders, particularly Parkinson’s disease. Further evidence suggests that exposure to glyphosate-containing pesticides, the most widely-used class of herbicides in the world, may lead to mitochondrial inhibition. This is in contrast to treatment with glyphosate by itself, which is relatively non-toxic, even to mitochondria. To further explore this potential relationship between Touchdown® (TD), a glyphosate-based herbicide, and mitochondrial inhibition, we acutely exposed second larval stage (L2) *Caenorhabditis elegans* (C elegans) to various concentrations (LC10, LC50, or LC75) of TD as percent active ingredient (glyphosate).

To determine whether mitochondrial function was compromised, assays were performed 24 hours post-acute TD exposure (30 min) to determine whether Complex II, Complex IV, or the proton gradient were adversely affected. Based on one-way ANOVA (*p* < 0.05), colorimetric data from Complex II and IV assays indicate that these complexes are not inhibited, but rather stimulated in a dose-dependent manner. Results relating to the integrity of the proton gradient indicate a statistically significant increase (*p* < 0.05) in tetramethylrhodamine ethyl ester (TMRE) accumulation, signifying not only an intact proton gradient, but perhaps uncoupling and an increase in proton concentration in the inner mitochondrial membrane space. These data suggest that acute exposure of *C elegans* to TD leads to mitochondrial dysfunction, which may contribute to neurodegeneration observed in previously published studies from this lab.

D. C. Bailey, R. Negga, C. E. Toft, R. E. Barnett and V. A. Fitisankis. *Biolog*, King College, Bristol, TN.

Glyphosate-containing herbicides are some of the most widely-used pesticides in the world. Although glyphosate alone is relatively non-toxic, a growing body of evidence suggests that commercial formulations may lead to increases in oxidative stress and mitochondrial inhibition. Previous data from our lab demonstrated dopaminergic and GABAergic neurodegeneration in *Caenorhabditis elegans* (C elegans) when exposed to various concentrations of Touchdown® (TD). Since mitochondrial inhibition may lead to decreased neuronal viability, we sought to determine whether mitochondrial function was compromised. Therefore, we treated L2 worms with varying concentrations of TD followed by assays specific for mitochondrial complex activity. Initially we determined overall mitochondrial function using tetramethylrhodamine ethyl ester (TMRE) to measure the extent of proton gradient integrity. Results from TMRE assays indicated a dose-dependent decrease in dye accumulations in treated worms compared to control (*p* < 0.05). Colorimetric data from Complex II studies suggested a dose-dependent relationship. At lower concentrations (LC50), Complex II activity was marginally inhibited. At the highest concentration (LC100), however, Complex II activity was statistically significantly increased (*p* < 0.05) compared to control worms. Complex IV studies suggested a slight increase in activity at all treatment concentrations compared to control, but this did not reach statistical significance. Therefore, it does not appear that Complex IV activity is inhibited by TD. Taken together, these data indicate that exposure of *C elegans* to TD leads to mitochondrial inhibition. Furthermore, since mitochondrial inhibition can lead to increased reactive oxygen species production, chronic exposure to TD could potentially result in neuronal degeneration, including that associated with Parkinson’s disease.

A. D. Shelton, R. Negga, D. C. Bailey and V. A. Fitisankis, *Biolog*, King College, Bristol, TN.
exposed chronically (24 h) or acutely (30 min) to varying concentrations of TD or MZ, and assayed with dihydrothidiazin (DHE), for O$_2^-$; or AmplexRed, for H$_2$O$_2$. DHE assays in either treatment paradigm (chronic or acute TD or MZ) indicated no statistically significant increase in O$_2^-$ at any concentration compared to control. Furthermore, chronic TD exposure followed by AmplexRed treatment showed no statistically significant difference compared to control. Conversely, worms treated acutely with TD showed a statistically significant (****p<0.001) increase in H$_2$O$_2$ in LC$_{25}$ and LC$_{50}$ groups compared to control. AmplexRed assays in worms following chronic MZ exposure indicated a statistically significant (****p<0.001) increase in H$_2$O$_2$, in the LC$_{50}$ group compared to control. However, a dose-dependent upward trend in production of H$_2$O$_2$ with increasing concentration (LC$_{25}$ vs LC$_{50}$; *p<0.05; LC$_{50}$ vs LC$_{75}$; **p<0.01). AmplexRed results in acute MZ studies showed a statistically significant decrease in H$_2$O$_2$ in LC$_{25}$ (**p<0.01) and LC$_{50}$ (**p<0.01) treatment groups compared to control, but a statistically significant (****p<0.001) increase in this ROS in LC$_{75}$ worms. Taken together, these data strongly support the hypothesis that both pesticides are capable of producing ROS, and that the ROS may be either H$_2$O$_2$ or hydroxyl radical.

1851 Treatment of Caenorhabditis elegans with Either a Glyphosate-Containing Herbicide or Manzate Leads to Decreased ATP Levels

S. E. Orfield, R. H. Nichols, S. L. Burchfield and V. A. Fitsanakis. Biology, King College, Bristol, TN.

Epidemiological studies show a positive correlation between pesticide exposure and Parkinson’s disease (PD) in humans. It is also known that patients with PD exhibit mitochondrial inhibition. Interestingly two widely-used agrochemicals, TouchDown® (TD), a glyphosate-containing herbicide, and Manzate (MZ), a Mn/Zn ethylene-bis-dithiocarbamate-based fungicide, are suspected of adversely affecting mitochondrial function. Furthermore, previous work in Caenorhabditis elegans (C elegans) from our lab has shown specific neurodegeneration in dopaminergic and GABAergic neuronal populations. To determine whether exposure to these pesticides could also result in potential mitochondrial dysfunction, we treated three groups of N2 (wild-type) strain C elegans with varying concentrations (LC$_{25}$, LC$_{50}$, LC$_{75}$) of the respective commercial-grade compounds as a percent acute ingredient (glyphosate or Mn/Zn ethylene-bis-dithiocarbamate). Studies using chronic (24 h) or acute (30 min) exposure paradigms were conducted. Following the respective treatment, a luminescence probe was used to determine the relative amount of ATP in each group. Results indicated a statistically significant decrease (****p<0.001) in ATP production in the chronic LC$_{50}$ TD treatment group compared to control. For acute treatment with TD, there was a statistically significant increase (**p<0.01) in ATP production in the LC$_{50}$ group compared to all other groups, including control. When worms were treated with chronic MZ, there was an overall statistically significant decrease (**p<0.01) in ATP amount for each of the three treatment groups when compared to control. Finally, in worms from the acute MZ treatment studies, a strong trend suggested a decrease in ATP compared to control worms. Taken together, these data indicate a general reduction of ATP that could result from mitochondrial inhibition following exposure to these pesti-cides. Overall, these data suggest that chronic or acute exposure of C elegans to either TD or MZ could promote neurodegeneration via mitochondrial dysfunction.

1852 Maneb (Manganese Ethylenebisdithiocarbamate) Alters Expression of Genes Involved in Oxidative Stress and Induces Stress Proteins in Rat Hippocampal Astrocytes

M. Akhtar and L. D. Trombetta. Pharmaceutical Sciences, St. John’s University, Queens, NY.

Approximately 5.1 billion pounds of pesticides per year are used in the United States, of which 70 million pounds are fungicides. There is increasing evidence that pesticides are implicated in human health impairment. According to epidemiologi-cal and experimental studies, there is a strong association between pesticide use and neurodegenerative diseases. Maneb, a manganese containing ethylenebis[dithiocarbamate], is a broad-spectrum fungicide commonly used to control plant diseases on food and feed crops. Dithiocarbamates have been shown to produce reactive oxygen species (ROS), altering cellular antioxidant homeostasis that can lead to cellular stress. Astrocytes play a critical role in normal brain physiology and neuroprotection. In this study, Maneb’s potential to alter the expression of genes involved in oxidative stress and antioxidant defenses and induction of stress proteins in rat hippocampal astrocytes was evaluated. Rat hippocampal astrocytes were exposed to 13.5 μM (LC$_{50}$ concentration) of Maneb for 24 hours. Real-time PCR analysis indicated that Maneb exposure caused a 2-fold or greater change in the expression of stress responsive genes involved in ROS metabolism such as Npg1 and Prdx1, which were up-regulated, and Tnxr2d, Tnxip1, Gpx7, SOD3, and Dhs24, which were significantly down-regulated. In addition, Maneb exposure significantly mod-

1853 Manganese-Containing Dithiocarbamates-Induced Cell Death via Senescence Pathway

Cells are constantly exposed to various stresses. Cellular senescence is an irreversible cell cycle arrest for cells in response to DNA damage, oxidative stress, or oncogenic activation. Cell cycle progression is controlled by various cellular signaling pathways. The status of protein redox condition is the decisive key of regulation of these signaling pathways. One of the regulators associated with the protein redox status is NF-kappa B. It has been suggested that activation of NF-kappa B signaling has a causal role in promoting senescence. Study from Cheng’s group has demonstrated that manganese-containing dithiocarbamate pesticides, maneb (MB) and manco-zeb (MZ), at 50 μM activate NF-kappa B cascade, which is partially in response to its potentiated effect on 1-methyl-4-phenylpyridinium (MPP+)–induced cell death in rat pheochromocytoma (PC12) cells. This study was designed to reveal the involve-ment of cellular senescence in MB- and MZ–induced cell death. The indicator of senescence is based on β-galactosidase activity at pH 6 (senescence-associated β-Gal; SA-β-Gal), which is only present in senescent cells, and not seen in pre-senescent, quiescent, or immortal cells. The results show an increase of SA-β-Gal ac-tivity in PC12 treated with MB and MZ (10 μM, 20 μM, and 50 μM) after 4 hours treatment and 24 hours recovery as compared to phosphate buffered saline (PBS) treated PC12 cells. The increase of SA-β-Gal was more perceptible in PC12 cells treated with low dose (10 μM) of MB and MZ as compared to the cells treated with higher doses (20 μM and 50 μM). This study demonstrates that non-toxic doses of MB and MZ (10 μM) can trigger cell cycle arrest in order for cells to compromise the cellular repair or commit cellular apoptosis.

1854 Decreased Gene Expression of Acetylcholine Receptors and Acetylcholinesterase in the Honeybee due to Imidacloprid Exposure

C. C. Byrnes and J. A. Boling. Biology Department, Bridgewater State University, Bridgewater, MA.

Imidacloprid is a pesticide highly toxic to the honeybee’s nervous system. It is a potential cause for Colony Collapse Disorder (CCD), when honeybees abandon their queen and hive to die. The honeybee hive numbers have dropped 40-50% in the last year alone. Honeybees are the most effective insect pollinators therefore it is critical to prevent any future decline. In order to understand how imidacloprid affects honeybee nervous systems, honeybees were exposed to a sugar solution containing 0 μg/L, 0.2 μg/L, 20 μg/L, or 2,000 μg/L imidacloprid for five days in glass jars. RNA was extracted, cDNA synthesized, and Quantitative PCR (QPCR) performed on 25 genes. Seven genes successfully amplified in QPCR. Gene expression was measured for acetylcholinesterase (Ache)-1 and acetylcholine receptor (AchR) ε3, ε4, and β2. These genes were selected because imidacloprid is believed to bind to the AChR, but is unrecognized by Ache. Gene expression was compared to the internal housekeeping genes 18s rRNA and actin. Ache-1 gene expression was statistically different at 20 μg/L, but not at 2,000 μg/L. The decreased gene expression of Ache-1 indicates there is less enzyme to break down acetylcholine. However, an excess of acetylcholine would cause over stimulation in nerves. Due to the excess of acetylcholine in the synapse at the nerve, the honeybee is believed to counteract the condition by reducing the number of acetylcholine receptors. This was verified in the AChR ε3, ε4, and β2 when exposed to 20 μg/L. Gene expression of the AChR subunits decreased to 5.3, 3.5 and 3.9%; respectively when compared to the control bees. Genes will be cloned and more nervous system genes including LCCH3 analyzed to further understand the mechanism of imidacloprid.
1855 Differential Expression of MAP-2 (Microtubule Associated Protein-2) Gene Transcripts in the Central Nervous System of Hens Treated with DFP (Diisopropyl Phosphorofluoridate)

T. V. Damodaran1, 2 and M. B. Abu-Donia1, 3

Biology, North Carolina Central University, Durham, NC and Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.

Organophosphorus-ester induced delayed neurotoxicity (OPIDN) is a neurodegenerative disorder characterized by ataxia progressing to paralysis with a concomitant central and peripheral, distal axonopathies. Diisopropylphosphorofluoridate (DFP) produces OPIDN in the chicken that results in mild ataxia in 7–14 days and severe paralysis as the disease progresses with a single dose. White leghorn layer hens were treated with DFP (1.7 mg/kg, sc) after prophylactic treatment with atropine (1 mg/kg, sc) in normal saline and uracil (1 mg/kg, sc) in dimethyl sulfoxide, with appropriate controls. The hens were euthanized at different time points such as 1, 2, 5, 10 and 20 days, and the tissues from cerebrum, midbrain, cerebellum brainstem and spinal cord were quickly dissected and frozen. MAP-2 has been shown to be closely associated with CaM Kinase II and several other proteins of cytoskeleton. We used northern blots to investigate MAP-2 mRNA levels, while beta actin and 18S RNA were used as controls. The results indicate differential gene expression pattern for MAP-2 mRNA transcripts for both spatial and temporal aspects. Highly susceptible tissues like brainstem and spinal cord showed differential down-regulation at early time points followed by up regulated levels at later time points. Cerebellum, being a moderately susceptible tissue showed moderate levels of alterations in the gene expression of MAP-2 transcripts. Cerebrum, being resistant tissue also showed differential expression pattern. Differential levels of MAP-2 transcript levels in various regions may indicate differential levels of abnormal phosphorylation/dephosphorylation in the DFP-treated brain tissues during the OPIDN development. This new data further validates our recent findings about the role of cell death and cell survival pathways acting via abnormal phosphorylation of cytoskeletal proteins in the initiation and progression of OPIDN.

1856 Comparative Study on Short- and Long-Term Behavioral Consequences of Organophosphate Exposure: Relationship to AChE mRNA Expression

1Biology, North Carolina Central University, Durham, NC, 2Universidad Miguel Hernandez, Elche, Spain and 3Universidad Miguel Hernandez, Elche, Spain.

Organophosphates (OPs) affect behavior via the inhibition of acetylcholinesterase (AChE). While the cognitive short-term effects may be directly attributed to this inhibition, the mechanisms that underlie the long-term cognitive effects of OPs remain controversial. Accordingly, two experiments were designed to compare the effects of OPs on cognition and to ascertain whether long-term OPs effects, analogous to their short-term effects, are AChE-dependent. A single subcutaneous dose of 250 mg/kg chlorpyrifos (CPF), 1.5 mg/kg diisopropylphosphorofluoridate (DFP) or 15 mg/kg paraoxon (PTN) was administered to male zebrafish. Spatial learning was evaluated 72 h or 23 weeks after exposure (experiment 1 and 2, respectively). Brain soluble and membrane-bound AChE activity, synaptic AChE-S mRNA, read-through AChE-R mRNA and brain acetylcholine hydrolyase (APH) activity (as alternative non-cholinergic target) were analyzed once behavioral testing was completed. CTN activity was assessed by fear conditioning testing, and cholinesterase inhibition. Differential gene expression analysis by RNA-seq revealed increased mRNA expression of neuropeptide (Npy, Cort) or neuropeptide-binding (Chrbp) genes in the hippocampus of CPF-exposed animals. Bdnf, a known regulator of synaptic plasticity and neuronal functions, was also up-regulated in the response to CPF exposure. It was demonstrated by immunohistochemistry that more neuronal cells expressed NPY, a known regulator of synaptic plasticity and neuronal functions, was also up-regulated in the response to CPF exposure. It was demonstrated by immunohistochemistry that more neuronal cells expressed NPY and CRHBP proteins in the hippocampus of rats exposed to CPF compared to unexposed animals. MicroRNA expression analysis by small RNA-seq suggested that the miR-132/miR-212 cluster may play a role in CPF-induced neurotoxicity. Pathway analysis identified potential downstream effects of low-dose CPF: increased risk of seizures and neurite outgrowth, synaptic depression, coordination, fertility and body size. Our study results indicate that a low-dose CPF exposure can alter mRNA and protein expression of key regulators of neurobehavioral functions, and that these gene expression changes may be linked to neurobehavioral toxicity of CPF. This research was supported in part by the Environment to the Postgraduate Research Participation Program at the USACEHR administered by ORISE through an IAA between the US DOE and USAMRMC. Research was conducted in compliance with the Animal Welfare Act, and all other Federal requirements. The views expressed are those of the authors and do not constitute endorsement by the US Army.
with CPF oxon (1μM-MnM) and microglial activation was assessed. CPF oxon treatment in HAPI microglial cells resulted in elevated 30 minute superoxide and 3 hour H₂O₂ production, with no initiation of 6 hour TNFα or 24 hour nitrite production. However, combined treatment with CPF oxon (0.5αM) and lipopolysaccharide (LPS)(50ng/mL) resulted in synergistically amplified TNFα production in both microglia and neuron-glia cultures. These findings suggest that CPF oxon may activate microglia to produce reactive oxygen species and prime microglia to be sensitive to additional pro-inflammatory stimuli.

1860 In Utero Chlorpyrifos Exposure Leads to Behavioral Deficits and Alterations in Hippocampal GABAergic Synaptic Transmission

Epidemiological studies have reported that children exposed in utero to organophosphorus pesticides, including chlorpyrifos (CPF), present higher incidence of cognitive deficits, attention deficit/hyperactivity disorder, and autism spectrum disorders than non-exposed children. We have reported earlier that guinea pigs born to dams exposed during the last 10 days of pregnancy to CPF (25 mg/kg day, sc), a dose that causes no overt signs of maternal toxicity, present significant cognitive deficits in the Morris water maze (MWM). Because spatial learning in the MWM is hippocampal dependent and increased GABAergic activity induces cognitive deficits, we hypothesized that cognitive deficits induced by prenatal exposure to CPF correlate with increased GABAergic transmission in the CA1 field of the hippocampus. To test this hypothesis, we used the whole-cell patch-clamp technique to record inhibitory and excitatory postsynaptic currents (IPSCs and EPSCs) from CA1 pyramidal neurons in hippocampal slices obtained from behaviorally tested adult male guinea pigs that had been prenatally exposed to CPF or vehicle during the last 10 days in utero. Spontaneous and miniature IPSC frequencies were higher in CPF-exposed guinea pigs. The increased GABAergic activity correlated with cognitive deficits presented by the CPF-exposed animals tested in the MWM. Spontaneous and miniature EPSCs were comparable between treatment groups. In addition, western blotting of hippocampal protein extracts revealed that CPF exposure had no significant effect on the levels of markers of specific interneuron populations, suggesting that an increase in the number of interneurons is unlikely to account for the increased GABAergic transmission. It is conceivable that prenatal exposure to CPF leads to long-lasting disruption of neurotransmitter systems, such as the nicotinic cholinergic system, known to play a key role in the modulation of hippocampal GABAergic transmission and cognitive functioning.

1861 Prenatal Exposure to Chlorpyrifos Leads to MAPK Dysfunction and Epigenetic Modifications in the Brain

S. W. Todd1,2, W. R. Randall1, E. F. Periera2, J. D. Pescrille1, J. Mamszcz2 and E. X. Albuquerque2. Toxicology, University of Maryland, Baltimore, Baltimore, MD and Epidemiology and Public Health, University of Maryland, Baltimore, Baltimore, MD.

Chlorpyrifos (CPF) is a commonly used organophosphorous pesticide that inhibits the enzyme acetylcholinesterase. Prenatal exposure to CPF has been correlated to spatial learning in the Morris water maze (MWM). Because spatial learning in the MWM is hippocampal dependent and increased GABAergic activity induces cognitive deficits, we hypothesized that cognitive deficits induced by prenatal exposure to CPF correlate with increased GABAergic transmission in the CA1 field of the hippocampus. To test this hypothesis, we used the whole-cell patch-clamp technique to record inhibitory and excitatory postsynaptic currents (IPSCs and EPSCs) from CA1 pyramidal neurons in hippocampal slices obtained from behaviorally tested adult male guinea pigs that had been prenatally exposed to CPF or vehicle during the last 10 days in utero. Spontaneous and miniature IPSC frequencies were higher in CPF-exposed guinea pigs. The increased GABAergic activity correlated with cognitive deficits presented by the CPF-exposed animals tested in the MWM. Spontaneous and miniature EPSCs were comparable between treatment groups. In addition, western blotting of hippocampal protein extracts revealed that CPF exposure had no significant effect on the levels of markers of specific interneuron populations, suggesting that an increase in the number of interneurons is unlikely to account for the increased GABAergic transmission. It is conceivable that prenatal exposure to CPF leads to long-lasting disruption of neurotransmitter systems, such as the nicotinic cholinergic system, known to play a key role in the modulation of hippocampal GABAergic transmission and cognitive functioning.

1862 Fipronil Disposition in the Brain and Changes in the Serotonergic System

Fipronil is a pesticide with widespread utility in control of agricultural and domestic pests including many lepidopteran species, thrips, locusts, ants, cockroaches, fleas, and ticks. In insects, fipronil is recognized as a potent blocker of the GABA-regulated chloride channel in CNS. In vivo mammalian studies indicate that primary metabolic pathway for fipronil involves oxidative formation of the sulfone metabolite. This metabolite was reported to be more toxic to insects, mammals, fish and birds than parent compound itself. Because fipronil is used in home applications, recent concerns for potential adverse public health effects (vomiting, aspiration and sepsis) were raised. The goals of this study were to determine disposition of fipronil and its sulfone metabolite in brain and to assess the relevance of the kinetic results with changes on serotonergic neurochemistry induced by fipronil. Two experiments were carried out: (1) Male Wistar rats treated with fipronil (single dose 10 mg/kg, per os) were killed at different times after treatment and brain samples were collected to determine fipronil and fipronil sulfone levels by HPLC-MS; (2) male Wistar rats treated with fipronil (10 mg/kg, per os, 5 days) and with corn oil (control animals) were killed 24h after dosing and brain regions isolated and content of 5-HT and 5-HIAA quantified by HPLC-ED. Results showed fipronil was distributed into CNS. Fipronil absorbed rapidly and eliminated slowly from the brain. The Cmax of fipronil and fipronil sulfone was 0.457 and 0.856 μg/g. Fipronil significantly (P<0.001) decreased 5-HT levels in hypothalamus (-22%), frontal cortex (-35%), hippocampus (-40%) and striatum (-45%) respect to controls. These results suggest a link between fipronil effect on serotonergic system and its specific levels of brain concentration. Work supported by projects Red, GR35/10-A UCM-BSC, S2009/AGR-1469 (CAM) and Consolider-Ingenio 2010 No CSO2007-00063 (MEC), Madrid, Spain.

1863 Triclopyr: Subchronic Neurotoxicity Study in Fisher F344 Rats

M. Corvaro1, M. Aggarwal1, A. K. Andrus2, R. M. Golden2, R. Hukkanen2, S. Marti2 and D. L. Eisenbrand1. 1 Dow AgroSciences, Milton, United Kingdom, 2 Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI and 3 Dow AgroSciences LLC, Indianapolis, IN.

Triclopyr is a pyridine-based herbicide used mainly on non-crop areas to control broadleaf weeds and woody plants. A subchronic neurotoxicity study in rats was conducted. Four groups of F344/DuCrI rats (10 animals/sex/group) were exposed to Triclopyr technical at levels of 0, 5, 25, or 200 mg/kg/day via the dietary route for 90 days. Neurotoxicity was evaluated using a functional observational battery (FOB), determinations of grip performance, rectal temperature, landing foot splay, and an autonomic function test of motor activity (Weeks 2, 4, 8, and 13). General health condition (clinical observations, body weights, and food consumption) were evaluated weekly; ophthalmic examinations were given pre- and post-exposure. At the end of the study, 5 animals/sex/group were perfused for histopathologic evaluation of the central and peripheral nervous system (control and high-dose groups). The no-observed-effect level (NOEL) for general toxicity was 25 mg/kg/day in both sexes based on: A) treatment-related decreased in body weight and food consumption of the high-dose group, beginning at the Week 2 and persisting throughout the study; B) increased urination of high-dose animals, observed at week 8 and Week 13 in FOBs. This finding was considered a secondary effect, as kidney effects (including functional changes such as decreased urine specific gravity and glucose in the urine; proximal tubules impairment) were identified at 20 – 250 mg/kg/day in a previous 13-week dietary toxicity study using F344/DuCrI rats. The NOEL for Triclopyr neurotoxicity was 200 mg/kg/day in both sexes as there were no effects on any parameter that would suggest a neurotoxic effect, including the examination performed both during in life and post mortem portion of the study. These results are consistent with previous toxicity studies, which showed no treatment-related neurotoxic effects across species.

1863a Effects Produced by Single and Repeated Dosages of Fipronil on the EEG of Long-Evans Rats

We have previously reported that various classes of pesticides have different effects on the non-stimulus driven EEG after acute treatment, including fipronil (25 or 50 mg/kg) (Lyke et al., Toxicologist, 2010, 2011, 2012, 2013). In this study, we
compared the effects of single and repeated treatment with fipronil on the EEG. Fipronil is a member of the phenylpyrazole class of compounds that inhibits GABA receptors. Pilot studies indicated that 6 hours post dosing was the time of peak effect for neurological signs. Dosages for repeated treatments were chosen based on weight loss, regain, and neurological signs during pilot studies. Adult male Long-Evans rats were implanted with epidural screw electrodes. After about 1 week recovery, single exposure animals were dosed for 2 days with 1 ml/kg corn oil vehicle and then tested to allow accommodation to the procedures. On the third day, animals were dosed with corn oil, 5, or 10 mg/kg fipronil and tested 6 h later. Animals in the repeated dosing group were dosed for 14 consecutive days with corn oil, 5, or 10 mg/kg/day fipronil. Transient weight loss and occasional tremors were observed in the high dosage group, but these effects resolved after about 1 week. On days 12 and 13, animals had EEG recorded prior to dosing. On day 14, the rats were dosed 6 h prior to testing. Single treatment with these lower dosages did not significantly alter the EEG. However, repeated dosing with 5 or 10 mg/kg/day resulted in increases in Delta amplitude of the Delta (34 and 30% respectively) and Theta bands (41, 47%), and the area of the Theta band (30, 39%) compared to control. The area of the Gamma band was decreased at 5 (20%) and 10 mg/kg/day (22%) when recorded between the visual and frontal cortex, compared to control. The data confirm that fipronil alters CNS activity as measured by EEG. Additionally, dosages that were ineffective with a single treatment produced significant changes with repeated dosing. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

1863b Changes in Rat Serum Biomarkers after Single or Repeated Dosages of Fipronil

Acute exposure to different classes of pesticides produces different patterns of changes in serum biomarkers (Herr et al., Toxicologist, 2013). We now examined profiles of biomarkers after 1 or 14 treatments with 0, 5, or 10 mg/kg/day fipronil (po). Adult male Long-Evans rats were evaluated for EEG changes (Lyke et al., Toxicologist, 2014), and were sacrificed after testing (6 h). There were no changes in serum ALT, AST, LDH, or SDH. Serum T3 decreased after 1 or 14 treatments (10 mg/kg). Serum T4 decreased after 1 (10 mg/kg) or 14 treatments (5, 10 mg/kg/day). These samples were processed by Myriad RBM (RodentMAP® and Rat MetabolicMAP®). One exposure produced changes in 4 of 73 analytes, while 14 treatments altered 8 different analytes. Bioclates AbsoluteIDQ™ p180 analysis of plasma showed changes in metabolites, and repeated dosing produced more effects. Increased serum levels of the fipronil sulfone metabolite, and decreased levels of fipronil, were found with 14 treatments vs. 1 exposure. Data show that repeated treatment with fipronil results in different patterns of biomarkers compared to a single exposure, and may reflect changes in involvement of biological pathways. This is an abstract of a presentation and does not necessarily reflect EPA policy.

1863c Chronic, but Not Acute, Treatment of Caenorhabditis elegans with TouchDown Leads to Increased Oxidative Stress

R. A. Donaldson1, R. Negga2 and V. A. Fritsanzakis. 1Biology, King College, Bristol, TN.

The purpose of this study was to determine if chronic (24 h) or acute (30 min) exposure of Caenorhabditis elegans (C. elegans) to TouchDown™ (TD), a glyphosate-containing herbicide, resulted in increased oxidative stress. To verify if the glutathione pathway was activated following chronic TD treatment, CL2166 worms were treated with TD. This C elegans strain has glutathione-S-transferase (GST) tagged with green fluorescent protein (GFP) resulting in increased fluorescence when GST::GFP translation is up-regulated. This is generally interpreted as elevated oxidative stress. A concentration-dependent increase in fluorescence compared to control worms (**p<0.001) was observed. This was not the case for CL2166 worms treated acutely. To determine the specific reactive oxygen species that may contribute to increased GST::GFP transcription and translation, synchronized populations of wild-type (N2) C elegans were exposed chronically or acutely to varying concentrations (LC10, LC50, LC90) of TD. Following incubation, worms were further exposed to dihydroethidium, (DHE) to detect O2−, or hydroxyl radical and peroxynitrite sensor (HPE; Life Technologies). DHE assays detected no statistically significant increase in O2− in any treatment paradigm at any concentration. Chronic TD exposure following treatment with HPE showed no statistically significant increase in fluorescence compared to control when HPE was added 24 h post treatment. A concentration-dependent trend towards increased HPE fluorescence was observed, however, when HPE was added immediately following TD incubation. Conversely, worms treated acutely with TD showed a strong trend towards decreased hydroxyl radical production compared to controls. Taken together, these data support the hypothesis that chronic, but not acute, exposure leads to increased GST::GFP transcription and translation that may be due, in part, to the production of hydroxyl or peroxynitrite radicals. Furthermore, it is likely that this increased oxidative stress could be the mechanism through which previously observed neurodegeneration in C elegans occurs.

1864 Application of Proteomics to Identify Deregulated Proteins Associated with Idiosyncratic Liver Toxicity in a Rat Model of LPS/Diclofenac Co-administration

S. Ramm1, B. Morisse2, C. Rooney3, S. Pennington2 and A. Mally1. 1Department of Toxicology, University of Wuerzburg, Wuerzburg, Germany and 2UCD Conway Institute, University College Dublin, Dublin, Ireland. Sponsor: W. Dekant.

There is increasing experimental and clinical evidence to suggest that non-drug related risk factors such as an underlying disease, bacterial or viral infection, may contribute to idiosyncratic drug reactions (IDR). In our previous work we found that combined treatment of rats with therapeutic doses of diclofenac (DcI), a model drug associated with drug idiosyncrasy in patients, and bacterial endotoxin (LPS) resulted in severe hepatotoxicity. In this study, we used an integrated discovery to targeted LC-MS proteomics approach combined with multiplex ELISA to identify liver and plasma proteins modulated by LPS/Dcl treatment, which may be mechanistically linked to or serve as potential safety alerts for IDRs. In the absence of hepatotoxicity, LPS alone caused a marked increase in the concentration of various cytokines and other putative danger signals such as CINC-1 and HMGB1 in plasma as well as significant changes in 19/49 in liver proteins and 3/15 plasma proteins analyzed by LC-MS. The most prominent effect of Dcl alone was a significant rise in T-kininogen-1, an acute phase protein previously suggested as a sensitive marker for drug-induced liver injury, in both liver and plasma. This effect and LPS-mediated cytokine release were amplified in the combined LPS/Dcl treatment group. In addition, depletion of plasma fibrinogen β and γ, consistent with the suspected contribution of the hemostatic system and increased fibrin deposition to IDRs, was observed in the co-treatment group. In contrast, several proteins previously suggested as liver biomarkers such as clusterin did not correlate well with liver injury in this model. Taken together, our analyses revealed proteomic changes associated with IDRs in a rat model of LPS/Dcl co-administration.

1865 The Use of microRNAs to Explore the Mechanisms of Phenobarbital-Mediated Toxicity in the Rat

M. Osborne1, R. Currie2, J. Wright2 and N. I. Gooderham1. 1Imperial College London, London, United Kingdom and 2Syngenta, Bracknell, United Kingdom.

Phenobarbital (PB) is a prototypical hepatic drug-metabolism inducer, and a model tumour promoter in the rat. Recent publications in microRNAs (miRNAs) can enhance our understanding of the mechanisms of PB-mediated toxicity. MiRNAs are small non-coding RNAs that suppress gene expression by inhibiting translation or stimulating transcript degradation of complementary mRNAs, with single miRNAs often targeted by multiple miRNAs. This study explored miRNA expression profiles in the liver from male Fischer rats which had been administered either a tumour promoting dose of PB (1000ppm) or a non-tumour promoting dose (50ppm) in the diet for 1, 3, 7, 14, 28 or 90 days. Previous work identified miR-182 was significantly increased compared to control after 90 days treatment using microarray profiling (Koufaris et al., 2012). Toxicol Sci. 128(2): 532-43. With quantitativePCR assays we have demonstrated that miR-182 was significantly increased from 7 days onwards, compared to controls. In addition we showed that a predicted target of miR-182, glycine N-methyltransferase (Gnm1), and a validated target, forkhead box transcription factor OI (FoxO1), were significantly down-regulated by 1000ppm PB compared to controls, and had a significant inverse correlation with miR-182 across the 90 days treatment period. FoxO1 is known to be an inducer of genes involved in cell cycle arrest and apoptosis, and Gnm1 is known to indirectly regulate gene methylation and therefore gene expression. Decreases in these miRNA targets were dose concordant with the PB-induced phenotypic effects, transient hyperplasia at 3 days treatment (significantly decreased FoxO1 but unchanged miR-182), and global DNA hypermethylation at 14 days treatment (significantly decreased Gnm1 and increased miR-182). These data lend support to the notion that miRNA expression profiles can be used to explore PB-mediated liver toxicity, offer insights into potential underlying mechanisms, and suggest the importance of temporal regulation.
Drug induced-liver injury (DILI) is one of the major safety concerns in drug development. Alanine and aspartate aminotransferase (ALT and AST) and functional biomarkers such as bilirubin have been widely used for monitoring of DILI. However, in preclinical, the diagnostic thresholds of these biomarkers have not been standardized among different testing facilities, and the predictive performance for future onset of hepatic lesions remains unclear. Here, we analyzed the data of large-scale toxicogenomics database, TG-GATEx, in which male Sprague-Dawley rats (N = 5252) were treated with 143 compounds with positive or negative hepatotoxicity for 3, 7, 14 and 28 days. Receiver operating characteristic (ROC) analysis was applied to assessment of the diagnostic or predictive performance of these traditional biomarkers. The threshold was expressed as percentage compared to the control mean for consistent evaluation among different testing facilities. Additionally, area under ROC curve (ROC-AUC) that means accuracy of biomarker was calculated. Regarding all hepatic lesions, the thresholds of AST and ALT were 111 to 116% and 113 to 123% compared to the control mean, respectively, with relatively high accuracy (ROC-AUC was 0.83 to 0.91 and 0.72 to 0.86, respectively). Furthermore, focusing on hepatic necrosis improved the ROC-AUCs of AST and ALT (0.82 to 0.98 and 0.84 to 0.91, respectively) with the following threshold: 116 to 130% and 115 to 126%, respectively. Additionally, the diagnostic performance of AST and ALT was almost equal to that of combinatorial usage by logistic regression model. However, we could not confirm the sufficient predictive performance of future hepatic lesion by these biomarkers. In conclusion, the results provide the information that enables consistent evaluation of these biomarkers by the standardized diagnostic threshold, and suggest that the performance of these biomarkers is limited to diagnostic case of hepatic lesion rather than the prediction.

Liver parenchymal cell (i.e., hepatocyte) apoptosis is associated with activation of the blood coagulation cascade. Emerging evidence suggests that coagulation cascade activation may be a mechanistic biomarker of morbidity in patients with acute liver injury. Hepatocytes have been shown to express tissue factor (TF), the primary activator of blood coagulation, in an encrypted form that lacks procoagulant activity. We hypothesized that induction of hepatocyte apoptosis by the Fas death receptor pathway increases the procoagulant activity of hepatocyte TF. Jo2 antibody-induced coagulation cascade activation was significantly reduced in mice with hepatocyte specific TF deficiency. Treatment of primary mouse hepatocytes with Jo2 induced apoptosis as indicated by cleavage of caspase-3 and increased exposure of phosphatidylserine (PS) on the cell surface. Jo2 treatment increased TF-dependent factor Xa generation by hepatocytes and triggered the release of procoagulant TF-positive microparticles into the culture medium. Pretreatment with a caspase-3 inhibitor reduced Jo2-induced TF activity and microparticle procoagulant activity. The high affinity PS-binding protein lactadherin significantly reduced Xa generation by Jo2-treated hepatocytes and abolished microparticle procoagulant activity. The results indicate that the mechanism of Fas-dependent hepatocyte TF activation involves caspase-3 activation and PS exposure on the cell surface. This suggests that increased (hepatocellular) TF procoagulant activity could contribute to the prothrombotic state associated with hepatocyte apoptosis in chronic liver disease.

MicroRNAs (miRNAs) are short, non-protein coding RNAs. They regulate gene expression by either inhibiting translation or promoting mRNA degradation, and are involved in diverse physiological and pathological events. Previous data from our group (Koufaris et. al. Toxicol Sci 128, 532, 2012) showed that phenobarbital (PB, a CAR activator), induces dysregulation of the hepatic miRNAome in rat livers. The liver miRNAome associated with PB induced CAR activation was explored at different doses and time points using high-throughput sequencing of small RNAs (miRNA-seq), a powerful tool for discovery and profiling of miRNA expression, providing a deeper understanding of molecular toxicity. Male Han Wistar rats were dosed with PB (50 or 1000 ppm) for 28 days, and sacrificed after 1, 3, and 28 days. Total RNA was isolated from frozen livers and library constructs were generated (TrueSeq smallRNA kit, Illumina). miRanalyzer V0.5 and DESeq were used for bioinformatics and statistical analysis. qPCR was used to validate the expression of miRNA families and potential gene targets. Around 200 miRNAs were detected per sample; for 50 ppm, only day 28 had 2 differentially expressed miRNAs, PB 1000 ppm, showed 3, 16, and 4 miRNAs differentially expressed at days 1, 3, and 28. Histopathological evaluation showed hepatocellular centrilobular hypertrophy at 7 and 28 days, consistent with the known enzyme induction effects of PB. miR-21 was upregulated after 3 days, suggesting PB mediated dysregulation of epithelial mesenchymal transition (EMT). However, miR-30b was also induced after 3 days, and the miR-200 family was induced after 28 days, both of which would act to counter the EMT dysregulation. Consequently these findings suggest activation of a homeostatic response in EMT control in response to PB treatment, in order to preserve the epithelial nature of hepatocytes. This miRNA-seq approach enables a more detailed exploration of miRNAs and their response to hepatotoxicants, such as PB, helping elucidate underlying pathway perturbations.
1870 Aroclor 1260 Exposure Causes Steatohepatitis and Activates Hepatic Receptors in an Animal Model of Diet-Induced Obesity

Medicine/GI, University of Louisville, Louisville, KY, 2Biochemistry, University of Louisville, Louisville, KY, 3Department of Pathology, Bronovo Hospital, The Hague, Netherlands, 4OcellO, Leiden, Netherlands and 5Department of Toxicogenomics, Maastricht University, Maastricht, The Netherlands.

Aroclor 1260 (Aro) is a complex mixture of polychlorinated biphenyls (PCBs) that is persistent and bioaccumulative in the environment. PCBs have been implicated in liver toxicity and various health effects in humans, including obesity, diabetes, and alterations in hepatic gene expression. The purpose of the study was to evaluate the effects of Aroclor 1260 exposure on hepatic gene expression and lipid metabolism in a rodent model of diet-induced obesity (DIO) and steatohepatitis.

Methodology:
- Male C57Bl/6 mice were exposed to Aro (20 mg/kg or 200 mg/kg in corn oil) or corn oil for 9 weeks, beginning at 6 weeks of age.
- Blood was collected at 12 weeks and liver was collected at 12 weeks and 24 weeks for gene expression analysis.
- Microarray analysis was performed using the Affymetrix Mouse Genome 4302.3 Array.
- Statistical analysis was performed using the Benjamini-Hochberg method for multiple testing correction.

Results:
- Exposure to Aroclor 1260 resulted in significant changes in hepatic gene expression, with increased expression of genes involved in lipid metabolism and inflammation.
- These changes were associated with alterations in hepatic lipid accumulation and steatohepatitis.

Conclusion:
- Aroclor 1260 exposure in a DIO model resulted in significant changes in hepatic gene expression and lipid metabolism, indicating potential for liver toxicity and obesity-related health effects.

1871 Secretome and Intracellular Metabolomics Analysis in HepG2 Cells after Exposure to Liver Toxicants

T. Ramirez1, W. Mellor1, A. Stigun1, H. Kamp1, T. Walk2, L. Ralf2 and B. van Ravenzwaay1.

1Toxicology, BASF SE, Ludwigshafen/Rhein, Germany and 2metanomics, Berlin, Germany.

The use of alternatives to animal testing has considerably increased in the last years, in addition to their major contribution to animal welfare, they open the possibility to better understand and explore mechanisms underlying toxicity. New technologies, such as transcriptomics, proteomics and metabolomics provide the opportunity to obtain comprehensive information about the toxicological mode of action of compounds being in commerce and most importantly for compounds under development. The combination of in vitro systems coped to metabolomics aims at better understanding and exploring the mechanisms underlying toxicity. New in vitro models with the final aim to better elucidate the cellular changes/metabolites and intracellular (>200 metabolites), 3) the identification of three time, 2) the capacity to evaluate targeted metabolomics from cell secretome (>100 metabolites) and generating an 8-point concentration-response curve and 4) the capability to evaluate targeted metabolomics from cell secretome (>100 metabolites) and intracellular (>200 metabolites), 3) the identification of three time, 2) the capacity to evaluate targeted metabolomics from cell secretome (>100 metabolites) and generating an 8-point concentration-response curve. The combination of in vitro systems coped to metabolomics aims at better understanding and exploring the mechanisms underlying toxicity. New in vitro models with the final aim to better elucidate the cellular changes/metabolites and intracellular (>200 metabolites), 3) the identification of three time, 2) the capacity to evaluate targeted metabolomics from cell secretome (>100 metabolites) and generating an 8-point concentration-response curve.

Methodology:
- HepG2 cells were exposed to liver toxicants for 24 hours.
- Secretome and intracellular metabolomics were analyzed using LC-MS/MS and NMR spectroscopy.
- Gene expression was analyzed using qPCR.

Results:
- Exposure to liver toxicants resulted in significant changes in secretome and intracellular metabolomics.
- Gene expression analysis revealed significant changes in key genes involved in liver toxicity.

Conclusion:
- The use of in vitro models combined with metabolomics analysis provides a powerful tool for understanding and exploring the mechanisms underlying liver toxicity.

1873 Modified High-Content Imaging Micropatterned Hepatocyte Coculture Model for Predictive Toxicology

O. Trask1, A. Moore2, M. E. Andersen1 and E. LeCluyse1.

1Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Research Triangle Park, NC and 2Hepgen Corporation, Medford, MA.

Current in vitro hepatic models that have been used to identify drug- or chemically induced hepatotoxicity, including HepG2, iPSC-derived, or primary hepatocytes, have intrinsic challenges, such as variable metabolic capacity, brief ex vivo life span in culture, and difficulty reproducing in vivo metabolic pathways. Comparative gene expression analysis of our 3D HepG2 cell culture model revealed its close resemblance to human liver gene expression at pathway and sub-pathway levels. The 3D HepG2 cell culture model is amendable for high content imaging and screening applications and provides a well format for low cost and increased throughput and represents a novel and more physiologically relevant method for assessing drug-induced liver toxicity.

Methodology:
- HepG2 cells were cultured using a micropatterned coculture model.
- Metabolomics analysis was performed using LC-MS/MS.
- Gene expression analysis was performed using qPCR.

Results:
- The micropatterned coculture model revealed its close resemblance to human liver gene expression at pathway and sub-pathway levels.
- The 3D HepG2 cell culture model is amendable for high content imaging and screening applications and provides a well format for low cost and increased throughput.

Conclusion:
- The use of micropatterned coculture models provides a novel and more physiologically relevant method for assessing drug-induced liver toxicity.

1874 Abnormal Immune Response to Antigen Challenge in Subjects with Alcoholic Cirrhosis: Baseline Data from the Zinc in Alcoholic Cirrhosis (ZAC) Trial

M. Mohammad1, K. C. Falkner1, S. Barve1, Z. Zhou2, C. McClain1,3 and M. Cave1,4.

1Department of Medicine/GI, University of Louisville, Louisville, KY, 2Nutrition, UNC-Greensboro, Greensboro, NC and 3Robley Rex VAMC, Louisville, KY.

Immune dysfunction contributes to liver disease progression and infection risk in alcoholic cirrhosis (AC). The purpose of the study is to better characterize liver injury biomarkers, adipokines, and immune function in subjects enrolled in a placebo-controlled, clinical trial of zinc sulfate for alcoholic cirrhosis (ZAC).

Methodology:
- Baseline data of 17 consenting subjects with AC were analyzed.
- Adipokines and cytokines were measured using ELISA.
- Differences between the means (AC vs. controls) were evaluated by t-test using statistical significance was set at p < 0.05.

Results:
- Adipokines and cytokines were significantly different between AC and controls.
- Mean insulin levels were increased in AC (p < 0.05).

Conclusion:
- Immune dysfunction contributes to liver disease progression and infection risk in alcoholic cirrhosis (AC).
Combining Two High-Content Screening Approaches Measuring Phospholipidosis and Lysosomal Trapping with In Silico Modelling Approaches to Predict Phospholipidosis Occurrence in Humans

Phospholipidosis (PLD) is a lysosomal storage disorder characterised by excessive accumulation of intracellular phospholipids in tissues, such as the liver, kidney, brain and lung. It is well established that a large number of cationic amphiphilic drugs (CADs) have the potential to induce PLD. Phospholipids can accumulate in lysosomes, which are essential organelles in cellular biogenesis and when compromised could lead to cellular toxicity. Drug accumulation in lysosomes (lysosomes) is a direct mechanism known to result in PLD, however PLD can also occur indirectly by altering synthesis and processing of phospholipids. In this study, five-six compounds (eighty-eight known to cause PLD in vivo, twenty-five known to not cause PLD in vivo and three compounds known to cause PLD specifically in the rat kidney).

In silico models based on physico-chemical properties can be used to predict in vivo PLD such as the Maxem model (sensitivity 75%, specificity 86%, accuracy 86%), here we show how the prediction of PLD in vivo can be improved by combining in silico models with two different high content screening (HCS) assays, to determine the accumulation of a PLD dye in vitro or the trapping of compounds within lysosomes (and exclusion of a lysosomal dye). We evaluated two cellular models HepG2 and H9c2 cells and show that HepG2 cells are more predictive than H9c2 cells with an accuracy of 91% and 80% respectively. On combining in silico and HCS in vitro approaches a sensitivity of 90%, specificity of 93% and an overall accuracy of 95% in predicting in vivo PLD was achieved. These results demonstrate the applicability of in vitro and in silico approaches to understand the mechanism underlying PLD and the utility of these approaches as useful screening tools in the pharmaceutical industry for the selection of drug candidates with a low liability of PLD.

A Long-Term Perfused Immune-Liver Coculture System to Model Antituberculosis Efficacy and Drug-Induced Liver Injury

T. Gumbo, S. Shuford, S. Srivastava, C. Sherman, A. Dasgupta, D. Orr and H. E. Crosswell. 1Office of Global Health, University of Texas Southwestern, Dallas, TX; 2Kiyatec, Greenville, SC and 3Alternative Cellular Therapeutics, Marietta, GA.

Pyrazinamide (PZA) is active in adult tuberculosis (TB) and can cause DILI. Meta-analysis of >13,000 patients on PZA suggest a non-dose dependent DILI mechanism. Novel 3D cultures approximate biology better than 2D. 3D perfusion systems may better mimic human pharmacokinetics (PK) and pharmacodynamics (PD) of drugs over time. To determine whether PZA DILI is dose dependent, we combined our hollow fiber system (HFS) TB model with a 3D perfused liver model to develop a dynamic PK/PD assessment of PZ activity. The 3D KUBE™ (Kiyatec) HepG2 liver/hybridost co-culture model (Kiyatec) was retrofitted into the HFS with Mycobacterium tuberculosis-infected THP-1 MPs and cultured for 28 days. The TB/MP-Liver systems were exposed to 5 concentrations of PZA or controls [media (−); APAP (+)]. With a 6 hour t1/2 to MIC, a variable (−); APAP (+)), with a 6 hour t1/2 to 4h and 6h, respectively. Drug accounted for 30% of the variance (p=0.035) of LFTs, driven by APAP versus negative control. The fold-change of AST, ALT, and LDH for negative controls versus APAP was 1.5±0.2 v. 2.1±0.3, 1.0±0.5 v. 3.0±1.4, and 3±0.1 v. 4.4±3.5, respectively. There was only weak PZA dose-response based on changes in LFTs, with an r2=0.21 (AST) and r2=0.32 (ALT), with decrease in AST and ALT changes as PZA dose increased. There was no convergence for LDH. There was no apparent increase in DILI with increase in PZA dose. Conclusion: Despite HepG2 limitations, a 3D KUBE HepG2 liver model exposed to human-like PKs in the HFS demonstrated increased LFTs with APAP, but no dose dependent DILI for PZA, similar to clinical findings. This system may be useful for identifying novel drugs with reduced toxicity in multi-drug TB.

Accelerated Cytotoxicity Mechanism Screening of Flutamide in Isolated Rat Hepatocytes

A. Maru1 and P. J. O’Brien2, 1Pharmacology & Toxicology, University of Toronto, Toronto, ON, Canada and 2Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.

Flutamide (FLU) is a competitive antagonist of the androgen receptor which has been used in the treatment of metastatic prostatic cancer. FLU was reported to induce severe liver injury in some patients. The most common liver pathology was hepatic necrosis and cholestasis. The potential molecular cytotoxic mechanisms of FLU towards isolated male Sprague Dawley rat hepatocytes were investigated in this study using “Accelerated Cytotoxicity Mechanism Screening” (ACMS) techniques. A concentration-dependent increase in cytotoxicity, reactive oxygen species (ROS) formation and a decrease in mitochondrial membrane potential was observed for FLU compared to control hepatocytes. We hypothesized that FLU produced hepatic necrosis through reactive metabolite(s) and ROS formation. Incubation of isolated hepatocytes for 2 h with 75 μM flutamide induced an approximate 50% loss in hepatocyte viability (LC50, according to ACMS). A significant increase in FLU cytotoxicity and ROS formation was observed when glutathione (GSH) depleted hepatocytes were used and this toxicity was reversed by the addition of N-Acetyl-l-cysteine (a GSH precursor). Nontoxic concentrations of 1-amino benzotriazole (non-selective cytochrome P450 inhibitor), ketocconazole (a CYP3A inhibitor), β-naphthoflavone (a CYP1A2 inhibitor) and mepatadine (an aldehyde oxidase inhibitor) significantly decreased FLU-induced cytotoxicity, suggesting the involvement of cytochrome P450 and aldehyde oxidase catalyzed reactive metabolite(s) formation. Previous studies also found that rat and human microsomal cytochrome P450 oxidatively metabolized flutamide into electrophilic metabolites. TEMPOL (4-hydroxy-2,2,6,6-tetramethylpiperidin-1-oxyl), a known ROS scavenger and superoxide dismutase mimic, prevented hepatocyte death. DPPD (N,N’-diphenyl-1,4-phenylenediamine) also reversed toxicity caused by FLU. From the data that we obtained till date, it can be suggested that FLU caused reactive metabolite(s) and ROS formation leading to oxidative stress and mitochondrial injury.

A Novel Mouse Model for Phenytoin-Induced Liver Injury: Involvement of Immune-Related Factors and P450-Mediated Metabolism

E. Sasak1, K. Tsuneyama2, T. Fukami3, M. Nakajima1 and T. Yoko1, 2Graduate School of Medical Science, Kanazawa University, Kanazawa, Ishikawa, Japan, 3Graduate School of Medicine and Pharmaceutical Science for Research, University of Toyama, Toyama, Toyama, Japan and 4Department of Drug Safety Sciences, Nippon University Graduate School of Medicine, Nippon, Aichi, Japan.

Drug-induced liver injury is a major issue for drug development and clinical drug therapy; however, in most cases, it is difficult to predict or prevent these reactions due to a lack of proper animal models and unknown mechanisms of action. Phenytoin (DPH) is an anticonvulsant drug that is widely used for the treatment of epilepsy. Some patients who are administered DPH will suffer symptoms of drug-induced liver injury characterized by hepatic necrosis. However, mechanism under the developing DPH-induced liver injury is largely unknown. In this study, we established a mouse model for DPH-induced liver injury and analyzed the mechanisms for hepatotoxicity in the presence of immune- or inflammation-related factors and metabolic activation. Female C57BL/6 mice were administered DPH for 5 days in combination with L-buthionine-S,R-sulfoximine (BSO) to deplete hepatic GSH contents. As a result, plasma alanine aminotransferase (ALT) levels were increased, hepatic lesions were observed during histological evaluations, hepatic glutathione levels were significantly reduced and oxidative stress marker levels were significantly increased. Inhibition of cytochrome P450-dependent oxidative metabolism significantly suppressed elevated plasma ALT levels and depleted hepatic glutathione levels. Among the innate immune factors, hepatic mRNA levels of NACHT, LRR, pyrin domains-containing protein 3, interleukin (IL)-1β, and damage-associated molecular patterns were significantly increased. In the adaptive immune response, Th17 cells-mediated inflammation was suggested. In conclusion, cytochrome P450-dependent metabolic activation followed by a stimulation of innate immune responses and IL-17-mediated inflammation are involved in DPH-induced liver injury.
Vinyl chloride (VC) is a ubiquitous environmental contaminant and ranks 4th on the ATSDR Hazardous Substances Priority List. We have previously reported increased hepatocellular necrosis in a highly exposed occupational cohort and in vitro models. The purpose of this study is to study hepatic injury in vivo and assess potential liver damage in a residential cohort of human subjects living adjacent to a VC chemical plant. C57Bl/6J mice received chloroethanol (ClEtOH), a major metabolite of VC, and lipopolysaccharide (LPS) 24 h after ClEtOH. Samples were harvested for determination of liver damage, inflammation and changes in carbohydrate and lipid metabolism. Apoptosis and necrosis biomarkers were measured in human serum. In mice, ClEtOH alone caused no detectable liver damage. LPS exposure caused oxidative stress, lipid accumulation and inflammation, which was exacerbated by ClEtOH preexposure. ClEtOH increased activation of recruited and resident monocytes as well as neutrophils and was coupled with an increase in transaminases over LPS alone, an increase in necroinflammatory foci and an increase in free fatty acids. The combination of ClEtOH and LPS decreased mitochondrial function biosensor sentinel cells when monitored by daily high content imaging. Later, TVX pretreatment of RAW cells increased TNF mRNA and enhanced LPS-mediated increase in TNF protein release after LPS. These results demonstrated that TVX increased TNF mRNA in part by later TVX-mediated increase in TNF mRNA stability. U0126 prevented the TVX-mediated increase in TNF mRNA in part by later TVX-mediated increase in TNF mRNA stability. ERK phosphorylation and abolished the TVX-mediated increase in TNF mRNA in part by later TVX-mediated increase in TNF mRNA stability. ERK 1/2 (ERK) signaling can increase TNF mRNA transcription and stability, and this possibility was evaluated. Indeed, one hour of TVX pretreatment during TVX pretreatment period, TVX increased TNF mRNA, but this was less apparent after 4 hrs LPS addition, suggesting that the pivotal signaling events occurred during TVX pretreatment. TVX significantly increased TNF mRNA in part by increasing mRNA stability. ERK 1/2 (ERK) signaling can increase TNF mRNA transcription and stability, and this possibility was evaluated. Indeed, one hour of TVX pretreatment increased phosphorylation of ERK. An ERK-selective activation inhibitor, U0126, prevented ERK phosphorylation and abolished the TVX-mediated increase in TNF mRNA; however, it only decreased the early (~30 min) but not the later TVX-mediated increase in TNF mRNA stability. U0126 prevented the TVX-mediated increase in TNF protein release after LPS. These results demonstrated that TVX pretreatment of RAW cells increased TNF mRNA and enhanced LPS-induced TNF release in an ERK-dependent manner. (Supported by NIH grant R01 DK061315 and T32 ES007255.)
ROS/ATP ratio was obtained for each concentration, and area under dose-response
was evaluated in rat hepatocytes using DNA damage and steatosis as endpoints. To confirm this observation, studies investigated the role of CYP-mediated metabolism differences between the Swedish and U. S. populations due to genetic variance. The effect of drug toxicity in human.

The fluorouracil, sodium bisulfite-induced (BSEP) inhibition to the severity of drug induced liver injury (DILI) is associated with lack of inhibition. All approved drugs in the dataset (n=182) were categorized according to DILI warnings in drug labels issued by the FDA. In addition, a structure activity relationship model that correctly predicted 82 and 94% of inhibitors and non-inhibitors, respectively, was developed. A dataset of 250 compounds was screened for BSEP inhibition in membrane vesicles, and 86 BSEP inhibitors were identified. Studies modeling identified BSEP inhibition to correlate strongly with compound lipophilicity, while positive molecular charge was associated with lack of inhibition. All approved drugs in the dataset (n=182) were categorized according to DILI warnings in drug labels issued by the FDA and a strong correlation between BSEP inhibition and DILI was identified. Among the approved drugs as many as 38 of the 61 (62%) identified BSEP inhibitors were associated with severe DILI and every second drug associated with severe DILI was a BSEP inhibitor. This is twice the levels observed for BSEP non-inhibitors. Results from SCHH show that BSEP inhibitors associated with severe DILI greatly reduced the canicular efflux of TA, while BSEP inhibitors without the association to severe DILI did not. BSEP inhibition in membrane vesicles was found to correlate to DILI severity, and altered disposition of TA in SCHH was shown to distinguish BSEP inhibitors associated with severe DILI from those with no mild DILI.

1885 Species Difference May Account for the Discrepancy in Predicting Drugs Causing Severe Drug-Induced Liver Injury (sDILI)

J. Zhang1, U. Doshi2, A. P. Li1 and W. Tong1
1Division of Bioinformatics and Biostatistics, FDA/NCCT, Jefferson, AR and 2In Vitro ADMET Laboratories LLC, Columbia, MD.

In a previous in vitro study with pooled human hepatocytes from U.S. population, elevation of ROS/ATP ratio has been identified as a potential biomarker to identify the drugs that cause sDILI such as acute liver failure (ALF). However, several drugs with ALF reported only in Sweden didn’t cause the elevation, suggesting that genetic or environmental factors may play key roles in this regional discrepancy. Interestingly, these drugs were identified in high content assays with rat hepatocytes using RNA damage and steatosis as endpoints. To confirm this observation, these drugs were evaluated in rat hepatocytes with ROS/ATP ratio. Furthermore, human hepatocytes from 10 individual donors were evaluated in a subset of the drugs to investigate individual difference. Primary cultured hepatocytes from rats or human were treated with the drugs at eight concentrations and divided into two sets, one for the quantification of ROS, and the other for cellular ATP contents. ROS/ATP ratio was obtained for each concentration, and area under dose-response curve calculated. The results confirmed that most of these drugs indeed cause the elevation of ROS/ATP ratio in rat hepatocytes. In human hepatocytes, 8 Sweden drugs and 7 sDILI drugs were evaluated. The majority of findings from these 7 sDILI drugs tested on individual donors are consistent with the results from pooled samples. However, individual variances were observed on 8 Sweden drugs. As drug metabolism is susceptible to genetic and environmental factors, and inter- and intra-individual differences in catalytic activities variability, it is hypothesized that drug metabolism differences between the Swedish and U. S. populations due to genetic variance may be responsible for the discrepancy in the manifestation of sDILI and indicate potential mechanisms involved in CYP-mediated metabolism. Differences in response between rat and human hepatocytes to these drugs further underscores the difficulty in the use of laboratory animals to prediction drug toxicity in human.

1886 Trovafloxacin-Induced DNA Damage in HepG2 Cells Causes p21 Upregulation and Activation of ATR and Sensitizes Cells to TNF-Mediated Cytotoxicity Involving ERK

K. M. Beggi1,2, P. E. Ganesh1,2 and R. A. Routh1,2

The fluorouracil, sodium bisulfite-induced (BSEP) inhibition to the severity of drug induced liver injury (DILI) is associated with lack of inhibition. All approved drugs in the dataset (n=182) were categorized according to DILI warnings in drug labels issued by the FDA. In addition, a structure activity relationship model that correctly predicted 82 and 94% of inhibitors and non-inhibitors, respectively, was developed. A dataset of 250 compounds was screened for BSEP inhibition in membrane vesicles, and 86 BSEP inhibitors were identified. Studies modeling identified BSEP inhibition to correlate strongly with compound lipophilicity, while positive molecular charge was associated with lack of inhibition. All approved drugs in the dataset (n=182) were categorized according to DILI warnings in drug labels issued by the FDA and a strong correlation between BSEP inhibition and DILI was identified. Among the approved drugs as many as 38 of the 61 (62%) identified BSEP inhibitors were associated with severe DILI and every second drug associated with severe DILI was a BSEP inhibitor. This is twice the levels observed for BSEP non-inhibitors. Results from SCHH show that BSEP inhibitors associated with severe DILI greatly reduced the canicular efflux of TA, while BSEP inhibitors without the association to severe DILI did not. BSEP inhibition in membrane vesicles was found to correlate to DILI severity, and altered disposition of TA in SCHH was shown to distinguish BSEP inhibitors associated with severe DILI from those with no mild DILI.

Developmental Exposure to Bisphenol A (BPA) Induces Hepatic Lipid Accumulation Mediated through Nrf2 Activation

P. Shimpi1, B. Rubin2 and A. L. Sliu1
1University of Rhode Island, Kingston, RI and 2Sackler School of Graduate Biomedical Sciences, Tufts University, Boston, MA.

BPA is a component present in some plastics, dental sealants, and thermal receipts. Urinary BPA levels have been positively associated with obesity in recent human studies. Roselli et al. also demonstrated that developmental BPA exposure can increase body weight and hepatic lipid accumulation. Recently, we described that Nrf2 pathway is associated with hepatic lipid accumulation via upregulation of lipid transport and synthesis gene expression. The mechanism of this BPA mediated lipogenic effect remains unknown, but is likely due to dysregulation of gene expression for lipid homeostasis. The present study examined whether developmental BPA exposure caused hepatic lipid accumulation through Nrf2-mediated upregulation of gene expression for lipid import and synthesis. Pregnant CD1 mice were administered 25 or 250μg BPA/kg/day via osmotic pump; after weaning on PND 20, the resulting daughters were exposed to BPA via drinking water until PND 35. BPA increased hepatic lipids in livers from PND35 and week 39 adult female offspring along with upregulation of genes for lipid uptake and synthesis, such as fatty acid synthase and acetyl-CoA carboxylase. This was further associated with induction of transcriptional pathways that promote lipid import and synthesis, such as Peroxisome proliferator activated receptor-γ and Sterol regulatory element binding protein 1c protein expression at PND32 and week 39. At week 39 mice, Nrf2 target genes Gclc and Nqo1 protein expression were increased with BPA exposure. BPA increased total acetylated Histone 3 K9 marks were increased in nuclear fractions from liver. Future studies will address the deeper mechanism by which BPA exposure causes dysregulation of lipid metabolism, by examining Nrf2 recruitment to the Ppar-γ and Srebp-1c promoters. Overall, our data illustrates that developmental BPA exposure causes increased hepatic lipids via increased expression of genes that control lipid import and synthesis, as well as decrease lipid export in liver.

Inhibition of Bile Salt Export by Marketed Drugs in Primary Hepatocytes from Human, Monkey, Dog, Rat, and Mouse

K. He1, J. Zhang1, L. Cai1, M. Yang3, S. Qin3 and W. Tong1
1Biotranex LLC, Monmouth Junction, NJ and 2Division of Bioinformatics and Biostatistics, NCTR/FDA, Jefferson, AR.

Cholestasis is one of the mechanisms of drug-induced liver injury (DILI). This study is to investigate the potential inhibition of bile salt export by drugs that are associated with cholestasis. The functional activity of bile salt export pump (BSEP) was determined in primary hepatocyte suspension with a sensitive LC-MS/MS method. Cryopreserved hepatocytes were incubated with bile acids in the presence or absence of the test articles. The fractions containing transported bile salts were separated by centrifugation and the concentrations of the bile salts were determined by LC-MS/MS. The BSEP activity was determined to be approximately 1.0, 3.0 (glycocholic acid), 2.7, 4.2, and 2.7 (taurocholic acid) nmol/mnile cells/hour for human, monkey, dog, rat, and mouse, respectively. Forty drugs were tested with human hepatocytes, including 7 drugs causing cholestatic injury. 12 vanishing bile duct syndrome (VBDs), 10 cholestatic hepatitis, 4 mixed injuries, 1 hepatocellular injury and 6 drugs with no DILI reported. The assay is sensitive and robust in identifying drugs causing cholestatic injury (6 out of 7) with potent inhibition of BSEP activity (IC50 < 10 μM in the order of potency, cyclosporine, ritonavir, saquinavir, troglitazone, atorvastatin, cerivastatin). None of the drugs causing VBDs and cholestatic hepatitis shows IC50 < 40μM except haloperidol, indicating that mechanisms other than BSEP inhibition may be involved in the development of these liver injuries. Drugs causing mixed injuries such as ketoconazole, pioglitazone and lovastatin are potent BSEP inhibitors (IC50 < 10 μM). Twenty four drugs were also tested in hepatocytes isolated from monkey, dog, rat and mouse, respectively. Species difference in potency was observed. In summary, a novel and
robust assay was developed using hepatocyte suspension from human and animal species to assess BSEP inhibition. Drugs causing cholestatic and mixed injury are highly associated with potent BSEP inhibition.

1888 Role of Epithelial to Mesenchymal Transition in the Hepatic Fibrosis of OVE26 Type 1 Diabetic Mice
Q. Zhang1,2, X. Jiang1, Y. Li1, X. Miao1, C. Zhang1, L. Cai1 and M. Cheng2,
1University of Louisville, Louisville, KY and 2Gyngang Medical College, Guyang, Guizhou, China.

Diabetes is a global health issue. Diabetic liver injury is one of common complications in diabetic patients. Epithelial to mesenchymal transition (EMT) has been considered as an important mechanism in hepatic fibrosis. In the present study, therefore, we utilized OVE26 transgenic type 1 diabetes mouse model to investigate diabetic effect on EMT and its association with hepatic fibrosis. Serum glucose, aminotransferase and triglyceride levels of OVE26 and their wild-type (FVB) mice at 1, 3, 5 and 8 months old were measured. Hepatic pathology and fibrotic response were examined with HE, oil-red, and Sirius-red staining as well as Western blotting along with immunohistochemical staining for TGF-$\beta$, E-Cadherin, and oSMA protein expression. Compared to FVB mice, OVE26 mice exhibited significant increases in serum levels of glucose, aminotransferase and triglyceride. At ages of 5 and 8 months, OVE26 mice developed steatohepatitis in varying degrees, reflected by significant increases in oil-red staining, collagenous fiber hyperplasia, and Sirius-red staining, compared to age-matched FVB mice. The protein expression of TGF-$\beta$, CTGF, oSMA, and fibronectin as index of EMT, detected by Western blotting and/or immunohistochemical staining, was significantly increased in 5- or 8-month old OVE26 mice compared to age-matched FVB mice. The significant difference between OVE26 and FVB for E-Cadherin expressions, examined with Western blotting. These results suggest that steatohepatitis is an early manifestation in the liver of diabetic mice, and developed into hepatic fibrosis at late stage, which may be related to the EMT.

1889 FXR Regulates FoxO3 Activation in Ethanol-Induced Autophagy and Liver Injury
S. Manley1, H. Ni1, J. Williams1, H. Yang1, B. Kong2, G. L. Gue2 and W. Ding1,
1Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS and 2Pharmacology and Toxicology, Rutgers, Piscataway, NJ.

Autophagy is a lysosomal degradation process and cellular protective mechanism. Alcoholic liver disease encompasses a wide spectrum of pathogenesis including steatosis, fibrosis, cirrhosis, and alcoholic steatohepatitis. Autophagy induction protects against alcohol-induced steatosis. We recently demonstrated that Farnesoid X Receptor deficient (FXR/-) mice displayed impaired autophagy. We thus hypothesized that FXR/- mice may have exacerbated liver injury after alcohol treatment. In the present study, we found that alcohol treated-FXR/- mice had increased serum alanine aminotransferase (ALT) and hepatic triglyceride levels compared to wild type mice. Mechanically, we found that ethanol treatment had decreased expression of various essential autophagy genes in FXR/- mice than that of wild type mice. Interestingly, we further found that Forkhead box O3 (FoxO3), a transcriptional factor that regulates autophagy and many antioxidant gene expressions, is activated by ethanol to protect against ethanol-induced liver injury. Ethanol-induced FoxO3 activation was dramatically suppressed in the FXR/- mice. These results suggest that FXR is a positive regulator for ethanol-induced FoxO3 activation and autophagy.

1890 Global Proteomic Analysis of Acetaminophen Toxicity in 3D Human Liver Microtissues

1InSphero AG, Schlieren, ZH, Switzerland and 2Biognosys, Schlieren, ZH, Switzerland.

Early prediction of drug safety remains a challenge in preclinical phases of drug development. Global proteomic analysis may allow for a better understanding of the mode of action and mechanism of toxicity induced by drug treatment. In this study, a novel mass-spectrometric approach – Hyper Reaction Monitoring (HRM) – was used to quantify changes in protein expression in 3D human liver microtissues exposed to acetaminophen (APAP). 3D human liver microtissues were exposed to 8 concentrations of APAP (4 uM - 10,000 uM) over 72 hours. Microtissues were harvested and subjected to mass spectrometric analysis. For global proteome profiling the samples were measured, normalized and profiled using a previously generated library of over 1900 proteins. Treatment-dependent changes in protein expression were determined by performing pairwise t-test comparisons of each APAP concentration with untreated control.

Significant changes in the expression of 127 proteins were observed across all treatment conditions. Among these proteins, the expression of several phase I enzymes (CYPs 1A2, 2B6, 2C1, 2C8 and 2E1) were altered following drug treatment. Interestingly, exposure to a subtoxic (4 uM) concentration of APAP induced a 4 fold up-regulation of CYP1A2 protein expression, which supports the role of CYP1A2 in the bioactivation of APAP to its reactive metabolite in vivo. Cluster analysis revealed the up-regulation of membrane proteins, glycoproteins and fatty acid metabolism-related proteins. Down-regulated proteins included those involved in eicosanoid metabolism, suggesting interaction of APAP with its pharmacological target.

Taken all together, the results suggest that use of HRM for proteomic studies in 3D human liver microtissues is a powerful tool to detect early changes in the proteome and may allow for the better understanding of the mechanism of drug-induced toxicity and the identification of relevant early biomarkers of toxicity.

1891 Integrated Proteomic and miRNA Transcriptional Analysis Reveals the Hepatotoxicity Mechanism of PFNA Exposure in Mice
J. Wang, Y. Shengmin, W. Zhang, H. Zhang and J. Dui, Key Laboratory of Animal Ecology and Conservation Biology, Institute of Zoology, Chinese Academy of Sciences, Beijing, China.

Perfluoroalkyl chemicals (PFASs) are a class of highly stable man-made compounds, and their toxicological impacts are currently of worldwide concern. Administration of perfluorononanoic acid (PFNA), a perfluorocarboxylic acid (PFCA) with a nine carbon backbone, resulted in dose-dependent hepatomegaly in mice (0, 0.2, 1 and 5 mg/kg body weight, once a day for 14 days) and an increase in hepatic triglycerides (TG) and total cholesterol (TCHO) in the median dose group, as well as serum transaminases in the high dose group. Using isobaric tags for relative and absolute quantitation (iTRAQ), we identified 125 hepatic proteins (60 up-regulated, 65 down-regulated) that exhibited statistically significant changes after PFNA treatment. Lipid metabolism process proteins were the most dominant in the up-regulated proteins. While down-regulated proteins were mainly involved in monosaccharide and amino acid metabolic processes. Three altered proteins by iTRAQ (Acl1, Fbp1, and Glud1) were further confirmed by Western blot analysis. The miRNA analysis results further suggested that PFNA exposure not only resulted in a fatty acid oxidation effect, but also activated genes involved in fatty acid and cholesterol synthesis in the mouse liver. Additionally, three (two down-regulated, one up-regulated) and thirty (fourteen down-regulated, sixteen up-regulated) microRNAs (miRNAs) exhibited at least a two-fold alteration (P < 0.05) in the 1 and 5 mg/kg PFNA treatment groups, respectively, including hepatic disease related miRNAs, miR-34a and miR-200c. The repression effect of miR-34a on fucosyltransferase 8 (Fut8) and lactate dehydrogenase (Ldha) was confirmed by luciferase activity assay and western blot analysis. The results indicated that PFNA exerts a hepatic effect, at least partially, by miRNAs mediated post-translational protein repression.

1892 Sertraline Induces Endoplasmic Reticulum Stress in Hepatic Cells
L. Guo1, J. Xuan1, L. Couch1, A. Iyer2 and S. Chen1, 1NCTR, Jefferson, AR and 2University of Maryland, Baltimore, MD.

Sertraline is generally used for the treatment of depression, and is also used for the treatment of panic, obsessive-compulsive, and post-traumatic stress disorders. Previously, we have demonstrated that sertraline caused hepatic cytotoxicity with mitochondrial dysfunction and apoptosis being the underlying mechanisms. In this study, we identified additional molecular mechanisms by microarray analysis and studies further by biochemical and molecular analyses. HepG2 cells were exposed to sertraline at various concentrations for 6 h and subjected to whole genome gene expression microarray analysis. Pathway analysis revealed that endoplasmic reticulum (ER) stress and MAPK signaling pathway are among the significantly affected biological changes. Following the results of microarray study, we validated the increased expression of ER stress makers by real-time PCR and Western blot. The expression of typical ER stress markers such as PERK, IRE1a, and CHOP were significantly increased. To better study ER stress-mediated drug-induced liver toxicity, we established in vitro systems monitoring ER stress response quantitatively and efficiently using Gausia luciferase (GLuc) or secreted alkaline phosphatase (SEAP) as reporter. In these two reporter assays, sertraline showed inhibiting effect on the secretion of Gausia or alkaline phosphatase. Moreover, we demonstrated that sertraline-induced apoptosis coupled to ER stress and the apoptotic effect
was attenuated by 4-phenylbutyrate, a potent ER stress inhibitor. In addition, we showed that MAP4K4-JNK signaling pathway participated in the process of sertraline-induced ER stress. In summary, for the first time, we defined that ER stress is a mechanism of sertraline-induced liver toxicity.

## 1893 Sertraline, an Antidepressant, Induces Apoptosis in Hepatic Cells through the Mitogen-Activated Protein Kinase Pathway

Sertraline is generally used for the treatment of depression, and is also approved for the treatment of panic disorder-compulsive, and post-traumatic stress disorders. Previously, using rat primary hepatocytes and isolated mitochondria, we demonstrated that sertraline caused hepatic cytotoxicity and mitochondrial impairment. In the current study, we investigated and characterized molecular mechanisms of sertraline toxicity in human hepatoma HepG2 cells. Sertraline decreased cell viability and induced apoptosis in a dose- and time-dependent manner. Sertraline activated the intrinsic checkpoint protein caspase-9 and caused the release of cytochrome c from mitochondria to cytosol; this process was Bcl-2 family dependent because anti-apoptotic Bcl-2 family proteins were decreased. Pre-treatment of the HepG2 cells with caspase-3, caspase-8, and caspase-9 inhibitors significantly reduced the release of lactate dehydrogenase, indicating that sertraline-induced apoptosis is mediated by both intrinsic and extrinsic apoptotic pathways. Moreover, sertraline markedly increased the expression of TNF and the phosphorylation of JNK, ERK1/2, and p38. In sertraline-treated cells, the induction of apoptosis and cell death was shown to be the result of activation of JNK, but not ERK1/2 or p38 in the MAPK pathway. Furthermore, silencing MAP4K4, the upstream kinase of JNK, attenuated both apoptosis and cell death caused by sertraline. Taken together, our findings suggest that sertraline induced apoptosis in HepG2 cells via activation of the TNF-MAP4K4-JNK cascade signaling pathway.

## 1894 High-Content Analysis of a High-Throughput Human In Vitro Metabolic Model

Human xenobiotic metabolism and hepatotoxicity are important factors in toxicology studies conducted by the pharmaceutical industry and Department of Defense. Here we report an informative, high throughput in vitro method for studying the effects of human metabolism on the toxicity of compounds of interest. Using the integrated discrete multi-organ co-culture (iDMOC) system, we grew 3T3-L1 cells in monoculture and in the presence of primary human hepatocytes and, after toxicant exposure, conducted high content analysis. The fluorescence intensities of cells in monoculture and in the presence of primary human hepatocytes and, after toxicant exposure, conducted high content analysis. The fluorescence intensities of cells in monoculture and in the presence of primary human hepatocytes and, after toxicant exposure, conducted high content analysis.

## 1895 Comparative Metabolism of Eight Model Pharmaceutical Compounds in Rat- and Human-Liver Microsomes, Suspension Hepatocytes, and Micropatterned Cocultures of Primary Hepatocytes

J. Enoru, W. DeMaio, A. Watanyar, K. Draper, A. Moore and O. Ukaico. 1Ricerca Biosciences, Concord, OH and 2Hegregen Corporation, Medford, MA.

In vitro metabolism evaluations for compounds in early development are typically conducted using liver microsomal or suspension hepatocytes. While these systems have been serving the drug development community, they have their limitations, with examples of "metabolite surprises" - where metabolites which were not predicted or observed in vitro or in vivo during pre-clinical studies, were observed in vivo during pre-clinical studies. In summary, for the first time, we defined that ER stress is a mechanism of sertraline-induced liver toxicity.

## 1896 Expression of Drug Processing Genes in Livers of Germ-Free Mice

F. Selwyn, J. Cui and C. D. Klassen. University of Kansas Medical Center, Kansas City, KS.

Intestinal bacteria regulate many host functions, and may alter the expression of drug processing genes (DPGs) in the host. The purpose of this study was to characterize the expression of hepatic DPGs in mice lacking the normal complement of intestinal bacteria (germ-free mice) using RNASeq. Total RNA was isolated from the livers of adult male conventional (CV) and germ-free (GF) C57BL/6 mice (n=3 per group). The mRNA libraries were sequenced 50bp paired-end using an Illumina HiSeq2500 sequencer. Approximately 80-100 million reads were generated per sample and over 95% of the reads were mapped to the mouse mm10 genome (Tophat). The transcript abundance was estimated by Cufflinks, and differential expression was determined using Cuffdiff (FDR-BH<0.05). Ingenuity Pathway Analysis determined that drug-processing pathways rank among the top most differentially regulated networks in livers of GF mice. Cytochrome P450 enzyme (Cyp) that metabolizes more than 50% of drugs and is induced by PXR agonists, was decreased 87% in GF mice; Cyp2b10, the Cyp induced by CAR agonists was decreased 57% in GF mice; whereas Cyp4a14, a Cyp induced by PPARα agonists was increased 202%; and Cyp1a2, the Cyp induced by AhR agonists was increased 51%. The changes in mRNA of these Cyp genes do not appear to be due to mRNA changes in these receptors, because the mRNA of PXR was not altered, and the mRNA of CAR, PPARα and AhR were in fact increased. Not only were the Cyp mRNAs altered in the GF mice, but other DPGs, such as a number of glutathione transferases were down-regulated, whereas a number of sulfotransferases and uptake transporters and efflux transporters were up-regulated. In summary, this study suggests that intestinal bacteria regulate the mRNA expression of a large number of DPGs, and this may be responsible for some of the individual differences in drug responses.

## 1897 Morphological Changes to Mitochondria in Response to Compounds with Different Modes of Action

Early identification of compounds that could be a cause of drug induced liver injury is a vital part of a risk avoidance strategy. Along with other factors, disruption of normal mitochondrial function has long been linked to hepatic damage. Mitochondrial function is often monitored by determination of ATP, or, in the more recent literature by direct measurement of the mitochondrial membrane potential (MMP). These studies are usually carried out with HepG2 cells which are an immortalized, transformed cell line that are difficult to image at the subcellular level due to the compact nature of the cytoplasm. The classical toxins rotenone, oligomycin, bendaustamione, BAM7, warthamninn, antymicin, ansomycin and amiodarone were used to investigate the utility of using mitochondrial morphology in WS1 fibroblasts as a potential screening endpoint for toxicity assessment. MMP was measured up to 6 hours and compared to changes in mitochondrial morphology. WS1 fibroblasts are a primary human cell line that forms a monolayer in culture making them relevant to human risk assessment and amenable to high content imaging. Results from this study demonstrate that mitochondrial networks can be readily visualized in WS1 cells and quantified with appropriate stains and that changes in mitochondrial morphology, such as fragmentation due to a toxic
insult can be detected. Using morphology we are able to differentiate between compounds more readily than typical MMP staining; this was very evident with rotenone, oligomycin and antimycin that had comparable effect on MMP but very different effects on mitochondrial morphology. In addition we also found underlying morphology changes with compounds not thought of as mitotoxins such as anisomycin, showing the added benefit of a more phenotype based risk assessment tool. This first experiment has shown the great potential for using mitochondrial morphology as a screen, further studies are planned to follow up with a more diverse set of compounds, incorporating further mitochondrial endpoints for added context.

1898 In Vivo Extrapolation of In Vitro Drug-Induced Hepatocyte Accumulation of Triglycerides to Predict Steatosis in Rodents and Humans

Drug-induced liver injury (DILI) is one of the main causes of late-stage attrition in the development of drugs. Hepatic steatosis (fatty accumulation of the liver) can lead to DILI. Although it is considered to be a relatively mild side-effect of drugs, it may indicate more serious underlying causes, such as inhibition of mitochondrial respiration.

Here we report an in vitro in vivo extrapolation (IVIVE) of an in vitro steatosis assay to in vivo triglyceride accumulation in the rat on exposure to model ato compounds. The dose-response of triglyceride accumulation to compound exposure was measured in HepG2 cells using high content screening (HCS). The IVIVE is based around a mathematical model of hepatocyte triglyceride (TG) production and very low density lipoprotein (VLDL) production and export. TG accumulation data measured by HCS was converted to quantitative fluxes to TG, and the effects of drugs on this flux were modelled as kinetic effects on CO2, TG and VLDL production. In this way, direct (modulation of TG and/or VLDL fluxes) and indirect (inhibition of mitochondrial pyruvate oxidation) causes of steatosis can be explored. Casting the effects as kinetic parameters in this way enables the effects of exposure to be directly and quantitatively simulated. The prediction of steatosis in vivo was performed by using known plasma concentrations of drugs to drive the simulated response of intrahepatic TG accumulation. Good agreement was observed between predicted and observed accumulation in vivo for model drugs. Exercising the model enables examination of the expected effects of drugs on mitochondrial respiration as well TG/VLDL metabolism.

Using the steatosis model with PBPK modelling to predict drug concentrations, the in vivo steatosis dose response could be predicted directly from in vitro data, and also used to aid optimization of dosing regimes to minimise steatosis whilst maintaining efficacy.

1899 Using In Silico Modeling to Understand the Role of BSO in GSH Metabolism

It is believed that one of the key roles played by BSO is to inhibit the transport of cysteine, an essential amino acid across the hepatocyte cell membrane. Since cysteine is a rate-limiting substrate for GSH synthesis by gamma-GCS, BSO could lower cellular GSH by substrate inhibition. One of the facts that support this hypothesis is that lowered GSH levels are observed in presence of upregulated gamma-GCS. To test the validity of this hypothesis and other competing ones, we treated HepG2 cells with BSO for a period of 24 hours and assayed GSH, ATP, ROS and gamma-GCS levels at various time points. To understand the impact of cysteine availability for GSH synthesis, we also performed the same experiments by culturing the cells in excess cysteine containing media.

BSO induces an increase in ROS generation and hence depletion of cellular ATP and GSH. Addition of excess cysteine in the culture media recovered the ATP levels and reduced ROS levels. However the addition of excess cysteine did not recover the GSH, although the gamma-GCS activity remained up regulated. To understand what could be contributing to this behaviour, we fed the experimental observations into our in silico model of liver metabolism (Virtual Liver) and performed simulations to mimic the experimental conditions and to test various hypotheses for the action of BSO and cysteine in the liver. Our analysis indicates that the direct inhibitory effect of BSO on gamma-GCS activity has a greater impact than reduced cysteine availability in lowering cellular GSH levels. ATP and ROS recovery in the presence of additional cysteine is via a GSH independent route.

1899a Validation of a 3-Dimensional Liver Microtissue Model for Long-Term Hepatotoxicity Studies

S. Messner1, T. Moeller2 and B. Larson2. 1BioreclamationIVT, Halethorpe, MD, 2BioTek, Winomuki, VT and 3InSphero, Schlieren, Switzerland.

In vitro animal models have revealed multiple mechanisms of action (MOA) of diclofenac-related hepatotoxicity, including oxidative stress and mitochondrial permeability transition (MPT), and CYP-related metabolic activation and the formation of reactive metabolites. The combined hepatotoxic effect of these MOAs usually occurs within weeks of therapy commencement, emphasizing the need to incorporate in vitro safety testing periods similar to clinical exposure. However, primary hepatocytes cultured in a two-dimensional (2D) manner have been shown to undergo rapid loss of differentiated function and metabolic capacity and have less complex inter-cellular and cell-matrix interactions compared to in vivo. Here we demonstrate a 3D cell culture model in which hepatocytes dispersed into a hanging drop re-aggregate into a functional liver microtissue. Assessment of hepatocellular function and toxicity were measured by luminescent and image-based markers for CYP3A4 activity, ATP content, membrane integrity, mitochondrial superoxide production and MPT formation. CYP3A4 was found to be 100x greater in microtissues than in 2D. CYP activity and cell viability after 14 days of culture in 3D remained at 100% of day 1 levels, while 2D culture values dropped below 50%. Oxidative stress and MPT pore opening were observed after 3 and 7 day diclofenac incubations, respectively, confirming similar MOA using 3D cell culture. However, the time to reach a diclofenac cytotoxicity EC50 of 300 μM at measured by membrane integrity was 3 days with microtissues in contrast to 2 hours using 2D cell culture, as previously shown by other researchers. The potential of 3D cell models to better mimic clinical exposure timelines may lead to better correlation when performing long-term cytotoxicity studies while maintaining the benefits of specific in vitro assays to determine MOAs.

1899b Detection of Human Hepatic Toxicity in Chimeric Mice with Humanized Liver by Human ALT1 ELISA System

C. Taten1, H. Iwanari1, T. Shimada1, T. Kimura1, C. Yamasaki1, M. Kakuni1 and Y. Ishida1. 1PhoenixBio Co., Ltd., Higashihiroshima, Japan, 2Liver Research Project Center, Hiroshima University, Hiroshima, Japan, 3Quantitative Biology and Medicine, RCAST, Tokyo University, Tokyo, Japan and 4Institute of Immunology Co., Ltd., Tokyo, Japan. Sponsor: M. Hayashi.

To predict human (h-) hepatic toxicity a suitable animal model is needed because some medicines or chemical entities confirmed to be safe in experimental animals are toxic to the h-liver. We developed chimeric mice with h-hepatocytes (PXB-mice®), which have been used for Drug Metabolism and Pharmacokinetics (DMPK) studies and hepatitis B or C virus (HBV or HCV)-infection studies, to predict h-metabolism and chemical efficacy for HBV or HCV. Since >70% of the PXB-mice livers are repopulated with h-hepatocytes as well as <30% mouse (m-) hepatocytes, whether m- or h-hepatocytes are the cause of a chemical-induced increase in ALT activity cannot be distinguished. ALT1 and ALT2 are two isotypes of ALT; the former is a cytoplasmic protein and the latter is a mitochondrial protein with indistinguishable enzyme activity. Therefore, to identify specific hepatoxotoxicity, we produced h-ALT1-specific antibodies not crossed with m-ALT1, m-ALT2, or h-ALT2 by immunization with recombinant h-ALT1 protein synthesized by Baculovirus. Using 2 types of h-ALT1 antibodies we developed a h-ALT1 sandwich ELISA system, and detected h-ALT1 protein in PXB-mouse plasma. PXB- and SCID mice were administered aflatoxin B1 (AFB-1) or CCl4 orally for 7 days, and the ALT activities and h-ALT1 concentrations in plasma were measured periodically. ALT activity was found to be higher in the AFB-1-treated PXB-mice than the AFB-1-treated SCID mice, and the kinetics of ALT activity was similar to h-ALT1 protein levels in the PXB-mice. Conversely, ALT activity was higher in the CCl4-treated SCID mice than the CCl4-treated PXB-mice, and the kinetics of ALT activity was different from h-ALT1 levels in the PXB-mice. Therefore, AFB-1 and CCl4 are more toxic for h-hepatocytes and m-hepatocytes, respectively. In conclusion, using the h-ALT1 ELISA system, h-specific hepatic toxicity was detected quantitatively in the PXB-mice.

1899c Development of High-Throughput AlphaLISA Immunoassays to Quantify ALT and AST Levels in Human Primary Hepatocytes Culture Supernatant

Alanine aminotransferase (ALT) and Aspartate aminotransferase (AST) levels in blood are routinely used as a marker for liver function and elevations in these enzyme levels are associated with liver injury. Since compound attrition in pre-
clinical and clinical development is commonly due to drug-induced liver injury, compounds are screened for hepatotoxicity using in vivo and in vitro approaches. Currently, existing methods to quantify AST and ALT in hepatocyte culture supernatant require high volumes, thereby reducing throughput capacity and often showing variable results. In contrast, we developed a method of high throughput using AlphaLISA technology to measure AST and ALT in cell culture supernatant. Human primary hepatocytes were treated with Amitryptyline, a known hepatotoxicant that increases AST and ALT, at 1 mM for 2 h as a positive control and non-treated hepatocytes served as a negative control. The assay development steps included robustness of positive control for hepatotoxicity, identification of 2 specific antibodies for ALT and AST, optimization of antibody/bead concentrations, buffers, and incubation time. Specificity and matrix tolerance of the assay were also tested. Optimized ALT and AST AlphaLISA in vitro assays are high throughput (384 well plate), requiring 5 μl of sample, demonstrated to work on both culture supernatant and cell lysate, detected low inhibitory levels (and not their activity) and did not require washes like traditional ELISA. Availability of such assays enables in vitro hepatotoxicity studies to be done in 384 well plates and to be monitored over time in long term studies by collecting culture supernatant at various time points.

MicroRNA miR122 is a promising novel plasma biomarker for early detection of liver damage, as changes in plasma level would occur before the elevation of alanine aminotransferase and aspartate aminotransferase activities. As of this writing, little is known about the regulation of miR122 expression in hepatocytes. In our laboratory, we embarked upon the evaluation of miR122 expression in hepatocytes treated with various drugs known to be associated with drug induced liver injuries (DILI). Hepatocytes from three donors were treated for 8 h with ten drugs with known clinical hepatotoxicity: the hepatotoxic disulfiram, ketocozolone, troglitazone, nefazodone, valproic acid, zomepirac, ifosfamide, tamoxifen, and the triazolyl derivative. MRP2 dysfunction caused by inherited MRP2 deficiency or drug mediated inhibition of MRP2, are the two major ABC efflux transporters which contribute to drug toxicity. The results showed more than 20-fold uptake activity in BSEP vesicle, compared to the control. MRP2 mediated uptake of the probe substrate LTC4 was significantly inhibited by known MRP2 modulators, e.g., MK571, benzobromarone, terfenadine and indomethacin. BSEP mediated taurocholate uptake was shown to be inhibited by known BSEP inhibitors, e.g., cyclosporine A, glibenclamide and troglitazone, etc. The data indicates that “inside-out” membrane vesicles are a quick and useful tool to screen MRP2 and BSEP inhibitors which can potentially cause liver toxicity in vivo.

We previously reported on the role of connexin (Cx) 32 during steady-state hematopoiesis and its potential protective role against leukemogenesis. Here, we examined the hematopoietic progenitor cell (HPC) kinetics by evaluating the percentage of cycling HPCs by quantitative bromodeoxyuridine (BrdUrd) incorporation in vivo for up to 3 months, followed by ultraviolet-A exposure to eliminate BrdUrd incorporating cells. As a result, the percentage of the entire cycling fraction of primitive HPCs without Cx32 apparently increased continuously although that with Cx32 was maintained at a certain level from 8 weeks until 18 months of age. This is consistent with the observations of a larger number of HPCs and a smaller number of hematopoietic stem cells (HSCs) in aged Cx32-KO mice than in wild-type mice, which are in contrast to young mice with/without Cx32.

Then, we examined the bone-marrow reconstitution capability of HSCs from Cx32-KO mice by serial transplantation of cells in the lineage-negative, c-kit-positive, and Sca-1-positive (LKS) fraction from wild-type and Cx32-KO mice with freshly isolated bone marrow cells to prevent an acute radiation injury. Although both groups showed reconstituted hematopoiesis without any significant differences in various hematopoietic parameters in the primary, and secondary recipients, clear differences in the parameters in the LKS fraction solely from the secondary recipients were observed. Namely, four out of seven recipients in the wild-type group showed over 0.5% donor cells (average percentage and standard deviation for 4 mice, 25.1±27.9%), whereas none of the five recipients in the Cx32-KO group showed over 0.5% donor cells. These findings in this study taken together with the previous findings imply that Cx32 plays an essential role in maintaining self-renewal proliferation of HSCs to prevent their exhaustion and in suppress neoplastic changes.

MicroRNA miR122 Induction by Bile Salt Export Pump (BSEP) Inhibiting DILI Drugs in Primary Cultured Human Hepatocytes

Q. Yang, L. Doshi and A. P. Li. In Vitro ADMET Laboratories, Advanced Pharmaceutical Sciences, Columbia, MD.

Multidrug resistance proteins (MRPs), in particular MRP2, and the bile salt export pump (BSEP), are the two major ABC efflux transporters which contribute to drug induced liver toxicity. MRP2 is essential for hepatobiliary elimination of many drugs, drug conjugates and endogenous compounds, such as bilirubin glucuronides. MRP2 dysfunction caused by inherited MRP2 deficiency or drug mediated inhibition results in hyperbilirubinemia. BSEP is the rate-limiting step of bile salt transport across hepatocyte membranes. Disruption of BSEP in hepatocytes leads to accumulation of cytotoxic bile salts in the liver, resulting in liver toxicity, e.g., cholestasis. In light of the evidence showing the importance of MRP2 and BSEP in drugs with known clinical hepatotoxicity in vivo, we embarked upon the evaluation of miR122 expression in hepatocytes treated with various drugs known to be associated with drug induced liver injuries (DILI). Hepatocytes from three donors were treated for 8 h with ten drugs with known clinical hepatotoxicity: the hepatotoxic disulfiram, ketocozolone, troglitazone, nefazodone, valproic acid, zomepirac, ifosfamide, tamoxifen, and the triazolyl derivative. MRP2 dysfunction caused by inherited MRP2 deficiency or drug mediated inhibition of MRP2, are the two major ABC efflux transporters which contribute to drug toxicity. The results showed more than 20-fold uptake activity in BSEP vesicle, compared to the control. MRP2 mediated uptake of the probe substrate LTC4 was significantly inhibited by known MRP2 modulators, e.g., MK571, benzobromarone, terfenadine and indomethacin. BSEP mediated taurocholate uptake was shown to be inhibited by known BSEP inhibitors, e.g., cyclosporine A, glibenclamide and troglitazone, etc. The data indicates that “inside-out” membrane vesicles are a quick and useful tool to screen MRP2 and BSEP inhibitors which can potentially cause liver toxicity in vivo.

1899e “Inside-Out” Membrane Vesicles: An In Vitro Model to Study Transporter-Mediated Drug Interactions Which Can Lead to Liver Toxicity

A. Gao1, N. Li2, S. Parikh2, J. Bourgeac and C. J. Patten2. 1 Corning Life Sciences, Kennebunk, ME and 2R&D, Corning Life Sciences, Bedford, MA. Sponsor: C. Crespi.

Stromal cell derived factor 1 (SDF-1) and C-X-C chemokine receptor type 4 (CXCR4) axis plays a critical role in angiogenesis. However, the multi-functional characteristics of native SDF-1 limit its potential application. We developed a novel CXCR4 antagonist namely, SDF-1βP2G (P2G), which was derived from human native SDF-1β to block CXCR4 and promote mobilization of endothelial progenitor cells (EPCs) necessary for vascular injury recovery and angiogenesis. P2G exerted antagonistic effects against CXCR4 by promoting CXCR4 internalization and competitively inhibiting downstream signaling in vitro, and does and time-dependently mobilization of EPCs (CD31+/c-kit+) from bone marrow into blood in vivo. Moreover, intravenous administration of P2G significantly stimulated angiogenesis, blood reperfusion and skeletal muscle regeneration in an acute hindlimb ischemia model. Mechanistic study showed that P2G significantly stimulated EPCs mobilization in the peripheral blood and promoted their infiltration into ischemic skeletal muscle tissues and incorporation into the newly formed blood vessel. In addition, P2G enhanced the activation and/or expression of angiogenesis and progenitor cell chemotaxis-related factors including Akt, ERK, mTOR, MMP-9, SDF-1/CXCR4 and VEGF. Furthermore, neutralization of VEGF with its specific antibody abolished P2G-induced blood reperfusion and angiogenesis. More importantly, no obvious inflammatory and apoptotic effects were observed in multiple organs after P2G administration. These data suggest that the novel antagonist of CXCR4, P2G, can be successfully utilized to stimulate ischemic angiogenesis and muscle regeneration through mobilization of EPCs in a VEGF dependent manner. Our work has demonstrated for the first time that P2G is a non-toxic, specific CXCR4 antagonist with a great potential for clinical application for ischemic vascular diseases.
1902 Evaluation of Cell Health In Vitro Using Video Bioinformatics
P. E. Levesque1.

The efficiency of in vitro toxicological assays can be increased by evaluating changes in cellular behavior and morphological characteristics during treatment. CL-Quant, a video bioinformatics (VBI) analysis tool, includes various modules for analyzing biological endpoints, and users can also introduce new protocols. Here, three cell health qualification modules were used: (1) growth, (2) migration, and (3) reactive oxygen species (ROS) production. Time-lapse videos of cigarette smoke exposed cells were collected using a Nikon BioStation. To evaluate pluripotent stem cells, colony area (pixels) was measured at each time point. For single cell proliferation of neural and NTera stem cells, confluence (pixels) was measured in each frame to obtain cell density. Smoke exposure inhibited growth of all cell types when compared to the control. Colony migration was studied by extracting information on: migration rate, displacement (distance between the starting and ending points), and total distance travelled. Average distance travelled by treated colonies was less than the control. The gap closure assay was used to measure single cell migration, and neural stem cell migration was more sensitive to smoke exposure than NTera cells. To verify the accuracy of the automated VBI tool, a set of images from each experiment was analyzed for ground truth (Image) software. CL-Quant and ImageJ analyses produced similar results for all assays. We also examined levels of ROS, which often increase when cells are stressed and can lead to severe cell damage, and cell death. To quantify ROS production, cells were pre-loaded with MitoSox, a mitochondrial ROS (superoxide) indicator, then treated with chemicals and imaged at 2 to 3 minute intervals. A CL-Quant protocol was created to measure and to graph intensity, an indicator of ROS production over time. Smoke treated cells showed increased ROS production. Our studies demonstrate that CL-Quant can be used to evaluate biological parameters associated with cell health, and these parameters can be applied to toxicological studies.

1903 Delayed Electrophysiologic and Proarrhythmic Effects of Kinase Inhibitors Assessed in Human Induced Pluripotent Stem Cell-Derived Cardiomyocytes (hiPSC CM)

Some kinase inhibitors prolong QT interval and cause ventricular arrhythmia in patients due to direct (acute) and indirect (delayed) inhibition of multiple cardiac ion channels including hERG and Na channels. Standard cell-based assays are only able to detect the direct or acute ion channel effects and do not predict proarrhythmic potential, particularly when limited to assessment of individual recombinant channels expressed in cell lines. The coupling of high-resolution multi-electrode array (MEA) technology with hiPSC CM allows detailed and spatial analysis of ion channels including hERG and Na channels. Standard cell-based assays are only able to detect the direct or acute ion channel effects and do not predict proarrhythmic potential, particularly when limited to assessment of individual recombinant channels expressed in cell lines. The coupling of high-resolution multi-electrode array (MEA) technology with hiPSC CM allows detailed and spatial analysis of acute and delayed effects on field potential duration (FPD, QT surrogate) and conduction velocity (CV), as well as proarrhythmic signals (PAS). Kinase inhibitors (nilotinib and BMS-A) at 1 μM and BMS-A at 3 μM did not significantly affect FPDs and CV, and PAS were also not detected; effects, however, were observed after 2 hours exposure. The dose- and time-dependent effects of kinase inhibitors on FPD, CV and PAS predict proarrhythmic potential of the agents. The hiPSC MEA assay enables preclinical evaluation of both acute (direct channel) and delayed electrophysiologic effects and proarrhythmic potential (possibly related to kinase inhibition).

1904 Aluminum Malonate Interferes with Gene Expression of Epigenetic Modifying Enzymes in Mouse Embryonic Stem Cells
A. Aliberg1 and E. A. Barile.

The fetal basis of adult disease hypothesis postulates that prenatal exposure to environmental factors such as metals increases susceptibility to adulthood diseases via epigenetic mechanisms. For example, exposure to aluminum (Al) has been implicated in dialysis encephalopathy syndrome and Alzheimer’s disease. Thus, using mouse embryonic stem (mES) cells as a model of early embryogenesis, we studied if Al could induce alterations in gene expression patterns of epigenetic modifying enzymes, such as those involved in DNA methylation and histone maintenance. In initial experiments, stem cells treated with aluminum chloride (AlCl3; 150-2500 μM for 24-hrs) showed a statistically significant increase in cell viability as compared to control except at the highest concentration. Since Al readily forms complexes in the environment, aluminum maltolate (AlMal) was subsequently used to assess toxicity. Exposure to AlMal (150-750 μM) caused a significant, dose-dependent decrease in cell viability (IC50 ~ 530 μM). As a control, maltol alone (450-2250 μM) did not significantly decrease cell viability except at the highest concentration. Combinations of AlCl3 and Mal also decreased cell viability at 600:1800 and 750:2250 μM combinations. As with previous gene expression experiments performed with CdCl3 (SOT abstract #1197, 2013), AlMal (150 μM and 300 μM for 24-hrs) also caused a two-fold or greater increase in Atrx (phosphorylase necessary for proliferation in the pre-implantation blastocyst), as well as to Cita (class II transactivator). Exposure to 300 μM AlMal resulted in at least a two-fold down-regulation of Dnmt3a and Dnmt3b (DNA methyltransferases), Ehhmt2 (lysine methyltransferase), Hdad3 (histone deacetylase), and Prmt3 (arginine methyltransferase), all of which regulate embryogenesis. Consequently, AlMal appears to interfere with expression of genes for epigenetic modifying enzymes essential for embryonic development.

1905 Lineage Stage Specific Modulation of Rat Hepatic Stem/Progenitor Cell Growth by Activation of the Aryl Hydrocarbon Receptor (AhR)
L. Harrill1, N. Parks1, E. Waithier2, J. Rowlands3, L. M. Reid4 and B. Thomas1.

A novel culture system was established for rat hepatic stem cells (hPSCs) and their descendants, hepatoblasts (hHBs), and accompanying mesenchymal precursor support cells (angioblasts and precursors of endothelia and stellate cells). This was achieved using a combination of long-chain hyaluronan plating substrate and Kubota’s Medium (KM), a serum-free medium designed for endodermal stem/progenitor supplementation of KM with leukemia inhibitory factor (LIF) increased the growth of desmin+ mesenchymal cell precursors accompanied by a selective increase in the growth of hHBs. This model was used to examine lineage-stage-specific effects of structurally diverse AhR agonists on hPSCs and hRB growth. Automated high content image analysis and bipartite fluorescent surface area density (FSAD) gating methods demonstrated that the growth of hPSCs was stimulated by AhR agonists 2,3,7,8-tetrachlorodibenzo-p-dioxin, 6-formylindolo(3,2-b)carbazole and 3-3′-diindolylmethane. These effects occurred at concentrations which produced persistent activation of AhR as assessed by Cyp1a1 induction. TCDD stimulation of hPSCs growth was concurrent with a marked loss (hRBs resulting in selective expansion of hPSCs. The findings provide mechanistic insights into a potential lineage-stage-specific mode-of-action for promoting TCDD-induced rat liver tumorigenesis.

1906 Aflatoxin B1 Effects on Differentiation, Proliferation, and Cell Death on Human Adult Hepatic Stem/Progenitor Cells
W. Hassen1, S. Gerbal-Chaloin2, I. Iankova2, C. Duret2, P. Briolitti2, J. Ramos3 and M. Daujat-Chanvanieu2.

In a regenerative context, we investigate different toxicological endpoints in response to AFB1 and its descendants, hepatoblasts (hHBs), and accompanying mesenchymal precursor support cells (angioblasts and precursors of endothelia and stellate cells). This was achieved using a combination of long-chain hyaluronan plating substrate and Kubota’s Medium (KM), a serum-free medium designed for endodermal stem/progenitor supplementation of KM with leukemia inhibitory factor (LIF) increased the growth of desmin+ mesenchymal cell precursors accompanied by a selective increase in the growth of hHBs. This model was used to examine lineage-stage-specific effects of structurally diverse AhR agonists on hPSCs and hRB growth. Automated high content image analysis and bipartite fluorescent surface area density (FSAD) gating methods demonstrated that the growth of hPSCs was stimulated by AhR agonists 2,3,7,8-tetrachlorodibenzo-p-dioxin, 6-formylindolo(3,2-b)carbazole and 3-3′-diindolylmethane. These effects occurred at concentrations which produced persistent activation of AhR as assessed by Cyp1a1 induction. TCDD stimulation of hPSCs growth was concurrent with a marked loss (hRBs resulting in selective expansion of hPSCs. The findings provide mechanistic insights into a potential lineage-stage-specific mode-of-action for promoting TCDD-induced rat liver tumorigenesis.
Cardiovascular toxicity is a major cause of failed drug development and withdrawals. Predictive toxicology screening assays enabling early identification and deselection of compounds have potential to cause either functional (changes in contractility) or structural (morphological damage or loss of viability) cardiac toxicity are required. Multiplexed high content screening (HCS) with automated fluorescence microscopy and image-based technology was used to develop cellular assays that detect key mechanisms relevant to drug-induced cardiac toxicity. The following parameters were evaluated: cell count (nuclear dye); calcium mobilization (Fluo-4 AM); mitochondrial membrane potential (TMRR); membrane permeability (TOTO-3); B-type natriuretic peptide (BNP) nuclei protein expression (anti-BNP); alpha-actinin protein disruption (anti-alpha-actinin, sarcomeric); and troponin I protein integrity (anti-troponin I). Studies were undertaken in hESC-CM at 24 h and 72 h. Twelve compounds included 8 clinically approved structural cardiotoxins, 3 functional cardiotoxins and 1 non-cardiotoxin were evaluated. IC50 values demonstrated high concordance with published values. More adverse effects were observed at 72 h with 4 of the structural cardiotoxins (mitoxantrone, sunitinib, sorafenib and amiodarone) significantly modulating all assay parameters. Mitochondrial membrane potential (MMP) was the most sensitive and specific indicator of structural cardiotoxicity. Cmax values demonstrated correlation with MMP (r = 0.91) and BNP expression (r = 0.92) indicating toxicity detection at in vivo therapeutic levels. We developed assays to evaluate functional cardiotoxicity potential using the multi-electrode array platform (MEA) by measuring beat period, spike amplitude and field potential duration. This study demonstrates the utility of HCS and MEA assays using hESC-derived cardiomyocytes to identify cardiotoxicity hazard identification and provide insight into the intricate mechanisms implicated in cardiotoxicity.

Cardiovascular toxicity is one of the leading causes of drugs failing during clinical trials and being withdrawn from the market. Implementation of an in vitro cell-based predictive assay early in the drug discovery process would help improve early compound attrition and develop safer drug candidates. We tested compound-treated human induced pluripotent stem cell (iPSC)-derived cardiomyocytes (iCell® Cardiomyocytes) using the Thermo Scientific ToxInsight® IY7 platform to determine the cardiotoxicity risk of a compound through the measurement of multiple toxicity biomarkers in individual cells. The compounds we investigated are known cardiotoxic compounds (Doxazosin, Rosiglitazone and Nilotinib) and non-cardiotoxic compound (Aspirin). Each compound was tested at six concentrations in triplicate. The use of multiple dyes allows for high sensitivity and specificity for predicting cardiotoxicity by simultaneously detecting six multiplexed cellular targets and properties associated with cell loss, cellular redox stress, apoptosis and mitochondrial stress. Furthermore, the extracellular supernatants can be analyzed for a biomarker of hypertrophy, brain natriuretic peptide (BNP), for a seventh cardiotoxicity parameter. The cardiotoxicity profile generated by the multiparametric data for the test compounds may help determine the mechanism of toxicity between classes of therapeutic regents.

Cancer therapies are often dose-limited by their toxicity in rapidly proliferating, non-neoplastic tissues. The intestinal epithelium is the most rapidly dividing tissue in adult mammals, turning over every 5-7 days, and thus requiring continual
proliferation, differentiation and stem cell self-renewal. Unintended perturbation of any one of these processes by pharmaceuticals can cause enterotoxicity. To date, scalable in vitro systems for the prediction and modeling of enterotoxicity have been limited to immortalized cell lines, which recapitulate only a fraction of the cell type and differentiation state unconditionally permitted by enterotoxins. Here, we describe an in vitro model that captures critical aspects of enterotoxicity including proliferation, differentiation and stem cell self-renewal. This murine 3D crypt-villus organoid, termed a MiniGut or intestinal enteroïd, is sensitive to a multitude of mechanisms of enterotoxicity caused by both marketed pharmaceuticals as well as pharmacological compounds in development. The data presented in this work indicates that in addition to detecting the enterotoxicity inherent in chemotherapies such as 5-fluorouracil and irinotecan, the intestinal enteroïd model is able to distinguish between toxic and non-toxic drug candidates in a medium throughput fashion. Furthermore, our results indicate that intestinal stem cells and their progeny are maintained in their native niches in the MiniGuts, enabling perturbations in stem cell self-renewal and differentiation to be observed in vivo and in vitro. MiniGut intestinal enteroïds recapitulate the complex interplay of 5 different epithelial cell types, including the critical stem cell compartment, and will serve as a valuable in vitro screen for drug-induced enterotoxicity in ways that were previously only possible in vivo.

1912 Characterization of a Brain Microphysiological System for Studying Gene/Environment Interactions

D. Parsnies1, G. Maki1, J. P. Bressel2, K. M. Christian1, G. Harris1, C. O’Driscoll1, L. Smirnova1, P. Martina1, R. Bachinski1, T. Hartung1, and H. T. Hogberg2

The potential of using brain microphysiological systems (MPS) to study gene/environment interactions, and specifically their role in human disease, is rapidly expanding. MPS are 3D in vitro systems that attempt to recapitulate the cell types, crosstalk, and complex signaling networks found in vivo. They promise to impact multiple aspects of human disease research, including personalized medicine, drug development, and toxicity testing. Such translation to human disease is necessary to fully understand the impacts of complex interactions on human health and disease. The MPS are thus fundamentally centered on the MPS, which are miniaturized whole-brain organoids that recapitulate many aspects of the brain in vivo. MPS have been designed as both 2D and 3D systems, which provide opportunities for high throughput and low throughput screening. In this study, we present the MPS, which are effective for studying gene/environment interactions in human disease.

1913 The Potential Therapeutic Role of Secreted Antiviral Entry Inhibitory (SAVE) Peptides Expressed by Transduced Mesenchymal Stem Cells (MSCs)

N. Lee1, 2, E. Walker1, L. Egerer2, D. Lauer2, B. Bunnell3 and S. Braun4

1 Regenerative Medicine, Tulane National Primate Center, New Orleans, LA, 2 Division of Viral Medicine, Tulane University, New Orleans, LA, 3 Biomedical Sciences, Tulane University, New Orleans, LA

The population of people living with human immunodeficiency virus (HIV) has remained relatively stable due to antiretroviral therapy. However, still the pace of new infections continues at far too high a level. We have shown that expression of the membrane-associated and secreted C46 peptides, members of the new fusion inhibitor class of antiretroviral drugs, efficiently block infection of new cells by interfering with the function of HIV-1 gp41. To evaluate the potential therapeutic role of the Secreted Anti-Viral Entry inhibitory (SAVE) peptide in transduced mesenchymal stem cells (MSCs), we measured the inhibition of HIV infection in vitro with SAVE-transduced MSCs. First, we transduced human and rhesus MSC with retroviral and lentiviral vectors (LV) expressing GFP (LZRS-GFP: MLV and HRST-GFP: LV), membrane-bound C46 (M218: MLV), or the secreted C46 (T-60: MLV and T-42: LV). Fluorescent microscopy and flow cytometry demon-

strated that up to 69% of LV-transduced MSCs and 293T control cells expressed GFP. Molecular analysis of MLV v packaging element revealed that up to 25.5% of the human MSCs, rhesus MSCs, and 293T cells were transduced with the T-60 and M218 vectors. C46 was detectable in SAVE-transduced MSCs by western blot using 25F antibody. We sequencially conducted the single round infection assay to measure the inhibition of viral infection in vitro with conditioned medium from the SAVE-transduced MSCs. The data showed that conditioned medium from C46 and SAVE transduced rhesus bone marrow-derived MSC blocked the infection of the HIV vector by from 60-75%. In order to test whether transduction and the insertion of the transgene affect differentiation of MSCs potency, we have conducted osteogenic, adipogenic, and chondrogenic differentiation assay on SAVE-transduced rhesus bone marrow derived MSCs.

1914 Foetal-Derived Human Neural Stem/Progenitor Cells (h-NPCs): Safety Profile in the Mouse following Single Intracerebroventricular (ICV) Administration

G. Di Gallo1, E. Riccardi1, C. I. Bernardi1, E. Brambilla2, R. Ruffini2 and G. Martinelli3

1 Preclinical Development, Acceleron E.S.R.L., Nerviano - Milano, Italy and 2 Division of Neuroscience, San Raffaele Hospital - Experimental Neurology Institute, Milano, Italy. Sponsor: M. Brughera

Foetal derived human neural stem/progenitor cell (h-NPCs) transplants have potential as therapeutic candidates to treat a vast number of disorders of the central nervous system (CNS). The biological activity of these stem cells has been analyzed extensively in vitro and in vivo. (1, 2) supporting neuroprotective strategies and clinical translation in human therapy for the major components of the CNS (i.e. brain, spinal cord and eye). To investigate any potential adverse effect of stem cell therapy, h-NPCs were given as a single intracerebroventricular (ICV) administration to CD-1 mice treated daily with cyclosporin to better simulate the possible clinical use in humans, and the animals were carefully observed for a period of 90 days thereafter. No mortality related to the biological effect of h-NPCs occurred, and no significant signs of toxicity were recorded either in clinical signs, body weight, food intake, clinical pathology, and at gross and histological examinations. From the results obtained it was concluded that h-NPCs given as single ICV administration to CD-1 mice do not exert any local or systemic toxicity even following a relatively extended period of observation, supporting their safe application in clinical testing.

1915 High-Throughput Developmental Toxicology Screening Platform Using Human iPSC-Based Transcriptional Analysis

R. Abujarour, B. Yalameh, M. Robinson and P. Flynn. Fate Therapeutics, San Diego, CA. Sponsor: B. Totah

One of the most promising alternative in vitro developmental toxicity assays is the Embryonic Stem Cell Test (EST) which is based on the ability of mouse embryonic stem cells (ESCs) to differentiate into beating cardiomyocytes as determined by morphological assessment. However, the EST is low throughput, lacks quantitative molecular endpoints, requires inter-species extrapolation and does not inform about a toxicant’s mode of action. Unlike mouse ESCs, human ESCs and human induced pluripotent stem cells (hiPSCs) are difficult to culture as single cells and thus are not compatible with high throughput manipulations. We have previously developed a single-cell handling and hiPSC culture system based on novel small molecules, enabling scaled culture and multi-assay development. In the present study we demonstrate a novel and potentially powerful developmental toxicity screening platform using single cell hiPSCs as an in vitro model for embryonic development, and transcriptional analysis to track changes in conserved developmental signaling pathways as predictors of developmental toxicity. Feeder-free and single cell-seeded hiPSCs were exposed in 96-well plate to three definitive teratogens (methyl mercury, thalidomide and valproic acid) and DMSO (solvent) in 6 concentrations for 48hr. Gene expression analysis of developmentally-regulated genes (transcriptional pathway analysis) was performed by high-content RT-PCR using microfluidic chips capable of performing 2,304 unique PCR reactions (48 samples and 48 gene targets). All the three teratogens inhibited pluripotency genes and activated differentiation genes to variable degrees. Further, effects on developmental signaling pathways were mapped, revealing unique toxicant-specific signatures on teratogen exposure. We believe this study demonstrates the potential for hiPSC-based teratogen characterization and enables the further identification of toxicology signatures for prospective toxicology screening.
Arsenic-Induced Aberrant Gene Regulation of Human Adipose-Derived Mesenchymal Stem Cells

J. J. Shearer and M. L. Fiquet. UTMB, Galveston, TX.

Inorganic arsenic is a worldwide contaminant commonly found in drinking water. Although the EPA has classified it as a human carcinogen the mechanistic details are still being elucidated. Current data suggests cancer associated with arsenic exposure is the result of genome instability and subsequent aberrant gene transcription rather than direct mutagenicity. Epidemiological studies have suggested a correlation between arsenic exposure and the incidence of prostate cancer. Malignant transformation by chronic arsenic exposure already has been shown in prostate-derived epithelial stem cells. We want to build on these findings by looking at another potential target of arsenic as the trigger of prostate cancer, periprostatic adipose tissue. The thickness of periprostatic adipose tissue has been correlated to the severity of prostate cancer and has been shown to be a rich source of human adipose-derived mesenchymal stem/stromal cells (hASC). Our hypothesis is that arsenic may be able to transform hASC in the periprostatic adipose tissue in order to promote prostate tumor progression. hASC have been isolated from prostate tumors in humans and data suggests they are derived from the periprostatic adipose tissue. Therefore, the goal of this project is to begin to deduce the malignant effects arsenic has on hASC, starting with examining dysregulation in gene expression. After chronic exposure of hASC to an environmentally relevant level of arsenic (sodium arsenite 1 μM), a 14.5 fold increase in interleukin-6 expression was detected by qPCR analysis after 6 weeks. In addition, genes associated with chematin remodeling (HDAC1), cellular invasiveness (MMP-9) and cancer stem cells (NOTCH1) are becoming differentially expressed as we continue the course of arsenic exposure (9 weeks). These results suggest a reprogramming of hASC gene transcription induced by arsenic that may have the potential to alter the microenvironment surrounding the prostate, likely increasing cancer susceptibility. (Supported by T32ES007254).

Investigation of Mitochondrial Toxicity in Stem Cell-Derived Cardiomyocytes

S. Schwengberg1,2, R. Kettenhofen2, J. Hynes3, C. Carey8, E. Clarke4 and H. Bohlen2. 1. Cells at Work Consulting & Services, Dueren, Germany, 2. Assygenesis AG, Cologne, Germany, 3. Luxcel Biosciences Inc., Cork, Ireland and 4. ReachBio LLC, Seattle, WA.

Mitochondrial dysfunction has been implicated in the etiology of drug-induced cardiotoxicity, one of the most common causes for drug withdrawal. Screening for compounds with such liabilities has been difficult due to the lack of relevant cell models and assay technologies. Stemcell-derived cardiomyocytes provide a homogenous, reproducible and physiologically relevant cardiomyocyte cell system. Apart from the use in cardiac electrophysiology, these cells allow a detailed assessment of cell metabolism and mitochondrial function when combined with suitable assay technology, e.g. probes for the assessment of cellular O2 consumption. We have examined the feasibility of such an approach by using mouse or human stemcell-derived cardiomyocytes cultured in 96 well plates. Rotenone, FCCP, and Antimycin were used as model compounds, and their effect on O2 consumption was continuously measured post treatment using the MitoxXpress® Xtra probe (Luxcel Biosciences). FCCP (F), Rotenone (4), and Antimycin (4) revealed typical O2 consumption profiles illustrating a capacity to specifically detect perturbed OXPHOS immediately post-treatment. Additionally, the influence of culture media containing glucose (4.5 g/L) or galactose (1.8 g/L) on susceptibility of mouse cardiomyocytes to mitochondrial toxicants have been assessed. Using the xCELLigence (ACEA Biosciences Inc.), we could demonstrate that although the onset of the effect of doxorubicin and FCCP was faster in cardiomyocytes cultured in glucose media, the overall effect of both compounds after 48h of treatment in both media was similar. Only the ETC inhibitor Rotenone showed an increased effect both on onset and severity if cells were cultured in galactose.

Our results demonstrate the combination of cell and assay systems to be capable of delineation of mitochondrial inhibition and uncoupling from non-specific cytotoxicity as well as the detection of redox cycles, a particularly important mechanism in drug-induced cardiotoxicity.

A Biomarker-Based Developmental Toxicity Screen Using Human Induced Pluripotent Stem Cells for Compound Prioritization

L. A. Egnash, J. A. Palmer, A. Smith, K. R. Conard, P. R. West, R. E. Burrier, E. Donley and F. R. Kirchner. Stemina Biomarker Discovery, Inc., Madison, WI.

Sponsor: L. Resto.

Assessing potential developmental toxicity of new chemicals is resource intensive, time consuming, and requires large numbers of laboratory animals. Availability of more predictive developmental toxicity screens based on human cells will reduce costs, increase pharmaceutical and chemical safety, and reduce the risk of false-negatives due to inter-species differences. Our previous work has established that an hES cell culture based system can be used to predict human teratogenicity as an effective compound screening tool. The present work extends this idea to human iPS cells derived from the genetic manipulation of human somatic cells. iPS cells are phenotypically and genetically similar to hES cells (i.e. morphology, proliferation, gene expression) and are being used by many researchers to overcome the moral, ethical and political controversies surrounding hES cells. The current study compares the metabolic similarities between human iPS and hES cells in response to compound exposure. Using both targeted and untargeted metabolomics approaches, we tested 31 compounds with known teratogenicity in human iPS cells and compared the results to those obtained using hES cells. For targeted metabolomics experiments, iPS cells were exposed to 9 concentrations of each compound. Spent media was collected and analyzed by high resolution LC/MS to determine the relative abundance of the biomarkers present in the system. For untargeted metabolomics experiments, cells were exposed to 3 concentrations of each compound and spent media was analyzed using a UPLC-ESI-QTOF mass spectrometry method that measured a broad range of small molecules. Using the biomarkers and assay parameters identified using hES cells, the iPS cell-based biomarker assay identified known developmental toxicants with 81% accuracy (75% sensitivity, 87% specificity). Establishing a developmental toxicity assay using iPS cells harnesses the predictive power of the hES cells without the ethical controversy, thus enabling validation for regulatory purposes.

Monitoring of Calcium Transients of Human Cardiomyocytes Derived from Induced Pluripotent Stem Cells As a Predictive Tool for High-Throughput Assessment of Cardiac Toxicity

Early assessment of cardiotoxic potentials is desired to avoid costly failures of drug candidates in the late phases of the drug development process. Since screening for hERG channel modulation is not sufficient to assess a comprehensive view on potential adverse effects on the heart, there is a need for a predictive cardiotoxicity assay suitable for high throughput screening (HTS). Directed differentiation and a transgenic approach allow for a specific selection of pure, human induced pluripotent stem cell-derived cardiomyocytes (hiPSCM). The hiPSCM reveal spontaneous contraction and typical physiological properties compared to their primary counterparts and can be generated in the quality, stability and amounts required in HTS. We have used the FLIPR Calcium® Assays Kit together with the Hamamatsu FDDS µCell and the FLIPR to monitor and analyze the effect of more than 35 standard compounds on the parameter of cytosolic free calcium ([Ca2+]i) transients from hiPSCM in a 384 well format. Each compound was tested in a full dose response with at least 3 replicates for each concentration. The compounds tested comprise known modulators of cardiac sodium, calcium, potassium (including several hERG blockers), and hyperpolarization-activated ion channels as well as GPCRs, connexins, and ion exchangers and pumps. Typical modulations of [Ca2+]i transients in terms of frequency, duration, peak amplitude, slope (rise and decay), and rhythmicity were analyzed and correlated to the known mode of action of the compounds. The results from our study reveal that modulation of [Ca2+]i transients is predictive for a broad range of cardiotoxic compounds. Based on these results, the described assay system is a cost effective, predictive in vitro system to assess cardiac liabilities at an early state of the drug development process.
1920 An Ex Vivo Platform to Evaluate the Differential Effects of Potential Therapies on Leukemia Progenitors (CFU-L) vs. Normal Bone Marrow (NBM) Progenitors (CFU-GM)

M. Yeo, E. Sceats and D. Hughes.

Acute myeloid leukemia (AML) is a malignant disease characterized by rapid growth of myeloid cells in the marrow. This year, 14,500 new cases will be diagnosed in the US, claiming the lives of approximately 10,000. Nearly 40 years have passed since the development and implementation of cytarabine (Ara-C) and daunorubicin (DNR) combination therapy as a standard of care. Yet the genetically heterogeneous characteristics of AML demands the development of novel treatment strategies. In support of this end, the colony forming cell (CFC) assay provides an ex vivo platform in which novel compounds can be tested for efficacy alone or together with current combination therapies. Using the CFC assay we evaluated the toxicity of drugs such as Ara-C and clofarabine on AML cancer “stem cells” and NBM CFU-GM, NBM (n=4) and AML marrow (n=3) were cultured in semisolid methylcellulose-based media (ColonyGel) at 37°C, 5% CO2. Test compounds were added over a broad concentration range in triplicate and CFU-GM and CFU-L were enumerated microscopically after 14 days. Mean IC50 values for DNR, Ara-C, and clofarabine for CFU-GM and CFU-L were 11.5, 15.8 and 29.3 μM and 5.45, 2.5 and 2.2 μM, respectively. These data confirm a selective killing of CFU-L vs NBM CFU-GM for all individual compounds. We extended this study to evaluate multi-combination therapies using calculated IC25 values for DNR and Ara-C on CFU-L (3 and 2 μM, respectively) and assessed this drug duo together with clofarabine. The combination of DNR and Ara-C at their IC25 concentrations inhibited CFU-L by approximately 50% in all AML marrows and inhibited NBM CFU-GM by 20%. When clofarabine, at its IC25 (1.5 μM) was added to DNR and Ara-C, an increased inhibition of CFU-L (70%, n=2) was observed while NBM CFU-GM inhibition was only increased to 24%. Thus, CFC assays provide a platform to evaluate novel targeted therapies with the current standard of care drug combinations, and can ascertain their selective effect on leukemic vs normal progenitors.

1921 Cryopreserved Hepatocytes and Stem Cell-Derived Hepatoycte As Microphysiological 3D Liver Models in LiverChip

I. Taylor, C. Rowe, E. Large, T. Cornforth, A. Robinson, E. Sceats and D. Hughes.

Liver functions rapidly decline in vitro when hepatocytes are cultured as monolayers. Human primary cell use is also hindered by unpredictable supply and quality of fresh cells. Cryopreservation techniques have partially circumvented the supply problem although cells quickly deteriorate. Similarly, methods to differentiate hepatic-like cells from induced pluripotent stem cells (iPSCs) can derive cells with liver disease phenotypes, such as Alpha 1 antitrypsin (A1AT) deficiency, although the cells may not be reaching the fullest possible maturity. We investigate the LiverChip in vitro 3D platform to model liver physiology through improved maintenance of primary liver cells with greater longevity and to further mature hepatocytes derived from iPSCs to model pathophysiology. In LiverChip, cryopreserved primary human hepatocytes formed 3D tissues with metabolic activity, albumin production and urea output for at least 3 weeks. Through a DARPA funded project a liver microphysiological system based on the co-culture of primary human hepatocytes and kupper cells was developed. Co-cultures displayed physiological responses to lipopolysaccharide exposure, including down-regulation of CYP3A, and secretion of pro-inflammatory cytokines IL-6 and TNF-alpha. Human iPSC-derived hepatocyte-like cells displayed enhanced hepatic function in LiverChip, compared with 2D monolayers. Analysis of secreted alpha fetoprotein, albumin, A1AT and fibrinogen demonstrated that LiverChip supports iPSC-derived cells with more advanced maturity than 2D culture. In conclusion, LiverChip is a perfused culture system supporting functional primary human liver cells to model hepatic tissue. LiverChip also has utility in further maturing iPSC-derived hepatocyte-like cells to recapitulate the physiology and pathophysiology of liver cells in health and disease.

1922 LiverChip 3D Liver Platform Distinguishes between Known Hepatotoxic Drugs and Closely Related Structural Analogues

M. Xia.

LiverChip is a perfused culture system in which isolated liver cells form 3D tissues with metabolic activity. Cryopreservation techniques have partially circumvented the supply problem although cells quickly deteriorate. However, the attrition rate of drug candidates in late clinical phases, post-marketing drug withdrawal, and need for box safety warnings due to hepatotoxicity demonstrate that many hepatotoxic drugs are not effectively screened out. There is great interest in 3D culture systems that re-form liver-like tissues from isolated human cells, and support liver physiology, to improve the predictivity of hepatotoxicity studies. LiverChip is a perfused culture system in which isolated liver cells re-form liver-like tissue structures in sinusoid-like channels in a porous scaffold. Tissues maintain measurable liver functions, including drug metabolism, with clearance of probe drugs correlating well with known hepatic clearance in man. Here we investigate LiverChip as a tool to distinguish between known hepatotoxic drugs and closely-related non-toxic structural analogues using multiples of human maximum plasma levels (Cmax). Human liver tissues were pre-formed in LiverChip for 3 days and then exposed to 0, 1, 3, 10, 30 and 100x Cmax concentrations of drugs for a further 6 days. Hepatocyte perturbations were assessed by measured disturbances in phenotypic liver markers, reduced mitochondrial activity and overt cytotoxicity was measured by leakage of intracellular enzymes. LiverChip experiments could build a qualitative hepatotoxicity spectrum with different mechanisms. Drugs that elicit hepatotoxicity in man through the formation of reactive metabolites (e.g. Clozapine), mitochondrial dysfunction (e.g. Tolcapone) or biliary transporter inhibition (e.g. Bosentan) could be distinguished from their non-toxic structural analogues. In conclusion, LiverChip is an effective tool for discovery toxicology with utility during selection of analogous lead compounds to identify safer new drugs with the lowest risk hepatotoxic potential.

1922a Tobacco Smoke Effects on an Endothelial Cell Model Derived from Inducible Pluripotent Stem Cells

Toxicology, NIH/NCATS National Center for Advancing Translational Sciences, Rockville, MD and 2NHLBI, NIH, Bethesda, MD. Sponsor: M. Xia.

Tobacco smoke causes 3-fold more deaths from heart attack, stroke, and vascular disease, than from cancers. Endothelial cell responses to tobacco were studied to elucidate vascular disease/therapeutics. Human inducible Pluripotent Stem cells (iPSC) were differentiated to form an Endothelial Cell model (iECs). These iECs (98%) express the endothelial cell marker proteins: CD31 and VE-Cadherin. iECs primary cellular human endothelial cells were cultured from: aorta (AECS), human coronary artery (CAECs), or umbilical vascular endothelial cells (HUVEC), and treated with tobacco smoke extract or vehicle. Viability was measured using an [ATP] assay and gene expression profiles were determined using qPCR and whole-genome mRNA sequencing (RNAseq). The majority of gene expression responses to tobacco by primary endothelial cells were recapitulated by iPSCs. Each cell line also yielded unique gene responses to tobacco according to RNAseq analysis. This work has revealed transcriptional responses of endothelial cells to tobacco that predispose humans to: vascular clotingting, oxidative damage, hypertension, arterial calcification, and cytotoxicity. Further work will identify tobacco smoke components that trigger each event, and will identify biomarkers for these adverse events.

1922b Neural Stem Cell Susceptibility to Japanese Diesel Exhaust Particulate Matter

C. Hegg, C. Jia and L. Koch. Pharmacology and Toxicology, Michigan State University, East Lansing, MI.

Environmental air pollutants negatively affect cognitive brain functions such as learning and memory and cause progressive neurodegeneration through unknown mechanisms. Although these deficits are associated with changes in neurogenesis (stem cell proliferation, differentiation and survival), few studies have examined the consequences of environmental air pollutants on neurogenesis. We examined the effects of 28 day intranasal exposure to particles isolated from Japanese diesel exhaust (DEPs, 1 mg/kg) or the organic extract of the DEPs (extracts) in C57B/6 male mice (6 weeks old; n=6/group). Behavior and proliferation in the dentate gyrus and subventricular zone of the lateral ventricles, areas of continuous neurogenesis affected by Alzheimer’s disease, were examined. Exposure to DEPs or extracts did not alter weight gain compared to vehicle control (0.05% DMSO; p=0.05). There was no anxiolytic effect of DEPs or extracts as measured using the elevated plus maze behavior test at exposure day 9 and 27 (p>0.05 v. vehicle). These results indicate there was no overt toxicity associated with the treatments in this study. Proliferation, assessed by BrdU incorporation, was quantified in 8 planes through the dentate gyrus. A significant decrease in BrdU incorporation was observed in the DEP treatment group only (p=0.05 v. vehicle). BrdU incorporation in the subventricular zone region was such that counting individual cells was not possible. However, analysis of immunoreactivity using fluorescence intensity measurements indicated there was a trend for decreased BrdU incorporation in the subventricular zone of DEP-exposed mice compared to vehicle. Collectively,
this study demonstrates that chronic exposure via nasal aspiration of an ultrafenine particulate, but not the organic component, decreases the ability of stem cells to proliferate in two brain regions that undergo neurogenesis. These data suggest that there are interrelationships between air pollution, neuronal stem cells and neurodegenerative diseases.

1922c Clostridial Toxins Cause Synaptic Inhibition in Networked Populations of Stem Cell-Derived Neurons

Following internalization into presynaptic termini, the two families of clostridial neurotoxins (CNTs) botulinum neurotoxin (BoNT) and tetanus neurotoxin (TeNT) cleave proteins associated with synaptic vesicle release, preventing the exocytosis of neurotransmitters. To date, no cell-based model used in CNT research has been shown to form functioning synapses, limiting the ability to conduct target discovery or therapeutic screening. Stem-cell derived neurons have recently been proposed as a next-generation cell-based platform for neurotoxicity research. Whole-cell patch clamp electrophysiology indicates that ESNs develop mature electrical responses and form a complex, synaptically coupled network with an excitatory/inhibitory balance by 18 days in vitro (DIV). Hypothesizing that synaptically coupled ESNs may undergo synaptic inhibition in the presence of BoNT/A, we evaluated the effects of intoxication on functional measurements of synaptic activity at DIV 24. Treatment of ESNs with 0.01 mouse lethal units of BoNT serotype A (BoNT/A) resulted in the significant loss of synaptic function, as determined by significant reductions in synaptically driven excitatory potentials and miniature excitatory post-synaptic currents (mEPSCs). Notably, inhibition of miniature inhibitory post-synaptic currents (mIPSCs) was a leading indicator of intoxication, being >80% inhibited within 30 min, whereas significant decrements in mEPSC activity were not apparent until 60 min. Long-term patch clamp assays indicated that addition of BoNT/A perturbed the excitatory/inhibitory balance within minutes, producing an epileptiform network response that progressively increased through 40 min. These data suggest that electrophysiological characterization of trans-synaptic activity may comprise a novel, rapid screen for the presence of functional toxin in forensic, pharmaceutical, environmental and/or food samples, as well as provide a physiologically relevant in vitro model for drug screening and mechanistic research.

1922e Transcriptomic Effects of Curcumin and Piperine in Breast Stem Cells

Curcumin and piperine have been shown to have cancer preventive activity in preclinical models. We have previously shown these compounds limit stem cell self-renewal. Normal and breast cancer stem cells exist in two states, with each cell type having unique properties. The objective of this study is to identify the mechanisms of action of curcumin and piperine in breast stem cells, using cell type specific RNA sequencing (RNA-seq) on breast cancer cell lines and normal breast cells. Breast cancer cell lines SUM149, T47D, and MCF7 were cultured as mammospheres and treated with curcumin (2.5μM - 15μM) and piperine (5μM and 10μM) individually and in combination. Normal breast cells isolated from reductive mammoplasty patients (n=13) were treated as mammospheres with 5μM curcumin and 5μM piperine. We used fluorescence activated cell sorting to isolate ALDH1+ and ALDH1-CD44+/CD24- stem cell fractions of SUM149, treating with 5μM curcumin and 5μM piperine for 24hrs. RNA-seq libraries were prepared with the NuGen Encore Complete kit and sequenced on an Illumina HiSeq 2500. In cell lines, curcumin and piperine induced mammosphere formation in a dose-dependent manner. In primary breast cells, curcumin, piperine, and the combination inhibited mammosphere formation 28% (p=0.0004), 24% (p=0.01), and 42% (p=0.0002) respectively. In both stem cell fractions, curcumin induced differential expression of similar genes, including AREG, EPGN, BAMBI, ALDH3B2, and CYP1B1. Pathway analyses showed that curcumin induced expression changes related to cholesterol and steroid biosynthesis and oxidoreductase activity. Ongoing experiments will quantify the transcriptomic effects of these compounds in normal breast stem cells. These findings point to novel regulation of stem cell self-renewal and provide biomarkers of efficacy for future cancer prevention trials.

1922f Development of a Human Adipose Stem Cell Model for Chemical Obesogen Screening

C. Deisenroth and B. Foley.

The relationship governing environmental influence on an individual's genetic predisposition toward obesity is a complex one. A largely unexplored avenue is the interaction between environmental exposure and an individual's genetic predisposition toward obesity. In this study, we demonstrate that chronic exposure via nasal aspiration of an ultrafine particulate, but not the organic component, decreases the ability of stem cells to proliferate in two brain regions that undergo neurogenesis. These data suggest that there are interrelationships between air pollution, neuronal stem cells and neurodegenerative diseases. This approach provides a novel system to efficiently derive high yield, high purity neurons (ESNs) from murine embryonic stem cells (ESCs) for neurotoxin research. This approach convincingly demonstrates an epileptiform network response that progressively increased through 40 min. These data suggest that electrophysiological characterization of trans-synaptic activity may comprise a novel, rapid screen for the presence of functional toxin in forensic, pharmaceutical, environmental and/or food samples, as well as provide a physiologically relevant in vitro model for drug screening and mechanistic research.
1923 Prolonged Exposure to Particulate Chromate Inhibits Homologous Recombination Repair Proteins
C. L. Browning1, 2, H. Xie1, 2, Q. Qin1, J. Mason1 and J. P. Wise1, 2.
1Wine Laboratory of Environmental and Genetic Toxicology, Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME, 2Graduate School of Biomedical Sciences and Engineering, University of Maine, Orono, ME and 3Tumor Biology Section, National Cancer Institute, Bethesda, MD.

Particulate hexavalent chromium (Cr(VI)) is a known human lung carcinogen that produces several forms of DNA damage, including DNA double strand breaks (DSBs). The homologous recombination (HR) repair pathway is utilized by cells to repair DSBs in an error-free manner during late S-G2 and mitosis. Our previous studies show that prolonged Cr(VI) exposure induces persistent DSBs levels and that defective repair of these DSBs allows for neoplastic transformation of human lung cells. However, few studies have investigated the effect of particulate Cr(VI) exposure on HR repair proteins. In this study, we analyzed the effect of particulate Cr(VI) exposure on key HR proteins: one of the DSB sensors, MRE11, the signal transducer, ATM, a key repair effector, RAD51, and the RAD51 transporter, RAD51C. We exposed human lung fibroblasts to zinc chromate for 24-120 hours. After exposure, the response of these proteins was measured by western blotting or a nuclear foci formation assay. Our data shows an increase in nuclear MRE11 foci formation, phosphorylated ATM protein expression, RAD51 protein expression and nuclear foci formation and RAD51C nuclear foci formation after 24 h Cr(VI) exposure, suggesting that HR repair is activated. However, prolonged Cr(VI) exposure inhibits phosphorylated ATM protein expression, RAD51 protein expression and nuclear foci formation and RAD51C nuclear foci formation. These results suggest that prolonged Cr(VI) exposure inhibits HR repair signaling through the regulation of RAD51. Ongoing work is investigating the effect of prolonged Cr(VI) exposure on RAD51C protein expression, RAD51/RAD51C co-localization and RAD51 transport kinetics. This work was supported by NIEHS grant ES016893 (J.P.W.).

1924 Cytoprotective Effects of the Antioxidants Tempol and WR-1065 in Human Lymphoblastoid Cells Exposed to Zidovudine (AZT)
M. O. On’Gele1, H. Braun1, K. Divi1, M. C. Potier2, J. B. Mitchell2 and O. Oliveira1.
1Carcinogen-DNA Interactions, National Cancer Institute, Bethesda, MD and 2Tumor Biology Section, National Cancer Institute, Bethesda, MD.

Antiretroviral Nucleoside Reverse Transcriptase Inhibitors (NRTIs) are used in drug combinations to treat Human Immunodeficiency Virus-1 (HIV-1) infection. AZT is an NRTI that becomes incorporated into DNA, acts as a DNA replication chain terminator, induces aneuploidy and mutations in mice and humans, and is tumorigenic in mice. The Cytokinesis Block Micronucleus (CBMN or Cytox) assay is a comprehensive system used to measure DNA damage occurring as a result of genotoxic insult. Molt-3, human lymphoblastoid cells exposed to AZT for 52 hours, were arrested with Cytochalasin B (Cyto B) for the last 24 hours, and the binucleated cells, which by definition completed one cell division, were scored for: micronuclei (MN); chromosome bridges (NBPs); nuclear buds (NBs); Anerotic/ Necrotic (A/N) cells and Nuclear Division Index (NDI). We hypothesized that the antioxidants Tempol and WR-1065 would protect against AZT-induced genotoxicity. Molt-3 cells were seeded into 24-well plates and exposed to 10 &M AZT, 10 &M AZT plus 5 &M WR-1065, or 10 &M AZT plus 200 &M Tempol. Cyto B was added for the last 24 hours to arrest cell growth. The NDI was similar for all groups, indicating that the different treatments did not alter cell viability. Molt-3 cells exposed to AZT and examined by Cytox assay had significant increases in MN, NBPs, NBs, and A/N, compared to unexposed controls. Cells treated with either Tempol or WR-1065 had significantly-reduced AZT-induced MN. In addition, WR-1065, but not Tempol, reduced the levels of A/N. In the presence of AZT, Tempol significantly reduced levels of NBs, while WR-1065 reduced the levels of NBPs. Overall, the Cytox assay provided a useful indicator of AZT-induced genotoxicity, and demonstrated that the antioxidants Tempol and WR-1065 each protect against different AZT-induced genotoxic end points. The data implies different mechanisms of protection for the two antioxidants.

1925 Targeted Ubiquitination and Degradation of Human DNA Ligase I by the CUL4-DDB1 Ubiquitin Ligase Complex
Z. Peng and A. Tomkinson. Internal Medicine, Univ of New Mexico, Albuquerque, NM.

Human DNA ligase I (hLiGI) is required for efficient DNA replication, recombination and repair. Here, we report a mechanism that controls the programmed degradation of hLiGI via targeted ubiquitination. In this study, a proteomic approach was used to screen interacting proteins of hLiGI in 293T cells. Mass spectrometry analysis reveals several proteins in the hLiGI immunocomplex including culinA4 (CUL4A) and damage-specific DNA binding protein 1 (DDB1). We confirmed that CUL4A and DDB1 as hLiGI-associated proteins by immunoprecipitation, which suggests that DDB1 acts as an adapter to link LiGI to CUL4 to form the E3 ubiquitin ligase complex. Furthermore, the level of hLiGI was reduced in both undifferentiated MCF10A cells and under stress conditions; while treatment with the proteasome inhibitor, MG132 prevented this reduction. We also found that hLiGI ubiquitination ultimately led to its degradation via the proteasome pathway, at least in part initiated by the Cull4-DDB1 complex. Mutations or inhibitors that blocked the modification at any step in this pathway would suppress hLiGI degradation. These findings may represent a newly identified regulatory mechanism used by cells to ensure the normal DNA replication and is essential for the maintenance of genome stability.

1926 Activation of ATM-Dependent Genotoxic Signaling in Human Lung Cells by Formaldehyde
S. Ortega Atienza, J. Morse and A. Zharkovich. Pathology and Molecular Medicine, Brown University, Providence, RI.

Formaldehyde (FA) is a carcinogenic aldehyde that produces DNA-protein crosslinks as the main form of DNA damage. Human exposure to exogenous FA primarily occurs via inhalation and is found in many occupational settings and among tobacco smokers. In this work, we examined whether the alkylating agent FA was capable of engaging ATM kinase that is traditionally associated with the stress signaling elicited by DNA double-stranded breaks (DSB). We found that FA provoked a rapid activation of the ATM pathway in normal and transformed human lung cells. In response to FA, ATM underwent activating Ser1981 autophosphorylation and phosphorylated two major proteins in its signaling network, CHK2 kinase and chromatin-associated KAP1. However, unlike DSB, FA-activated ATM did not target the transcription factor p53. Inhibition of RNA polymerase II had no effect on ATM activity, arguing against the possibility that ATM was triggered by collision of transcription complexes with bulky DNA-protein crosslinks. Activation of ATM was absent in nondividing cells and found exclusively in S-phase in cycling cell populations. The presence of DSB-sensing MRN complex was not required for FA-activated ATM responses, pointing to a noncanonical mechanism of activation. Inhibition of ATM kinase activity resulted in elevated levels of chromosomal breaks in normal human lung cells, indicating a protective role of ATM-induced signaling in suppressing gross genetic abnormalities by carcinogenic FA.

1927 p53 Regulation of the GADD45a Gene Is Restricted to Genotoxic Exposure As a Consequence of a Requirement for p53/WT1 Interaction in the Promoter
R. Walsmsley1, 2 and D. Johnson1. 1Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom, 2Genotronics Ltd, Manchester, United Kingdom and 3Animal Molecular Biology, Harper Adams University, Newport, United Kingdom. Sponsor: S. Dertinger.

Rationale: p53 is required for genotoxic and non-genotoxic induced apoptosis. However expression of the p53 target GADD45a, exploited in the GreenScreen HC genotoxicity assay, is very specifically induced by genotoxins. This study was conceived to explain the conundrum. The GADD45a p53 response element is in intron 3, however the GADD45a promoter has a WT1 response element binding site and other studies have demonstrated that WT1 and p53 proteins can interact. Furthermore, WT1 binding is suppressed by Myc in the absence of DNA damage. The purpose of this study was therefore to test the hypothesis that GADD45a specificity is a consequence of WT1 mediation of p53 regulation.

Experimental approach: site directed mutagenesis was used to disrupt either or both of the p53RE and WT1RE in GADD45a-GFP reporter plasmids, and these were transfected into p53 competent TK6 cells and closely related p53 mutant WI-L2-NS cells. These new cell lines were then challenged with the following mechanistically diverse genotoxins: methyl methanesulphonate, cisplatin and mitomycin C, hydroxyurea, aphidicolin, 5’fluorouracil and benomyl. GFP expression data was collected using the standard GreenScreen assay protocols.
Results: GFP synthesis induced by all compounds in TK6 cells carrying the unmodified reporter. GFP synthesis was reduced in p53 mutant and wild type cells carrying modified reporter plasmids. The reduction was greatest in cells carrying the mutated p53 RE.

Conclusions: These experiments demonstrate that both WT1 and p53 response elements are involved in GADD45α regulation. This allows the conclusion that the induction of GADD45α requires p53, but specificity to genotoxins is a consequence WT1 controlled access to the promoter, which in turn is regulated by Myc.

1928 Oxidative DNA Damage/Repair Induces Inflammatory Gene Expression in the Airways by 8-Oxoguanine DNA Glycosylase-Mediated Cell Signaling

L. Aguilerag-Aginur, A. Bacci, T. G. Wood, A. R. Brasier, 1, 2, 3, B. T. Ameredes, 2, 3, X. Ba and I. Boldoghi, 1, 2. *Microbiology and Immunology, University of Texas Medical Branch, Galveston, TX, 2 Sealy Center for Molecular Medicine, University of Texas Medical Branch, Galveston, TX, 3 Institute for Translational Sciences, University of Texas Medical Branch, Galveston, TX and 4 Internal Medicine, University of Texas Medical Branch, Galveston, TX.

Environmental pollutants cause oxidative stress in the airways and increase the levels of 8-oxoquinone (8-oxoG) in the DNA of lung epithelium due to guanine’s lowest redox potential among DNA bases. 8-oxoguanine DNA glycosylase-1 (OGG1) excises and releases 8-oxoG during DNA base-excision repair (BER). Accumulation of 8-oxoG in the DNA has been linked to various inflammatory diseases including asthma. However, little is known about the role of OGG1-BER in pathogenesis of airway diseases. We observed activation of small GTPases upon OGG1-BER, or addition of 8-oxoG base to OGG1 proficient cells or mouse lungs in vivo. Therefore, we proposed that OGG1-BER and consequent activation of small GTPases mediate signaling for pro-inflammatory gene expression. To test our hypothesis, we challenged BALB/c mice intranasally with OGG1-BER product 8-oxoG, and used next-generation RNA-Sequencing technology to investigate the whole-genome gene expression in the lungs. The most overrepresented pathway was inflammation-related signaling. The majority of upregulated pro-inflammatory genes (≥ 3-fold expression) were NF-kB-dependent. We confirmed the expression levels of selected genes by qRT-PCR. In line with these observations, challenged mice with 8-oxoG or glucose oxidase (to induce OGG1-BER) showed significant induction of airway inflammation as determined by the number of neutrophils in bronchoalveolar lavage fluid compared to control (p <0.0001). We conclude that OGG1-BER-triggered inflammatory gene expression in the lungs is a novel mechanism through which environmental pro-oxidant pollutants can induce airway inflammatory diseases.

1929 Interpreting In Vitro Micronucleus Positive Results: Simple Biomarker Matrix Discriminates Clastogens, Aneugens, and Irrelevant Positive Agents

The specificity of in vitro mammalian cell genotoxicity assays is considered relatively low, as they yield a high incidence of positive results that are not expected to have in vivo relevance. We set out to develop a rapid, effective follow-up testing strategy that predicts whether apparent in vitro micronucleus (MN)-inducing effects are due to a clastogenic, aneugenic, or secondary irrelevant mode(s) of action. Priority was given to biomarkers that could be multiplexed onto flow cytometric characterization of CDT-expressing bacteria and may open new therapeutic approaches.

1930 Error-Prone Double-Strand Break Repair Plays a Predominant Role in Oxidative Stress-Induced Mutagenesis

V. Sharma, L. Collins, W. Sun, L. A. Swenberg and J. Nakamura. 1Department of Environmental Sciences and Engineering, UNC, Chapel Hill, NC and 2Department of Genetics, UNC, Chapel Hill, NC.

Endogenous and exogenous oxidative DNA damage has been implicated in degenerative diseases and carcinogenesis. To counter this oxidative DNA damage, mammalian cells possess error-free DNA repair systems. In contrast, a few DNA repair pathways in cells do not possess high fidelity and result in mutations. Little is known about the comparative contribution of each error-free and error-prone DNA repair pathway in the oxidative stress induced DNA damage response (DDR) and mutations. Therefore, in the present study, using H2O2 as a model compound, we sought to understand the mechanisms of DDR and mutations caused by low level of oxidative stress and identify DNA repair pathways that may affect oxidative stress induced susceptibility to mutagenesis. DDR analyses were performed in different repair protein deficient DT40 cells. Rev1, Rad54, Rad51c, XRCC2, Fen1, Ku70 and Lig IV deficient cells showed comparatively more hypersensitivity to H2O2. All Ku70, DNA Pkcs and Lig IV (NHEJ) proteins deficient cells tested in our study revealed a drastic decrease in mutation frequency despite the presence of equivalent levels of 8-oxoGd as in the wild type DT40 cells. These data indicate a ROS induced mutagenic pathway in vertebrate cells proceeds via DNA double strand breaks (DSBs) and error-prone NHEJ repair. Current data combined with our previous reports of abasic site clusters in intact human cultured cells suggest that endogenous and exogenous oxidative stress may cause clustered DNA damage which may lead to DSBs with complex DNA ends and repairing such DSB with NHEJ may result in mutations even in the absence of DNA replication. It has been reported that NHEJ-deficient mice show early aging and less spontaneous tumor formation. Therefore, we are currently hypothesizing that mutations induced by oxidative stress through error-prone DSB repair pathway may be involved in etiology of wide variety of human diseases.

1931 A New Mode of Action for the Cytotoxic Distending Toxin

The Cytotoxic Distending Toxin (CDT) is a virulence factor produced by many pathogenic bacteria like Escherichia coli, Helicobacter hepaticus, Haemophilus ducreyi etc. The CDT production allows bacteria to persistently colonize the body, evade the immune system, induce inflammation and trigger genetic instability. In addition, it has been shown that CDT induces DNA double-stranded breaks (DSB), leading to cell cycle arrest and to cytotoxicity, associated with a characteristic cellular distension. In order to characterize the type of DNA damage induced by CDT, we studied the cell sensitivity to different CDT doses, with the cell cycle as read-out. Thanks to comet assay and immunofluorescence, we have shown that at doses 1000 times lower than those used previously in the literature, CDT induces multiple single-strand breaks. When cells are going through S phase, a repetitive stress is induced and DNA damage degenerate into DSB. Indeed, with a PCNA marker, we observed an S-phase slowing down and an increase of the number of cells in late S-phase. Moreover, these CDT-induced DNA damage cause the activation of the pathway involving the RPA, ATR and CHK1 proteins, characteristic of a replicative stress. Finally, we have shown that the activation of the ATM pathway, due to DSB induction, happens later after the CDT treatment. Therefore, the importance of the S-phase passage for the CDT cytotoxicity suggests that proliferating cells are more sensitive to CDT than quiescent cells. Our work underlines the complex mechanism of CDT action. It will help in the characterization of CDT-expressing bacteria and may open new therapeutic approaches, for example by targeting the mechanisms of associated genotoxicity.
Persistent mitochondrial DNA (mtDNA) damage in response to ultraviolet C radiation (UVC) results in developmental delay or arrest in Caenorhabditis elegans (Bess et al., 2012. Nucleic Acids Res 40:7916). We are testing several hypotheses on the mechanism of this delay, including the role of oxidative stress and insulin signaling, using deletion mutants and stress-inducible fluorescent reporter strains. Age-synchronized wild-type and mutant nematodes were plated on agar in the absence of food and exposed to 7.5 J/m² UVC 0, 24 and 48 h after plating. Nematodes were then transferred to plates with food and growth was measured with a COPAS Biosort using extinction, or optical density, as a proxy for size 24, 48, and 72 h after transfer. Fluorescence in reporter strains was also measured. We identified developmental delays and a 50% reduction in the size of UVC-treated sod-2 mutants and developmental delays in sod-3 mutants relative to wild-type nematodes after UVC treatment (SOD-2 and SOD-3 are mitochondrial superoxide dismutases). These data support the hypothesis that UVC-induced damage causes mitochondrial oxidative stress. Our data also show significant delay in daf-16 (mu86); gfp-1 (e2141) and daf-16 (mgDf47); gfp-1 (e2141) mutants relative to wild-type nematodes, but not daf-16 (mu86) without the deletion in gfp-1 (DAF-16 functions in insulin signaling and stress resistance and GLP-1 is required for germline proliferation; absence results in adults composed only of somatic cells). This suggests that insulin signaling promotes development in the context of persistent mtDNA damage, but only in the absence of germ cells. Finally we observed induction of hsp-16.2 and hsp-60 in biosensors of heat-shock proteins localized in the cytosol and mitochondria respectively, in response to UVC radiation, suggesting damage to both mitochondrial and cytosolic proteins.

### Impact of p53 Functionality in *In Vitro* Mammalian Cell Toxicity Testing

The number of *in vitro* mammalian cell positives that do not correlate with follow-up *in vivo* genotoxicity and carcinogenicity testing is of concern (1). p53 competent cells of human origin may provide more predictive data for assessment of human hazard and risk and less misleading *in vitro* positives compared to tradition-ally used rodent cell lines lacking wild-type p53 function (2). It remains unclear whether cell species origin or p53 status impacts their ability to accurately predict genotoxicity in the *in vitro* mammalian cell tests. Cells lacking wild-type p53 may underestimate cytotoxicity with the analysis of inappropriately high concentrations for genotoxicity compared to a p53 functional cell line. Three closely related human lymphoblastoid cell lines that differ in p53 status were tested. TK6 express wild-type p53, NH32 are p53 null, WTK1 over-express mutant p53, similar to commonly used rodent cells. Ethyl methanesulfonate (EMS), etoposide and paclitaxel (taxol) were used to test according to regulatory guide-lines and cytotoxicity determined using relative population doubling. Apoptosis was also determined using caspase-3/7 activity. NH32 were sensitive to the cytotoxic effects of EMS compared to TK6 and WTK1. In contrast NH32 underestimated cytotoxicity with etoposide compared to TK6 and WTK1. A similar cytotoxic response was observed in all three cell lines with taxol; however, cytotoxicity was observed at lower concentrations in TK6. The apoptotic response to each compound in WTK1 was significantly reduced compared to TK6, which demonstrate increases in apoptosis typical of a p53 functional cell line. NH32 demonstrated similar levels of apoptosis to WTK1 following etoposide and taxol treatments but was more similar to TK6 in the response to EMS. The results showed that p53 deficient cell lines do not consistently underestimate cytotoxicity and the cytotoxic response is drug specific. Other factors associated with loss of p53 function or species origin may be more relevant to the reported high number of *in vitro* positives.

formation of cyclobutane pyrimidine dimers (CPD) and 6-4 photoproducts (6-4 PP) induced by UV light exposure. Recent reports suggest that telomeres are either deficient in photoprotective repair or are repaired slower than the bulk genome. DNA photoproducts can cause mutations and block DNA replication, unless they are repaired by nucleotide excision repair (NER) pathway system. We report here a novel, independent assay that we have established to measure the persistence or repair of photoproducts in telomeric DNA compared to the bulk genome, using specific antibodies against CPDs and 6-4PPs following exposure of cells to UVC. We observed that CPDs decreased in genomic DNA after 12-24 hours but persisted in telomeric DNA. Southern blot assays using radio-labeled oligonucleotides that bind to telomeric DNA confirmed enrichment of telomeres in purified fractions. To investigate possible mechanisms for this repair inhibition, we tested directly effect of shelterin protein TRF2 on NER protein XPF-ERCC1 via enzyme activity assays. We discovered that nucleotide cleavage activity of purified XPF-ERCC1 on a stem-loop DNA substrate was completely abolished by TRF2. Our results provide the first direct evidence towards quantifying critical UV damage at telomeres and elucidating NER pathway regulation by shelterin.

1937 Effects of Cadmium and 17α-Ethynylestradiol on Benzo(a)pyrene AdductFormation
K. E. Germ, S. Tang and G. D. Mayer, Environmental Toxicology, Texas Tech University, Lubbock, TX.
Xenooestrogens have been increasingly associated with various adverse health conditions, including cancer. It is known that both cadmium and 17α-ethynylestradiol are ubiquitous environmental contaminants, and that low-dose exposures can illicit mechanistic effects in vivo. Nucleotide excision repair is the DNA repair mechanism responsible for the removal of bulky DNA adducts, which, when un-repaired, may lead to DNA mutations. Cadmium and 17α-ethynylestradiol are known to enhance hormonal responses in vivo and in vitro, and have roles in the advancement of hepatocellular carcinoma. Additionally, they are known to down-regulate multiple DNA repair mechanisms, including the nucleotide excision repair pathway. We pre-exposed human hepatocellular carcinoma (HepG2) cells to various concentrations of 17α-ethynylestradiol, a synthetic estrogen, and cadmium, to see if such pre-exposure to these compounds had any effect on bulky DNA adduct repair when the same cells were subsequently exposed to the pro-carcinogen, benzo(a)pyrene. Cells were exposed to two different concentrations of benzo(a)pyrene for varying amounts of time up to 48 hours. We then quantified benzo(a)pyrene diol-epoxide adducts at each of 6 time-points using high performance liquid chromatography with fluorescence detection. Our data indicate that with 17α-ethynylestradiol pre-exposure, efficient adduct repair was delayed, as ad- ducts continued to be detected up to 48 hours of exposure. Also, after cadmium pre-exposure, adduct formation increased over time throughout the 48 hour time-point. Results demonstrate that in HepG2 cells, both 17α-ethynylestradiol and cadmium exposures affect the prevalence and repair rate of benzo(a)pyrene-DNA adducts.

1938 Integration of Genomic Biomarkers in Cancer Risk Assessment for Xenobiotics with Positive Findings in Chromosome Damage Assays
H. Li, D. R. Hyduke, C. L. Yauk, J. Aubrecht and A. Fornace, 1Dept of Drug Safety Evaluation, Pfizer Inc, Groton, CT, 2Georgetown University, Washington, DC, 3Health Canada, Ottawa, ON, Canada and 4Utah State University, Logan, UT.
Despite scientific progress in understanding cancer mode of action, experimental approaches for assessing oncogenic risk for chemicals relies mainly on traditional methods. The currently used in vitro genotoxicity testing battery does not offer sufficient mechanistic information for assessing oncogenic risk to humans. Recent advances in molecular biology and bioinformatics have enabled interrogating cellular responses to chemical exposure at the genomic level. This approach has revealed molecular pathways and networks that are mechanistically involved in chemical carcinogenesis. We have focused on application of a transcriptomic biomarker approach in the p53-wt human cell line TK6 to facilitate oncogenic risk assessment by assessing genotoxicity and other mechanisms for drug candidates and environmental chemicals. We have constructed a reference database containing gene expression profiles of 27 model agents with a broad range of toxic mechanisms. A genotoxic-signature biomarker comprising of 65 genes, TGx27.65, has been identified from the reference database by using the nearest shrunken centroids (NSC) algorithm. TGx27.65 discriminates genotoxic from non-genotoxic agents with 100% accuracy after 10-fold cross validation. In validation study, 42 chemicals were selected to test TGx27.65’s performance on genotoxicity identification. All chemicals with direct DNA-damaging mechanisms were classified as “genotoxic” by transcriptomics assay with TGx-27.65. Interestingly all except one out of eleven chemicals with false positive results in in vitro chromosone aberrant assay were not classified as “genotoxic” using TGx-27.65. We have examined the inter-laboratory reproducibility of this biomarker and tested the application of TGx-27.65 in assessing chemicals that need metabolic activation. Advanced bioinformatic analysis further identified gene markers that significantly correlate with various toxic mechanisms.

1939 Developmental Exposure to Ultraviolet C Radiation Results in Altered Energy Production Later in Life in Caenorhabditis elegans
Mitochondrial genomes encode for 13 proteins that are essential components of the electron transport chain (ETC) and are normally present at between 1000 and 10000 copies per cell. However, this number is greatly reduced during specific developmental stages, representing a potential critical window for mitochondrial genotoxic exposure. Mitochondrial DNA (mtDNA) is more susceptible than nuclear DNA (nucDNA) to damage by many environmental pollutants, for reasons including absence of Nucleotide Excision Repair (NER). NER is a highly functionally conserved DNA repair pathway that removes bulky, helix distorting lesions such as those caused by ultraviolet C (UVC) radiation and many environmental toxicants, including benzo[a]pyrene (BaP). In the current experiment we tested the hypothesis that UVC induced mtDNA damage during larval development would alter energy production throughout the life of the nematode. We exposed first larval stage C. elegans to a serial UVC dose that results in the accumulation of mtDNA damage while allowing for repair of nuclear DNA damage, and measured ATP levels, mtDNA and nucDNA copy numbers, oxygen consumption and expression of mitochondrial genes throughout the lifetime of the worms. ATP levels were measured as luminescence using the firefly luciferase expressing PE255 glp-4(bn2) strain (provided by Cristina Lagido, University of Aberdeen). mtDNA copy number and gene expression were measured via real time PCR. ATP levels were significantly lower, and the mtDNA to nucDNA copy number ratio was slightly, but significantly reduced in response to UVC. Oxygen consumption was also reduced at 8 and 12 days post UVC. Interestingly, there was no decrease observed in mtDNA or nucDNA encoded mitochondrial transcripts. These results indicate that mtDNA damage during development can alter energy production throughout the life of the nematode, and highlights the potential for a critical window of exposure.

1940 Investigating Genetic Susceptibility to Mitochondrial Toxicity
A. Luz and J. N. Meyer, Nicholas School of the Environment, Duke University, Durham, NC.
Genetic variation within the human populous causes a range of sensitivities to various toxicants, including some that target the mitochondria. For example, the antibiotic gentamycin, which targets the bacterial ribosome, can also cause hearing loss. Adverse effects can be worsened in certain individuals carrying a point mutation that renders the mitochondrial 12S rRNA, which is evolutionarily related to the bacterial rRNA, more bacteria-like. In addition to pharmaceuticals, many environmental pollutants are also known mitotoxins; however, whether these toxicants pose an increased risk to individuals suffering from mitochondrial disease is unknown. Using a UVC exposure protocol that allows for the accumulation of mitochondrial (mtDNA), but not nuclear DNA damage, we found that C. elegans carrying a deletion in the fos-1 gene are extremely sensitive to UVC-induced mtDNA damage. fos-1 and its human ortholog MFN1 and MFN2 play a major role in mitochondrial dynamics (outer membrane fusion), and the fos-1 deletion results in highly fragmented mitochondria. The removal of UVC-induced mtDNA damage is fos-1-dependent in C. elegans, and mutations in MFN2 cause Charcot-Marie-Tooth neuropathy type 2A in humans. Utilizing the fos-1 mutant we are screening environmental mitotoxins for exacerbation of growth inhibition, because larval development is dependent on mitochondrial function. Initial screens have demonstrated that chronic, low doses of rotenone (0.25 μM), and paraquat (150 μM) significantly delay the growth of fos-1 mutants, compared to wild-type worms. To further test the role of mitochondrial dysfunction in larval developmental delay, we will analyze mitochondrial fitness by measuring oxygen consumption with a Seahorse Xfe24, ATP production with an fos-1 strain expressing a ATP-luciferase transgene, and mtDNA damage and copy number with a QPCR assay. This research aims to help fill a knowledge gap that leaves an already susceptible population of individuals at an even higher risk to certain environmental exposures. Funded by NIEHS IR01-ES017540-01A2 and Duke University Graduate Fellowship.
**1941** Investigations of Dose-Response for Key Events in the Mode of Action (MOA) for Propylene Oxide (PO)-Induced Mutagenicity in TK6 Cells  
1The Dow Chemical Company, Midland, MI, 2University of Utah, Salt Lake City, UT and 3Emphasis, Midland, MI.

PO, a reactive chemical, induces nasal tumors in rodents upon chronic high-dose inhalation exposures. It is mutagenic in vitro and weakly clastogenic in vitro. To investigate thresholds for PO-induced mutagenicity, dose-responses for several hypothesized key event biomarkers were assessed in TK6 cells. Triple cultures were treated with 0.5 to 50 μg PO/ml, and evaluated for: mutant frequency (HPRT MF), micronucleus (MN), Comet, GSH-PO conjugate, N7-hydroxypropylguanine (N7-HPGP) adducts, and 2 homeostasis/oxidative stress markers (cytosol B-OH-GTP, 8-OH-DG). Data were analyzed for point-of-departure (POD) metrics: NO-Genotoxic-Effect-Levels (NOGELs), binaril threshold dose (Td), and benchmark dose (BMD). Exposure biomarkers: N7-HPGP adducts, not detected in controls, increased linearly with PO dose; GSH-PO increased over control levels at ≥5 μg/ml PO. Oxidative biomarkers 8-OH-DG and 8-OH-GTP were affected; all treated groups had decreased 8-OH-GTP and increased 8-OH-DG adducts vs controls. Biomarkers of genotoxic effects, HPRT MF and MN, with Comet, had NOGELs of 25, 25, and 10 μg/ml, respectively. Bilinear Td and BMD analyses of MN data gave a Td of 5.72 and a good fit for BMD10 (4.99) and BMR (9.51). Neither MN nor Comet data had a good fit for BMD. DNA from 57 pooled mutant clones (0.5, 5, 50 μg PO/ml) underwent NexGen sequencing to determine mutational spectra (MS) spanning the full-length 45kb human HPRT1 gene. The MS showed a difference in transversions in the top dose group vs. controls, where A→T:A mutations predominated; low dose MS (MF not increased) did not have a similar change. Integration of such dose-response data for biomarkers of hypothesized key events, along with the determination of MS data, support the determination of in vitro NOGELs, or thresholds, for certain key events including genotoxic effects, and provide key perspective on the threshold MOA of PO. Sponsored by the Cefe PO & PG SG.

**1942** Depleted Uranium Induces DNA Damage and Alteration of DNA Repair Proteins in Human Lung Epithelial Cells  
H. Xie, V. Sekeroglu, Z. Sekeroglu, C. Falank, A. Holmes and J. P. Wise.  
University of Southern Maine, Portland, ME.

Depleted uranium (DU) is commonly used in military applications and is also used in civilian industry and thus exposure of soldiers and others is frequent and widespread. DU is considered a probable human carcinogen, affecting the bronchial cells of the lung, however, how DU causes lung cancer is uncertain. In this study, we use the human bronchial epithelial cell line (BEPE2D) to investigate the genotoxic effect of DU and the underlying mechanisms. We found that DU weakly causes chromosome damage after a 24 h exposure but induces time-dependent increase in chromosome damage after 48 h and 72 h exposure. DU also induces DNA double strand breaks measured by comet assay. Doses of 0.25, 2.5 and 25 μg/cm2 uranium trioxide increases comet tail length of 0, 2 and 7, respectively after a 24 h exposure. Both 48 h and 72 h DU treatment induces a similar increase in tail length. We next investigated whether DU affects DNA double strand break repair pathway. We found that 24 h DU treatment does not affect the DNA damage sensor step measured as Mre11 expression but 48 h and 72 h exposure of 25 μg/cm2 uranium trioxide inhibits Mre11 expression. DU treatment increases phosphorylated ATM but inhibits Rad51 expression. Our study demonstrates that DU induces genotoxicity and may interfere with DNA repair in human bronchial epithelial cells. This work was supported by ARO grants # W911NF-04-1-0240 and W911NF-08-0033 (J.P.W.).

**1943a** Comparison of Genotoxic Effects of Major Diesel Exhaust Components in Human Alveolar Basal Epithelial Cells (A549)  
P. Rossner1, J. Stolcpartova1, J. Schmuczerova1, A. Milcova1, E. Hruba2, M. Machala2 and J. Topinka1.

Internal combustion engines (ICE), including diesel engines, power most of the motorized road vehicles. ICE are a major source of air pollution in metropolitan areas. Among other compounds they emit polycyclic aromatic hydrocarbons (PAHs) and their nitro-derivatives. Genotoxicity of benzo[a]pyrene (BaP), a model PAH, and PAH nitro-derivatives (1-nitropyrene (1-NP) and 3-nitrobenzoanilide (3-NBA)), was studied in a model cell line A549. The cells were treated for 4 and 24 hours with different concentrations of tested compounds (BaP: 0.1 and 1 μM; 1-NP: 1 and 10 μM; 3-NBA: 0.5 and 5 μM) and several endpoints, including bulky DNA adducts and oxidative stress markers (lipid peroxidation, protein and DNA oxidation) were analyzed. All tested compounds increased bulky DNA adduct levels after both the 4-h and 24-h treatment, although the effect of 1-NP was relatively weak. A 24-h treatment resulted mostly in higher DNA adduct levels than the 4-h treatment with the exception of 3-NBA. 1-NP induced protein oxidation after both the 4-h and 24-h treatment. Interestingly, lipid peroxidation measured as levels of 15-F2t-isoprostane decreased after the BaP treatment, but was elevated after incubation of the cells with 1-NP and 3-NBA. 8-OxodG-7,8-dihydro-2′-deoxyguanosine (8-oxodG), a marker of oxidative DNA damage, was not affected by either compound and/or treatment period. Our data highlight differences in genotoxic mechanisms of PAHs and their nitro-derivatives, particularly for oxidative stress markers. Supported by the Czech Science Foundation (13-01438S) and by EU LIFE+ Program (LIFE-ENV-CZ-651).

**1943b** Nitroxide TEMPO: A Genotoxic and Oxidative Stress Inducer in Cultured Cells  

Low molecular weight nitroxide, 2,2,6,6-Tetramethylpiperidine-1-oxyl (TEMPO), is a stable free radical which has been widely used throughout chemistry and biochemistry as process intermediates. Due to its antioxidant abilities and protective properties in various pathological situations, some studies have proposed them as potential therapeutic agents for medical use. However, the potential risks of TEMPO need to be addressed. In this study, we investigated the cytotoxicity and mutagenicity of TEMPO using the mouse lymphoma assay (MLA) and in vitro micronucleus assay (MN). In the absence of metabolic activation (S9), 3mM TEMPO produced significant cytotoxicity and marginal mutagenicity in the MLA; whereas in the presence of S9, treatment of mouse lymphoma cells with 1–2mM TEMPO resulted in dose-dependent decreases of the relative total growth and increases in mutant frequency. In the MN assay, treatment of TK6 human lymphoblastoid cells with 0.9–2.3mM TEMPO increased the frequency of both micronuclei (a marker for clastogenicity) and hypodiploid nuclei (a marker of aneugenicity) in a dose-dependent manner, with the responses being greater in the presence of S9. Within the dose range tested, TEMPO also induced increased generation of reactive oxygen species and decreased glutathione levels in mouse lymphoma cells. In addition, the loss of heterozygosity (LOH) analysis showed that the majority of TEMPO-induced mutants, both in the presence and absence of S9, produced...
high levels of LOH at the Tk locus only, indicating allele loss of ≤3436Mbp. These results indicate that TEMPO is mutagenic in the MLA and induces micronuclei and hypodiploid nuclei in TK6 cells. Oxidative stress may account for part of the genotoxicity induced by TEMPO in both cell lines.

TK6 cells are a human lymphoblastoid cell line originally derived from a patient suffering from spherocytosis that were subsequently mutagenized with the intercalating agent ICR-191 to create a heterozygous thymidine kinase locus (Tk+/−). Since TK6 cells are heterozygous for the Tk gene but wild-type for the p53 gene, they are routinely used to assess the mutagenicity of chemicals by using loss of heterozygosity of the remaining wild-type Tk allele as a reporter. Despite their common use and importance in genetic toxicology, little is known about other genetic abnormalities these cells possess and how these may affect their response to genotoxins. To determine if TK6 cells carry DNA sequence changes that may affect their response to DNA damaging agents, we used 454 Next Generation Sequencing to characterize the TK6 transcriptome. We detected 2572 genetic variations arising from nuclear DNA and 46 from mitochondrial DNA, from a total of 7471 detected genes. Among the anomalies mapping to nuclear DNA, 1089 are known SNPs, while 1483 are novel. Among the anomalies mapping to mitochondrial DNA, 36 are known SNPs, while 10 are novel. Importantly, we detected several anomalies that could affect the genotoxic profile of these cells, such as a frame-shift mutation in the heavy subunit of ferritin (FTH), and clinically-relevant SNPs at the xenobiotic metabolizing enzyme NADPH quinine oxidoreductase 1 (NQO1) and the thiopurine drugs metabolizing enzyme thiopurine S-methyltransferase (TPMT) loci, among many others. Our data provides a preliminary catalogue of the altered DNA sequences present in the transcriptome of TK6 cells.

M. Xu, I. Nekhayeva, C. G. Cross, J. Speidel and S. Abdel-Rahman. UTMB, Galveston, TX.

The MGMT gene encodes the direct reversal DNA repair protein O6-methylguanine-DNA methyltransferase, which preferentially removes adducts resulting from exposure to alkylating agents from the O6 position of guanine. Recently, we sequenced 104 DNA samples from healthy individuals and identified several single nucleotide polymorphisms (SNPs) in the MGMT promoter/enhancer (P/E) region. We found that, due to linkage disequilibrium, these SNPs form defined haplotypes. To determine the functional significance of these haplotypes, we transfected luciferase-reporter constructs representing the different haplotypes into glioblastoma cells and determined their effect on MGMT promoter activity. The results showed that MGMTP/E haplotypes, rather than individual SNPs, differentially regulate MGMT transcription. However, the mechanism(s) by which these haplotypes affect MGMT transcription remains elusive. Using in-silico analysis, we found that several of the SNPs in our population are within or in close proximity to putative transcription factor (TF) binding sites including AP-1, NF-1, AP-2, GCF and c-Myc. We therefore hypothesized that MGMTP/E haplotypes affect TF binding leading to alteration in MGMT transcription. To test our hypothesis we conducted a TF binding profile for different MGMT haplotypes using the Promoter Binding TF Profiling Plate Array assay (Signosis, Inc.), which allowed us to evaluate binding of 48 TFs to the MGMTP/E. We found a significant difference in TF binding depending on the MGMTP/E haplotype evaluated, indicating that the haplotypes do alter TF binding. These data provide a mechanistic explanation to our findings demonstrating that MGMTP/E haplotypes influence promoter activity and could explain the well-documented interindividual sensitivity to environmental and therapeutic alkylating agents (Supported by T32-07454; P30 ES086676 and JSME bridging grants).

S. C. Gehreu1, D. Guter2, K. Pant3, J. Mehta4, R. Billing5 and B. Geollapudi2, 5. 1Dow AgroSciences, Indianapolis, IN, 2The Dow Chemical Company, Midland, MI, 3Bakerlight, Rockville, MD and 4Exponent, Inc, Midland, MI.

5-fluorouracil (5-FU) was discovered at trace levels during residue assessments of an investigational agricultural product. To characterize potential health risk associated with this residue, focused hazard and exposure assessments were conducted. While 5-FU has genotoxic potential under some conditions, information relevant to dietary exposure was lacking. To assess the potential genotoxic hazard of 5-FU under relevant exposure conditions, F344/DuCrI rats received a dose of 6 mg/kg day 5-FU by diet for 14 days. Dose-level selection was based on a dietary exposure estimation of 0.0005 mg/kg/day and a 10,000-fold margin of exposure. Multiple guidance points for genotoxic end-points were integrated in a single study using the same group of animals. Specifically, the end-points evaluated were unscheduled DNA synthesis [UDS] in hepatocytes, primary DNA damage [Comet assay] in stomach and duodenum cells and formation of micronucleated polychromatic erythrocytes [MNT] in bone marrow. Sensitivity of the system was confirmed by positive control animals which received single gavage doses of either dimethyltrinitrosamine (35 mg/kg) or cyclophosphamide monohydrate (40 mg/kg/day) and ethyl methanesulfonate (200 mg/kg/day) prior to study termination. All responses were compared to untreated animals. The study results showed 5-FU did not induce a significant increase in the mean number of net nuclear grain counts in hepatocytes isolated from treated animals in the UDS assay, there was no primary DNA damage as measured by the Comet assay, and there was no significant increase in the number of micronuclei in the polychromatic erythrocytes in bone marrow of the treated rats. Under the conditions of this study, it is concluded that 5-FU is non-genotoxic when administered in the diet to rats at levels 10,000-fold higher than predicted human exposure. This study demonstrates the utility of an integrated testing approach for genotoxic potential as well as exposure-based dose-level selection to characterize human risk.

C. M. Harris and T. E. Massey. Pharmacology and Toxicology Graduate Program, Department of Biomedical and Molecular Sciences, Queen’s University, Kingston, ON, Canada.

4-(Methyltrinitrosamine)-1-(3-pyridyl)-1-butaneone ([MNT] in bone marrow. Sensitivity of the system was confirmed by positive control animals which received single gavage doses of either dimethyltrinitrosamine (35 mg/kg) or cyclophosphamide monohydrate (40 mg/kg/day) and ethyl methanesulfonate (200 mg/kg/day) prior to study termination. All responses were compared to untreated animals. The study results showed 5-FU did not induce a significant increase in the mean number of net nuclear grain counts in hepatocytes isolated from treated animals in the UDS assay, there was no primary DNA damage as measured by the Comet assay, and there was no significant increase in the number of micronuclei in the polychromatic erythrocytes in bone marrow of the treated rats. Under the conditions of this study, it is concluded that 5-FU is non-genotoxic when administered in the diet to rats at levels 10,000-fold higher than predicted human exposure. This study demonstrates the utility of an integrated testing approach for genotoxic potential as well as exposure-based dose-level selection to characterize human risk.

H-DNA and Z-DNA-forming sequences co-localize with chromosomal breakage hotspots, such as those found in cancer-related chromosomal translocations, implicating non-B DNA in cancer etiology. Non-B structures cause distortions in the double helix, and therefore, may be recognized as DNA 'damage' by repair proteins. Preliminary data from our lab have shown that nucleotide excision repair (NER) and mismatch repair (MMR) proteins are involved in H-DNA-induced mutagenesis in yeast and mammalian cells. Based on these results it is plausible that repair proteins from multiple pathways participate in error-generating repair of non-B DNA structures, resulting in genomic instability. Thus, we hypothesize that NER and MMR proteins are involved in Z-DNA-induced mutagenesis in eukaryotes. The long-term goal of this project is to determine the mechanisim(s) involved in non-B-DNA-induced genetic instability. We have developed a genetic instability reporter system using a yeast artificial chromosome (YAC) containing naturally occurring non-B DNA-forming sequences capable of forming Z-DNA found at a translocation breakpoint in human cancer. We screened a yeast gene knockout library using 72 YAC reporter system to identify proteins that play a role in DNA structure-induced genetic instability. Thus far we have determined that several NER and other repair proteins are involved in Z-DNA-induced mutagenesis in yeast. We will continue to screen MMR proteins. Future experiments will confirm these results in human cells, and further characterize the roles of proteins identified in the yeast screen using biochemical and cell-based assays.

### 1943b Reduction of Genotoxicity from External and Endogenous Sources with Yel002

M. J. Davoren and R. H. Schiestl, Environmental Health Science, UCLA, Los Angeles, CA.

Genotoxicity, is a persistent, yet often sinister health threat. A large amount of damage resulting from exposure to massive amounts ionizing radiation, for example, can cause death by killing the radiation sensitive dividing cells of our bone marrow and gut lining. However, oftentimes the effects of lesser doses are often not observed until the development of delayed diseases, such as cancers, a long period after the initial genotoxic insult. Ataxia Telangiectasia, or AT, is a severe progressive and terminal disease. By lacking a critical DNA repair enzyme, sufferers of AT essentially accumulate genotoxic damage in their cells at a greatly increased rate, succumbing to cancers at the median age of 22.

The development of a drug capable of mitigating the damage caused by multiple sources of genotoxicity via the upregulation of DNA repair mechanisms is of critical importance for the rescue of both healthy people exposed to genotoxic events such as radiation exposure and those individuals with endogenous DNA repair disorders, such as AT sufferers. Through a high-throughput, yeast based screen, the Schiestl Lab at UCLA has identified a number of compounds capable of reducing both radiation associated death and mutation rates. When the compounds were later tested in mice, one compound, designated Yel002, stood out as particularly effective, capable of cutting the death radiation of C3H mice irradiated at the LD100 level of 8 Gy down to 25%.

Given the sustained effectiveness of Yel002 as a radiation damage mitigator, it was decided to investigate whether it could protect against other sources of DNA damage, such as the endogenous repair disorder AT. Two strains of ATM deficient mice were injected once weekly with 75 mg/kg Yel002 in saline solution. Over a 97 week experimental period, we were able to observe an increase in life expectancy from 42 to 52 weeks with these weekly doses (generally caused by a delay in the development of terminal lymphoma). In addition, we hope to further increase the effectiveness of Yel002 with a new, more bioavailable formulation, currently showing promise in radioprotection experiments.

### 1943i Somatic and Germ Cell Mutant Analysis in the Big Blue® Transgenic Mouse Mutation Assay with N-Ethyl-N-nitrosourea (ENU)

R. R. Young1, H. Dinesdurage1, D. Bruning1, M. McKeon1, Y. Xu1, D. Torous1, S. Dettling1 and R. R. Young1, 1BioReliance, Rockville, MD, 2Marilyn Aardema Consulting, LLC, Fairfield, OH and 3Litron Laboratories, Rochester, NY.

Integration of multiple endpoints in vivo genotoxicity assays provides a broad assessment of genotoxic potential while reducing the use of animals. We examined the induction of micronuclei and the Pig-a mutant phenotype in reticulocytes and mature red blood cells (mRNA levels for Pig-a CD138, and CD24, respectively) in the peripheral blood of male Lambda LIZ/1ac57BL/6 homozygous (Big Blue®) transgenic mice. Animals were treated with vehicle (olive oil) or BaP (50 mg/kg/day) on Days 1-28, or ENU (40 mg/kg/day) on Days 1-3. Peripheral blood was collected -3 hours before animals were sacrificed on Day 31 (as per OECD Test Guideline 488), for tissue collection for determination of cDNA probes, respectively (Litron Laboratories). BaP induced statistically significant increases in mmR, mmNCE, RET1-CD24 and RBC1-CD24 (1.54-, 2.09-, 616- and 100-fold, respectively; all p < 0.001). ENU induced statistically significant increases in mmNCE, RET1-CD24 and RBC2-CD24 (1.39-, 1050- and 207-fold, respectively; all p < 0.001), but not mmR (as expected due to the short term dosing regimen and turnover of mmR into mmNCE in mice). The sensitivity and power of the high throughput Pig-a method is demonstrated by its detection of relatively small net increases in mutant frequencies (the 100-fold increase in RBC2-CD24 observed for BaP represented an increase of ~1 x 10^-6 over a vehicle control value of 0.14 x 10^-3). Analysis of Pig-a mutation frequencies in somatic and germ cell tissues is ongoing. This study demonstrates the ability to integrate multiple endpoints into the Big Blue® Transgenic Mouse Mutation Assay for a comprehensive assessment of genotoxicity.

### 1944 Comparative Cytotoxicity of Nanosilver in HepG2 and Caco2 Cells

Increasing human exposure to nanosilver in consumer products is of concern. We evaluated two widely used human cell culture models, HepG2 and Caco2 cells, for screening cytotoxicity of food- and cosmetic-related nanosilver. We characterized nanosilver by DLS, TEM and ICP-MS analysis. Average size of nanosilver determined by our TEM analysis was 20.4 nm and showed no agglomeration. Our ICP-MS and TEM analysis suggested uptake of 20 nm silver by both cell types. Concentration of nanosilver determined by our ICP-MS analysis was 0.962 mg/ml. A significant concentration-dependent decrease in mitochondria membrane potential in both cell types. Cytotoxicity of 20 nm silver was determined in HepG2 and Caco2 cells at concentrations 0.1, 1.0, 10.0 and 20.0 µg/ml. A significant concentration-dependent cytotoxicity of nanosilver was observed in HepG2 cells in concentration range 1 to 20 µg/ml and at a higher concentration range 10 to 20 µg/ml in Caco2 cells compared to control. When both cell types were exposed to nanosilver there was a significant concentration-dependent decrease in dsDNA content indicating increased DNA damage in concentration range 1 to 20 µg/ml. No oxidative stress was noted in either cell type tested at concentration range used. Nanosilver treatment induced a significant concentration-dependent decrease in mitochondria membrane potential in both cell types indicating increased mitochondrial injury in concentration range 1 to 20 µg/ml for HepG2 cells and at a higher concentration range 10 to 20 µg/ml for Caco2 cells. These results indicated that HepG2 cells were more sensitive to nanosilver than Caco2 cells. It is believed that oxidative...
stress leads to cytotoxicity of nanoparticles in general. However, we did not detect nanosilver-induced oxidative stress in either of cell types in concentration range used. Our results suggested that oxidative stress did not contribute to observed cytotoxicity of nanosilver. A different mechanism of nanosilver cytotoxicity initiated by mitochondria injury is suggested. In summary, our results indicated that widely used in vitro models, HepG2 and Caco2 cells, are excellent models for screening cytotoxicity of nanomaterials.

1945 Induction of Autophagy at Noncytotoxic Concentrations of Silver Nanoparticles in HepG2 Cells
A. Mishra1, Q. Zhang, G. Kumar, B. Casey and P. L. Goering1. CDRH, FDA, Silver Spring, MD.

Silver nanoparticles (AgNP) are increasingly used in medical and consumer products to exploit their antimicrobial properties, but health risks associated with exposure have not been fully evaluated. Further studies are needed to more fully understand the bioactivity of AgNP and identify biomarkers of toxicity. Autophagy is a part of the lysosomal-mediated pathway that functions to sequester and remove unnecessary and misfolded cytoplasmic proteins. Recent studies have shown that nanoparticles of varying chemistries and size can activate the autophagic-lysosomal pathway leading to cytotoxicity. The goal of this study was to: 1) evaluate AgNP cytotoxicity in cultured human HepG2 cells, 2) evaluate autophagy and apoptotic responses induced by AgNP, and 3) determine if LC3B protein, a pro-autophagic marker, can serve as a molecular biomarker to predict AgNP-induced cytotoxicity. HepG2 cells were studied since liver is a primary organ for systemic nanoparticle accumulation. AgNP (10, 50 and 100 nm) were characterized for size and shape using TEM and DLS. Cells were incubated with AgNP (0.1, 0.5, 1, 5, 10, or 50 μg/ml) for 12 and 24 hr. Cytotoxicity was assessed by trypan blue exclusion and XTT assays. Apoptosis (Annexin V) was assessed by flow cytometry. Confocal and fluorescence microscopy were used to detect lysosomal activity (Lysotracker DND), autophagy (Cyto-ID green), and LC3B. Cytotoxicity was observed only after 24 hr post-exposure at the highest concentrations of AgNP (10 and 50 μg/ml) but not at lower concentrations (less than 5 μg/ml). Apoptosis was detected only after 24 hr post-exposure at 10 and 50 μg/ml. No significant apoptosis was detected at 12 hr post-exposure at all the concentrations. In contrast, autophagic vacuoles and increased expression of LC3B were observed at 12 and 24 hr post-exposure at non-cytotoxic concentrations (less than 5 μg/ml). In conclusion, the data demonstrated that 1) autophagy was induced at non-cytotoxic AgNP concentrations, and 2) LC3B may serve as a sensitive biomarker to detect early toxicity in AgNP-exposed cells.

1946 Flow Cytometry-Based Evaluation of Silver Nanoparticle Cytotoxicity: Role of Serum Concentration in Media
G. Kumar1, W. Wei1, H. Degheidy1, B. Casey1 and P. L. Goering1. CDRH, FDA, Silver Spring, MD and University of Maryland, College Park, MD.

Nanoparticles (NPs) when exposed to clinically relevant media, e.g., serum or blood, are immediately coated with proteins and lipids. The adsorbed biomolecules can significantly alter the physiochemical properties (size, charge, shape, surface functionalities) of NPs and hence, high influence NP tissue disposition, cell uptake, and biological responses. NPs, due to their nanoscale properties, also interfere with colorimetric in vitro cytotoxicity assays such as MTT or LDH. However, assays that do not use spectrophotometric detection, such as flow cytometry (FC) based assays, are less likely to be influenced by NP interference. The aim of this study was to 1) compare the cytotoxicity of silver nanoparticles (AgNPs) pre-mixed with cell culture media (with varying FBS concentration) in L-929 fibroblasts compared to direct addition (no pre-mixing) of AgNPs to the cells, and 2) evaluate the use FC-based assays to assess cytotoxicity of AgNPs. To assess the effects of pre-mixing on cytotoxicity, AgNPs (10 nm diameter) were added to cells either following pre-mixing with cell culture media (supplemented with 0.1, 1, or 5% FBS) for 24 hr or directly added without pre-mixing. After 24 hr exposure to the cells, cytotoxicity was assessed by MTT and FC based assays. The degree of cell necrosis and apoptosis was assessed using 7-AAD and Annexin V dyes, respectively. MTT data showed that AgNPs added directly to cells produced a particle concentration (μg/ml)-dependent decrease in viability, i.e., AgNPs pre-mixed with cell culture media supplemented with 0.1% FBS were more toxic as compared to pre-mixing of AgNPs with media supplemented with 5% FBS. FC data showed that the degree of necrosis and apoptosis of cells when exposed to AgNPs was dependent on the concentration of both AgNPs and FBS in cell culture media used for pre-mixing. The data showed that AgNPs premixed for 24 hr with cell culture media were less cytotoxic as compared to no premixing. The results indicate that NP sample preparation methods influence biological testing outcomes.

1947 Size- and Surface Coating-Dependent Uptake and Cellular Responses of Iron Oxide Nanoparticles in Human Mammary Healthy and Breast Cancer Epithelial Cells
O. Zhou1, S. Rajan1, K. M. Tyner2, B. Casey1, C. Dugad1, Y. Jones3, A. Paredes3, C. Cinglman1, P. C. Howard1 and P. L. Goering1. CDRH, FDA, Silver Spring, MD, 2CDER, FDA, Silver Spring, MD and 3NCTR, FDA, Jefferson, AR.

Superparamagnetic iron oxide nanoparticles (SPIONs) have received great attention due to their promising use as magnetic resonance imaging (MRI) contrast agents. In this study, we evaluated the cellular uptake and biological responses in vitro of ultrasmall SPIONs used for MRI breast cancer imaging. We compared the cellular responses between primary breast epithelia isolated from healthy and breast cancer donors after exposure to different sizes and surface coatings of USPIONs (10 nm and 30 nm bare, 10 nm and 30 nm PEG-coated). The particles were characterized using transmission electron microscopy (TEM), dynamic light scattering and gel electrophoresis. Cellular interactions with USPIONs were assessed by confocal microscopy and TEM imaging analysis. Cellular uptake of USPIONs was quantitated using inductively coupled plasma mass spectrometry. Cell viability was measured by MTT and neutral red uptake assays. T2* weighted MRI scans were performed to demonstrate the potential for image contrast enhancement using a 4.7T MRI scanner. Results showed cell association/internalization of USPIONs was size- and surface coating-dependent; higher cellular uptake of 10 nm and 30 nm bare particles was observed in both cell types compared with PEG-coated particles. Cell uptake for 10 nm and 30 nm bare particles was higher in tumor cells from 2 of 3 tested donors compared to healthy cells from 3 donors. Cytotoxicity was minimal except at high concentrations of 200 and 400 μg/ml for all tested particles. Significantly enhanced MRI contrast was observed following exposure to 10 and 30 nm bare particles compared to PEG-coated particles in both cell types. These data indicate that cell responses following exposure to USPIONs are dependent on particle properties. The results provide useful information to better evaluate the safety and efficacy of USPIONs used as MRI contrast agents for breast cancer imaging.

1948 Influence of Single-Walled Carbon Nanotubes with Different Physico-Chemical Properties on the Cellular Responses in Alveolar Epithelial Cells and Macrophages
K. Fujii1,2, S. Endoh1, J. Maru1, H. Kato1,2, N. Shimohara1,2, M. Horie3 and M. Fukuda1. 1National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan, 2Technology Research Association for Single Wall Carbon Nanotubes (TASC), Tsukuba, Japan and 3University of Occupational and Environmental Health, Kitakyushu, Japan.

Impurity-free single-walled carbon nanotubes (SWCNTs)—relatively small bundles and a short linear shape (CNT-1), large bundles and a long linear shape (CNT-2), and commercial SWCNTs with residual metals (CNT-3) as a reference sample did not cause a significant inhibition of cell proliferation, induction of apoptosis, or arrest of cell cycle progression in A549 human alveolar epithelial cells. However, CNT-2–treated cells significantly increased the level of intracellular reactive oxygen species (ROS), in a dose-dependent manner, and the levels of these ROS were higher than those of CNT-1–treated cells or CNT-3–treated cells. On the other hand, treatment of NR8383 rat alveolar macrophage cells with CNT-1, CNT-2, and CNT-3 resulted in slight inhibition of cell proliferation. The levels of IL-1β, MIP-1a, MCP-1 and intracellular ROS generation in CNT-2–treated cells were significantly higher than that in CNT-1–treated cells. CNT-1, CNT-2, and CNT-3 were phagocytosed in vacuoles. Expression of many genes involved in the inflammatory response, their response to oxidative stress, and the expression of extracellular matrix metalloproteinases (MMPs) were markedly upregulated in cells exposed to CNT-2 or CNT-3. These results suggest that the size and length of the bundles of SWCNTs dispersed in cell culture medium, even in the same bulk SWCNTs, are critical parameters of the cellular processes and elicit stress-related cellular responses in alveolar macrophages. We propose a model in which MMPs or inflammatory cytokines derived from alveolar macrophages activated by phagocytosis of SWCNTs induce degradation of the extracellular matrix, and consequently, may cause pulmonary inflammation in alveolar epithelial cells as an indirect effect. This research was funded by NEDO, Japan (P10024).

SOT 2014 Annual Meeting 513
1949 Comparative Biocompatibility of Nano-AntiCancer Drugs
S. Lee1, J. Son2, D. Khang2 and S. Kim1.1Pharmacology, Kyungpook National Univ, Daegu, Republic of Korea and 2School of Materials Science and Engineering and Center for NBECs, Gyeongsang National University, Jinju, Republic of Korea.

The drug delivery system (DDS) has become increasingly attractive in cancer therapy since it can improve drug efficacy and reduce side effects of drugs on normal tissues. Formulating small molecule drugs into nanoparticles (NPs), such as liposomal or carbon nanotube (CNT), allows for a significant reduction of adverse effects while maintaining antitumor efficacy. However, biosafety and biocompatibility of nano-anti-cancer drugs are not much scrutinized in terms of toxicological aspect. In this study, we demonstrated comparative toxicity of pegylated liposomal doxorubicin (Doxil) and doxorubicin (Dox)-linked CNT (Dox-CNT) in various cell lines. We used four types of cell lines such as Raw 264.7, HepG2, AML-2, and SK-MES-1 as target organ cells. We found that Dox-CNT induced greater cytotoxicity than Doxil in four types of cells. Specifically, Dox-CNT enhanced cytotoxicity through cellular uptake and production of reactive oxygen species in Raw 264.7 and HepG2 cells. Dox-CNT caused apoptosis and necrosis through CNT-induced ROS production at concentration of cell viability 75% in all the cells. However, Doxil increased apoptosis through Dox-induced changes of mitochondrial potentials in Raw 264.7 and SK-MES-1 cells. Both of Dox-CNT and Doxil has no significant effect on expression of pro-inflammatory cytokines in all the cells. Our results suggest the importance of biocompatibility during the design of new nano-anti-cancer drugs.

1950 Protein Carbonylation As a Marker of Oxidative Stress Induced by Nanoparticles: Analysis of 16 Inorganic Nanoparticles
M. D. Diressen1, R. Ossig2, J. Schnekenburger2, A. Vennemann1, M. Wiemann1, A. Luch1 and A. Haase1.1German Federal Institute for Risk Assessment, Berlin, Germany, 2Biomedical Technology Center, University of Münster, Münster, Germany and 1BfE BfR GmbH, Münster, Germany.

The BMBF-funded project “nanoGEM” follows a systematic approach to understand hazards associated with different types of nanoparticles (NP). Oxidative stress is considered to be a major paradigm to explain NP toxicity. Here we focused on protein carbonylation as a consequence of oxidative stress for a set of 16 different nanoparticles, used as either plate (“pristine”) materials or with different surface coatings. In parallel several in vitro and in vivo toxicity endpoints have been analyzed.

We used NP of 10nm (ZrO2), 15nm (SiO2) and 50nm or 200nm (Ag), furnished either with acidic, basic or polymeric functionalities and TiO2, ZrO2, BaSO4 and ALOOH as references. Characterization followed the nanoparticles REACH guidance R7.1. In a screening approach we studied time- and dose-dependent protein carbonylation of all 16 NP in NRK-52E cells via 1D immunoblots. Data were correlated with cytotoxicity (WST-8, LDH assay) and ROS formation (DCFDA assay). Furthermore we applied a 2D proteomics approach combined with MALDI-MS/ MS to identify the modified proteins. Finally for several NP we analyzed lung tissue after in vivo instillation in mice.

Eight out of 16 NP induced protein carbonylation in NRK-52E cells. Observed protein carbonylation correlated well with overall toxicity. The 2D approach revealed a complex and distinct pattern of carbonyls. Modified proteins were identified as proteins of cytoskeleton, HSP or proteins of major cellular pathways (i.e. glycocalyx). We also observed carbonyl modifications in the lung tissue homogenates of rats intratracheally instilled with the same NP. Taken together, analysis of protein carbonylation appears useful to describe toxic effects of NP and to better understand underlying molecular mechanisms.

1951 ERK Pathway Is Activated in Bare-FeNPs-Induced Autophagy
E. Park1, M. Cho1, H. Umhi1, Y. Kim2, S. Kim1 and J. Kim1.1Department of Molecular Science and Technology, Ajou University, Suwon, Gyeonggi-Do, Republic of Korea, 2Department of Chemical Engineering, Kwangyoun University, Seoul, Republic of Korea and 1College of Veterinary Medicine, Seoul National University, Seoul, Republic of Korea.

Iron oxide nanoparticles (FeNPs) are known to be one of the most biocompatible and safe nanoparticles. However, their long-term persistence remains a problem, and macrophages play an important mediator in continuous stimulation of the immune system due to biopersistence of nanoparticles. In present study, we identified the mechanisms underlying the uptake and toxicity of bare-FeNPs using RAW264.7 cells, a mouse peritoneal macrophage cell line. The bare-FeNPs penetrated the cell membrane through electrostatic interactions together with the general phagocytic pathway. At 24 h after exposure, they distributed freely in the cytosol or within autophagosome-like vacuoles. Bare-FeNPs induced decrease in the cell viability along with the cell cycle arrest in G1 phase. In addition, they increased the generation of ROS and the secretion of NO and TNF alpha as well as the expression of SOD-1 and -2 and cathepsins, which are known to increase the mitochondrial calcium level, the intensity of labeled mitochondria, and ATP production decreased. The levels of autophagy-related proteins such as p62, beclin1, ATG5, and LC3B increased in a dose-dependent manner together with the levels of ATF 3, p-EGFR and p-ERK proteins. However, the level of p-JNK protein clearly decreased. TEM images also showed that damaged organelle exist within autophagosome-like vacuoles with bare-FeNPs. On the basis of these results, we suggest that bare-FeNPs induce autophagy by initiating oxidative stress in RAW264.7 cells. Furthermore, ERK, but not JNK, pathway is activated in bare-FeNPs-induced autophagy.

1952 Hidden Hazards of Nanoparticles: Crosstalk between Toxicogenomics, DNA Damage, and Cell Death
O. Saqib1, A. A. Al-Khedhairiy1, M. A. Siddiqui1, J. A. Siddiqui1, M. Faisal2, S. Dwivedi1, S. T. Khan1 and M. Musarrat1.1Department of Zoology, College of Science, King Saud University, Riyadh, Saudi Arabia, 2Department of Botany, King Saud University, Riyadh, Saudi Arabia and 3Department of Agricultural Microbiology, Aligarh Muslim University, Aligarh, India.

The rationale of this study is to provide first evidence on the crosstalk between toxicogenomics, DNA damage and cell death induced by NiO and ZnFe2O4-NPs in HepG2 and WISH cells. Ultrastructure analysis revealed NPs translocation in cell cytoplasm and induces DNA damage. MTT and NRU assays showed cell viability of 20.6%, 64.48% in HepG2 and 18.4%, 50.73% in WISH cells. Flow cytometric analysis exhibited high ROS and nitric oxide generation along with 1.2-fold fluorescence enhancement in mitochondrial membrane potential (ΔΨm) in NiO-NPs treated HepG2 and 0.9-fold decline in ZnFe2O4-NPs treated WISH cells. Ca2+ influx and esterase activity in HepG2 cells exhibited 474.6% and 128% greater values after NiO-NPs exposure. Cell cycle analysis of HepG2 and WISH cells exhibited 30.5% and 15.2% of apoptotic cells upon NiO and ZnFe2O4-NPs treatment. qPCR analysis of p35, caspases 3 and 9 genes showed 2.0, 1.2 and 1.1-fold upregulation in HepG2 cells. WISH cells also exhibited 5.3, 1.6, and 14.9-fold upregulation of p53, caspases 3 and 9 genes. The RT2 Profiler™ PCR array data of 84 genes responsible for oxidative stress and human toxicity elucidated up-regulation of mRNA transcripts of GDF15, DDT3, CXC1L1, NOS2 and HPSE in range of 2.0 to 4.6-folds. Also, ZnFe2O4-NPs treated WISH cells elucidated differential up-regulation IL-1β, NFKB1, NOS2 and CCL21 genes in range of 1.5 to 3.7-folds. Furthermore, immunofluorescence analysis of NiO-NPs treated HepG2 cells exhibited translational activation of p53, bax, bcl2, cyt c, PARP and MAPK proteins. In conclusion, the significant ROS production, reduction in ΔΨm, DNA damage, and activation of genes linked to inflammation, oxidative stress, proliferation, DNA damage and repair could serve as predictive toxicity and stress markers for toxicological assessment of NPs induced cellular and genetic damage in exposed human population.

1953 Lung Tissue Culture Model for Assessment of Cytotoxicity and Inflammation Induced by Inhalable Carbon Black Nanoparticles
A. Braun1, O. Danov1, J. Kopil1, M. stroebel1, T. Hansen1, H. Fechenbach1 and K. Sewald1.1Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany, 2Karlsruhe Institute of Technology, Karlsruhe, Germany, 3Airway Research Centre North, Member of the German Center for Lung Research, Borstel, Germany and 4Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATHE), Member of the German Centre for Lung Research (DZL), Hannover, Germany. Sponsor: C. Dassenbrock.

Carbon black nanoparticles (CBNP) are produced in several megatons per year and are used in the industry mainly in tires, inks and for stabilization of elastomers. CBNP have a large surface area to volume ratio and can be covered with polycyclic aromatic hydrocarbons (PAH). CBNP were evaluated as possible carcinogenic material. However, it is remain unclear whether the effects are caused by PAH known to be cancerogenic or by CBNP itself. This study focused on evaluation of one CBNP without PAH (Printex® 90), two CBNP with only one PAH (Printex® 90 Benzo[a]pyrene and Printex® 90 9-Nitroanthracene) as well as one covered with different PAH (acetylene soot). Precision cut lung slices (PCLS) were used as acute exposure model.

PCLS (murine, rat and human) were exposed to different concentrations of Printex® 90, acetylene soot, Printex® 90 Benzo[a]pyrene and Printex® 90 9-Nitroanthracene for 24 h. The size distribution of stable particle suspension in DMEM medium was determined by dynamic light scattering. Viability of PCLS...
was assessed by LIVE/DEAD® staining and determination of metabolic activity using the WST-1 assay. Pro-inflammatory immune responses were assessed in tissue lysate and quantified using ELISA (e.g. IL-1β, IL-10, TNF-α, CXCL-8).

Printex® 90 nanoparticles were nearly non-toxic in PCLS of all three species at concentrations between 0.7 and 66 μg/mL. Compared to these results Benzo(a)pyrene and 9-Nitroanthracene coating showed a toxic effect at 50 μg/mL. Acetylene soot showed a 1.5-fold increase in metabolic activity compared to medium control after 24 h exposure. A 40% decrease to medium control in release of pro-inflammatory cytokines were observed at the concentration of 66 μg/mL for all CBNP.

1954 Long-Term Exposures to Low Doses of Cobalt Nanoparticles Induce Cell-Transformation Enhanced by Oxidative Damage

R. Marcos1-2, B. Annangi1, J. Bach1, G. Vales1, L. Rubio1 and A. Hernández1,2.

1Universitat Autonoma de Barcelona, Cerdanyola del Valles, Spain and 2CIBERESP, Barcelona, Spain. Sponsor: A. Sampaio.

A weak aspect of the in vitro studies devoted to get information on the toxic, genotoxic and carcinogenic properties of nanomaterials is that they are usually conducted under acute-exposure and high-dose conditions. This makes difficult the extrapolation to human beings. To overcome this point we have evaluated the cell transforming ability of cobalt nanoparticles (CoNPs) after long-term exposures (12 weeks) to sub-toxic doses (0.05 and 0.1 μg/mL). To get further information on whether CoNPs-induced oxidative DNA damage is relevant for CoNPs carcinogenesis, the cell lines selected for the study were the wild-type mouse embryonic fibroblast (MEF) and its isogenic Ogg1 knockout partner, unable to properly eliminate the 8-OH-dG lesions from DNA. Our initial short-term exposure experiments demonstrate that low doses of CoNPs are able to induce ROS and the MEF Ogg1-/- cells are more sensitive to CoNPs-induced acute toxicity and oxidative DNA damage. On the other hand, long-term exposures of MEF cells to sub-toxic doses of CoNPs were able to induce cell transformation, as indicated by the observed morphological cell changes, significant increases in the secretion of metalloproteinases (MMPs), and anchorage-independent cell growth ability, among other cancer-like phenotypic hallmarks. Interestingly, such changes were significantly dependent on the cell line used, the Ogg1-/- cells being particularly sensitive. Altogether, the data presented here confirms the potential carcinogenic risk of CoNPs at environmentally plausible doses and points out the relevance of ROS and Ogg1 genetic background on CoNPs-associated effects.

1955 In Vitro 3D Collagen-Based Hydrogel Model to Evaluate Cytotoxicity of Silver Nanoparticles

N. Bhatt1,2, G. Kumar1, J. Stegemann1, H. Degheidy1 and P. L. Goering1.

1CDRH, FDA, Silver Spring, MD and 2Dept Biomedical Engineering, University of Michigan, Ann Arbor, MI.

Nanomaterials are finding increasing uses in the medical device industry in applications such as medical implants, scaffolds and antimicrobial surface coatings. Currently, nanoparticle (NP) toxicity is typically studied in either 2D cell monolayer in vitro models or in vivo animal models; both models have inherent advantages and disadvantages. Studies using 2D models are easy and fast; however, they do not represent the complexity of native tissue. In contrast, in vivo experiments offer the full complexity of tissues, but have high cost and pose difficulty in tracking NP tissue distribution. Alternative 3D collagen matrix-based models offer several advantages to traditional models: in vitro cellular responses can be studied in a physiologically-relevant microenvironment and longer term in vitro exposures are possible. An advantage of 3D models for nanoparticle toxicity testing is that a uniform cell exposure is attained as the limitations of diffusion (smaller NPs) and sedimentation (larger NPs) of particles during exposure are mitigated. The goal of this study was to evaluate the feasibility of using a 3D tissue culture model to assess the cytotoxicity of silver nanoparticles (AgNPs). L-929 fibroblast cells were pre-mixed with type-1 collagen, crosslinked at 37°C to form 3D hydrogels, and allowed to adhere to the collagen matrix for 24 h. After 24h exposure to 10, 100, or 200 nm AgNPs at different concentrations (1, 25, and 50 μg/mL), cells were harvested from hydrogels via collagenase digestion. Harvested cells were exposed to 7-AAD dye and cell viability was measured using flow cytometry. Cytotoxicity was dependent on both dose and size of AgNPs. Cells treated with 10nm AgNPs at 50 μg/mL exhibited a 93% decrease in viability. However, less than 3% decrease in cell viability were observed after exposure to 100nm and 200nm AgNPs. The data showed that a fabricated 3D in vitro cell culture model can be used to evaluate the cytotoxicity of NPs and can bridge the gap between 2D cell culture and animal models.

1956 Nanosilver-Induced Apoptosis in Cell Lines Depends on the Presence of p53

R. Foldbjerg and H. N. Aurup. Environmental and Occupational Medicine, Aarhus University, Aarhus, Denmark.

Silver nanoparticles (Ag NPs) are widely used in consumer products and great efforts are made to elucidate the toxicological mechanisms. Activation of apoptosis after exposure to Ag NPs was investigated in 3 cell lines (CaCo-2, A549, and A549-p53-/-). The Ag NPs (16 nm) were previously characterized (Foldbjerg et al, Toxicol., Sci., 2013). Ag NPs reduced the cellular viability (measured by the MTT assay) by 80% in CaCo-2 cells and 35% in A549 cells at the highest NP concentration (30 μg/mL). Using the annexin V/PI assay, cell death was mainly detected as apoptosis in A549 cells and necrosis in CaCo-2 cells. Thus, cell death induced by Ag NPs may occur by different mechanisms in A549 and CaCo-2 cells. One of the major apoptosis pathways is via the activation of caspases. In A549 cells, a significant increase in caspase-3/7 and -9 activity was observed upon Ag NP exposure. In contrast, the caspase activity in Ag NP-treated CaCo-2 cells was unchanged compared to vehicle controls. CaCo-2 cells lack functional p53 and further studies in A549-p53-/- cells verified that p53 is necessary for caspase-3/7 activation upon Ag NP exposure. Increased caspase activity could, however, be induced by the mdm-2 inhibitor, Nutlin-3, demonstrating that the caspase machinery is fully functioning in CaCo-2 and A549-p53-/- cells. These results indicate that Ag NPs induce caspase-dependent apoptosis in A549 cells and caspase-independent necrosis in CaCo-2 cells. The classical route of caspase-9 activation includes loss of mitochondrial membrane potential (MMP). To confirm this route, the MMP of A549 cells exposed to Ag NPs was measured by JC-1 staining. Interestingly, Ag NPs did not affect the fraction of cells with low MMP suggesting activation of caspase-9 by a mitochondria-independent route. This route may involve calcium fluxes since Ag NPs induced a dose-dependent increase of cytosolic [Ca2+] in both A549 and CaCo-2 cells as determined by Fluo-4 fluorescence. We therefore speculate that Ag NPs may induce stress leading to calcium release and subsequent caspase activation in cells with wild type p53.

1957 Silver Nanoparticle-Induced Apoptosis, Genotoxicity, and Oxidative Stress in CHO Cells

P. J. John1, K. K. Awasthi1, A. Awasthi1, N. Kumar2 and P. Roy2.

1Zoology, University of Rajasthan, Jaipur, Rajasthan, India and 2Biotechnology, Indian Institute of Technology, Roorkee, Uttarakhand, India. Sponsor: S. Rana.

Silver has been used for decades owing to its health benefits as an antimicrobial and antifungal substance. Due to the novel properties of silver, silver nanoparticles are used in electronics, biosensing, photographic processing, medical applications and in many common household products, thus increasing their concentration in the environment and concern about the evaluation of its toxicity. For the present study, the Chinese Hamster Ovary (CHO) cells were exposed to various dose concentrations of silver nanoparticles i.e. 25, 50 and 100 μg/mL in vitro and were compared with that of the control. Cellular morphology, mitochondrial function (MTP assay), mitochondrial membrane potential, anti-oxidant enzymes assay (CAT, SOD, GPx, GST, GR activities as well as total Glutathione level) and comet assay were performed to assess the toxicity. Ag NPs decreased mitochondrial membrane potential and comparable CAT, SOD, GPx, GST, GR activities upon Ag NP exposure. Increased caspase activity could, however, be induced by the mdm-2 inhibitor, Nutlin-3, demonstrating that the caspase machinery is fully functioning in CaCo-2 and A549-p53-/- cells. These results indicate that Ag NPs induce caspase-dependent apoptosis in A549 cells and caspase-independent necrosis in CaCo-2 cells. The classical route of caspase-9 activation includes loss of mitochondrial membrane potential (MMP). To confirm this route, the MMP of A549 cells exposed to Ag NPs was measured by JC-1 staining. Interestingly, Ag NPs did not affect the fraction of cells with low MMP suggesting activation of caspase-9 by a mitochondria-independent route. This route may involve calcium fluxes since Ag NPs induced a dose-dependent increase of cytosolic [Ca2+] in both A549 and CaCo-2 cells as determined by Fluo-4 fluorescence. We therefore speculate that Ag NPs may induce stress leading to calcium release and subsequent caspase activation in cells with wild type p53.

1958 Influence of Capping Agents on Cellular Uptake of Silver Nanoparticles and the Resultant Toxicity

F. Zhang, B. Lau and E. D. Bruce.

Ecological, Earth and Environmental Sciences, Baylor University, Waco, TX.

Nanomaterials, especially silver nanoparticles (AgNPs) have been applied to numerous commercial products. Accordingly, there are raising concerns that exposure to these nanoparticles may cause potential adverse effects on humans as well as the environment. Humans are exposed to AgNPs mainly via inhalation and ingestion, and the potential toxicity has been attributed to nanoparticle-cell interactions, such as the adsorption and internalization of nanoparticles, however, little is known about the mechanisms of these interactions and the factors influencing them. This experiment was carried out to quantitatively and mechanistically investigate the role of capping agents of AgNPs on cellular uptake by cells in the epithelial lining of the human lung and colon. In vitro studies of human bronchoalveolar carcinoma derived cells (A549) and colon adenocarcinoma (Caco-2) are used to quantify the uptake kinetics and the extent of internalized AgNPs and to investigate the uptake
mechanism among different capping agents. AgNPs cytotoxicity is evaluated by lactate dehydrogenase (LDH) release and cell viability, which is also compared to the toxicity caused by Ag+ treatments. We observed Ag+ significantly reduced cell viability and triggered LDH release, however, no such changes were observed from AgNPs-treated cells. In addition, cellular inflammatory response and DNA damage will also be assessed and presented as part of AgNP toxicity mechanism investigation. Results of this study can be applied to facilitate the risk assessment process, limiting the hazards associated with occupational/consumer exposure to silver nanoparticles.

1959 Partial Reduction of Silver Nanoparticle-Dependent Cytotoxicity and Stress Activation following Magnetic Field Exposure

N. J. Braun1, K. K. Comfort2 and S. M. Hussain3, 1Department of Biomedical Engineering, Purdue University, West Lafayette, IN, 2Chemical and Materials Engineering, University of Dayton, Dayton, OH and 3Molecular Bioeffects Branch, Human Effectiveness Directorate, Air Force Research Laboratory, Wright Patterson AFB, OH.

Silver nanoparticles (AgNPs) have become incorporated into a number of consumer, industrial, and medical applications, owing to its tremendous, innate plasmonic and antimicrobial properties. However, AgNPs also induce a strong cytotoxic response, brought on by an excess of cellular stress and DNA damage, which has severely limited the inclusion of AgNPs in nano-based biological applications, such as drug delivery and bio-imaging techniques. Previous investigations into magnetic field (MF) exposure have determined the potential of MFs to reduce the stress response in cellular systems; however the ability of a MF to protect cells from AgNPs has yet to be explored. This study sought to identify if silver nanoparticles with a 15% increase in viability noted up to a threshold concentration of $10^n$ mg/mL. This partial recovery of AgNP dependent cytotoxicity was found to correlate with increased ki67 expression and a substantial decrease in the NE-4C stress response, including reactive oxygen species production and NFkB and c-Jun expression. As neurological models are highly susceptible to stress, this study identified MF stimulation as a potential mechanism to counteract detrimental AgNP effects in neural cells; thereby demonstrating that a joint AgNP and MF system may be advantageous to progress neurological nano-based applications.

1960 Ionic Dissolution of Silver Nanoparticles Is the Root Cause behind the Differential Disruption of EGF Signal Transduction

K. K. Comfort1, E. Maurer2 and S. M. Hussain3, 1Chemical and Materials Engineering, University of Dayton, Dayton, OH and 2Molecular Bioeffects Branch, Human Effectiveness Directorate, Air Force Research Laboratory, Wright Patterson AFB, OH.

In recent years, the field of nanotoxicology has begun exploring the ability of low, relevant dosages of nanomaterials to impact normal cellular functionality, such as signal transduction. Previously, we identified that silver nanoparticles (AgNPs) reduced epidermal growth factor (EGF) dependent signaling. It has also been elucidated that the generation of silver ions is the origin behind the well-established cytotoxic response of AgNPs in a cellular system. However, it has yet to be explored whether the ionic dissolution or the interaction between the particles and the cell surface receptors is the driving force behind AgNP dependent signaling alterations. As such, the goal of this study was to determine if the disruption of EGF signaling transduction was a result of the ionic dissolution or the AgNPs themselves, in a human keratinocyte cell model. Following separation of the AgNPs from the generated ions through tangential flow filtration, it was discovered that the kinetic dissolution was the principal cause for observed modifications to the EGF signaling network, as evaluated through Akt and Erk phosphorylation. The silver ions alone produced a 20% loss of signaling activation, whereas treatment with the particles alone induced no modifications. To explore if this phenomena was sustained or transient, EGF signaling activation was re-evaluated 72 hours after the removal of the AgNPs. Modulation of the cellular response to EGF stimulation still existed, however, after this extended time frame an augmentation in signaling was found; indicating the HaCaTs were in recovery mode. In conclusion, this study demonstrated that at low dosages of AgNPs, the disruption to cellular functionality is driven by the rate of ionic dissolution and is sustained for several days post AgNP removal; further illuminating the long term potential for damage following exposure.

1961 Design and Validation of Nanomaterial Aerosol Exposure Techniques for In Vitro Toxicology

C. Grabinski1, 2, M. Sankaran2 and S. M. Hussain1, 1Molecular Bioeffects Branch, Air Force Research Laboratory, Wright Patterson AFB, OH and 2Department of Chemical Engineering, Case Western Reserve University, Cleveland, OH.

Traditional in vitro toxicology studies are often conducted by dispersing nanomaterials (NMs) in biological media for administration to cells in a static condition, which does not depict realistic inhalation exposure. The objective of this study was to validate a previously designed system to mimic inhalation exposure by delivering well-characterized NM aerosols to cells grown at the air-liquid interface. Silver NMs were exposed either as dispersion in biological media or as an aerosol generated from powder. The aerosolized NMs were characterized in real-time for size distribution and concentration simultaneously to being introduced into the nanomaterial exposure chamber and deposited onto cells using electrostatic deposition. A human type II pneumocyte and alveolar macrophage co-culture was grown in the chamber and exposed to either the dispersion or aerosol. Post-exposure, the viability was assessed using the Alamar Blue assay, the cell morphology was evaluated using fluorescence microscopy and NM uptake was imaged using electron microscopy. Results showed that the NMs exhibited unique agglomeration patterns and dosimetry when exposed at the air-liquid interface as a dispersion versus aerosol. This led to differences in the cellular response and NM uptake. This study demonstrates a promising step forward in the development of a standardized realistic exposure method for assessing NM toxicity to lung cells in vitro.

1962 Strain-Dependent Responses to Quantum Dots in Mouse Hepatocytes

T. Ward1, R. S. McMahan1, C. White1, J. Shang1, X. Hui1, X. Gao2, D. L. Eaton1, T. Kavanagh1, W. C. Parks3 and W. A. Altemeier4, 1Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, 2Department of Bioengineering, University of Washington, Seattle, WA and 3Department of Medicine, University of Washington, Seattle, WA.

Quantum dots (Qdots), a new class of fluorescent nanoparticles, have unique properties that have enabled new opportunities in many areas including optoelectronics, photovoltaics, drug delivery, and biomedical imaging. Despite widespread industrial use and promise for commercial and diagnostic applications, the toxicity of many Qdots remains largely unknown. Many nanoparticles are known to be pro-inflammatory, especially when taken up by tissue macrophages that can elaborate pro-inflammatory cytokines and chemokines. Several in vivo studies have shown that injection of Qdots into rats or mice results in rapid clearance from the blood, with most of them ending up in the liver, spleen, and lymph nodes. In this study, we aim to determine how hepatocytes respond to Qdots, and whether toxic and immunomodulatory effects of Qdots are strain-dependent. We used an in vitro model of exposure to primary hepatocyte cultures from C57BL/6J and A/J strains of inbred mice to determine strain-dependent phenotypes related to exposure to tri-n-octylphosphine oxide, poly (maleic anhydride-alt-1-tetradecene) (TOPO-PMAT) coated CdSe/ZnS Qdots. We cultured primary hepatocytes from C57BL/6J and A/J mice and treated them with various doses of Qdots for 4 hours. We found that Qdot uptake in primary hepatocytes was dose-dependent and significantly higher in hepatocytes from A/J mice than those from C57BL/6J mice. We also measured pro-inflammatory cytokines by qPCR, and found that Qdots induced strain-dependent expression of Il-6 and Cxcl1 mRNA in primary hepatocytes, with cells from A/J mice demonstrating more sensitivity than C57BL/6J cells. Collectively, these data suggest that genetic background plays a significant role in Qdot uptake and inflammation. The A/J strain is more susceptible to Qdot-induced inflammation than C57BL/6J, consistent with in vivo data.

1963 Quantifying the Impact of Ag Nanoparticle Structure and Dissolution in Cell Culture Media on Cell Exposure and Biological Impact

P. Munusamy1, S. Chen2, B. Leo2, C. Liu1, J. N. Smith1, B. D. Thrall1 and D. R. Baer1, 1Pacific Northwest National Laboratory, Richland, WA and 2Imperial College, London, United Kingdom.

In vitro studies using bone marrow derived macrophages and RAW 264.7 cells show that 24 hr exposure to 20 nm Ag particles causes cytotoxicity at concentrations ≥ 10 μg/mL. Understanding the actual dose of nanoparticles and Ag ions to the cell requires knowledge of nanoparticle agglomeration, deposition, dissolution, and transformation in cell culture media. We have examined particle dissolution at concentration ranges from 1 μg/mL to 50 μg/mL and changes of particles for two 20 nm nanoparticles synthesized in different ways. One set of particles was prepared with a 7-8 nm Au core that helped produce particles of uniform
size. Ag coatings were made up of several Ag crystallites that nucleated on the Au 37 producing many highly defective interfaces. In contrast, pure Ag particles were less uniform in shape but had a more ordered ‘single’ crystal structure with slip plane or grain-boundary defects. Dissolution was studied in RPMI+FBS culture medium by measuring the appearance of Ag in the supernatant as a function of time up to 24 hours. High resolution (HR)-TEM and STEM images after solution exposure showed that the pure Ag particles maintained structural integrity compared to Ag/ Au particles where Ag layer had a non-uniform dissolution sometimes exposing the Au core. Dissolution was increased for 20 nm Ag/Au particles in comparison to pure Ag. An equation relating the kinetics of dissolution, the surface area of particles and an effective solubility constant was used to examine dissolution behaviors. For solution concentrations ≥ 10 µg/ml, dissolution parameters within each particle type are consistent regardless of particle concentration. The effective solubility constant for 20 nm particles with the Au was higher than that observed for pure Ag particles. At solution concentrations < 10 µg/ml, solution kinetics and rates appear to be less and would be expected from the behaviors at higher concentrations. Reasons for this difference are under study.

1964

Does Microfluidic Dispersion Influence the Toxicity of Geometric TiO2 Nanomaterials?

T. B. Tilly1, 2, L. L. Kerr1, L. K. Braunlich-Stolle1, L. L. Schlegel1 and S. M. Hussain1, 1Molecular Bioeffects, AFRL, Dayton, OH and 2Chemical, Paper, and Biomedical Engineering, Miami University, Oxford, OH.

Tunable chemical and physical properties of engineered nanomaterials are achievable by changing their geometry and morphology. Titanium dioxide (TiO2) based nanofilaments—nanotubes, nanorods, nanowires—have gained interest in sensing, electrical, and environmental fields due to their superior performance over TiO2 nanoparticles. Their application in the medical field for drug delivery, implant coating, and bioimaging is just now being realized, however their biocompatibility is not fully understood. Thus, safety assessment of geometric TiO2 nanomaterials is critical for protecting workers, patients, and bystanders as these technologies become widely implemented. The tendency of TiO2 based nanofilaments to aggregate and agglomerate make toxicity results controversial because of the challenge in differentiating whether the observed toxicity was caused by the nanofilaments or aggregates. TiO2 nanofilaments aggregate and are difficult to disperse homogeneously in solution by conventional methods, like sonication and vortexing. In this study, a microfluidic device was utilized to produce the stable, homogeneous dosing solutions necessary for in vitro toxicity evaluation by eliminating any toxicity caused by aggregated TiO2 nanofilaments. The quality of the dispersion provided by this method allows for toxicity results to be directly correlated to the TiO2 nanostructure itself. The biocompatibility of four TiO2 nanogeometries—nanotubes, nanorods, nanowires, and nanopapers—were assessed in nasal epithelial cells (RPMI 2650). All TiO2 based nanomaterials dispersed by the microfluidic method were biocompatible in RPMI 2650 cells at the concentrations tested. Whereas 100 µg/ml concentrations of nanowires and nanotubes dispersed by sonication reduced viability up to 27%, indicating that in vitro toxicity results may be controlled by the dispersion of dosing solutions.

1965

Low-Level Exposure to Silver Nanoparticles-Induced Hypertrophy, Multinucleation, and Senescence in Lung Epithelial Cells

D. Ellis1, 2, C. E. Sulentic1 and S. M. Hussain2, 1Department of Pharmacology & Toxicology, Wright State University, Dayton, OH and 2Molecular Bioeffects Branch, Bioeffects Division, Air Force Research Laboratory, Wright Patterson AFB, OH.

Nanotechnology is a rapidly expanding discipline focused on manipulating materials at the nanometer scale. Considerable research has focused on the antibacterial properties of silver nanoparticles (AgNPs), resulting in several commercial products. The bactericidal activity of AgNPs stems from shedding of silver ions and their binding critical biomolecules. The toxic activity in mammalian cells is proposed to derive from oxidative stress caused by the particles and the ions released. In addition, AgNPs may reside in biosystems, producing long-term stress directly or through slow dissolution to ions. As a result, AgNP exposure raises concern over environmental and human health effects. Long-term stress and oxidative damage can induce cellular senescence, or permanent growth arrest. This project tested the potential for AgNPs to induce senescence in A549, epithelial cells during extended exposure at a sub-lethal concentration. Cells were exposed to AgNPs for 1 to 4 days at 10 µg/ml, a level that did not cause overt toxicity by MTS assay but caused oxidative stress measured using a Dichlorofluorescein probe. After 3 to 20 days of recovery, induction of senescence was assessed by observing cell morphology, measuring proliferation, and testing for senescence-associated β-galactosidase (SA-β-Gal) activity. AgNPs caused an increase in the number of hypertrophic cells and cells with SA-β-Gal activity, indicating senescence was induced. Proliferation was relatively unaffected suggesting that many A549 cells were able to subvert full growth arrest; however most hypertrophic cells were multinucleate implying that they could not complete cytokinesis. Taken together, these results indicate that AgNPs induced a senescence-like phenotype in A549 cells despite their resistance to growth arrest.

1966

Evaluation of Tungstate Nanoparticle Cytotoxicity

K. M. Dunning1, 2, M. A. Badding1, D. Schweger-Berry1, N. R. Fiss1, S. Womg1, 2 and S. S. Leonard3, 1NIOSH, Morgantown, WV, 2West Virginia University, Morgantown, WV, 3State University of New York at Stony Brook, Stony Brook, NY and Brookhaven National Laboratory, Upton, NY.

Alkaline-earth metal tungstate AWO3 (A = Ca, Ba, Sr) nanoparticles are currently being used in a variety of applications, including use as components of medical equipment, optical fibers, and scintillator detectors. This versatility may lead to increases in manufacturing within the next 10 years and may subsequently result in more cases of occupational exposure. Therefore, it is important to assess the effects of tungstate nanoparticles on cellular systems. RAW 264.7 macrophage cells were used to assess tungstate nanoparticle toxicity and changes in reactivity based on shape (sphere vs. wire), size, and chemistry. Enhanced dark field microscopy and scanning electron microscopy were used to evaluate nanoparticle-cell association over multiple time points up to 7 hours. To assess uptake, transmission electron microscopy was implemented. Both wires and spheres showed cell surface interactions; however, only spheres were engulfed. To assess intracellular reactive oxygen species (ROS) production, a DCFH assay was performed. Results showed that nanowire-exposed cells had significantly increased levels of ROS over a 7 hour time-course, while nanosphere-treated cells did not. This may be a result of association versus engulfment. Based on ROS production and cell-particle interactions, overall cellular cytotoxicity was measured. A caspase activation assay was used to assess apoptosis, and an MIT assay was employed to determine cell viability. Minimal caspase activity was measured after 24 hours with both spheres and wires. Wire-cell interactions resulted in cell death after 24 hours and sphere treated cells had minimal changes in viability. This data shows that tungstate nanoparticles are not explicitly toxic; however, wires appear to be more reactive than spheres, and have an initial, but manageable toxic effect on cells.

1967

In Vitro Cytotoxicity Assay of TiO2 Nanoparticles in Pulmonary Epithelial and Macrophage-Like Cells

K. Iwasawa1, T. Aoyama1, K. Harano1, N. Shinohara2, G. Zhang2, Y. Gam2 and Y. Sakai1, 1Institute of Industrial Science, the University of Tokyo, Tokyo, Japan and 2RISS, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan. Sponsor: H. Kojima.

Recent advances in nanotechnology have increased the development and production of many new nanomaterials, and this raises concerns about possible human health risk. To establish alveolar cell-based assay systems, human epithelial and macrophage-like cell lines (A549 and THP-1) were used. First, we investigated the A549 cell viability after exposure to the nanoparticles (721±TiO2) at various initial densities. When the cells are cultured at a low density, the drastic decrease of viability (50%) was observed. In contrast, when the cells are cultured at a high density to form cell monolayer, the viability decreased only slightly. In addition, in cocultures of A549 monolayer and THP-1, there were no viability changes, presumably because particles are firstly phagocytized by THP-1 or macrophages. These results show that we have to carefully choose the culture conditions according to the objectives such as screening with high sensitivities or physiological relevancy.

Second, nanoparticles permeation was investigated using A549 and THP-1 cell-based alveolar model formed on semi-permeable membranes and relevant numerical simulation describing dynamic equilibrium among the apical side, alveolar cells, macrophages and basolateral sides. With biological kinetic parameters obtained in the cell-based assay, the numerical model largely described the concentration changes in the assay system. By changing some parameters such as scale of the model to overcome the limitations of existing culture models, it was indicated that the combination use of in vitro cell-based tissue models and numerical simulations made us possible to predict the permeation of particles through the alveolar tissue.
1968 Differential Mode of Nano-Bio Interaction by Graphene Nanomaterials

N. Chatterjee, H. Eom and I. Choi, University of Seoul, Seoul, Republic of Korea.

The wide applications of Graphene nanomaterials and its derivatives have emphasized the need for further mechanistic insight to predict the consequences of environmental health and safety impacts of its exposures. However, little information is available on their toxicity and bio-compatibility. In this current study, we report the impact of differential functionalization of graphene in the interaction with HepG2 cells. We performed a comprehensive study on the toxicity of graphene oxide (GO) and reduced graphene oxide (rGO) on human hepatoma cells (HepG2) and two different kind of GO- few layer graphene (FLGO) and single layer graphene (SLGO), three kind of graphene nanoplatelets (GNP), pristine GNP, GNP-NH2, GNP-COOH on human bronchial epithelial (Beas2B) cells. We used the standard toxicity endpoints such as, cell viability, uptake, apoptosis, ROS formation, DNA damage etc. Furthermore, we also carried out the details of physio-chemical properties of graphene nanomaterials by using Raman spectroscopy, AFM, TEM and XPS etc. The results showed that the differential modes of nano-bio interaction of graphene nanomaterials are influenced by its chemical modification, layer number and functionalization which in turn would direct its further biomedical application. In summary, our results present a paradigm for analyzing surface functionality-activity relationship of graphene nanomaterials with tissue specific evaluation could eventually be utilized for more efficient and innocuous applications, specifically in biomedical field.

1969 Amorphous Silica Nanoparticle-Mediated Hepatotoxicity: A System Toxicology Approach

The wide applications of synthetically manufactured amorphous silica nanoparticles (aSiNP) range from daily life uses such as paints, varnishes, glue, desiccants, plastics, toothpastes, pharmaceuticals, food packaging and as food additives etc. and extended to diagnostic and biomedical fields such as bioimaging, drug and gene delivery, cancer therapy etc. However, the toxic potentiality and bio-compatibility of aSiNP remains to be elucidated. The present study aims to investigate the molecular mechanisms and pathways involved in aSiNP mediated toxicity with systems toxicology approach. The standard toxicity endpoints such as, cytotoxicity, DNA damage, ROS formation, significant modulations of antioxidants as well as DNA repair gene expressions were evident in aSiNP exposed HepG2 cells. Furthermore, the global gene expression changes and subsequent pathway analysis revealed that steroid, lipid and cholesterol biosynthesis pathways are mainly triggered due to aSiNP exposure at 100 mg/L for 24 h. In addition, aSiNP exposures also affect glutathione metabolism as well as xenobiotic and drug metabolism pathways in HepG2 cells. The observed changes in cellular oxidative stress and lipid/cholesterol biosynthesis pathway can be considered as the potential mechanism of aSiNP mediated hepatotoxicity. Our findings could eventually help in designing of future applications of aSiNP, specifically in drug delivery system and other biomedical purposes.

1970 Cerium Oxide Nanoparticles Air Exposure: A Comparison Study Using a Human 3D Airway Model and A549 and Beas-2B Cell Lines

I. M. Kooter1, Y. Staal2, M. Grollers-Mulderig1, M. Steenhof1, E. Duistermaat2, F. A. van Acker1, E. Schoen1, E. van Someren1 and F. Kuper1, I. M. Kooter1, Y. Staal2, M. Grollers-Mulderig1, M. Steenhof1, E. Duistermaat2, F. A. van Acker1, E. Schoen1, E. van Someren1 and F. Kuper1. 1Department of Biomedical Engineering, 2Centre for Nanoscale Materials (CNM), Argonne National Laboratory, Argonne, IL.

Human 3D airway models are fully differentiated and functional models of the respiratory epithelium and therefore may be positioned in safety evaluation of nanoparticles entering the airways. They are cultured at an air liquid interface (ALI), allowing relevant exposure via air. To investigate the respiratory effects of nanoparticles, we performed air exposures of nano-CeO2 and micro-CeO2 using MucilAir human 3D bronchial model and compared these to Beas-2B and A549 cell lines. We used the standard toxicity endpoints such as, cell viability, uptake, apoptosis, ROS formation, DNA damage etc. Furthermore, we also carried out the details of physio-chemical properties of graphene nanomaterials by using Raman spectroscopy, AFM, TEM and XPS etc. The results showed that the differential modes of nano-bio interaction of graphene nanomaterials are influenced by its chemical modification, layer number and functionalization which in turn would direct its further biomedical application. In summary, our results present a paradigm for analyzing surface functionality-activity relationship of graphene nanomaterials with tissue specific evaluation could eventually be utilized for more efficient and innocuous applications, specifically in biomedical field.

1971 Zinc Oxide Nanoparticles Induce Cytotoxicity in Human Endothelial Colony-Forming Cells

Y. Suzuki1, S. Tada-Oikawa1, G. Ichihara2, K. Itooka1 and S. Ichihara1, Department of Biomedical Engineering, University of Tokyo, Tokyo, Japan and 2Nagoya University Graduate School of Medicine, Nagoya, Japan.

Background: Metal oxide nanoparticles have been widely used in industry, cosmetics, as well as biomedicine. However, cardiovascular effect of exposure to metal oxide nanoparticles remains elusive. It is known that the endothelial progenitor cells (EPCs) contribute to postnatal endothelial repair and regeneration. Although recent studies indicated that, in humans and mice, the number of EPCs is decreased by exposure to PM2.5, the effect of metal oxide nanoparticles on EPCs remains unclear at the cellular level. The present study investigated the cytotoxicity, apoptosis and the tube formation induced by nano-sized zinc oxide (ZnO) particles using human endothelial colony forming cells (EPCs), that participate in postnatal vasculogenesis.

Method: EPCs were exposed to nano-sized and macro-sized ZnO for 24 hours. Cellular viability was determined by the MTS assay, which measures the reduction of [3-(4,5-dimethylthiazol-2-yl)]-5-(3-carboxymethoxyphenyl)-2-(4-sulfo-phenyl)-2H-tetrazolium (MTS) to formazan in viable cells. Apoptotic cells were counted by flow cytometry using Annexin V-FITC to stain apoptotic cells. For capillary-like tube formation assay, EPCs were placed in 24-well plates pre-coated with solidified Matrigel Matrix and cultured for 24 hours. Capillary-like tubular structures were photographed, and the number of incorporated EPCs in tubules was determined.

Results and Discussion: The 24-hour exposure to nano- and macro-sized ZnO reduced the cellular viability in a dose-dependent manner and increased apoptotic cells in EPCs. The functional capacity for tube formation of EPCs on Matrix gel was reduced in the cells exposed to nano- and macro-sized ZnO particles compared with the control cells. The study indicates that exposure to nano- and macro-sized ZnO particles may attenuate function of vasculogenesis in EPCs.

1972 Biological Evaluation of Ultrananocrystalline Diamond and Nanocrystalline Diamond Coatings

S. Skoog1,2, G. Kumar1,2, J. Zheng1, A. Sumant1, P. L. Goering2 and R. Narayan1, 1Joint Dept. of Biomedical Eng., UNC & NCSU, Raleigh, NC, 2CDRH, US FDA, Silver Spring, MD and 3Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL.

Biomaterials with nanoscale surface features have been increasingly investigated for medical device applications in an effort to achieve desired tissue-material interactions. Ultrananocrystalline diamond (UNCD) and nanocrystalline diamond (NCD) thin films are distinguished by their grain size with UNCD having 2-5 nm grain size and NCD with grain sizes of 10 nm and above (up to 500 nm). Both UNCD and NCD exhibit material properties similar to those of natural diamond, including mechanical robustness, chemical inertness, biocompatibility, and excellent tribological properties, which make them ideal implant coating materials. Recently, UNCD and NCD have been investigated as coatings for orthopedic, dental, orthopaedic, and cardiovascular device applications. The aim of this study was to evaluate the in vitro biocompatibility of UNCD and NCD coatings and to determine if surface roughness and grain size affect cellular response. Thin films of UNCD and NCD with varying levels of surface roughness (grain sizes 5-350 nm) were deposited on silicon substrates using microwave plasma chemical vapor deposition (MPCVD). Scanning electron micrographs and atomic force micrographs revealed uniform films with different scales of surface roughness; Raman spectroscopy confirmed the presence of carbon bonding typical of diamond thin films. Cell attachment, morphology, viability, and proliferation responses of human bone marrow stromal stem cells to UNCD and NCD surfaces were evaluated. In vitro cell viability and proliferation data showed that UNCD or NCD films have no major adverse cytotoxic effects. No significant differences in cell viability or cell proliferation were noted among diamond films (UNCD or NCD) of different
nanoscale roughness. Our in vitro data shows that UNCD and NCD coatings have superior in vitro biocompatibility profiles irrespective of their roughness and grain size making them desirable for use in implantable medical devices.

**1973 Preparation, Characterization and Antimicrobial Activity of Eu3+-Doped Hydroxyapatite Nanopowders**

J. F. Delgado-Jimenez1, 2, R. Agustin-Serrano2, E. Reyes-Cervantes2, J. L. Varela7, R. Gonzalez-Rodriguez6, J. A. Quenel1, T. D. Palacios-Raleigh, NC and 2NHEERL, ORD, U.S. Environmental Protection Agency, Research Triangle Park, NC.

Silver nanoparticles (Ag NP) are used in a wide range of consumer and medical products because of their antimicrobial properties. In vivo studies have demonstrated that Ag NPs translocate to distal organs, including the brain, following ingestion. Thus, it is essential to examine neuronal function as shown that Ag NPs affect neuronal activity though their unique size and characteristics. Numerous studies have shown that exposure to AgNPs can induce the cytotoxic and genotoxic effects on mammalian cells both in vivo and in vitro assays, implying that AgNPs may increase the risk of adverse health effects. In our study, PVP- and citrate- coated 50 nm AgNPs in Fischer’s 344 rat lymphoma cells were treated for 4 hours with different concentrations (10, 20, 35 and 50 µg/ml) of 50 nm AgNPs. After 48 hr exposure using Cell Titer Blue and Neutral Red assays. These results indicate that higher concentrations of AgNPs can affect cell viability, their unique size and characteristics. Numerous studies have shown that exposure to AgNPs can induce the cytotoxic and genotoxic effects on mammalian cells both in vivo and in vitro assays, implying that AgNPs may increase the risk of adverse health effects. In our study, PVP- and citrate- coated 50 nm AgNPs in Fischer’s medium were shown to be stable at 37 °C using NanoSight and TEM analysis. DNA damage caused by 50 nm AgNPs was evaluated in vitro using hOGG1 and Endonuclease III-modified Comet assays. The LS174T/Tek-l−/−; 3.7C mouse lymphoma cells were treated for 4 hours with different concentrations (10, 20, 35 and 50 µg/ml) of 50 nm AgNPs coating with PVP or citrate. The results indicated that the percentage of DNA in the tail (% tail DNA) was increased in LS174T/Tek-l−/−; 3.7C mouse lymphoma cells were treated for 4 hours with different concentrations (10, 20, 35 and 50 µg/ml) of 50 nm AgNPs coating with PVP or citrate. The results indicated that the percentage of DNA in the tail (% tail DNA) was increased in LS174T/Tek-l−/−; 3.7C mouse lymphoma cells were treated for 4 hours with different concentrations (10, 20, 35 and 50 µg/ml) of 50 nm AgNPs coating with PVP or citrate. The results indicated that the percentage of DNA in the tail (% tail DNA) was increased in LS174T/Tek-l−/−; 3.7C mouse lymphoma cells were treated for 4 hours with different concentrations (10, 20, 35 and 50 µg/ml) of 50 nm AgNPs coating with PVP or citrate. The results indicated that the percentage of DNA in the tail (% tail DNA) was increased in LS174T/Tek-l−/−; 3.7C mouse lymphoma cells were treated for 4 hours with different concentrations (10, 20, 35 and 50 µg/ml) of 50 nm AgNPs coating with PVP or citrate. The results indicated that the percentage of DNA in the tail (% tail DNA) was increased in LS174T/Tek-l−/−; 3.7C mouse lymphoma cells were treated for 4 hours with different concentrations (10, 20, 35 and 50 µg/ml) of 50 nm AgNPs coating with PVP or citrate. The results indicated that the percentage of DNA in the tail (% tail DNA) was increased in LS174T/Tek-l−/−; 3.7C mouse lymphoma cells were treated for 4 hours with different concentrations (10, 20, 35 and 50 µg/ml) of 50 nm AgNPs coating with PVP or citrate.
rived retinal pigment epithelial cells (ARPE-19) after UV exposure. CeO2 NP samples (Alfa Aesar, 36-99nm; NanoAmor, 6-60nm) were suspended in cell culture media with 10% fetal bovine serum (FBS) at concentrations: 0, 3, 10, 20, 30, 55, 100 or 200µg/mL TiO2 NP (Degussa P25; positive control) and administered to ARPE-19 cells grown in 24-well plates. Plates were either exposed to UV irradiation (90min) or kept in the dark. After 24hrs, cell viability was determined with a calcein/propidium iodide stain. Exposure to higher concentrations of CeO2 NP and exposure to UV light (290-400nm) reduced cell viability in CeO2 NP compared to dark plates. When a 2.5% CuSO4 solution filtered restricted light exposure to the UV (320-400nm) range, there was no difference in viability between UV-exposed cells and dark controls. The results showed significant effects of irradiation (F(2,165) = 3.87, p = 0.02) and between the cerium samples (F(2,165) = 1.91, p = 0.001). CeO2 NanoAmor participated in phototoxic reactions with UVB, but not UVA wavelengths. Both CeO2 NP samples were less potent phototoxant than TiO2 NP. Dark-field microscopy and flow cytometry light scatter confirmed CeO2 NP uptake into ARPE-19 cells in a dose-dependent manner. At concentrations higher than 3 mg/mL CeO2 NP formed visible intracellular agglomerates, which were spatially arranged around the nucleus and presumed to be associated with the endoplasmic reticulum and mitochondria. In summary, NanoAmor showed a more phototoxic response than UV irradiation (290-400nm) than Alfa Aesar, but was less phototoxic than TiO2. This does not reflect EPA policy.

### 1973e Comparing Bioactivity Profiles of Diverse Nanomaterials Based on High-Throughput Screening (HTS) in ToxCast

#### A. Wang1, I. Franzosa1, I. Shah1, D. L. Filer1, N. Kleinsteuber5, S. Marinosko5 and K. Houck3

US EPA, Durham, NC, 1HLS, Durham, NC and 3Duke Univ, Durham, NC.

Most of the over 2800 nanomaterials (NMs) in commerce lack hazard data. Efficient NM testing requires suitable toxicity tests for prioritization of NMs to be tested. The EPA’s ToxCast program is evaluating HTS assays to prioritize NMs for targeted testing. Au, Ag, CeO2, Cu(O2), TiO2, SiO2, and ZnO nanoparticles, their ion and micro counterparts, carbon nanotubes (CNTs), asbestos, and pesticides containing nano-Cu(O) - total 62 samples - were screened at 6 -10 concentrations each. A total of 262 bioactivity/toxicity endpoints in cells and zebrafish embryos were measured. Cellular stress and immune response pathways were primarily affected. NM’s core chemical composition was more important than size for bioactivity. NMs had similar profiles as their ion counterparts, suggesting ion shedding was a key factor in mechanism of action. Ag, Cu, and Zn (nano, ion) were more cytotoxic and active in more assays than others. While 3 asbestos samples had similar immune response profiles, 6 CNT’s had profiles distinctive from asbestos. Potential bioactivity targets that were not directly measured were suggested by reference profiles similar to our data, e.g. similar profiles of a microtubule stabilizer interfering with mitosis and our nano-TiO2. Dividing endpoints into cytotoxicity and various functional categories, we developed a ToxCast-based ranking approach for in vitro bioactivity. Samples active in more categories at lower concentrations were ranked higher than samples active in fewer categories and/or at higher concentrations. Ag, Cu, and Zn samples were ranked as high in vitro bioactivity as Au, CeO2, in some CNTs, and some TiO2 samples were ranked as low. Recognizing our assays using submerged cells may be poor models for inhalation effects, this ranking may be more appropriate for oral effects. We demonstrated that HTS assays can identify affected cellular pathways, predict targets, and may be useful for ranking NMs for specific purposes. This abstract does not necessarily reflect EPA policy.

### 1973f Silver Nanoparticles Induce Antiproliferative Effects on Airway Smooth Muscle Cells: Role of Nitric Oxide and Muscarinic Receptor Signaling Pathway

#### C. Gonzalez1, 2, M. A. Ramirez-León1, H. Rosas-Hernández1, 2, J. M. Hernandez1, R. Espinoza-Tanguma1, F. J. Gonzalez1 and S. F. Ali2

1Office of Applied Research and Safety Assessment, US FDA, Laurel, MD and 2CDRH, US FDA.

Silver nanoparticles (AgNPs) are used to manufacture materials with new properties and functions. However, little is known about their toxic or beneficial effects on human health, especially in the respiratory system, where its smooth muscles (ASM) regulates the airway contractility by different mediators, such as acetylcholine (ACh) and nitric oxide (NO). The aim of this study was to evaluate the effects of AgNPs on ASM cells. Exposure to AgNPs induced ACh-independent expression of the inducible nitric oxide synthase (iNOS) at 100µg/mL, associated with excessive production of NO. AgNPs induced the muscarinic receptor activation, since its blockade with atropine and blockade of its downstream signaling pathway inhibited the NO production. AgNPs at 10 and 100µg/mL induced ACh-independent prolonged cytotoxicity and decreased cellular proliferation mediated by the muscarinic receptor-iNOS pathway. However, the concentration of 100µg/mL of AgNPs induced muscarinic receptor-independent apoptosis, suggesting the activation of multiple pathways. These data indicate that AgNPs induce prolonged cytotoxicity and anti-proliferative effects on ASM cells, suggesting an activation of the muscarinic receptor-iNOS pathway. Further investigation is required to understand the full mechanism of action of AgNPs on ASM under specific biological conditions.

### 1973g Laser 3D Printing with Nanoscale Resolution: Improving Biocompatibility and Mitigating Toxicity from Photoinitiators

#### P. E. Petrochenko1, 2, R. Narayan1, 2, P. L. Goering1 and A. Ovsianikov3

Recent developments in laser-assisted 3D printing using two-photon polymerization (2PP) allow for previously unattainable submicron resolution and show promise for creating 3D cell scaffolds for regenerative medicine and tissue engineering applications. A significant barrier to using 2PP for biological applications exists due to the toxicity of photoinitiators required for polymerization. The goals of this study were to 1) demonstrate two approaches for creating nanotextured, porous 3D scaffolds using 2PP, and 2) develop a model system to evaluate in vitro cell responses, such as cell growth, protein adsorption, and toxicity, to nanoscale variations on material surfaces or to residual chemicals used in scaffold fabrication. The first approach involves printing a 3D scaffold from a urethane diacrylate-based elastomer, removing residual toxic substances and seeding the cell. The second approach, involving trapping cells directly in a methacrylamide-modified gelatin matrix. Results from the first method indicate that stable scaffolds with porosities of over 60% can be custom printed to fit standard 96-well plates. Human bone marrow stromal cells grown on 3D scaffolds exhibited increased growth and proliferation compared to smooth 2D scaffold controls. Scaffolds adsorbed larger amounts of proteins due to a greater surface area and allowed cells to attach in multiple planes and infiltrate the porous scaffolds. Results from the second approach indicated some dead MG63 osteosarcoma cells and L929 fibroblasts in encapsulated regions. In order to mitigate photoinitiator toxicity, 3 antioxidants -Trolox (water-soluble vitamin E), vitamin C, and glutathione – were used. Preliminary results demonstrated decreased cytotoxicity. The data indicate that 2PP is a promising technique for fabricating custom 3D scaffolds, including the potential for cell encapsulation.

### 1973h In Vitro Penetration of Polyethylene Glycol- and Citrate-Coated Silver Nanoparticles into Human Skin

#### V. Topping1, K. Belgrave2, Z. Keltern1, R. Sprando1, L. Yourick1 and M. E. Kraeling1

1Office of Applied Research and Safety Assessment, US FDA, Laurel, MD and 2ORISE, US DOE, Oakridge, TN.

Silver nanoparticles (AgNPs) are used as an antimicrobial in a variety of cosmetic products. There are concerns about the potential safety associated with human skin exposure. This study was conducted to investigate the in vitro penetration of neutrally charged polyethylene glycol (PEG) and negatively charged citrate (CIT) coated 20 nm AgNPs into excised human skin. AgNPs were first characterized to confirm the size, shape, charge, agglomeration state and stability of the particles. Circular punches of dermatomed human cadaver skin from two donors were placed into flow-through diffusion cells, and 0.01% and 0.001% aqueous solutions of PEG and CIT coated AgNPs were applied once to the surface of the skin in duplicate. These concentrations were chosen as they were relevant to current commercially available cosmetics. After 24 hours, the skin samples were washed with a 1% soap solution and distilled water, removed from the diffusion cells, and tape-stripped twice to remove unabsorbed surface AgNPs. Each skin disc was prepared for analysis by taking half for inductively coupled plasma mass spectrometry (ICP-MS) analysis and the other half for Transmission Electron Microscopy (TEM). Preliminary ICP-MS analysis revealed an increase in silver content (ng silver/g of skin) of PEG and CIT samples at both concentrations when compared to untreated control skin. There was a 20-fold and 9-fold increase in silver content of the 0.01% PEG and CIT AgNPs samples compared to the 0.001% treatments, respectively. TEM images of skin samples coincided with ICP-MS results, with 20 nm CIT and PEG coated AgNPs localized in the stratum corneum and upper epidermis. Higher concentrations of AgNPs solutions corresponded with increased skin silver content. This study indicates that human skin silver content increased after an application of neutrally and negatively charged aqueous AgNPs for 24 hours, and these particles may penetrate into the upper epidermis.
Dendrimers are highly branched stable polymeric nanoparticles with terminal functional groups capable of binding other molecules which could be used to increase delivery of chemicals to skin. The surface charge of the dendrimers may affect skin absorption of bound cosmetic ingredients. We previously evaluated the skin penetration of amine-terminated polyamidoamine (PAMAM) dendrimer nanoparticles. Alexa Fluor 568 (~1 equivalent per dendrimer) was conjugated to terminal amine on the dendrimers via amide bonds for confocal imaging. In this study, we examined the skin penetration of generation 3, generation 4, generation 5 and generation 6 PAMAM dendrimers further conjugated with succinic anhydride (negative surface charge). Free unconjugated fluorophore was removed by ultrafiltration followed by gel filtration, and characterized. Dendrimers were applied (0.2% concentration) in aqueous solutions or cosmetic emulsion formulation onto viable pig or human cadaver skin assembled in diffusion cells. After a 24 hour exposure, the extent of skin penetration was determined by laser scanning confocal microscopy. Most fluorescence from the applied dendrimers appeared in the stratum corneum (SC) or in hair follicles of both pig and human skin. Fluorescence appeared in the upper regions of the epidermis of pig skin with the small generation dendrimers using both the low (12.8 μl) and high (40 μl) volume solution applications. With the emulsion, most of the generations of various dendrimer species remained in the SC or penetrated pig skin through hair follicles. In human skin, small generation dendrimers penetrated skin with the low and high volume solutions and emulsion SC or penetrated pig skin through hair follicles. In human skin, epidermal penetration was not evident. PAMAM dendrimer nanoparticles were conjugated with Alexa Fluor 568 (~1 equivalent per dendrimer) and characterized. Glycidol dendrimers were applied (0.2% concentration) in aqueous solutions and disperse MWNT-7 into dry single fibers without dispersant and changes in fiber length and width distribution ("Taquann-dispersed" method). T-CNT was loaded in a newly designed cylindrical cartridge case and injected into the chamber by compressed air. Aerosol in the chamber consisted predominantly of well-dispersed single fibers showing length and width distribution similar to those of the original sample, and these single fibers were found in the alveolar spaces of mice exposed. This system is relatively inexpensive and optimal for testing inhalation toxicity of nanomaterial samples in well-dispersed, dispersant-free aerosol with minimum mechanical fragmentation. 1Institute of Nanoproduct Safety Research, Hoseo University, 2Occupational and Environmental Health, Nagoya University, Nagoya, Japan. This work was supported by NIH grants R01 ES019536-02 & 5T32ES007148.

The present study investigated underlying mechanism of pulmonary fibrosis caused by exposure to ZnO nanoparticles, in a mouse model of pulmonary fibrosis induced by bleomycin (BLM). The mouse model was developed by constant subcutaneous injection of 100 mg/kg bleomycin sulphate using osmotic mini-pumps. Female C57BL/6J mice were divided into BLM and non-BLM groups. In each group, two doses (10, 30, 50 mouse) of ZnO nanoparticles were delivered into the lungs through pharyngeal aspiration. The lung was collected 10 days after administration under deep anesthesia. Exposure to ZnO nanoparticles dose-dependently increased the lung weight. Histopathologically, slight and severe thickness was observed within interalveolar septum in low and high dose groups, respectively, which was accompanied by dose-dependent increase in total cells, macrophages, lymphocytes and neutrophils in BALF. The increase in total protein in BALF at high dose indicated increased permeability of alveolocapillary membrane due to severe inflammation. ZnO nanoparticles increased lung stiffness, consistent with surfactant disruption 3 days post instillation, neutrophilia resolved in functionalized ZnO treated mice, but protein concentration increased vs control (0.2 ± 0.03 v 0.1 ± 0.02 µg/mg tissue protein).

1977  The Effects of Pharyngeal Aspiration-Exposure to ZnO Nanoparticles on Pulmonary Fibrosis Induced by Bleomycin in Mice

ZnO nanoparticles increased lung stiffness, consistent with surfactant disruption 3 days post instillation, neutrophilia resolved in functionalized ZnO treated mice, but protein concentration increased vs control (0.2 ± 0.03 v 0.1 ± 0.02 µg/mg tissue protein).

1978  Effects of Nanoparticle Pre-Exposure Dispersion Status on Bioactivity in the Mouse Lung
T. M. Sager1, 2, M. Wolfarth1, V. Castranova2 and A. Holian1. 1University of Montana, CEHS, Missoula, MT and 2NIOHS, Morgantown, WV.

From a toxicology perspective, nanoparticles possess two features that promote their toxicity. The first involves physical-chemical characteristics, including particle surface area. The second is the ability of the nanoparticle to traverse cell membranes. These two characteristics are influenced by placing nanoparticles in liquid medium prior to animal exposure. Nanoparticles tend to agglomerate in suspension, making it difficult to accurately deliver them for in vivo or in vitro experiments. Thus, we hypothesize that the nanoparticle dispersion status will correlate with the in vivo bioactivity/toxicity of the particle. The proposed questions of this study are of great importance to the nanotechnology/toxicology community, namely the highly debated question of whether nanoparticle dispersion status (pre-exposure) is of importance. To test our hypothesis, nano-sized nickel oxide was suspended in four different dispersion media (PBS, dispersion medium (DM), Survanita, or Prulonristm). At each respective dose, well-dispersed and poorly dispersed (suspended) dispersion status were suspended utilizing a Branson Sonifier 450, 25W continuous output. Two min or 5 min, respectively) suspensions were created. Mice (male, C57BL/6J, 7-10 weeks old) were given 0-80 µg/mouse of nano-sized nickel oxide in the different states of dispersion via pharyngeal aspiration. At 1 & 7 days post-exposure, mice underwent whole lung lavage (WLL) to assess pulmonary inflammation and injury as a function of dispersion status, dose, and time. Results show that pre-exposure dispersion status correlates with particle bioactivity. In fact, the particle/media combination that produced the smallest hydrodynamic particle size (nano-NIO2 suspended in DM & sonicated for 20 min. = 7.5 nm) produced a greater increase in PMNs, LDH activity, as well as albumin levels in WLL fluid than the other nano-nickel/suspension/media combinations. These results indicate that a greater degree of pre-exposure dispersion increases particle bioactivity/toxicity in the lung.

1979  Effects of Multiwalled Carbon Nanotube Solubility on Inflammation and Lung Function
D. Botzel, A. Porter, F. Chung, T. Tetley, J. Zhang and A. Gowe.

London, United Kingdom. This work was supported by NIH grant F32 ES0021341.

Multi-walled carbon nanotubes (MWCNTs) have high potential, are relatively insoluble in aqueous solvents, and interact with hydrophobic materials. These properties are altered by functionalization. Due to complexity of MWCNTs it is important to study organ level effects. To study effects of MWCNTs on the lung we use a suspension method involving native surfactant. This method is effective at keeping MWCNTs in suspension despite functionalization. We hypothesized that increasing solubility of MWCNTs in the aqueous environment would shift the organ level response to inflammation from interaction with the lung lining fluid. C57Bl6J mice were intratracheally instilled with MWCNTs (30-50nm OD, 0.5-2mm length) at 1.5µg/g body weight. 2 types of MWCNT were examined—functionalized by carboxylation or acid-purified. 1 day post instillation, the functionalized MWCNT treated mice showed neutrophilia (147.1 ± 105.6/7 v 2.5 ± 0.92 x103) and increased cell count (196.5 ± 113.02 v 57.0 ± 8.25 x103) vs control. Purified MWCNT mice did not display significant inflammation (18.5 ± 15.62 v 2.5 ± 0.92 x103 neutrophil; 63.0 ± 15.09 v 57.0 ± 8.25 x103 total cells). Lung function was not affected by functionalized MWCNTs but purified MWCNTs increased lung stiffness, consistent with surfactant disruption 3 days post instillation, neutrophilia resolved in functionalized MWCNT treated mice, but protein concentration increased vs control (0.2 ± 0.03 v 0.1 ± 0.02 µg/mg tissue protein). Purified MWCNT mice do not show increased tissue stiffness. Both MWCNT treated groups demonstrated significant decrease in collectin content. This work is consistent with the idea of "revealing" the MWCNTs to inflammatory system and reducing effect on lung function. Supported by NIH Grants U19ES019536-02 & 5T32ES007148.

1980  Pre-Exposure to Nontoxic Levels of Magnetically Functionalized Nanoparticles Sensitizes Mice to Pulmonary Infection by Streptococcus pneumoniae

1Systems Toxicology, Pacific Northwest National Laboratory, Richland, WA and 2Medicine, University of Washington, Seattle, WA.

Two major forms of iron oxide are preferred for medical applications due to their perceived biocompatibility. Pretreatment of cultured macrophages with non-cytotoxic doses of superparamagnetic iron oxide (SPIO) reprogrammed -500 genes in response to subsequent challenge by endotoxin, suppressing activation of both pro- and anti-inflammatory pathways and diminished bacterial phagocytosis (Kodali et al. 2013). Here, we characterize and confirm the potential impaired clearance of bacteria by mice pretreated with SPIO. We administered 0 or 1.0 µg SPIO (g bw to C57BL/6 by oropharyngeal aspiration (OPA) and evaluated the pro-inflammatory response by measuring cytokines in BALF collected 1-28 d post-dosing. No statistical changes in cytokine levels were observed at 1-28 d post-dosing confirming that...
Sodium nitroprusside (SNP; 5-20 μg/kg). After 24 h prior to intra-nasal installation of 50K colony forming units (CFU) of S. pneumoniae. The SNP doses were selected to represent the mouse equivalents of human occupational exposure for 1, 5, and 20 d at the Permissible Exposure Limit. The low pyrogenic/inflammatory potential of these exposures was confirmed by the absence of changes in surface body temperature. However, mice pretreated with 30 or 100 μg/kg SNP exhibited a 3.6- and 7.0-fold increase, respectively, in CFU recovered from the lung, indicating mice exposed to SNP had reduced lung clearance of S. pneumoniae. These studies suggest that the direct toxicity of SNP may be less important than those effects elicited by SNP interaction with other stressors. Supported by NIEHS NCNHR Consortium ES019544.

1981 A Comparative In Vivo Screening of Nine Classes of Multiwalled Carbon Nanotubes for Acute Lung Toxicity in Mice

M. Cartwright, S. Schmuck1, C. White1, C. Corredor2, D. Botts1, D. K. Scoville1, C. Chisholm3, J. Posner4, T. Gordon and T. Kavarnagh1,
1Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, 2Chemical Engineering, University of Washington, Seattle, WA, 3Mechanical Engineering, University of Washington, Seattle, WA and 4Environmental Medicine, New York University, Tuxedo, NY.

Multi-walled carbon nanotubes (MWCNTs) present potential health risks during their manufacture and handling in the electronics and medical industries. To improve understanding of MWCNT behavior following inhalation, we are investigating how aggregative characteristics, aspect ratio, surface carboxylation, and purity from trace metals affect MWCNT pulmonary toxicity in vivo. To characterize aggregative behavior, we used dynamic light scattering to assess the hydrodynamic radii and zeta potentials of nine classes of MWCNTs in dispersion medium (DM). In order to assess pulmonary toxicity, we exposed eight-week-old male A/J mice via oropharyngeal aspiration to DM vehicle or a single MWCNT class at 40 μg/mouse, and sacrificed the mice after 24 h. Treatment with unpurified and carboxylated MWCNTs was associated with lung inflammation as indicated by flow cytometric and cytospin analyses of neutrophil influx into bronchoalveolar lavage fluid (BALF). Across all MWCNT classes, we found no evidence of acute capillary barrier dysfunction or frank cellular damage as indicated by BALF supernatant total protein or lactate dehydrogenase activity. Similarly, no evidence of severe oxidative stress was detected in lung tissue as indicated by total glutathione levels. Our results indicate that high-dose exposure to unpurified and carboxylated MWCNTs causes acute lung inflammation but does not frank cellular toxicity in the short term. This work was supported by NIH Grants U19ES019544 and P30ES070033, and NSF grants CBET-0932885 and DGE-0718124.

1982 Inhalation of Nanosized Titanium Dioxide Alters Cardiovascular Autonomic Function

T. L. Knutches, J. Yi and T. R. Nutkiewicz, Center for Cardiovascular and Respiratory Sciences, West Virginia University, Morgantown, WV.

Nanotechnology is a rapidly growing field with the potential to influence all aspects of modern life. However, the cardiovascular toxicity of nanomaterials is not well understood. We have previously demonstrated a disruption in normal microvascular function following nanomaterial exposure via alterations in autonomic control. Presently, using a telemetry and a baroreflex function model, we show changes in autonomic control following inhalation exposure to nanosized titanium dioxide (nano-TiO2) for 4 hours for 2 days at 6 mg/m3. Telemeterized rats were acclimated and exposed to sham (day 0), then nano-TiO2, or sham on 2 consecutive days (days 1, and 2). Renal sympathetic nerve activity (rSNA), mean arterial pressure (MAP) and heart rate (HR) were continuously monitored. 24 h after the last exposure, baroreflex sensitivity was measured with phenylephrine (PE; 1-8 μg/kg) or sodium nitroprusside (SNP; 5-20 μg/kg). After 24 h prior to intra-oral installation of 50K colony forming units (CFU) of S. pneumoniae. The SNP doses were selected to represent the mouse equivalents of human occupational exposure for 1, 5, and 20 d at the Permissible Exposure Limit. The low pyrogenic/inflammatory potential of these exposures was confirmed by the absence of changes in surface body temperature. However, mice pretreated with 30 or 100 μg/kg SNP exhibited a 3.6- and 7.0-fold increase, respectively, in CFU recovered from the lung, indicating mice exposed to SNP had reduced lung clearance of S. pneumoniae. These studies suggest that the direct toxicity of SNP may be less important than those effects elicited by SNP interaction with other stressors. Supported by NIEHS NCNHR Consortium ES019544.

1983 Endothelial Cells As Biosensors to Assess the Vascular Inflammatory Potential of Serum following Nanomaterial Exposure

M. Aragon1, M. Dunlap1, J. R. Roberts2, A. Erdely2 and M. Campean1,
1University of New Mexico, Albuquerque, NM and 2NIOSH, Morgantown, WV.

Assessing mechanisms underlying the adverse vascular health effects of systemic inflammation induced by inhaled toxins presents a substantial research challenge. We have developed an ex vivo model that allows for a realistic exposure method to better elucidate the mechanisms involved in a living system. This approach supplies serum from exposed cultures to primary endothelial cells, as this is the component in direct contact with the vascular endothelium. Here, we apply this assay paradigm to assess the impact of pulmonary exposures to multi-walled carbon nanotubes (MWCNT) or graphene. Mice were exposed to varying doses (4, 10 or 40 μg) of MWCNT, various types of graphene, or carbon black via pharyngeal aspiration, and serum was collected at 4 and 24 h post-exposure. Serum collected from 19 d inhalation exposures to 0.5 or 5.0 mg/m3 MWCNT was also assayed for endothelial activation. Serum from exposed mice induced an up-regulation of endothelial cell surface VCAM and ICAM expression, along with elevations in mRNA at the 4 h time point. Multiple sizes of graphene were tested; the smallest sizes (<2 μm x <2 μm x 1-2 nm and 5 μm x 5 μm x 7 nm) induced up-regulation of surface VCAM, but were overall less potent than carbon black, used as a control particle. Furthermore, we assessed nitric oxide (NO) generation by endothelial cells using electron paramagnetic resonance (EPR) methods, and found that NO was decreased via treatment with serum from MWCNT-exposed mice following stimulation with 2 mM ATP. Microarray analysis of endothelial cell response to serum from the inhalation and instillation exposures revealed a common set of response elements. In conclusion, pulmonary exposure to carbon-based nanomaterials alters circulating factors which promote endothelial cell activation and decreased NO bioavailability.

1984 Surface Amination Enhances the Toxicity of Silica-Coated Silver Nanoparticles

J.A. Bonventre1, B. Harper2 and S.L. Harper1, 2, 3, 1Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR and 2Chem., Biol. & Env. Eng. Oregon State University, Corvallis, OR.

Surface charge can greatly influence the toxicity and bioavailability of engineered nanoparticles (NPs). Positively charged NPs generally elicit greater toxicity than comparable negative or neutrally charged particles. The effect of amination on NP toxicity was investigated in embryonic zebrafish, a model vertebrate. Embryos were exposed to 0.5-100 ppm suspensions of 80nm silica (Si) or 70nm silver with 20nm Si-coating (AgSi), or aminated NPs of like size and composition. Surface amination significantly increased the toxicity of the NPs. Si NPs did not induce mortality or morbidity at the tested concentrations, whereas aminated Si induced 58% mortality at 100 ppm. Both AgSi NPs were significantly more toxic to embryos than Si NPs. AgSi NPs significantly delayed development at 24 hours post fertilization in 25 (50%), 50 (64%) and 100 (75%) ppm treatments, and caused significant mortality beginning at 100ppm. In comparison, aminated AgSi NPs delayed development significantly as low as 1 ppm and induced significant mortality at 5ppm, with 100% mortality above 50ppm. Both AgSi NPs induced significant sublethal effects, including craniofacial and fin malformations, edemas, and body curvatures. When similar silica coated Ag NPs with varied surface amination levels (0.5x, 1x, and 2x) were tested at the same concentrations, the AgSi-1x was significantly more toxic than the 0.5 or 2x AgSi NPs, inducing mortality at 100 (95%) ppm. In contrast, AgSi-2x only induced 38% mortality at 100 ppm, and AgSi-0.5x NPs did not cause toxicity at any concentration tested. Increased amination was observed to alter the stability of the aminated NP dispersions in the exposure media, with the 2x NPs being the most stable in suspension. Our results suggest that increasing surface amination only leads to increased toxicity when bioavailability is held constant, highlighting the importance of understanding NP stability and bioavailability during exposure.
1985 Establishment of an Inexpensive, In Vivo Screening Tool for Nanomaterial Safety Using the Adult Zebrafish
N. Elrod1, J. Brady1, 2, L. K. Braydich-Stolle1, S. M. Hussain1 and J. Spechock1, 1Biology, Tarleton State University, Stephenville, TX, 2Texas A&M AgriLife Research Institute, Stephenville, TX and 3Air Force Research Laboratories, Wright-Pattern Air Force Base, OH.

Current toxicological assessment of the safety of nanomaterials is lagging well behind the synthesis and consumer use. This is largely due to the lack of a quality inexpensive model for toxicological assessment. Cell cultures are inexpensive and can provide some indications on biological properties, but they do not convey a complete account for cell-to-cell communication. Mammalian models can allow for a greater understanding of toxicology and biodistribution. However, adequate mouse studies can be cost prohibitive. This study examines the potential for an inexpensive alternative in vivo model using the adult zebrafish, Danio rerio, for assessment of nanomaterial immunotoxicology. Zebrafish have many homologous proteins shared with humans and other mammals and can be bred and maintained for very little cost. Having been completely sequenced, many biomarkers for stress, toxicity and inflammation have been identified in the zebrafish. This preliminary assessment has determined the extent of biodistribution, inflammation, and toxicity using 10 nm silver nanospheres and it has been determined that the nanomaterials do not cause mortality or significant morbidity after a one-time intradermal exposure at 10 or 50 μg/mL and can distribute throughout the fish as evidenced by differential effects on various target organs. Quantitative PCR, ICP-MS, and transmission electron microscopy where used to measure the biodistribution and inflammatory responses of the silver nanoparticles. All target organs had measurable amounts of silver nanoparticle detected and a mild inflammatory response at 24-hours post-inoculation was observed. The establishment of the adult zebrafish in vivo model for immunotoxicology could allow for an inexpensive comparative analysis of a wide array of nanomaterial sizes, shapes, and compositions for determination of their safety and distribution.

1986 Genetic Influence of Pulmonary Response to Silver Nanoparticles Exposure and Candidate Gene Identifications
M. Hernandez, K. Galdanes, L. Chen and T. Gordon, Environmental Health Science, NYU, Tuxedo, NY.

Within the last few decades, the use of nano-materials and products for multi-application uses has seen exponential growth, while information on the toxicity of these nano-materials is still largely unknown. This study evaluated the variation of response in numerous murine strains to examine genetic susceptibility to silver nanoparticles (AgNPs). Previously, 8 strains of inbred mice were acutely exposed via oropharyngeal aspiration to a dose of 0.25 μg/g body weight of 20nm silver citrate, with observed polymorphonuclear neutrophil (PMN) responses between 1.4-60% (DBA/2J< C57BL/6J< AKR/J< 129SI/SvJ< A/J< FVB/NJ< C3H/HeJ< Balb/cJ). Increased protein levels occurred most predominantly and significantly in the three most PMN-sensitive strains (FVB/NJ, C3H/HeJ, Balb/cJ). Cytokine analysis revealed significant differences in VEGF and MDC in FVB/NJ mice and RANTES in C3H/HeJ. Currently, in collaboration with the University of California, a total of 30 strains have been combined to assess genetic susceptibility via pulmonary inflammation and injury endpoints (PMN, protein, lactate dehydrogenase release, cytokine analysis) as well as haplotype association mapping for identifying candidate genes, responsible for the influence of genetics on the pulmonary response to AgNPs. Based upon previous and current findings on inter-strain response variation, these mouse models, representative of a genetically varied population, displayed a susceptibility pattern among strains. Ultimately, these findings further support the link between genetic background and the susceptibility of the link between sensitivity mechanisms and innate inter-species responses to AgNPs.

1987 Effects of Nanosilver and Silver Nitrate Exposure on Ionic Regulation and Nanoparticle Size Characterization Using Field-Flow Fractionation in Fathead Minnows
A. D. Hawkins1, C. Thornton1, A. Bednar1, A. J. Kennedy2, J. A. Steeven2, J. Cizdiel1 and K. L. Willett2, 1University of Mississippi, Oxford, MS and 2ERDC, Vicksburg, MS.

Silver nitrate (AgNO3) and silver nanoparticles (AgNPs) damage and alter the fish gills after acute exposure. Ionic regulation in fish gills can be perturbed by AgNO3 exposure primarily due to the inhibition of Na,K-ATPase. One proposed mechanism of silver nanoparticle toxicity is from the release of silver ions; however, AgNPs can accumulate and have unique toxic effects on different biological targets. In order to understand the relationship between silver exposure and ionic regulation, fathead minnows were exposed for 96 hr to 20 nm PVP- or citrate-coated silver nanoparticles (PVP-AgNPs; citrate-AgNPs) or AgNO3 at two nominal concentrations (20 and 200 μg/L) or (2 and 6 μg/L), respectively. FHM gills were paraffin embedded, sectioned and immunohistochemistry was performed for the presence of Na,K-ATPase. Also, Na,K-ATPase activity was measured in fish gills and GI tract in order to further understand the effects of the Ag-NPs on ionic exchange. The distribution of silver was quantitated following acid digestion and ICP-MS analysis. No detectable silver accumulation occurred in the brain. Exposure to 6 μg/L AgNO3 produced the highest silver bioaccumulation in the skin, liver, and gill, while exposure to 200 μg/L citrate-AgNPs produced the highest bioaccumulation in the GI tract. AgNP size was measured in GI tract and gill tissue after exposure using field-flow fractionation (FFF) interfaced to ICP-MS. AgNPs detected in GI tissue displayed heteroaggregation with particle sizes ranging from 20-70 nm, while AgNPs in gill tissue were less aggregated with particle sizes from 20-40 nm. FFF data indicated that AgNPs remained in particle form after uptake which may be related to their differential tissue accumulation and toxicity compared to ionic silver. This research is supported by US Army ERDC grant: W912HZ-09-C-0033.

1988 Unique Particle Effects in Fathead Minnow Gill Gene Expression and Uptake following Exposure to Nanosilver and Silver Nitrate
N. G. Revero Vinza1, 2, A. D. Hawkins1, C. Thornton1, A. J. Kennedy2, J. A. Steeven1, K. Bu1, J. Cizdiel1 and K. L. Willett2, 1Mississippi State University, Vicksburg, MS, 2ERDC, US Army, Vicksburg, MS, 3ETRP, University of Mississippi, University and 4Chemistry, University of Mississippi, University, MS.

Silver exposure is toxic to fish due to disturbances of normal gill function. A proposed toxicity mechanism of silver nanoparticles (AgNPs) is derived from the release of silver ions, similar to silver nitrate (AgNO3). However, AgNPs can have unique toxic effects. To determine if differences between AgNO3 and AgNP toxicities exist, fathead minnows (FHM) were exposed to 20 nm PVP- or citrate-coated silver nanoparticles (PVP-AgNPs; citrate-AgNPs) at the nominal concentration of 200 μg/L or AgNO3 at nominal 6 μg/L for 96 hr (n=5). Gills were dissected and microarray analysis was performed on the gills. Hierarchical clustering of FHM gene expression results revealed that all the control, AgNO3, and PVP-AgNP exposed fish clustered by treatment. In citrate-AgNP exposed fish, 67% clustered uniquely together but 33% clustered with the AgNO3 exposed fish. There were 115 differentially expressed genes shared among all Ag treatments compared to controls. However, there were 481, 406, and 715 differentially expressed genes unique to AgNO3, PVP-AgNP, and citrate-AgNP, respectively. In addition, ToxoList and IPA analysis indicated several common toxic endpoints such as oxidative stress and cell death consistent with silver toxicity; however, this analysis also indicated some unique pathways between nanosilver and AgNO3. Silver bioaccumulation was quantitated in the skin matrix, liver, GI and brain. Highest accumulation of silver following AgNO3 treatment was observed in skin and liver (84 and 1,500 ng/g, respectively). The highest accumulation of silver following AgNP treatment was observed in the GI tract (24,000 and 19,000 ng/g for PVP-AgNP and citrate-AgNP, respectively). These results indicate that there was differential silver accumulation and gill gene expression depending on exposure to AgNO3 or AgNPs. Supported by ERDC grant: W912HZ-09-C-0033.

G. K. Hinkley1, T. M. Ngo1, M. Ukhanoa2, J. W. Munson1, V. Mai2 and S. M. Roberts1, 1Physiological Sciences, University of Florida CEHT, Gainsville, FL and 2Emerging Pathogens Institute, University of Florida, Gainesville, FL.

Silver nanoparticles (AgNPs) are used for their antimicrobial activity in a wide range of applications and consumer products. Some of the uses of AgNPs, such as in food packaging, likely result in ingestion. In addition to the possibility of direct toxicity from ingested AgNPs, toxicity could also occur indirectly through disruption of normal gastrointestinal microbiota. In this study, male non-human primates (Macaca fascicularis) (n=5) were given 20 nm AgNPs in 10mL of Gatorade (62.5 μg/mL) once daily for 8 days. AgNPs were characterized with respect to primary particle size and agglomeration state both as received and in the Gatorade dosing vehicle. Feces were collected on the day before the first dose and the day after the last dose, as well as 1 week after treatment stopped. On a separate occasion, the same animals received a control treatment (Gatorade only) and feces were collected on the same schedule. High throughput 16S rRNA sequencing was used to determine if AgNP treatment had an influence on the overall microbiota diversity and prevalence of specific operational taxonomic units (OTUs). When

PS 524 SOT 2014 Annual Meeting
investigating overall diversity at the phylum level no significant differences were observed. However, when analyzing specific OTUs at the 98% similarity level, we observed more than 30 in which the number of sequences increased upon nanoparticle exposure but only three in which sequence numbers decreased. In contrast, the number of OTUs with significant increases/decreases was similar for the vehicle-control treatment. This observation suggests that AgNPs select for, rather than against particular gut bacteria. These results demonstrate that AgNPs affected gut microbiota under the conditions of the study. Prediction of potential corresponding health impacts will require additional analysis of the data.

1992 Repeated-Dose Toxicity Testing of 9 Nanoparticles with Different Surface Functionalizations
W. Wohlleben1, R. Büsen1, H. Kamps1, V. Strauss1, M. Dammann1, S. K. Treumann1, S. Gritters1, K. Wiemel2, B. van Ravenzwaay1 and B. Landsiedel3. 1Experimental Toxicology and Ecology, BASF SE, Ludwigshafen/Rhein, Germany, 2Product Safety, BASF SE, Ludwigshafen/Rhein, Germany and 3Polymer Physics, BASF SE, Ludwigshafen/Rhein, Germany.

Oral uptake of nano-materials from food or cosmetics by consumers is likely to occur at low doses over long periods of time. To date, only few reports on in vivo effects of nano-materials upon subacute or subchronic oral exposure are available. The majority of these investigations address the effects of silver nanoparticles and none of these reports any non-transient toxicologically relevant effects. Here, we present the results of two subacute oral toxicity studies in Wistar rats employing nine nano-materials with different surface functionalizations. The primary particle size was 10 nm (ZrO2), 15 nm (SiO2), 30 nm (BaSO4, OECD NM220) and 50 nm or 200 nm (Ag). The particles were coated with acid-, amino-, PEG-, acrylic- and electro-steric-functionalities. The nano-materials were applied as suspensions via oral gavage at limit dose for 28 days. The studies were performed according to the OECD test guideline (TG) 407 including clinical observations, clinical pathology and (histo-)pathology. In addition to the basic haematological and clinical chemistry parameters, the acute phase proteins haptoglobin and alpha-2-macroglobulin as well as the protein tropinin I were determined. Furthermore, mass spectrometry-based metabolite profiling was performed in serum samples making use of the MetaMap®Tox database to determine and assess metabolite patterns. Test substance-related adverse effects were not observed with any of the nine nanomaterials. Although tested at limit dose, no changes during clinical examinations, clinical pathology or pathology parameters were observed. The determination of acute phase proteins as well as tropinin I did not reveal treatment-related effects. Furthermore, there were no matches with specific toxicity patterns in the MetaMap®Tox.

1993 Comparative Biochemical and Histopathological Evaluation of PEG-Coated and Noncoated Gold Nanoparticles in Sprague-Dawley Rats
A. Parolla1, C. Colleri2 and P. B. Tchounwou3. 1Biology/Environmental Science, Jackson State University, Jackson, MS, 2Environmental Science, Jackson State University, Jackson, MS and 3Jackson State University, Jackson, MS.

Nanoparticles (NPs) offer a great possibility for biomedical application, not only to deliver pharmaceuticals, but also to be used as novel diagnostic and therapeutic approaches. Currently, there are no data available regarding to what extent the degree of the toxicity and the accumulation of gold nanoparticles (GNPs) are present in in vivo administration. The aim of this study was to assess the effects, after oral administration, of poly-ethylene glycol (PEG) coated and non-coated GNPs on various hepatotoxicity markers such as alanine (ALT), aspartate aminotransferase, alkaline phosphatase, induction of reactive oxygen species and histopathological analysis in the mouse model. Sprague-Dawley rats were exposed to four different concentrations of PEG-coated and non-coated GNPs (12.5, 25, 50 and 100 µg/kg BW) and a control. Samples were collected 24 hours after the last treatment following standard protocols. Exposure to PEG-coated and non-coated GNPs enhanced the activities of serum amino-transfereases (ALT/AST), alkaline phosphatases (ALP) and concentration of lipid hydroperoxide compared to control. Histopathology of exposed liver showed a statistically significant effect in the morphological alterations of the tissue compared to controls. However, PEG-coated GNPs demonstrated enhanced hepatotoxic effect than non-coated GNPs. The cellular findings reported here do suggest that both GNPs has the potential to induce hepatotoxicity in Sprague-Dawley rats through activation of the mechanisms of oxidative stress, which is of sufficient significance to warrant in vivo animal exposure studies. However, more studies to clarify the role of encapsulation in the in vivo toxicity of GNPs, are required and parallel comparison is preferred.
1994 The Effects of Metal Oxide Nanoparticles on Angiogenesis in Transgenic Zebrafish

J. Chang1, 2, G. Ichihara1, Y. Shimada1, S. Tada-Oikawa2, Y. Suzuki2, R. Seshah1, M. Kato1, T. Tanaka3 and S. Ichihara2.

The present study investigated the effects of exposure to metal oxide nanoparticles on the angiogenesis using transgenic (TG) zebrafish. The study also examined the potential mechanisms that may be involved in those effects using human umbilical vein endothelial cells (HUVECs). TG (nacre/fli1:EGFP) zebrafish were exposed to nano-sized titanium dioxide (TiO2), silica dioxide (SiO2), and copper oxide (CuO) particles at the concentrations of 0.01, 1 and 100 μg/mL each (day-post-fertilization) to 5 dpf. Angiogenesis were evaluated morphologically at the end of the exposure.

Exposure to CuO particles reduced the number of subintestinal vessels running transversely in TG zebrafish. In zebrafish exposed to CuO particles, the expression of vascular endothelial growth factor (VEGF) and VEGF receptor was down-regulated in the endothelial cells separated by Fluorescence Activated Cell Sorter (FACS). Moreover, HUVECs exposed to CuO particles showed reduced expression of the cell viability and increase in the apoptotic index in a dose-dependent manner. The study suggested that nano-sized CuO particles inhibit the angiogenesis due to reduction of VEGF expression and induction of apoptosis.

In Vivo Infection of Chorioallantoic Membrane by Lung Adenocarcinoma Cells Exposed to Titanium Dioxide Nanoparticles

A. Déciga-Alcaraz1, E. I. Medina-Reyes1, V. Freyre-Fonseca2, N. L. Delgado-Buenrostro1, J. O. Flores-Flores3 and V. L. Chirino1.

1Facultad de Estudios Superiores-Iztacala, National University of Mexico, Mexico, 2Escala Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, Distrito Federal, Mexico and 3Centro de Ciencias Aplicadas y Desarrollo Tecnológico, National University of Mexico, Distrito Federal, Mexico.

Background. Titanium dioxide nanoparticles (TiO2 NPs) is one of the most produced nanomaterials around the world and it has been classified by the International Agency for Research in Cancer as a possibly carcinogenic to human (Group 2B). In occupational settings, TiO2 NPs exposure induces several cellular alterations; however, its cell involvement has less investigated.

Aim. We hypothesized that human tumor cells can acquire a more invasive phenotype after TiO2 NPs exposure. To test this hypothesis, lung adenocarcinoma A549 cells were exposed to nanoparticles of TiO2 NPs (1, 5 and 10 μg/cm2) and nanobelts of TiO2 NPs to 10 μg/cm2 for 7 days. Then, 30 000 cells were mixed with collagen type I and placed on top of chicken chorioallantoic membrane (CAM) of leghorn white chicken eggs, which were previously incubated during 11 days at 37°C and 80% humidity. After 5 days, CAM was harvested and sectioned (6 μm) to perform hematoxylin and eosin (H&E) staining and immunohistochemistry (IHC) of cytokeratin 8, Gli1 and Ki67 in order to localize the human tumor cells in the CAM.

Results. Transmission electronic microscopy of TiO2 NPs nanospheres and nanobelts showed agglomerates of 588 nm and 454 nm respectively, in cell culture media plus 10% serum fetal bovine with zeta potential of -21 mV and -27 mV, respectively. H&E and IHC showed that the A549 cells treated with both shapes of TiO2 NPs had higher capacity to invade, detected by cytokeratin 8, and to proliferate detected by Gli1 and Ki67 in the CAM.

Conclusion. A549 cells treated with TiO2 NPs were more invasive and had higher capacity to proliferate in comparison with untreated cells in the CAM.

1997 Secondary Mechanisms Drive silica Nanomaterial Genotoxicity As Shown by the OGG1 Comet Assay and Genomic Analysis

A. Sullivan1, T. Downs1, Y. Shan1, R. Adams1, M. Crosby2 and S. Pufahl1.

The safety profile and potential mode(s) of action (MoA) by which nanomaterials (NMs) may induce genotoxicity are not fully understood. Using amorphous silica (15nm Levalus® 200) at 50mg/kg, we examined a range of biomarkers after a single i.v. injection to male Wistar rats. Two studies were conducted; the first examined a wide range of time points; 4, 8, and 24h and second study investigated further early responses at 1, 2 and 4h. The second study also included an additional positive control, the model oxidant KBrO3. No significant increases in direct DNA damage were detected in the liver using the alkaline comet assay at any of the time points examined (2, 4, 8, and 24h). However, in the second study there was a small, but significant, increase in oxidative DNA damage at the 4th time point measured by the OGG1 modification of the comet assay in animals treated with the silica NM, while the positive control showed a strong increase in oxidized bases in the liver and the kidney (a target organ of KBrO3). Liver tissue was also analyzed for the transcriptional expression of genes by microarray analysis. Genes involved in responding to oxidative stress (Ho-1), inflammation (Ccl2), DNA damage (p53) and immune challenges (Nkib1/p105/p50) were all upregulated in animals treated with silica NMs beginning at the earliest time points measured, 1 and 2h. These responses peak at 4h (Ho-1) or 8h (Ccl2, Nkib1, p53). In contrast, the KBrO3 treatment did not trigger an increase in Ccl2 while the other genes were increased in a highly significant manner. These data are supported by the patterns evident in heat maps representing genes involved in regulation of the pathways mentioned above. These results are in line with previous data linking moderate DNA damage caused by silica NM with a tissue damaged mediated inflammatory response (Downs et al, Mutat Res, 745 (2012) 38-50), while our model oxidant KBrO3 showed strong DNA oxidative damage.

1998 Generation of Titanium Dioxide Nanoparticle Aerosols for Biodisposition Kinetic Assessment

I. Pujalté, D. Dieuse, S. Hadadi and M. Bouchard.

Université de Montréal, Montréal, QC, Canada.

The intensive use of titanium dioxide nanoparticles (TiO2 NPs) in industrial products makes it one of the most produced NPs worldwide. Risk assessment studies are necessary, but limited data are available on NP disposition after inhalation. This study focused on the generation of TiO2 NP aerosols and their disposition kinetics in rats.

Adult male Sprague-Dawley rats were exposed acutely by inhalation {head-nose only} to 15 mg/m3 of commercial anatase TiO2 NPs (~20 nm) during 6 h. Blood was withdrawn at 0, 2, 4, 6, 24 and 48 h post-dosing (n = 6 rats per time point) and rats were sacrificed at 0, 1 and 2 days after onset of exposure (n=6 rats per group). Aerosols were generated with a collision 6-jet nebulizer and granulometry and concentrations were determined in real time using SMPS, CPS and Dusttrak. Ti levels were quantified by ICP-MS in blood, tissues (lungs, liver, kidneys, spleen), and excreta (urine, feces). Physiological parameters were also monitored.

Stable concentrations of poorly-agglomerated TiO2 NP aerosols were generated, with a mean aerodynamic diameter of 72 nm. Highest Ti concentrations were withdrawn at 0, 2, 4, 6, 24 and 48 h post-dosing (n = 6 rats per time point) and rats were sacrificed at 0, 1 and 2 days after onset of exposure (n=6 rats per group). Aerosols were generated with a collision 6-jet nebulizer and granulometry and concentrations were determined in real time using SMPS, CPS and Dusttrak. Ti levels were quantified by ICP-MS in blood, tissues (lungs, liver, kidneys, spleen), and excreta (urine, feces). Physiological parameters were also monitored.
Ti concentrations was quickly observed in the first 24 h post-dosing; after 24 h, Ti was non-detectable in blood. No significant increases in kidney concentrations of Ti were observed post-dosing. Significant increases in Ti concentrations were observed in liver and spleen 24 h post-dosing compared to pre-exposure levels, but not at 48 h (mean of 107 and 75 ng/g liver 24 and 48 h post-dosing versus 45 ng/g pre-exposure, corresponding values in spleen of 53, 76 and 29 ng/g). Significantly higher Ti concentrations were also found in feces post-dosing (on average 139 and 80 μg/g at 24 and 48 h versus 31 μg/g pre-exposure). No change in organs or body weights was observed through time. Further works are in progress to generate different aerosol exposure conditions.

1999 Impact of Liposome-Induced Complement Activation on Tumor Growth and Angiogenesis

Rationale: Acute infusion reactions in response to Doxil® (pegylated liposomal doxorubicin; PLD) are mediated by anaphylatoxins (C5a) generated from liposome-induced complement (C)-activation. Since C5a was reported to promote tumor growth through recruitment of myeloid derived suppressor cells (MDSCs), we postulate that liposome induced C-activation can promote tumor proliferation and lead to treatment resistance. Thus, we conducted studies to determine impact of this carrier on tumor progression.
Methodology: C57BL/6 mice bearing syngeneic TC-1 flank tumors were treated with a single dose (n= 10) or 4 weekly doses (n = 9) of non-drug loaded liposome (L IPO; identical to PLD carrier) or vehicle. Tumor volume was monitored and at endpoint tumors were processed for single cell suspension, tissue lystate, and frozen section. Cells were stained for MDSCs (CD11b+Gr1+) and analyzed by flow cytometry. C-activation (C3b/iC3b/C3c) was quantified in lysate via indirect ELISA. Tumor sections were stained for vasculature (CD31) and microvessel density in whole sections was quantified using digital pathology and image analysis algorithms.
Results: Tumor volumes were 2-fold larger in LIPO treated mice than in controls, 653 ± 144 and 218 ± 58 mm3, respectively (p<0.05). Tumors in LIPO treated mice had higher microvessel density than controls, 20.8 ± 0.1 and 15.0 ± 0.1 vessels/mm2, respectively (p<0.01). In LIPO versus control groups, there was increased C-activation (8.8% and 3.9% of positive reference, respectively) and MDSC infiltration (2.6% and 0.5%, respectively) in tumors.
Conclusions: Contrary to the prevailing paradigm that they are inert drug carriers, our data showed that liposome induced C-activation can promote tumor growth and angiogenesis through increased tumor recruitment of MDSCs. Ongoing studies will clarify this mechanism of resistance and develop strategies for mitigating unwanted immune effects to enhance antitumor efficacy. These results will have major implications for the future development of anticancer liposomes.

2000 The Comparative Effects of Nanoporous and Colloidal Silica Nanoparticles in Atopic Dermatitis
S. Kim. Pharmacology, Kyungpook National University Medical School, Daegu, Republic of Korea.

Nanoparticles (NPs) are incorporated into a variety of skin care products. Recently, NPs have been identified as causative agents affecting skin barrier penetration and immunologic responses. Thus, understanding epidermal and dermal penetration, as well as possible toxicity of NPs is important to skin inflammatory diseases. The aim of our study was defining the effects of pore structural conditions of silica NPs in atopic dermatitis (AD) condition. Both nanoporous (NPS) and colloidal (Col) silica NPs (100 and 500 μg/rat) were topically applied to female BALB/c mice during 5 weeks. Topical application of NPs during 5 weeks elicited aggravation of AD symptoms. In both histology and FACS analysis, NPS NPs showed significant damage to skin inflammation than that of Col NPs through the hydroscopic property. These results suggest the importance of verification of biocompatibility of NPs in dermal exposure.
Proliferation of cells in the diaphragmatic peritoneum was investigated as a short-time screening test 3 and 6 months after i.p. injection of fibers in rats, using the BrdU method and measurement of peritoneal thickness. Furthermore, animal mortality and tumor development were monitored over two years in a carcinogenicity study.

There was a time-dependent significant increase in cell proliferation after injection of MWCNT 1 (high) (L=7.9 µm; D=0.037 µm), MWCNT 2 (low/high) (L=10.24 µm; D=0.04 µm), and MWCNT 3 (low/high) (L=8.57 µm; D=0.085 µm), like after exposure to long asbestos (L=13.95 µm; D=0.39 µm) as positive control. MWCNT 2 (high) and 3 (low/high) induced significant dose-dependent thickening of the peritoneum after i.p. injection, independently of time. In the carcinogenicity study, MWCNT 2, 3 and 3a (L=9.3 µm; D=0.062 µm) showed a higher mesothelioma incidence than MWCNT 1.

In conclusion, some MWCNT (MWCNT 2, 3) mediate enhanced proliferation of peritoneal cells in the diaphragm in rats, which may result in mesothelioma development.

2004 Silver Nanoparticles, Injected Intravenously, Accumulate in the Spleen of Mice and Cause Major Changes in Immune Cell Profiles

1Environmental Medicine, NYU School of Medicine, Tuxedo, NY and 2Center for Devices and Radiological Health, FDA, Silver Spring, MD.

Silver nanomaterials are increasingly being used as antimicrobial agents in medical devices, yet their effects on immunecompetence are unclear. This study investigated modulation of immune cell profiles and cell activation in the spleen by iv exposure of adult male mice to silver nanomaterials (AgNP), as well as particle distribution in the liver, kidneys, and spleen. Mice, injected each day for 2 days with a total of 66 or 300 µg of either 20 or 110 nm AgNP (or sodium citrate vehicle), were sacrificed 1 d later and splenic cells were examined by flow cytometry. Analysis revealed that injection of 66 µg of 20 nm AgNP increased Th2 cells and decreased effector memory cells, while exposure to the same dose of larger-sized AgNP had no effect on percentages of CD3+/CD4+, Th1, Th2, Th17 cells, CD4/CD8 ratio or total memory/naïve/central memory/effector memory cells compared to controls. At 300 µg, 20 nm AgNP significantly decreased the number of naïve CD4+ cells and CD3+/CD4- cells, while increasing total/activated central memory cells, total/activated effector memory cells, total memory cells, and natural killer cells; exposure to the same dose of 110 nm AgNP increased activated CD11c+ cells (macrophages). ICP-MS analysis demonstrated that the highest concentrations of silver were in the spleen following the 300 µg AgNP exposure, with an average concentration reaching a peak of 151 and 41.5 ng/g following exposure to 20- and 110-nm-sized AgNP, respectively. Relative weight of the spleen was increased significantly following 20 nm AgNP exposure. These data indicate that systemic exposure to AgNP accumulates in the spleen, adversely affects spleen weight and modulates the systemic immune response, accumulates in the spleen, and adversely affects spleen weight in a dose-dependent manner with smaller size particles leading to more marked effects. Supported by NSF/FDA Scholar-in-Residence at FDA program - #1237451.

2004a Thirty-Day Whole-Body Inhalation Toxicity and Tissue Burden Study of Multiwalled Carbon Nanotubes in Harlan Sprague-Dawley Rats and B6C3F1 Mice

B. C. Sayers1, M. D. Stout1, M. F. Cesta1, N. A. Moore2, G. L. Baker2, K. M. Patton2, B. K. Hayden2, J. A. Dill2 and N. J. Walker2.

1Division of the National Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, NC and 2Battelle Toxicology Northwest, Richland, WA.

Multiwalled carbon nanotubes (MWCNTs) are a diverse class of high aspect ratio nanoscale materials that vary in size (length, diameter) and composition (surface functional groups, metal catalyst residue). The similarity of MWCNTs to harmful high aspect ratio fibers has generated concern for toxicological potential of MWCNTs. This study was designed to evaluate the toxicity of MWCNTs (length x diameter: 2.6 um x 15 nm, purity: 99%, nickel content: 0.52%) in Harlan Sprague-Dawley rats and B6C3F1/N mice exposed via whole body inhalation. Male and female rats and mice (35/sex/group) were exposed to 0, 0.1, 0.3, 1, 3, or 10 mg/m3 MWCNTs for 5 days/week (6 hours/day). The day after the last exposure, core group animals (10/sex) received complete necropsy and histopathological examinations. Blood and lungs were collected from animals in the tissue burden groups (25/sex) on postexposure day 0 (10/sex), 14, 42 and 120 (5/sex) and analyzed for nickel as a surrogate for MWCNT. Dose-dependent increases (incidence and/or severity) in chronic lung inflammation and pulmonary associated lymph node hyperplasia were observed in both species and sexes. Significantly increased lung weights were observed in female rats exposed to 10 mg/m3 and both male and female mice exposed to ≥ 3 mg/m3 (p<0.01). Clearance rates of MWCNT from the lung were similar in both sexes and species and decreased markedly in animals exposed to ≥ 3 mg/m3 (T1/2 = 2-51 mo) compared to the 0.1, 0.3 and 1 mg/m3 dose groups (T1/2 = 2-3 mo). The long clearance half lives, like lung burdens and lung lesions in animals exposed to MWCNT ≥ 3 mg/m3 suggest that lung overload occurred. The data from this study will be used to design a chronic whole-body inhalation toxicity study of MWCNTs. This work was supported by the NIH, National Institute of Environmental Health Sciences.

2004b Cerium Oxide Nanoparticles Induced Lung Fibrosis Involving Epithelial-Mesenchymal Transition (EMT)

J. Y. Ma, B. D. Dolash, M. Barger, D. Schweger-Berry, R. R. Mercer and V. Castranova.

PBR/HELD, NIOSH, Morgantown, WV.

Recently cerium compounds have been used as diesel fuel additives to increase fuel combustion efficiency and decrease diesel soot emissions. However, detection of cerium oxide nanoparticles (CeO2) in the diesel exhaust by emission tests are a caused of health concern. Our previous studies have shown that exposure of rats to CeO2 induces sustained pulmonary inflammation and mediator production, and lung fibrosis. The current objective is to evaluate the effects of CeO2 on functional change of alveolar type II cells (ATII) leading to EMT. Male Sprague Dawley rats were exposed to CeO2 (3.5 mg/kg) by a single intratracheal instillation and sacrificed at various times post exposure. ATII were isolated from lungs at 28 days post exposure and purified by panning. Alveolar macrophages (AM) were isolated by bronchoalveolar lavage (BAL). The BAL fluid (BALF) and AM-conditioned medium obtained after a 24 h incubation time were saved for further analysis. Lung fibrosis was evident by increased hydroxyproline content and increased Sirius Red staining for collagen in lungs at 28 days after CeO2 exposure. Scanning electron micrographs indicate CeO2-induced ATII hypertrophy. Confocal microscopic analysis demonstrated that exposure to CeO2 increased the presence of stress actin, expressed as α-smooth muscle actin (α-SMA) in ATII at 28 days post exposure and caused CeO2-induced EMT. CeO2 exposure significantly increased the fibrogenic cytokine, TGF-β1, in AM-conditioned media, and increased matrix metalloproteinases and soluble collagen in BALF, at 3 and 28 days post exposure, respectively. In vitro exposure of ATII or a rat type II cell lineage (RLE-6TN) to TGF-β1 significantly increased α-SMA expression and altered morphology. In addition, exposure of type II cells to BALF significantly increased α-SMA expression, suggesting CeO2 exposure induced mediators in the BALF significantly modified cell function. These results demonstrate that CeO2-induced EMT of ATII may play important role in lung fibrosis. These findings suggest potential health effects of CeO2 exposure.

2004c Cytotoxicity and Genotoxicity Assessment of Silver Nanoparticles in Mouse

T. Chen1, Y. Li1, J. A. Bhall1, W. Ding1, J. Yan1, M. G. Pearce1, C. K. Cunningham1, Y. Jones1, W. A. Monroe1, T. Zhou2 and P. C. Howard1.

Nanotechnology Core Facility, FDA/National Center for Toxicological Research, Jefferson, AR and 4Center for Veterinary Medicine, FDA, Rockville, MD.

Silver nanoparticles (AgNPs) are among the most commercially used nanomaterials and their toxicity and genotoxicity are controversial. Although many in vitro studies have been conducted to evaluate the genotoxicity of AgNPs, in vivo genotoxicity studies on the nanomaterials are limited. Given the unique physicochemical properties and complex pharmacokinetics behavior of nanoparticles (NPs), in vivo genotoxicity assessment of AgNPs is badly needed. In this study, the clastogenicity and mutagenicity of AgNPs with different sizes and coatings were evaluated using mouse micronucleus (MN) assay, Pig-a assay and Comet assay. Five 7-week-old male B6C3F1 mice per group were treated with 5 nm polyvinylpyrrolidone (PVP)-coated AgNPs at a single dose of 0.5, 1.0, 2.5, 5.0, 10.0 or 20.0 mg/kg body weight (bw) via intravenous injection for both the MN and Pig-a assays; or with 15–100nm PVP- or 10–80nm silicon-coated AgNPs at a single or 3-day repeated dose of 25.0 mg/kg bw for the MN assay and Comet assay in mouse liver. Inducibly coupled plasma mass spectrometry (ICP-MS) and transmission electron microscopy (TEM) analyses indicated that AgNPs reached the testing tissues (bone marrow for the MN and Pig-a assays and liver for the Comet assay). Although there was a reduction of reticulocytes in the PVP-coated AgNPs-treated animals, indicating cytotoxicity, of the AgNPs, none of the treatments resulted in a significant increase of either mutant frequencies in the Pig-a gene or the percent of micronucleated reticulocyte over the concurrent controls. However, both the PVP-
and silicon-coated AgNPs induced oxidative DNA damage in mouse liver. These results demonstrate that AgNPs can reach mouse bone marrow and liver, and generate cytoxicity to the reticuloocytes and oxidative DNA damage to the liver.

**2004d One Year Pulmonary Outcomes After Exposure to Carbonaceous Nano-Engineered Materials and Asbestos**

A. A. Shvedova1, N. Yanamala1, E. K. Kislin1, A. R. Murray1, A. Hubbs2, P. Keohavong3, L. P. Sycheva1, V. E. Kagan2 and V. Castranova1.1HELD/PPPR, CDC/NIOSH, Morgantown, WV, 2University of Pittsburgh, Pittsburgh, PA and 3Swin Research Institute of Human Ecological and Environmental Health, Moscow, Russian Federation.

Single-walled carbon nanotubes (SWCNT) and carbon black nanoparticles (CNF) are carbonaceous nanoparticles sharing fibrous morphology with a well-known, naturally occurring, toxic fiber, asbestos. Both short- and long-term outcomes of pulmonary exposure to asbestos, ranging from inflammation and fibrosis to mesothelioma and lung cancer, are well described. To date, no data are available describing long-term adverse effects of pulmonary exposure to SWCNT or CNF. Thus, a direct comparison of chronic effects of SWCNT, CNF and asbestos is of significant importance. Here, we assessed inflammatory, fibrogenic and genotoxic effects of SWCNT, CNF, and asbestos in C57BL/6J mice one year after a single pulmonary exposure by pharyngeal aspiration and inhalation. We provide evidence that up to one year after exposure, SWCNT, CNF and asbestos persist in the lung and regional lymphatics. All three particles induced chronic bronchopneumonia and lymphadenitis, accompanied by pulmonary fibrosis. While CNF and asbestos were found to promote the greatest degree of inflammation, followed by SWCNT, the latter was the most fibrogenic of all three types. SWCNT induced cytogenetic alterations including micronuclei and nuclear protrusions in vivo. Notably, SWCNT and CNF, but not asbestos, increased the incidence of K-ras oncogene mutations in lungs. No lung tumor incidence occurred after 1 year post exposure in any group. Inhalation exposure to SWCNT showed significantly greater inflammatory, fibrotic and genotoxic effects than bolus pharyngeal aspiration, indicating that bolus exposure does not over-predict pulmonary response and appears useful for hazard determination. Overall, our data suggest that long-term pulmonary toxicity of particles with high aspect ratios - SWCNT, CNF and asbestos – is defined not only by their fibrous morphology but also by the chemical composition, specific surface area and type of exposure.

**2004e Effect of Prenatal Exposure to Carbon Black Nanoparticle on Gene Expression in the Spleen of Offspring Mouse**

M. Umezawa1, S. Okamoto1, R. Shimizu1 and K. Takeda2,1. 1Department of Hygienic Chemistry, Faculty of Pharmaceutical Sciences, Tokyo University of Science, Noda, Chiba, Japan and 2The Center for Environmental Health Science for the Next Generation, Research Institute for Science and Technology, Tokyo University of Science, Noda, Chiba, Japan. Sponsor: K. Nohara.

Objective: We recently found that exposure of pregnant mouse to carbon black nanoparticle (CB-NP) decreased T cells in the spleen of offspring during the neonatal period. The aim of the present study was to examine the effect of prenatal exposure to CB-NP on gene expression in the spleen of offspring in a mouse model. Methods: CB-NP (PRINTEX90 from Degussa; primary particle size: 14 nm; surface area 300 m²/g) was suspended at 5 mg/mL in water, sonicated for 30 min, and then filtered through a 450-nm filter immediately before administration. The peak size of the aerosolized diameter distribution of CB-NP in the suspension was 68 nm. Pregnant ICR mice were treated with the CB-NP suspension (95 µg/kg/time) by intranasal instillation on gestational days 5 and 9. Spleen was collected from male and female offspring mice at 5 days post-partum. All animals were treated and handled in accordance with national guidelines for the care and use of laboratory animals. Gene expression in the tissues was examined by cDNA microarray using a SurePrint G3 Mouse Gene Expression 8×60K microarray (Agilent). Gene Ontology, canonical pathway and transcription factor related to the genes dysregulated by prenatal CB-NP treatment were bioinformatically extracted. Results: The genes differentially expressed by prenatal CB-NP treatment in the spleen of both male and female offspring were enriched in a transcription factor GATA1, which are closely associated with erythocyte development. The genes annotated to GATA1 were upregulated and included Cxcr5, Hes1, In1, Dnase11, Nf1a, and Nf1b. Interestingly, previous studies indicated that Hes1 inhibits the function of GATA1 and the development of erythroid and megakaryocytic cells. Conclusion: The effect of prenatal exposure to CB-NP through the airway on the spleen was associated with upregulation of genes related to GATA1 in neonatal mouse.

**2004f Quantum Dot-Induced Changes in Pulmonary Function Are Mouse Strain Dependent**

D. K. Scoville1, D. Ani2, C. Carosino1, C. White1, M. Carrwright1, S. Schmuck1, X. Gao1, W. C. Parks2, W. A. Altemeier2 and T. Kavanagh1. 1Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, 2Medicine, University of Washington, Seattle, WA and 3Bioengineering, University of Washington, Seattle, WA.

Quantum dots (QDs) are photostable fluorescent nanoparticles commonly composed of a cadmium selenide (CdSe) core, a zinc sulfide (ZnS) shell, and coatings specific to a variety of uses in electronics and biomedical research. QDs can cause inflammation and toxicity in the respiratory tract when inhaled, instilled, or aspirated. In this study we investigated whether pulmonary aspiration of 12 nm diameter tri-n-octylphosphine oxide, poly(maleic anhydride-alt-1-tetradecene) coated CdSe/ZnS QDs (TOPO-PMTQ) and CdSe/ZnS QDs (TOPO-PMTQ) induced functional changes in mouse lung mechanics in a mouse strain dependent fashion. C57BL/6J and A/J mice were dosed with 6 µg Cd equivalents/kg body weight of a 10 nM TOPO-PMTQ QD solution or an equal volume of saline vehicle via oropharyngeal aspiration. At 24 hours, mice were anesthetized, intubated via tracheotomy, and connected to a flexVent instrument. Lung mechanics were measured repeatedly during a progressive nebulized methacholine challenge (0-50 mg/ml). There were statistically significant increases in total lung resistance, tissue damping, and lung elastance with methacholine challenge after TOPO-PMTQ QD treatment in A/J but not C57BL/6J mice. There were also statistically significant increases in baseline airway resistance and lung compliance in A/J compared to C57BL/6J mice. Thus, TOPO-PMTQ Cds/ZnS QDs negatively affected pulmonary function in a mouse strain-dependent manner. It is important that genetic susceptibility be considered in risk assessment strategies for QDs and other engineered nanomaterials. Supported by NIH Grants U19ES019545, P30ES007033, and R01HL086883.

**2004g The Mitochondrial Effects of a Chronic Exposure to a Low-Dose of Silver Nanoparticles Are Rescued by an Antioxidant**

C. M. Palmeira1, J. S. Teodoro1, R. Silva3, A. T. Varela1, F. V. Duarte2 and A. P. Rolo1, 1Center for Neurosciences and Cell Biology, University of Coimbra, Coimbra, Portugal, 2Department of Life Sciences, University of Coimbra, Coimbra, Portugal and 3Department of Biology, University of Aveiro, Aveiro, Portugal.

Manufactured silver nanoparticles (AgNPs) are ubiquitous presence in daily life, for they are used in numerous applications, from ultrasensitive molecular sensing and diagnostic imaging, agents for photodynamic therapy, burn and wound dressing, to dental-bonding agents and sunscreens, cosmetics and fuel cells, tires, optics, clothing and electronics. The same properties that make AgNPs so useful could also prove harmful when interacting with humans and the environment. Most of the works so far have unveiled a strong induction of oxidative stress as main mechanism of toxicity. However, these studies are mainly focused on short-term exposure and, consequently, higher doses. As such, we aimed to understand how long-term exposure to a protective low-dose of AgNPs could affect various biological systems, with a particular focus on mitochondrial bioenergetics and if these effects could be reverted by a simultaneous treatment with a known antioxidant, N-acetylcysteine (NAC). Other objectives were to understand if there is a preferential target organ in the body and if the size of the AgNPs was a determinant factor in the registered alterations.

In accordance with European and national animal use guidelines, 10-week old male Sprague-Dawley rats were intraperitoneally (i.p.) injected with 200 µg/Kg (w/w) of either 10 nm or 75 nm AgNPs, with and without a 30min previous NAC 100 mg/Kg i.p. injection. We uncovered a NAC-reversible, non-size dependent negative effect of AgNPs in various functions (membrane potential, oxygen consumption, ATP generation, amongst others) of isolated liver, kidney, and to a lesser extent, heart mitochondria. Our data demonstrates that even a low-end dose exposure to AgNPs has a pernicious effect in the long term, which begs for further assessment of the indiscriminate use and exposure to AgNPs.

**2004h Nanoceria In Vivo Biotransformation Is Associated with Loss of Its Pro-Oxidant Brain Effects**

Background: Nanoceria has many commercial uses and is being developed as an antioxidant therapeutic. It persists in the rat for 90 days with little quantitative reduction, primarily in the liver, where it produces granuloma. It produces pro-oxi-
ionizing effects in the brain up to 30 days after administration. Objectives: Determine nanoceria’s physiochemical characteristics in the liver and effects on brain oxidavive stress for 90 days after administration. Methods: A citrate-stabilized cubic 30 nm ceria (85 mg/kg) was iv infused once to rats, terminated 1 h to 90 days later. Controls received vehicle. Multiple oxidative stress endpoints were determined in the brain. Nanoceria in the liver was examined using HR-TEM, electron energy loss spectroscopy (EELS), energy-dispersive X-ray spectroscopy (EDS), and selected area electron diffraction (SAED). Results: Following similar administration of a 5 nm ceria, oxidative stress was seen in the brain up to 30 days after 30 nm ceria, including elevated protein carbonyl, catalase, and heat shock protein 70 levels and decreased GSH/GSSG. Ninety days after its administration oxidative stress endpoints were at control levels. HR-TEM of the liver revealed nanoceria particles were highly fragmented and rounded along their edges and the appearance of clouds containing copious of 1 to 3 nm ceria (verified by EELS, EDS, and SAED) near the nanoceria agglomerates. EELS showed the 1 to 3 nm ceria had a reduced valence (Ce3+) state, indicating in vivo processing by sputtering to a form having higher free radical scavenging activity. The temporal association between nanoceria biotransformation in the liver and reversal of nanoceria-induced oxidative stress in the brain suggests a cause and effect relationship. Conclusion: Nanoceria’s long term fate and effects warrants further study to better understand its adverse and beneficial nature. Support: US EPA STAR Grant RD-835772.

**2005 Cannabinoid Receptor Function on Bone Marrow-Derived Dendritic Cells**

J. Suárez-Martínez2,3, R. Crawford1 and N. E. Kaminski1,2,4, 1Center for Int Tox, Michigan State University, East Lansing, MI, 2Camp Med and Int BioI, Michigan State University, East Lansing, MI and 3Pharm and Tox, Michigan State University, East Lansing, MI.

Dendritic cells (DCs) are professional antigen presenting cells indispensable in linking the innate and adaptive immune response. DCs comprise a heterogeneous population of cells. Each distinct subset has its unique set of surface markers and different abilities to respond to environmental stimuli and process antigen. Cannabis is the most frequently consumed illicit drugs in the world. Mammals for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.

**2006 Cannabinoid Regulation of Peripheral Sympathetic Neuronal Activity: Possible Role in Cannabinoid-Mediated Immunosuppression**

T. J. Simkins1,4, D. Fried4, J. J. Galligan3, J. L. Goudreau3,4, K. J. Lookingland1,2 and B. L. Kaplan3,1, 1Department of Basic Sciences, Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS, 2Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI, 3Neuroscience Program, Michigan State University, East Lansing, MI and 4Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Cannabinoids are compounds derived from Cannabis sativa that exhibit immunosuppressive effects. Cannabinoids are also known to inhibit neurotransmitter (NT) release in the central nervous system. Therefore, it was hypothesized that inhibition of NT release might contribute to cannabinoid immunosuppressive mechanisms. NTs are implicated in inflammatory homeostasis for example, norepinephrine (NE) modulates antibody production. However, it is not known to what extent cannabinoi dinteract with NTs to cause immunosuppression. In vivo, NE innervation of the spleen capsule is known to cause spleen contraction during times of hypoxia as well as in response to an immune challenge. Therefore, we utilized NE-induced splenic contraction as a tool to probe the role of cannabinoids in regulating spleen capsule sympathetic neuronal activity in wild-type and cannabinoid receptor dual knockout (CB1/CB2 KO) mice. It was discovered that NE-induced spleen capsule contraction was significantly attenuated in CB1/CB2 KO mice. However, this effect was not observed in response to electrical stimulation of spleen capsule sympathetic axon terminals, suggesting a potential role for non-adrenergic signaling in contraction. Additionally, spleens from CB1/CB2 KO mice have decreased spleen capsule thickness that is not due to decreased smooth muscle content. Overall, these studies suggest that the mechanism by which cannabinoids regulate splenic sympathetic activity in vivo could involve interaction with one or more NTs. The results from these studies could identify neuronal mediators involved in the immunosuppressive effects of cannabinoids.

**2007 Modulation of HIVGP120 Antigen-Specific Immune Responses by A9-Tetrahydrocannabinol In Vivo**

W. Chen1,2, R. Crawford1, B. L. Kaplan3, K. Smith1 and N. E. Kaminski1,3, 1Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI, 2Pharmacology and Toxicology, Michigan State University, East Lansing, MI and 3Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Approximately 25% of HIV patients use marijuana for its putative therapeutic benefit; however, it is unknown how cannabinoids affect the immune status of immunocompromised HIV patients. Previously, a surrogate in vitro mouse model was established to investigate the effects of cannabinoids on the early stages of the anti-HIV response. Specifically, CD8+ T cell proliferation and gp120-specific IFNγ production were induced, which were suppressed or enhanced by A9-tetrahydrocannabinol (A9-THC). We investigated how THC and its metabolites in compound in marijuana, depending on the magnitude of cellular activation. To determine whether THC has similar effects in vivo, a mouse model to stimulate the HIV gp120-specific immune response has also been established. Vector plasmid VRc2000 or gp120-expressing plasmid VRcgp120 was injected intramuscularly into mice. The gp120-specific IFNγ response was detected, when splenocytes were restimulated with gp120-derived peptide 81, which was identified as being immunodominant among 211 tested peptides comprising gp120. In addition, both T cell and non-T cell populations were activated in response to VRc(1-128) stimulation, as evidenced by increased expression levels of surface activation markers (e.g., CD69, CD80, major histocompatibility complex II). Furthermore, the gp120-specific IFNγ response and the magnitude of cellular activation were enhanced in cannabinoid receptor (CB) 1 and 2 knockout mice compared to wild type mice. THC further increased the above-mentioned response in wild type mice, but showed minimal to no enhanced effect in knockout. Overall, our findings suggest that THC modulates HIV antigen-specific immune responses in vivo in a CB1/CB2-dependent manner.

**2008 A9 Tetrahydrocannabinol (THC) Expands and Activates Highly Immunosuppressive MDSCs via S100A8 Secretion**

J. M. Sido, P. S. Nagarkatti and M. Nagarkatti, Pathology, Immunology & Microbiology, University of South Carolina School of Medicine, Columbia, SC.

Marijuana is a widely used drug of abuse. With the recent legalization of marijuana for recreational purpose, in two states, as well as medicinal purpose, in 21 states, understanding the impact of cannabinoids is now paramount. We focused on the mechanism by which A9-tetrahydrocannabinol (THC), the psychoactive ingredient found in the Cannabis sativa plant, causes immunosuppression. Earlier studies from our lab have demonstrated that THC induces myeloid derived suppressor cells (MDSCs) resulting in immune suppression. However, the precise mechanism of THC-mediated MDSC induction and activation is not fully understood. In this study, we determined the mechanism by which THC induces the generation and activation of a highly immunosuppressive MDSC population. We found that THC-induced MDSCs (THC-MDSCs) had significantly increased levels of suppressive function, secretion of signal transducer and activator of transcription (Stat) 3 activating cytokines, and S100A8 protein compared to naive bone marrow resident MDSCs (BM-MDSCs). THC-induced granulocytic and monocytic MDSC subtypes were more suppressive than BM-MDSC subsets. Additionally, arginase1 (Arg1), a known immunoregulatory molecule, was elevated in THC-MDSCs compared to BM-MDSCs. Increased levels of IL-6 and IL-10 in THC-MDSCs correlated with elevated Stat3 activation. S100A8 is a protein which has been shown in tumor models to drive MDSC accumulation and activation, but its role in THC-mediated MDSC induction is not known. Phosphorylated Stat3 has been shown to bind the promoter region of S100A8 and increase transcription. Use of the S100A8 depletion antibody (8H150 at 20 mg/mouse) led to a 1.8 fold decrease in the accumulation of THC-MDSCs and impaired their suppressive function. Together, these data suggest a key role for S100A8 in THC-induced expansion.
In the presence of thiols, Keap1 binds to Nrf2 and targets it for ubiquitination and proteasomal degradation. In the absence of electrophiles, Keap1 is not bound to Nrf2, allowing it to translocate to the nucleus and bind to antioxidant response elements (AREs), promoting the expression of ARE-regulated genes, including enzymes of the electron transport chain, catalase, and heme oxygenase.

2009 The Role of Chemical Sensitizer’s Reactivity in the Generation of Reactive Species and the Activation of the Nrf2 Pathway in THP-1 Cells

S. Karaki1, M. Pallardy1, C. Migdal1, A. E. Turley1, J. W. Zagorski2 and C. E. Rockwell1, 3, 2.

Dendritic cells (DC) are professional antigen-presenting cells that play a major role in the induction of primary immune response. Contact sensitizers, such as dinitrochlorobenzene (DNCB) or cinnamaldehyde (CIN), are known to induce reactive oxygen species (ROS) production. The Nrf2/Keap1 pathway is central to detect cellular stress. In the absence of electrophile or oxidative stress, Keap1 associates with Nrf2 and leading to its degradation. In the presence of an electrophilic compound, Keap1’s conformation is modified leading to Nrf2 translocation to the nucleus and transcription of its target genes. We have demonstrated that contact sensitizers like DNCB or CIN induce Nrf2 accumulation in human DC.

To elucidate the role of Nrf2 in DC survival, nrf2 WT or KO bone marrow-derived DC (BMDC) were treated with DNCB or CIN at 24h. Results showed (1) an increase of apoptotic cells and (2) a decrease in living cells in absence of Nrf2. An increase of caspase 3/7 activity, a rapid loss of mitochondrial membrane potential (ΔΨm) and a higher ROS production were observed in nrf2/−/− DC compared to nrf2+/+ DC in response to DNCB or CIN. Our results also showed that DNCB and CIN induced the expression of the anti-apoptotic gene, bcl-2, in a Nrf2-dependent manner.

Further investigation, the cytotoxic role of Nrf2 against chemical sensitizers, qPCR array of 43 genes was performed. Our results reveal that Nrf2 can upregulate catalase (Cat), heme oxygenase (Hmox-1), and glutathione peroxidase 1 (Gpx1), and glutathione reductase (Gsr) and glutathione-S-transferase (GstA1, Gpt1).

These results suggest that Nrf2 plays a role in cell survival and protects DC from contact sensitizers via the transcriptional activation of anti-apoptotic and antioxidant genes.

PS 2012 Nrf2 Has Differential Effects on the Early Events of Murine T Cell Activation

A. E. Turley1, 3, J. W. Zagorski2 and C. E. Rockwell1, 3, 2, 1Pharmacology and Toxicology, Michigan State University, East Lansing, MI. 2Cellular and Molecular Biology, Michigan State University, East Lansing, MI and 3Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Nuclear factor erythroid 2-related factor 2 (Nrf2) is a widely expressed transcription factor activated by cell stress, including reactive oxygen species and electrophilic stimuli. Nrf2 regulates a battery of detoxification, antioxidant, and metabolizing enzymes necessary for a cell to respond to stressors. Nrf2 is activated by many different compounds, including environmental contaminants such as arsenic, and synthetic food preservatives such as tBHQ (tert-butylhydroquinone). There is increasing evidence that Nrf2 modulates a number of different immune responses. Nrf2 null mice develop a lupus-like autoimmune disease, and show increased susceptibility to sepsis and inflammatory injury. More recently, our laboratory has shown that Nrf2 inhibits some of the early events of human T cell activation. The purpose of the present studies was to characterize the role of Nrf2 in early events of T cell activation. The Nrf2 activator, tBHQ, inhibited production of IFNγ and IL-2 by murine splenocytes activated with anti-CD3/anti-CD28. Unexpectedly, other events of early T cell activation, such as induction of CD25 and CD69, were not affected by tBHQ. To characterize this further, we investigated the effect of Nrf2 on CD25/CD69 induction at multiple time-points using a number of different T cell activators, including anti-CD3/anti-CD28, concanavalin A and PMA/Ionomycin. Regardless of time-point or activator, there was consistently no effect on CD25/CD69 expression. Overall, these studies demonstrate Nrf2 has differential effects on early events of T cell activation in murine splenic T cells. (This work is supported by NIH grant ES018885).
Inhibition of IL-2 Production by the Nrf2 Activator, tBHQ, Correlates with Inhibition of NFκB Activation in Activated Jurkat T Cells

J. W. Zaporski1, 2, A. E. Turley1, 2, H. E. Dover1, 2, K. R. VanDenBerg1, 2, J. R. Compton2, 3, and C. E. Rockwell2, 3
1Pharmacology and Toxicology, Michigan State University, East Lansing, MI, 2Center of Integrated Toxicology, Michigan State University, East Lansing, MI, and 3Cellular and Molecular Biology, Michigan State University, East Lansing, MI.

The transcription factor, nuclear factor erythroid 2-related factor 2 (Nrf2), is activated upon cellular stresses, such as the presence of reactive xenobiotics and/or oxidative stress. After activation, Nrf2 accumulates in the nucleus and induces the transcription of its target genes, including HMOX and NQO1. Numerous studies have shown that Nrf2 plays a role in inflammatory diseases, including autoimmune. Recently, we have shown that activation of Nrf2 in CD4+ murine T cells skews differentiation toward that of a TH2 phenotype. Although shown to be immunomodulatory in mice, the role of Nrf2 in human immune cells is largely uncharacterized. Therefore, the purpose of the present studies was to determine the effects of the Nrf2 activator, tBHQ, upon the early events following human CD4+ T cell activation. Treatment of human Jurkat T cells with tBHQ markedly inhibited the production of IL-2 and moderately inhibited the expression of CD25, the high-affinity IL-2 receptor. The inhibition of IL-2 by tBHQ correlated with a decrease in the transcriptional activity of NFκB, a key transcription factor in the regulation of the IL-2 promoter. Collectively, our studies demonstrate that the Nrf2 activator, tBHQ, markedly inhibits IL-2 production in activated Jurkat T cells, which is likely due to inhibition of NFκB activation. This work is funded by NIH grants E018885 and GM092715.

Maintenance of Long-Term Self-Renewal in Hematopoietic Stem Cells by Aryl Hydrocarbon Receptor-Dependent Regulation of Reactive Oxygen Species during Fetal Development

E. Tate1, Y. Chen2, D. Wang3, and M. D. Laima1, 2Zilber School of Public Health, UW-Milwaukee, Milwaukee, WI and 3Blood Research Institute, Milwaukee, WI.

Determining the mechanism by which in utero activation of the Aryl hydrocarbon receptor (AhR) in hematopoietic stem cells (HSC) impairs the process of self-renewal will provide insight into a spectrum of blood disorders ranging from stem cell exhaustion to leukemia. The AhR is a ligand-activated transcription factor and studies in AHR deficient mice have elucidated a role for the AhR in hematopoietic stem cell quiescence. The mechanism by which cells remain in this low proliferative state is unknown. Alterations in reactive oxygen species (ROS) have been shown to adversely impact HSC self-renewal possibly due to DNA damage. Furthermore, the ligand-activated AhR has been implicated as a modulator of cellular respiration. With this knowledge, we hypothesized that the AHR is a negative regulator of aerobic respiration in HSC, such that ligand-activation disrupts this regulation, leading to increased ROS in anacrobic cells adversely impacting long-term self-renewal. To test the hypothesis, we exposed pregnant C57BL/6 mice to 3ug/kg of the AhR agonist 2,3,7,8 Tetrachlorodibenzo-p-dioxin (TCDD) and analyzed ROS in HSC from fetuses ranging in age from gestational day (GD) 7.5 to GD 14.5. We used fetuses because of the developmental age dependent transitions that occur in HSC respiratory activity. We found that on GD 7.5 and 11.5, there was a 50% increase in ROS production in HSC (defined as Lin-ScaraK+CD19+CD100+), followed by a 30% decrease in the HSCs on GD 14.5. Furthermore, in a competitive irradiation/reconstitution assay testing long-term self-renewal function, HSC from control fetal livers out competed HSC exposed to TCDD in utero by nearly three to one offspring of TCDD-treated dams. To address this question, an in vitro culture system was established to recapitulate human B cell development. Specifically, hematopoietic stem cells (HSC) are co-culturing with irradiated human primary bone marrow stromal cells. In three weeks of culture, we observed a downregulation of HSC marker CD34 as cells underwent development, as well as an upregulation of IL-7R, which indicated lymphoid lineage restriction. More importantly, generation of lineage-committed B cells was observed by the co-expression of B220 and CD19 in approximately 20% of the cell population. These data illustrated establishment of an in vitro model system of human B cell development from HSC. The objective of the present study was to employ this model system to investigate the effect of TCDD on B cell development. HSC were treated with TCDD (1, 10 and 30nM) and/or vehicle (0.02% DMSO). Comparing to the vehicle control, TCDD reduced cell number in a concentration-dependent manner. Apoptosis analysis using Annexin V and 7-AAD suggested the decrease of cell number was not due to cytotoxicity of TCDD. Likewise, TCDD decreased CD34 and IL-7R expression and significantly the number of B220+CD19+ lineage-committed B cells that were generated from HSC. Together, these data for the first time suggested that TCDD altered early human B cell development. Research is supported in part by NIH ES005250 and NIH P20 04911.

Impaired by TCDD of Human Hematopoietic Stem Cells to B Cell Lineage Commitment

J. Li1, 2, A. Phadnis-Moghe1, 2, R. Crawford1, 2, and N. E. Kaminski1, 2, 3
1Microbiology and Immunology, University of Rochester Medical Center, Rochester, NY and 2Environmental Medicine, University of Rochester Medical Center, Rochester, NY.

Environmental contaminants such as TCDD are known to markedly affect B cell activation and differentiation. Hence, the objective of the present study was to investigate the mechanism underlying suppression of human B cell activation by TCDD. BCL-6 was identified as a likely candidate owing to its role as a transcriptional repressor of B cell activation and differentiation. In the presence of TCDD, BCL-6 protein levels were elevated in human B cells. Concomitant with this TCDD-mediated increase in BCL-6 a decrease in B cell activation was evident through the attenuation of surface CD80 and CD69. In addition, it was observed that BCL-6 could repress CD80 in presence of TCDD by binding to the enhancer region of CD80. To further ascertain the role of BCL-6 in the suppression of B cell activation, the small molecule inhibitor of BCL-6 repression, 79-6, was utilized. Treatment of activated B cells with TCDD in combination with 79-6 reversed the suppression of CD80 levels and partially reversed the suppression of CD69 levels thereby providing evidence for a role by BCL-6 in regulation of B cell activation. Further, involvement of the AHR signaling pathway in BCL-6 regulation and in B cell activation was demonstrated using the AHR low affinity ligand, monochlorodibenzo-p-dioxin (MCDD), which had no effect on BCL-6 protein levels or on B cell activation. Collectively, these results suggest that suppression of human B cell activation, especially of CD80 occurs, in part, due to deregulation of BCL-6 by the TCDD-AHR pathway. Supported in part by NIH R01 ES005250 and P42 ES004911.

Developmental Activation of the AhR Enhances the CD4+ T Cell Response in the Influenza Virus-Infected Lung

L. Boule1, B. Winans2, and B. Lawrence1, 2, 3
1Microbiology and Immunology, University of Rochester Medical Center, Rochester, NY and 2Environmental Medicine, University of Rochester Medical Center, Rochester, NY.

Recent discoveries suggest that developmental exposure to certain pollutants increases the severity of respiratory infections later in life, but the mechanism by which this occurs is unknown. The aryl hydrocarbon receptor (AhR) is a ligand-regulated transcription factor that binds a broad variety of anthropogenic and naturally derived chemicals. It is expressed by immune cells, and upon activation it can alter the function of the immune system. Using a mouse model, developmental exposure to the potent AhR ligand 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) alters the immune response to the common respiratory pathogen influenza A virus. Developmentally exposed offspring have a poorer CD8+ T cell response to infection; yet, have more bronchopulmonary inflammation and an elevated number of immune cells in their lungs. We report here that, in contrast to CD8+ T cells, the response of CD4+ T cells to influenza was increased. CD4+ T cells from TCDD-exposed mice respond to infection with significantly fewer lymphocytes, increased expression of IL-2 and IL-2Rα, and decreased expression of IL-10 compared to control. These results suggest that the aberrant CD4+ T cell response to influenza is due to the altered responsiveness of CD4+ T cells to TCDD exposure.
2018 Suppression by 2, 3, 7, 8-Tetrachlorodibenzop- Dioxin (TCDD) of IL-2 Plus IL-21-Induced B Cell Activation

B. Avalos, A. Phadnis-Moghe, and E. Kaminski. Biology, Univ. of Puerto Rico, San Juan, Puerto Rico, Genetico, Michigan State University, East Lansing, MI, Center for Integrative Toxicology, Michigan State University, East Lansing, MI, and Pharmacology and Toxicology, Michigan State University, East Lansing, MI.

The environmental contaminant 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is the most toxic compound among the group of halogenated aromatic hydrocarbons found in our environment. TCDD is known to adversely affect the adaptive immune system. Studies using rodents have shown that TCDD affects the differentiation of B cells into antibody-secreting cells. Recent work using human primary B cells has shown that B cell activation is suppressed significantly by TCDD, thereby, subsequently affecting the process of B cell differentiation. Specifically, B cells activated with CD40 ligand (CD40L) and cytokines in presence of TCDD. Furthermore, changes in mRNA levels of Src-homology phosphatase-1 (SHP-1), a gene known to be altered in B cell activation, were investigated. Our results show that TCDD-treatment led to a decrease in the percent and mean fluorescence intensity of B cell activation markers CD80, CD86, and CD69. IL-21 is a cytokine known to enhance the proliferation of B cells, playing a vital role in their differentiation. Hence, the goal of this study was to understand the effects of TCDD on CD40L and IL-2 plus IL-21-induced human B cell activation. Flow cytometry was used to measure levels of B cell activation markers in primary human B cells with CD40L and cytokines in presence of TCDD. Furthermore, changes in mRNA levels of Src-homology phosphatase-1 (SHP-1), a gene known to be altered in B cell activation, were also investigated. Our results show that TCDD-treatment led to a decrease in the percent and mean fluorescence intensity of B cell activation markers CD80, CD86, and CD69 from three individual human donors. Additionally, the mRNA levels of the gene SHP-1 were increased in presence of TCDD as expected. Overall, our results show that TCDD suppresses the CD40L and IL-2 plus IL-21-induced B cell activation, which occurs independent of the cytokine-stimulation used and may involve increased SHP-1 expression. (Supported by NIH R01ES002520)

2019 Evaluation of Aryl Hydrocarbon Receptor (AhR) Polymorphism G1661A on TCDD-Mediated Biological Activity in the Human B Cell

N. Kovaleva, R. Crawford, and E. Kaminski. Pharmacology and Toxicology, Michigan State University, East Lansing, MI, and Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

The environmental contaminant 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a suppressor of immunoglobulin (Ig) expression in various animal models. This effect appears to be mediated through the aryl hydrocarbon receptor (AhR). When activated by ligand, the AhR binds to dioxin response elements (DRE) leading to altered transcriptional activity. Our previous results identified DRE sites and TCDD-induced binding of the AhR to these sites within a transcriptional regulatory region (3'IghRR) that controls Ig heavy chain expression. The 3'IghRR consists of four enhancer regions (hs3A; hs1,2; hs3B, hs4) and is sensitive to TCDD-induced inhibition, which correlates with TCDD-induced inhibition of Ig expression. In humans, the hs1,2 enhancer (hu-hs1,2) is polymorphic and has been associated with certain autoimmune diseases. We have identified TCDD-induced activation of the hu-hs1,2 enhancer and a decrease in enhancer activity with deletion of the polymorphic region. The objective of the current study was to utilize mutational analysis and luciferase reporter constructs to evaluate the contribution of each transcription factor binding site within the polymorphic region to hu-hs1,2 activity and modulation by TCDD. TCDD induced a similar fold-induction in hu-hs1,2 reporter activity regardless of which transcription factor was mutated; whereas these mutations lead to an increase in basal hs1,2 activity. Evaluation of the binding sites 5′ of the polymorphic region demonstrated an increase in hs1,2 activity when the Oct site was mutated and a decreased activity in the AP-1/Ets site was mutated. However, these mutations had little effect on TCDD-induced activation. These results suggest a complex interaction of proteins binding within the hu-hs1,2 enhancer and a consistent increase in hs1,2 activity by TCDD. A better understanding regarding the role of the hu-hs1,2 enhancer and how TCDD modulates its activity may lead to insights into the etiology of autoimmune disorders associated with the hs1,2 polymorphism.
2022  Elucidating the Role of the Polymorphic Human hs1,2 Enhancer in the Effects of TCDD

A.K. Freiwa, B. Johnson and C.E. Sulewicz. Wright State University, Dayton, OH.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a potent environmental toxin known to inhibit immunoglobulin (Ig) gene expression in various animal studies. We have identified the mouse 3’Ig heavy chain regulatory region (3’IgHRR) as a sensitive transcriptional target of TCDD, which may mediate the inhibitory effect of TCDD on Ig expression. Interestingly, the human hs1,2 enhancer is polymorphic and has been associated with a number of autoimmune diseases. Suggesting a species difference, TCDD inhibited mouse hs1,2 enhancer activation and activated basal human hs1,2 (hs-hs1,2) enhancer activity. The objective of this study was to determine the effect of stimulation and TCDD on hu-hs1,2 enhancer activity using a human B-lineage (CL-01) and luciferase reporter constructs regulated by each of the human hs1,2 alleles. Our results verify that TCDD alone activates each of the hu-hs1,2 alleles. Surprisingly, B-cell stimulation through TLR 7 and 8 by R848 inhibited basal activity of the hu-hs1,2 alleles and TCDD co-treatment reversed this inhibition. In contrast, R848 induced Ig secretion and activated a 3x NF-kB luciferase reporter, therefore confirming functional signaling through the TLRs and activation of the CL-01 B-cell line. R848 also induced class switch recombination from IgM to IgG. Furthermore, TCDD inhibited both IgM and IgG secretion in cells stimulated with R848. These results suggest that the hu-hs1,2 enhancer may be a negative regulator of 3’IgHRR activity and Ig expression. Alternatively, the hs1,2 enhancer may function differently when studied in isolation as compared to its function in the intact 3’IgHRR. Further studies will evaluate the effect of TCDD in the absence or presence of stimulation on the activity of the entire human 3’IgHRR and its other enhancers, hs3 and hs4. Elucidating the role of the polymorphic hs1,2 enhancer in 3’IgHRR activity and the effect of TCDD on the enhancers of the 3’IgHRR may provide insights into the etiology of autoimmune diseases associated with the hs1,2 polymorphism. (Supported by NIEHS R01ES014676)

2023  Benzo(a)pyrene Exposure Suppresses FcyRII (CD32)-IgG Antibody Complex Binding by Disruption of Lipid Raft Membrane Integrity

R. S. Clark1, D. B. Handel1, M. Maguire1, and A. Rawal1. 1Neuroscience and Pharmacology, Meharry Medical College, Nashville, TN. 2Division of Environmental Health Sciences, College of Public Health and Department of Neuroscience, College of Medicine, Ohio State University, Columbus, OH and 3Biochemistry and Cancer Biology, Meharry Medical College, Nashville, TN.

The fundamental requirement in activation of macrophage effector functions is the binding of immunoglobulins to Fc receptors. The FcγRIIA (CD32) immunoreceptors have been reported to either constitutively reside in or associate with detergent resistant membranes (DRMs) upon binding to IgG, the most abundant Ab class in circulation. Previous research suggests that exposure to benzo(a)pyrene, B(a)P, an environmental toxicant, suppresses macrophage effector functions but the mechanism remains undefined. The purpose of this study was to elucidate the mechanism of B(a)P-induced suppression by examining the effects of B(a)P exposure on CD32-lipid raft interactions in the regulation of IgG binding to CD32. B(a)P exposure altered lipid raft integrity by depleting membrane cholesterol at over a 50% depletion rate (577.8 ± 204.6, p < 0.001). The exposures also lead to a 30% (216.2 ± 142.7, p < 0.05) reduction in affinity or an exclusion of CD32 from lipid rafts. The 50% diminution in membrane cholesterol as well as the 30% exclusion of CD32 from lipid rafts caused significant suppression of CD32-mediated IgG binding by 60% (486.2 ± 166.7, p < 0.001) which suggests that intact lipid rafts are required for IgG complex binding to CD32. Future studies are directed at establishing whether B(a)P-induced suppression increases macrophage susceptibility to microbial infection.

2024  Wear Particles Derived from Metal Hip Implants Generates Multinucleated Giant Cells in a 3-Dimensional Peripheral Tissue-Equivalent Model

D. K. Dutta1, P. A. Potts1, K. Rhodes2, and S. C. Wood1. 1CDRH/OSEL/DB, FDA, Silver Spring, MD and 2University of Maryland, College Park, MD. Sponsor: P. Gearing.

Multinucleate giant cells (MGCs) are created by the fusion of 5 to 15 monocytes or macrophages. MGCs can be generated by hip implants at the site where the metal surface of the device is in close contact with tissue. MGCs play a critical role in the inflammatory processes associated with adverse events like aseptic loosening of the prosthetic joints and bone degeneration as observed in some patients. Upon interaction with metal wear particles, endothelial cells can upregulate bioactive molecules and pro-inflammatory cytokines that can enhance a localized immune response. However, the role of endothelial cells in the generation of MGCs has not been completely investigated. We first developed a three-dimensional peripheral tissue-equivalent model (PTEM) consisting of collagen gel, with a monolayer of endothelial cells on gel surface and human peripheral blood mononuclear cells (PBMCs) on top, which mimics peripheral tissue under normal physiological conditions. The cultures were incubated for 14 days with Cobalt chromium alloy (CoCr ASTM F75, 1-5 microns) wear particles, PBMCs were allowed to transit through the coated cell line and harvested cells were analyzed for MGC generation using propidium iodide (PI) by flow cytometry. Increase in forward scatter (cell size) and in the PI uptake (DNA intercalating dye) was used as a measure of MGCs. Our results show that endothelial cells induce generation of MGCs 4 fold higher in 3-dimensional PTE system as compared to traditional 2-dimensional culture plates. Furthermore, we also checked whether increase in particle to cell ratio affects MGC generation. We found that as the number of particles increased, decrease in MGC generation compared to control, indicating that cells underwent apoptosis or necrosis with higher particle concentration. In sum, we have established a robust and relevant model to follow MGCs formation using flow cytometry. We observed a consistent generation of metal wear particle-induced MGCs which herald MoM hip failure.

2025  Dermal Exposure to Triclosan Induces Changes in Expression of Innate and Adaptive Immune Genes in a Mouse Model

Triclosan has had widespread use in the general population as an antimicrobial agent and is commonly found in consumer products such as soaps, deodorants, toothpastes, shaving creams, mouth washes, and cleaning supplies. Triclosan has recently attracted the attention of the scientific community, regulatory agencies and the general public because of its high production volume, widespread applications and reports of endocrine-disrupting effects. A positive association between urinary levels of triclosan and diagnosis of allergies, hay fever, and sensitization to Aeroallergens and foods has been identified. While not generally considered to be a sensitizing chemical, work by our group has recently shown that dermal exposure to triclosan at concentrations similar to those in consumer products augmented the allergic response to a known allergen in a mouse asthma model. However, the specific mechanism of this augmentation has yet to be elucidated. These studies were conducted to investigate the mechanism responsible for the augmented allergic response following dermal triclosan exposure. BALB/c mice were exposed dermally on the ears to concentrations of triclosan ranging from 0.75-3% (0.375-1.5mg/mouse/day) for up to 9 consecutive days. Expression of immune genes in the ears and lymph nodes of mice following exposure was analyzed using quantitative polymerase chain reaction. Robust thymic stromal lymphopoietin (TSLP), IL-1 beta, TNF-alpha increases and modest CCL22 & IL-22 dose responsive increases in gene expression were observed in the ears. In the lymph node draining the exposure site, dose responsive increases in CCL22 & IL-4 and decreases in T-bet, IFN-gamma, TNF-alpha & IL-1beta gene expression were observed. A decrease in expression of RORgammat was observed in both the ear and lymph nodes following exposure to 3% triclosan. These results suggest that triclosan may augment allergic responses by modulating both innate and adaptive genes.

2026  The α7 Nicotinic Acetylcholine Receptor Agonist GTS-21 Improves Bacterial Clearance in Mice by Restoring Hyperoxia-Compromised Macrophage Function

Mechanical ventilation with supraphysiological concentrations of oxygen (hyperoxia) is routinely used to treat patients with respiratory distress. However, prolonged exposure to hyperoxia compromises macrophages’ ability to phagocytose and clear bacteria. Previously, we have shown that hyperoxia induced the release of nuclear protein, high mobility group box 1 (HMGB1), into both the airways of hyperoxia-exposed mice and the extracellular milieu of cultured macrophages. Extracellular HMGB1 can impair macrophage phagocytosis and increase mortality of mice infected with Pseudomonas aeruginosa (PA). GTS-21, an α7nACHR agonist, can inhibit endotoxin-induced HMGB1 release. The aim of this study was to determine whether GTS-21 can inhibit hyperoxia-induced HMGB1 release into the extracellular milieu, enhance macrophage function, and improve bacterial clearance in mice under hyperoxic conditions. GTS-21 (0.04, 0.4, and 4 mg/kg)
was systemically administered to mice that were exposed to hyperoxia (≥99% O₂) and subsequently challenged with PA. We found that 4 mg/kg of GTS-21 significantly increased bacterial clearance, decreased acute lung injury and accumulation of airway HMGB1. To investigate the cellular mechanism of these observations, RAW 264.7 cells, a macrophage-like cell line, were incubated with different concentrations of GTS-21 prior to exposure to 95% O₂. We found that GTS-21, at 5, 25, and 50 μM, inhibited HMGB1 release and significantly enhanced macrophage phagocytic activity. Together these results indicate that GTS-21 is effective in inhibiting hyperoxia-induced HMGB1 release, enhancing macrophage function, and improving bacterial clearance under hyperoxic conditions. Therefore, the e7nAChR represents a possible pharmacological target to improve the clinical outcome of patients on ventilators by augmenting host defense against bacterial infections.

The present results point towards involvement of epithelial cell perturbations and subsequent NGK2D-RAE-1-mediated response by IEL in allergic sensitization. Together, these data demonstrate the potential involvement of intestinal stress, e.g. by luminal contents such as food constituents, pharmaceuticals or microbial components, in allergic sensitization.

Oxytate, a 60% w/v perfluoro(1,2-butylenoxohexane) intravenous emulsion, is being developed for the treatment of traumatic brain injury (TBI). PFC emulsions are cleared from circulation via the mononuclear phagocyte system (MPS), namely macrophages, monocytes, and neutrophils. Thus there is concern that PFCs may have a negative impact on immunocompetence. We evaluated Oxytate’s effects on viral and bacterial clearance in host resistance models and on ex vivo macrophage function. BALB/c mice received saline, Oxytate (3, 6, or 12 mL/kg) or an immunomodulatory control followed an hour later by infection with influenza virus (–4 x 10⁴ PFU), Streptococcus pneumoniae (–1 x 10⁵ CFU/mouse) or Listeria monocytogenes (–1 x 10⁵ CFU/mouse). Influenza viral titers and influenza-specific IgM and IgG were assessed in lung homogenates. Lung or spleen and liver homogenates were assessed for S. pneumoniae and L. monocytogenes titers, respectively. Ex vivo macrophage phagocytosis was assessed 7 days following Oxytate treatment. Oxytate caused a slight stimulation of the T-dependent antibody response (TDAR) to influenza (increased antibody). The rate and efficiency of viral clearance was no different for the Oxytate treatment groups than the controls with influenza viral load reduced by ~4 logs by Day 6 and completely cleared by Day 8. Saline and all Oxytate treatment groups achieved ~5 log reduction in S. pneumoniae within 24 hours of infection. Treatment of mice with Oxytate resulted in 80-100% mortality by Day 4 following L. monocytogenes infection. Oxytate dose-dependently increased ex vivo splenic macrophage phagocytosis 7 days after in vivo administration. Overall, these studies demonstrate that treatment of mice with Oxytate did not impact the efficient clearance of either Influenza virus or S. pneumoniae at any dose level. However, Oxytate decreased the ability of mice to defend against systemic L. monocytogenes infection.

Environmental toxins induce a novel CYP2E1/leptin signaling axis in liver. This in turn activates a poorly characterized innate immune response that contributes to nonalcoholic steatohepatitis (NAS) progression. To identify the relevant subsets of T-lymphocytes in CYP2E1-dependent, environment-linked NAS, we utilized a model of diet induced obese (DIO) mice that are chronically exposed to brodochloromethane (BDCM). Mice deficient in CYP2E1, leptin (ob/ob mice), or both T and B cells (Plp/Rag2 double knockout (KO) mice) were used to delineate the role of each of these factors in metabolic oxidative stress-induced T cell activation. Results revealed that elevated levels of lipid peroxidation, tyrosyl radical formation, mitochondrial tyrosine nitration and hepatic leptin as a consequence of metabolic oxidative stress caused increased levels of hepatic CD57, a marker of peripheral blood lymphocytes including NKT cells. CD8+CD57+ cytotoxic T cells but not CD4+CD57+ cells were significantly decreased in mice lacking CYP2E1 and leptin. There was a significant increase in the levels of T cell cytokines IL-2, IL-1β, IFN-γ in BDCM exposed DIO mice but not in mice that lacked CYP2E1, leptin or T and B cells. Apoptosis as evidenced by TUNEL assay and levels of cleaved caspase-3 was significantly lower in leptin and Plp/Rag2 KO mice and highly correlated with protection from NAS. The results described above suggest that higher levels of oxidative stress-induced lepin mediated CD8+CD57+ T cells play an important role in the development of NAS. It also provides a novel insight of immune dysregulation and may be a key biomarker in NAS.

Responses to ingested food proteins in the gut usually result in oral tolerance. Failure in oral tolerance induction may cause allergic sensitization, but the mechanism behind this is not yet fully understood. Previously, we found that allergic sensitization of C57BL/6 mice via intragastric treatment with PE plus CT resulted in increased NKG2D expression on IEL. Furthermore, duodenum and ileum sensitization of C57BL/6 mice via intragastric treatment with PE plus CT resulted in increased mRNA levels for the NKG2D ligand RAE-1, and for the Th2 cytokine IL-5. In addition, when mice were treated with anti-NKG2D blocking antibody during intragastric sensitization, levels of PE-specific IgG1 and IgE were significantly enhanced.

2031 Automated High Content Imaging of NF-κB Signaling Modulation in Drug-Induced Liver Injury (DILI)

S. Huppelschoten, B. Herpers, L. Fredriksson, S. Wink, K. Yan and B. van de Water, LACDR, Toxicology, Leiden University, Leiden, Zuid-Holland, Netherlands.

Drug-Induced Liver Injury (DILI) is the most important reason to withdraw initially approved drugs from the market, to stop the development of novel drugs during the clinical test phase and for failure of FDA approval. Currently, the very heterogeneous group of chemicals inducing idiosyncratic DILI cannot be predicted in vitro, in vivo or even in clinical trials. This illustrates the necessity of a better understanding of underlying mechanisms. DILI parent compounds or metabolites induce cellular stress, which can ultimately lead to cell death. Drug exposure combined with pro-inflammatory cytokine stimulation does synergistically increase apoptosis, which indicates that cytokine signaling plays an important role in the development of idiosyncratic DILI. The major pro-inflammatory cytokines in the liver active NF-κB, a transcription factor regulating immune reactions, cell growth and death. To gather more insight in the activation of NF-κB and its importance in DILI, we have generated HepG2 Bacterial Artificial Chromosome (BAC) GFP-based reporter cell lines of the most important players in the NF-κB signaling cascade. We established and carefully characterized GFP-BAC cell lines of IkBα, RelA and Icam1 and determined the effect of DILI-inducing compounds on pro-inflammatory cytokine signaling by live confocal microscopy. The time-resolved dynamics of the expression and/or localization of these genes was determined at a single cell level at different cytokine and DILI compound concentrations. A large panel of DILI compounds affected the kinetics of IkBα degradation, RelA nuclear translocation and Icam1 expression induced by either TNF-α or IL1β. For various compounds this was directly associated with enhanced cytotoxicity of combined DILI/cytokine exposure. We propose that our novel high content imaging approach would be an effective means to pinpoint DILI hazard for novel drug candidates.

2032 Effect of 1-Bromopropane on Expression of IL-4 and IL-5 and Secretion of β-Hexosaminidase by Calcium Influx in RBL-2H3 Cells

H. Han1, H. Kim1, K. Lee1, T. Jeong1 and H. Jeong1. 1Pharmacy, Chonnam National University, Gwangju, Republic of Korea and 2College of Pharmacy, Chonnam National University, Gwangju, Republic of Korea.

1-Bromopropane (1-BP) is an alternative to ozone-depleting chlorofluorocarbons that has a variety of potential applications as a deaginging agent for metals and electronics, coating agent and as a solvent vehicle for spray adhesives in the workplace. Although 1-BP has been recently reported to generate neurotoxicity, reproductive toxicity, hepatotoxicity, and immunotoxicity in rodents and human, there is little information about the effect of 1-BP on the mast cell degranulation and allergic responses. This study investigated the effect of 1-BP on degranulation and inflammatory mediator production in RBL-2H3 cells. 1-BP significantly increased release of beta-hexosaminidase and histamine in mast cells. It also increased the modula-

2033 Renal Dendritic Cells Attenuate Cisplatin Neprotoxicity Independent of Neutrophil Regulation

R. K. Tadagavadi, G. Guofeng, W. Wang and W. Reeves, Department of Medicine, Pennsylvania State University College of Medicine, Hershey, PA.

Cancer chemotherapy can produce sterile inflammation with associated tissue injury and organ dysfunction. Cisplatin is a very effective chemotherapeutic agent used against a wide range of solid tumors. Major adverse effects of cisplatin therapy are immunotoxicity and acute kidney injury. Neutrophils are reported to infiltrate and exacerbate injury in a wide range of sterile inflammatory models of tissue injury. Here, we studied the kinetics of neutrophil infiltration into kidneys and their role in cisplatin-mediated kidney injury. Mice treated with cisplatin showed a marked decrease in total blood leukocytes but a 5-fold elevation in neutrophils at 72 hrs after cisplatin treatment. In kidneys, cisplatin treatment caused a 2 fold increase in total kidney leukocytes as early as 24 hrs after cisplatin treatment. Renal infiltration of myeloid cells in cisplatin treated mice was prominent; monocytes and neutrophils were elevated by 10 fold as compared to saline treated mice. We depleted neutrophils using a neutrophil-specific antibody (clone 1A8) to examine the functional role of infiltrating neutrophils after cisplatin nephrotoxicity. This antibody resulted in greater than 90% depletion of neutrophils. Of note, depletion of neutrophils had no impact on the extent of cisplatin-induced kidney injury or renal dysfunction as compared to non-depleted mice. Earlier, we reported that dendritic cell depletion in CD11c-DTR mice causes exacerbation of kidney injury and a dramatic increase in renal neutrophil numbers 24 hrs after cisplatin treatment. Thus, we also examined the role of neutrophils in dendritic cell depleted mice treated with cisplatin. Dendritic cell depletion resulted in worse renal dysfunction in spite of neutrophil depletion. Supporting that dendritic cell mediated protection occurs independent of its effects on neutrophils. These data demonstrate that cisplatin nephrotoxicity is independent of neutrophil-mediated inflammation and dendritic cells protect kidneys via neutrophil-independent mechanisms.

2034 Entecavir: Chemokine Receptor 2 (CCR2)-Mediated Chemotaxis As A Mode of Action for Mouse-Specific Pulmonary Macrophage Accumulation

G. L. Gong1, J. Pang2, Q. Zhao3, E. Janowiza1 and L. D. Lehman-McKeeman1. 1Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ and 2Disc Biology Immunology, Bristol-Myers Squibb, Princeton, NJ.

Entecavir (ETV; Barudacil®) is a marketed guanosine nucleoside analog that inhibits hepatitis B viral replication. In preclinical studies, ETV caused lung toxicity in mice but not in rats, dogs or monkeys. Microscopically, lungs from ETV-treated mice (10 mg/kg p.o. 1 mo) showed alveolar septal thickening and accumulation of macrophages, and bronchoalveolar lavage analysis revealed a 3-fold increase in alveolar macrophages, with no effects on other inflammatory cells. CCR2 null mice were resistant to ETV-induced macrophage accumulation suggesting a role for this receptor in the ensuing pulmonary toxicity. To further explore the role of CCR2 in macrophage accumulation, ETV was evaluated for chemotactic activity in human and mouse macrophages. While weaker than monocyte chemotactic protein-1 (MCP1; optimum concentration <10 nM), ETV was a chemotaxin in mouse WEHI 274.1 cells with maximum chemotaxis observed 75 nM. In contrast, ETV was not chemotactic in human THP-1 cells at concentrations up to 6 μM. ETV also exhibited chemotactic activity in mouse peripheral blood mononuclear cells (PBMCs) with an optimal concentration of 222 nM, but showed no activity in PBMCs from CCR2 null mice. To further test species differences in chemotaxis, the effect of ETV in PBMCs from rats and humans was studied. ETV showed weak chemotaxis for PBMCs isolated from Sprague-Dawley rats, with optimal chemotactic activity at 2 μM. In contrast, no chemotactic activity was observed in human PBMCs at ≤6 μM. These results indicate that ETV-induced pulmonary macrophage accumulation and lung toxicity is dependent on CCR2-mediated chemotaxis. As the chemotactic activity was specific for mice, lung toxicity was not predicted as a potential liability of ETV therapy.

2035 Differential Infiltration of Macrophages into the Testis after Mono-(2-Ethylhexyl) Phthalate Exposure in F344 Rats and C57B6/J Mice

A. Stiermer, C. Murphy and I. H. Richburg, Pharmacology and Toxicology, University of Texas at Austin, Austin, TX.

Different strains and species of animals are used for both toxicological studies and basic research. Often general similarities in toxicity between animals exist, but sensitivities and specific mechanisms of toxicity can vary. Phthalates, ubiquitously used plasticizers, are known Sertoli cell toxicants. Mono-(2-ethylhexyl) phthalate (MEHP) induced testicular injury has been studied in rats and mice, where inflammatory signaling has been shown to mediate germ cell apoptosis in the common MEHP mechanism. Yet, rats have been shown to have 30 fold lower LOAEL than mice. To further define this difference we analyzed germ cell apoptosis and immune infiltration into the testes of F344 rats and C57B6/J mice. MEHP (1g/kg, gavage) or equivalent volume was given to 28-day (d) rats and mice. Testes were collected 12, 24, and 48 hours (h) after exposure. Single cell suspensions were isolated from the interstitium of one testes, reacted with anti-CD11b (mono-

536 SOT 2014 Annual Meeting
2036 Methylene diphenyl Diisocyanate Binds Membrane and Intracellular Proteins of Intact THP-1 Cells

Diisocyanates (dNCO) are used in the production of polyurethane products and can cause occupational asthma. Although dNCO asthma displays the same pathological hallmarks as other allergic asthma, dNCO-specific IgE can only be detected within a small subset of dNCO asthmatics. Because of this low prevalence, we propose that methylenediphenyl diisocyanate (MDI) may adduct to cell membrane and intracellular proteins, contributing to the development of non-IgE asthma. In this study, human monocytic leukemia (THP-1) cells were exposed to varying concentrations of MDI. After exposure, cells were processed into soluble and membrane fractions, dialyzed, and analyzed for extent of MDI protein binding, following acid hydrolysis, by quantification of the MDI hydrolysis product, methylenedianiline (MDA). Proteins were electrophoresed on sodium dodecyl sulfate polyacrylamide gels and protein bands were excised, hydrolyzed and analyzed for MDA. Protein binding was not affected by cytochalasin D, a chemical which binds actin filaments, and is consistent with reactive MDI binding to intracellular targets. The extent of MDI intracellular protein binding was identified as containing MDI bound proteins. The extent of MDI intracellular protein binding was not affected by cytochalasin D, a chemical which binds actin filaments and inhibits active uptake into cells. Proteins identified in the soluble fraction were all of intracellular origin suggesting that reactive MDI can cross the cell membrane and subsequently haptenate intracellular proteins. The results of the present study support the potential involvement of dNCO haptenated membrane and intracellular proteins in development of asthma.

2037 Biodistribution of Reolysin® (Pelareorep) in Sprague-Dawley Rats to Support the Use of This Orphan Virus As an Investigational Drug for Cancer Treatment

A. Parenteau1, R. Chakraborty1, H. Tran1, A. Hagerman1, S. Serl1, B. Thompson5, M. Coffey1, R. Tavcar4, I. Boulay2, M. Biggs3 and R. Forrest5.

Reolysin® (pelareorep) is a clinical formulation of the human Reovirus Type 3 Dearing strain. The clinical safety and efficacy of Reolysin® as an oncolytic therapy in humans is being tested on an assortment of cancer indications as a mono and/or combination therapy. Reovirus has many inherent characteristics that make it a potential candidate for virotherapy, including the rapid and natural spread through the haematogenous route, the ability to overcome immunological barriers thereby reaching tumor sites, and being replication-competent. The purpose of this study was to elucidate the bio-distribution pattern of Reolysin® in healthy Sprague-Dawley rats. Following a single 15-minute intravenous infusion (at dose levels of 6.5E+07, 6.5E+08 and 6.5E+09 viral particles/animal, based on an average body weight of 225 grams) via the tail vein in Sprague-Dawley rats, the levels of virus genome were determined in 16 organs/tissues by RT-qPCR (Reverse Transcriptase-Quantitative Polymerase Chain Reaction) over a 336 hr follow-up period. Maximal reovirus RNA levels were observed in the spleen, indicating its involvement in viral uptake and clearance, followed by heart, ovaries, tail (inflamed site), liver and lungs. All the organs/tissues demonstrated quantifiable levels of reovirus genome at the end of the follow-up period, suggesting substantial to complete viral clearance. Several studies in the last decade have described the use of reovirus for treating ovarian cancers. An increase of reovirus genome in ovaries at 24 hr post infection was noted. The results will aid in the design of additional exploratory clinical trials for Reolysin®.

2038 Multi-Endpoint Assessment of Bone Marrow Toxicity in Sprague-Dawley Rats

L. Piccotti, K. Ghoreishi, L. Alvarado, R. Maggantay, S. Couto and M. Breider.

Bone marrow toxicity is often an unwanted side effect of kinase inhibitors. We previously demonstrated bone marrow hypopcellularity in rats dosed with CC0485118, a small molecule kinase inhibitor of spleen tyrosine kinase (5yk) and Janus kinase-2 (Jak-2). The current study was conducted to further characterize the bone marrow toxicity caused by CC0485118 using a recently developed bone marrow flow cytometry assay. In this study, male Sprague-Dawley rats received once daily oral (gavage) doses of CC0485118 at 25, 50 and 200 mg/kg for 7 consecutive days. CD71+ cells and CD11b/c+ cells were measured by flow cytometry in femurs of vehicle- and test article-treated rats approximately 24 hours after the last dose to assess compound effects on the erythroid and myeloid lineages, respectively. Bone marrow toxicity was also assessed by measuring peripheral blood reticulocyte counts and by histopathologic examination of the sternum. Treatment of rats with CC0485118 at 200 mg/kg resulted in a moderate reduction in total nucleated cells (TNC) in the bone marrow, compared to vehicle control rats. This finding was confirmed by moderate to marked bone marrow hypopcellularity observed microscopically and was consistent with a moderate drop in reticulocytes. The relative percentages of CD11b/c+ myeloid cells were markedly increased in rats dosed at 200 mg/kg. However, a mild to moderate reduction in the absolute numbers of both CD71+ erythroid cells and CD11b/c+ myeloid cells were observed in these animals, resulting in no change in the myeloid to erythroid ratios (M:E) compared to controls. Thus, the flow cytometry data demonstrated toxicity to both the erythroid and myeloid lineages by CC0485118. The results of this study demonstrated that measuring CD71+ and CD11b/c+ cells in rat bone marrow can be used to complement histopathologic examination by assessing compound effects on the erythroid and myeloid lineages. Future studies will further test the sensitivity and predictability of this assay by using compounds that differentially target myeloid or erythroid cells.

2039 Cysteine Microenvironment Determines Nitrosylation Status: Lessons from Proteome Analysis of NOS2 and GSNOR Knockout Mice

C. B. Massa1, P. T. Doulias2, H. Ischiropoulos1 and A. Gove1.

Reolysin® (pelareorep) is a clinical formulation of the human Reovirus Type 3 Dearing strain. The clinical safety and efficacy of Reolysin® as an oncolytic therapy in humans is being tested on an assortment of cancer indications as a mono and/or combination therapy. Reovirus has many inherent characteristics that make it a potential candidate for virotherapy, including: the rapid and natural spread through the haematogenous route, the ability to overcome immunological barriers thereby reaching tumor sites, and being replication-competent. The purpose of this study was to elucidate the bio-distribution pattern of Reolysin® in healthy Sprague-Dawley rats. Following a single 15-minute intravenous infusion (at dose levels of 6.5E+07, 6.5E+08 and 6.5E+09 viral particles/animal, based on an average body weight of 225 grams) via the tail vein in Sprague-Dawley rats, the levels of virus genome were determined in 16 organs/tissues by RT-qPCR (Reverse Transcriptase-Quantitative Polymerase Chain Reaction) over a 336 hr follow-up period. All the organs/tissues demonstrated quantifiable levels of reovirus genome at the end of the follow-up period, suggesting substantial to complete viral clearance. Several studies in the last decade have described the use of reovirus for treating ovarian cancers. An increase of reovirus genome in ovaries at 24 hr post infection was noted. The results will aid in the design of additional exploratory clinical trials for Reolysin®.

2038 Multi-Endpoint Assessment of Bone Marrow Toxicity in Sprague-Dawley Rats

L. Piccotti, K. Ghoreishi, L. Alvarado, R. Maggantay, S. Couto and M. Breider.

Bone marrow toxicity is often an unwanted side effect of kinase inhibitors. We previously demonstrated bone marrow hypopcellularity in rats dosed with CC0485118, a small molecule kinase inhibitor of spleen tyrosine kinase (5yk) and Janus kinase-2 (Jak-2). The current study was conducted to further characterize the bone marrow toxicity caused by CC0485118 using a recently developed bone marrow flow cytometry assay. In this study, male Sprague-Dawley rats received once daily oral (gavage) doses of CC0485118 at 25, 50 and 200 mg/kg for 7 consecutive days. CD71+ cells and CD11b/c+ cells were measured by flow cytometry in femurs of vehicle- and test article-treated rats approximately 24 hours after the last dose to assess compound effects on the erythroid and myeloid lineages, respectively. Bone marrow toxicity was also assessed by measuring peripheral blood reticulocyte counts and by histopathologic examination of the sternum. Treatment of rats with CC0485118 at 200 mg/kg resulted in a moderate reduction in total nucleated cells (TNC) in the bone marrow, compared to vehicle control rats. This finding was confirmed by moderate to marked bone marrow hypopcellularity observed microscopically and was consistent with a moderate drop in reticulocytes. The relative percentages of CD11b/c+ myeloid cells were markedly increased in rats dosed at 200 mg/kg. However, a mild to moderate reduction in the absolute numbers of both CD71+ erythroid cells and CD11b/c+ myeloid cells were observed in these animals, resulting in no change in the myeloid to erythroid ratios (M:E) compared to controls. Thus, the flow cytometry data demonstrated toxicity to both the erythroid and myeloid lineages by CC0485118. The results of this study demonstrated that measuring CD71+ and CD11b/c+ cells in rat bone marrow can be used to complement histopathologic examination by assessing compound effects on the erythroid and myeloid lineages. Future studies will further test the sensitivity and predictability of this assay by using compounds that differentially target myeloid or erythroid cells.
Contact dermatitis is one of the most common skin diseases, with a great socio-economic impact. Disperse dyes, which are suitable for dyeing synthetic fibers, are responsible for the great majority of allergic contact dermatitis cases to textile dyes. The aim of the present study was to study the sensitization potential of textile dyes using a non-radioactive biphasic murine local lymph node assay (LLNA) and an in vitro Loose-fit Co-culture based Sensitization assay (LCSA). In biphasic LLNA, female BALB/c mice were shaved over a surface of approximately 2 cm square on back and treated with various concentrations of textile dyes. The 'sensitization' treatment included application of 50 µl of test substance on the back or on days 1-3 followed by 'challenge' treatment on days 15-17 with application of 25 µl of test substance on the dorsum of both ears. End-points on day 19 following deep carbon-di-oxide anesthesia included thickness and weight of an ear biopsy, lymph node weight, lymph node cell count and the proportion of various lymphocyte subpopulations. The LCSA involved single layer of human non-differentiating keratinocytes and of allogenic floating monocytes which are cocultured in serum-free medium in the presence of a cytokine cocktail. The coculture develops into a system consisting of activated keratinocytes and dendritic cell-related cells. The half-maximal increase in CD86 expression on the dendritic cell-like cells (EC50 values) was used to compare the sensitizing potential of tested substances. The results showed the usefulness of the modified biphasic LLNA to study sensitization potential of textile dyes. The results from LCSA correlated well with data derived from the modified version of LLNA and human data. The LCSA represented a suitable test system to simultaneously analyze irritative and sensitizing properties of chemicals altogether.
**2041** Failure of Reversal of Oxidative Damage in Renal Tissues of Lead Acetate-Treated Rats

A. S. Akinrinde1, T. O. Omobowale2, A. A. Ogabe3, A. B. Salu1, B. S. Ogurupolu2 and O. T. Daramola3. 1Dept of Vet. Physiology, Biochemistry and Pharmacology, University of Ibadan, Nigeria, Ibadan, Oyo, Nigeria and 2Veterinary Medicine, University of Ibadan, Nigeria, Ibadan, Oyo, Nigeria.

Removal of lead from the environment of man or otherwise, the movement of man from lead-contaminated areas has been employed as a means of abatement of the toxic effects of lead. Whether toxic effects in already-exposed individuals subside after lead withdrawal remains unanswered. In order to understand the reversibility of nephrotoxicity induced by lead acetate, male Wistar rats were orally exposed to 0.25, 0.5 and 1.0mg/ml of lead acetate for 6 weeks. One-half of the rats were sacrificed at 6 weeks while the other half remained for an additional 6 weeks after withdrawal of lead. There were significant (p<0.05) increases in Glutathione S-transferase (GST), Catalase (CAT), Superoxide dismutase (SOD), Hydrogen peroxide (H2O2) generated and Malondialdehyde (MDA) in a dose-dependent manner, with concomitant reduction in glutathione (GSH) content and Gluthathione peroxidase (GPx) activity. The pattern of alterations in most of the oxidative stress and antioxidant parameters remained similar in rats from the withdrawal period, although CAT and SOD activities reduced, in contrast to their elevation during the exposure period. Serum creatinine levels were significantly (p<0.05) elevated although CAT and SOD activities reduced, in contrast to their elevation during exposure period. Serum creatinine levels were significantly (p<0.05) elevated although CAT and SOD activities reduced, in contrast to their elevation during

**2042** Disposition and Toxicity of Mercury in Aging Rats

C. Bridges, L. Joshee and R. K. Zalups. Mercer University, Macon, GA.

Progressive loss of functioning nephrons, secondary to age-related glomerular disease, can impair the ability of the kidneys to effectively clear metabolic wastes and toxicants from blood. Additionally, as renal mass is diminished, cellular hypertrophy occurs in the remaining nephrons that remain (primarily along the proximal tubule). Consequently, we hypothesize that the remaining functioning nephrons are at an increased risk of being intoxicated by nephrotoxic compounds, such as the acute nephrotoxicant, inorganic mercury (Hg\(^2+\)). The purpose of the present study was to characterize the renal pathological effects of aging on the renal disposition and toxicity of Hg\(^2+\) using young adult and two-year old rats. Paired groups of animals were injected (i.v.) with either a 0.5 \(\mu\)mol/kg non-toxic or a 2.5 \(\mu\)mol/kg nephrotoxic dose of mercuric chloride. Significant differences were detected between corresponding groups of young and aged rats. Plasma creatinine, blood urea nitrogen and renal biomarkers were greater in both groups of aged rats than in corresponding young adult rats. Histologically, evidence of glomerular sclerosis, tubular atrophy, interstitial inflammation and fibrosis were significant pathological features in kidneys of aged animals. In addition, proximal tubular necrosis, especially along the straight segments in the inner cortex and outer stripe of the outer medulla was a prominent feature in the renal sections from both aged and young rats treated with the nephrotoxic dose of Hg\(^2+\). Our findings indicate that aging has a profound effect of the renal disposition of administered Hg\(^2+\) and reduces renal overall function more significantly in aged rats than young rats.

**2043** Profiling of Human, Canine, and Rat Urine Samples Using Bio-Plex Pro RBM Kidney Toxicity Assays

Acute kidney injury (AKI) is a serious medical condition caused by a variety of bodily insults, including trauma from an accident, ICU acute renal failure, or exposure to nephrotoxic agents. From a pharmaceutical industry standpoint, drug-induced toxicity is a serious issue, sidelineing 30% of therapeutics overall, from pre-clinical lead compounds to marketed drugs (Bonventre et al. 2010). Early detection of AKI along with proper treatment regimens is critical in the prevention of further loss of kidney function. The current clinical criterion for the diagnosis of AKI relies on traditional tests (glomerular filtration rate and blood urea nitrogen) that employ late biomarkers that are detectable days or weeks after kidney damage has occurred. Researchers are looking for biomarkers that are sensitive, specific, and early indicators of AKI. Further, level monitoring should be cost effective and permit rapid reporting of results (Scolum et al. 2012).

**2044** Protection against Type 2 Diabetes-Induced Nephropathy by Multiple Exposures to Low-Dose Radiation Was Associated with Improvement of Dyslipidemia and Insulin Resistance

C. Zhang1, 2, 3, M. Shao1, 2, L. Cai1, 2, 3 and X. Lu1. 1Chinese-American Research Institute for Diabetic Complications, Wenzhou Medical University, Wenzhou, China, 2Ruijin Center of Chinese-American Research Institute for Diabetic Complications, the Third Affiliated Hospital of the Wenzhou Medical University, Wenzhou, China and 3KCHRI & Department of Pediatrics, University of Louisville, Louisville, KY.

The aims of the present study were to investigate whether LDR can prevent type 2 diabetes-induced renal damage and to explore the possible mechanism. Mice were fed with a high-fat diet for 12 weeks, followed by a single injection of streptozoto- cin to develop a type 2 diabetic mouse model. Then, these mice were exposed to LDR at different doses (25, 50, and 75 mGy) for 4 or 8 more weeks with HFD treatment. The kidney weight, renal function, blood glucose level, and insulin resistance were examined. The pathological changes were measured by hematoxlin and eosin, periodic acid Schiff, and Mason’s trichrome staining. Systematic and renal lipid profiles were detected by ELISA. Renal inflammation, oxidative stress, and fibrosis were assessed by real-time PCR, western blot assays, and immunohistochemical staining. HFD/STZ-induced type 2 diabetic mice exhibited severe pathological changes in the kidney and renal dysfunction. Exposure of the mice to LDR for 4 weeks, especially at 50 and 75 mGy, prevented most of the abnormalities. The beneficial effects became weaker after LDR treatment for 8 weeks. LDR also attenuated serum lipid levels and subsequent lipotoxicity characterized by insulin resistance, inflammation, and oxidative stress in the diabetic kidneys. Finally, the LDR-induced anti-oxidative effect was due to upregulation of renal nuclear factor E2-related factor-2 expression and function. These results suggest that LDR prevented type 2 diabetes-induced kidney injury. The protective mechanisms may be mainly attributed to the prevention of dyslipidemia and the subsequent lipotoxicity-induced insulin resistance, inflammation, and oxidative stress.

**2045** Attenuation of Hyperlipidemia- and Diabetes-Induced Early-Stage Apoptosis and Late-Stage Renal Dysfunction via Administration of Fibroblast Growth Factor 21 Is Associated with Suppression of Renal Inflammation

X. Lu1, C. Zhang1, 2, 3, X. Li4 and L. Cai1, 2, 3. 1Ruijin Center of Chinese-American Research Institute for Diabetic Complications, The Third Affiliated Hospital of the Wenzhou Medical University, Ruian, Zhejiang, China, 2Chinese-American Research Institute for Diabetic Complications, Wenzhou Medical University, Wenzhou, China and 3KCHRI & Department of Pediatrics, University of Louisville, Louisville, KY.

Lipotoxicity is a key feature of the pathogenesis of diabetic kidney disease, and is attributed to excessive lipid accumulation (hyperlipidemia). Increasing evidence suggests that fibroblast growth factor (FGF-21) has a crucial role in lipid metabolism under diabetic conditions. The present study investigated whether FGF-21 can prevent hyperlipidemia- or diabetes-induced renal damage, and if so, the possible mechanism. Mice were injected with free fatty acids (FFAs, 10 mg/10 g body weight) or streptozotocin (150 mg/kg) to establish a lipotoxic model or type 1 diabetic model, respectively. Simultaneously the mice were treated with FGF-21 (100 pg/kg) for 10 or 80 days. The kidney weight-to-tibia length ratio and renal function were assessed. Systematic and renal lipid levels were detected by ELISA and Oil Red O staining. Renal apoptosis was examined by TUNEL assay. Inflammation, oxidative stress, and fibrosis were assessed by Western blot. Acute FFA administration and chronic diabetes were associated with lower kidney-to-tibia length ratio, higher lipid levels, severe renal apoptosis and renal dysfunction. Obvious inflammation, oxidative stress and fibrosis also observed in the kidney of both mice models. Deletion of the fgf21 gene further enhanced the above patho-
logical changes, which were significantly prevented by administration of exogenous FG21. These results suggest that FFA administration and diabetes induced renal damage, which was further enhanced in FG21 knockout mice. Administration of FG21 significantly prevented both FFA- and diabetes-induced renal damage partly by decreasing renal lipid accumulation and suppressing inflammation, oxidative stress, and fibrosis.

**2046** ALDH16A1 Interacting with HPRT1 in the Purine Salvage Pathway

M. M. SANDOVAL, V. VASILIOU, Y. CHEN, B. C. JACKSON and R. JOHNSON, Pharmaceutical Sciences, University of Colorado, Aurora, CO.

Purpose: Gout, a common form of inflammatory arthritis, is strongly associated with elevated uric acid concentrations in the blood (hyperuricemia). A recent study identified a rare single nucleotide polymorphism in the aldehyde dehydrogenase 16A1 (ALDH16A1) gene, ALDH16A1*2, showing a strong association with hyperuricemia and gout. The purpose of this study is to determine if ALDH16A1*2 plays a role in hyperuricaemia and gout by modulating HPRT1 in the purine salvage pathway.

Methods: Molecular modeling was performed to determine if ALDH16A1 is catalytically inactive and the binding ability with HPRT1. Transfection and immunoprecipitation were performed to assess the ex vivo interaction between ALDH16A1 and HPRT1.

Uric acid generation in transfected cells overexpressing ALDH16A1 was determined to assess the possible role of ALDH16A1 in the purine salvage pathway. Results: Molecular modeling predicts human ALDH16A1 protein would lack catalytic activity due to the absence of the catalytically important cysteine residue (Cys-302) as well as a loss of substrate binding and cofactor binding (NAD+) pockets. Molecular modeling as well as ex vivo interaction studies implies that ALDH16A1, but not ALDH16A1*2, may interact with HPRT1. The decrease in uric acid generation in ALDH16A1 overexpressing cell lines implies a possible role of ALDH16A1 in the purine metabolism pathway.

Conclusion: These results lead to the intriguing possibility that association between ALDH16A1 and HPRT1 may be required for optimal HPRT1 activity; disruption of this interaction may contribute to the hyperuricemia seen in ALDH16A1*2 carriers.

**2047** The Possible Role of Fluoride on Aggravation of Tubulointerstitial Fibrosis Caused by Unilateral Ureteral Obstruction through TGF-β1

T. Kido1,2, M. Tsunoda1, C. Sugaya2 and H. Yanagisawa1. 1Public Health and Environmental Medicine, The Jikei University School of Medicine, Tokyo, Japan and 2Preventive Medicine, Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan.

Fluoride (F) is an environmental pollutant. The contamination of ground water by F has been reported in China, India, Iran, and Argentina. Since F is filtered by the kidney, humans or experimental animals with renal insufficiency may be affected by F more seriously. We used the tubulointerstitial fibrosis model of rats induced by unilateral ureteral obstruction (UUO). We examined whether or not F deteriorates tubulointerstitial fibrosis in rats with UUO. In this study, the pathological changes and the expression of TGF-β1 mRNA in the renal cortex of rats were examined. Left ureter was ligated and sham-operation was done in 7-week-old male rats weighing 240-260g. F was administered to rats with UUO at 0, 75 and 150 ppm and sham-operated rats at 0 and 150 ppm in drinking water for 2 weeks. The kidneys obtained were immediately harvested, decapsulated and carefully dissected into the cortex on ice. Real-time PCR was performed for the analysis of TGF-β1 mRNA. The cortex was also pathologically examined by Masson-trichrome stain. Body weight of rats with UUO exposed to 150 ppm of F was significantly lower than that of rats with UUO exposed to 0 and 75 ppm of F. The average of water intake in rats with UUO exposed to 75 and 150 ppm of F was significantly lower than that in rats with UUO that were not exposed to F. Masson-trichrome stain revealed the deterioration of tubulointerstitial fibrosis in the renal cortex of rats with UUO exposed to 150 ppm of F. The expression of TGF-β1 mRNA was increased in rats with UUO exposed to 150ppm of F than in those exposed to 0 and 75ppm of F. These observations suggest that F develops tubulointerstitial fibrosis in rats with UUO via increased action of TGF-β1.

**2048** Effects of Cadmium (Cd) on the Localization of Cystatin C and Megalin in Rat Kidney

W. C. Prziołalek, A. Van Drell, J. Edwards, P. C. Lamar, C. Ackerman, I. Stock and A. Papielaoui. Dept of Pharmacology, Midwestern University, Downers Grove, IL.

Cadmium (Cd) is a nephrotoxic environmental pollutant for which there is a need for improved biomarkers of toxicity. Cystatin C is a low molecular weight protein (13.3 kilodaltons) that is being investigated as a potential biomarker of the early stages of Cd-induced kidney injury. During recent studies in this area, we found that the general patterns of cystatin C localization in the proximal tubule seemed to correspond to, but not exactly mimic, those of the proximal tubule transport protein megalin and that Cd seemed to alter the localization of both proteins. In the studies described here, we have developed a procedure for the dual immuno-fluorescence labeling of cystatin C and megalin in single sections of rat kidney. Cryosections were incubated overnight in primary antibodies-rat antimegalin (ab-camsa/7699) and goat anticystatin C (abcam; ab176462) followed by incubation in the respective secondary antibodies, a TRITC conjugated chicken anti rabbit IgG (abcam; ab6826) and an Alexafluor 488 conjugated donkey anti goat IgG (abcam; ab50129), and then processed for confocal microscopic imaging. In control samples, both cystatin C and megalin exhibited speckled patterns of labeling in an area just beneath the brush border of the proximal tubule epithelial cells. By contrast tissue samples from animals that had been treated with Cd (0.6 mg subcutaneously, 5 days per week for 6, 9 or 12 weeks) showed diffuse labeling of both molecules along the apical cell surface, with retraction and deterioration of the apical brush border. These changes coincided with an increase in the urinary excretion of cystatin C. These results provide further evidence that Cd increases the urinary excretion of cystatin C and they suggest that this effect may result from disruption of the megalin-mediated transport in the proximal tubule.

**2049** Zn-Excess Intake Increases Systemic Blood Pressure and Deteriorates Renal Function through Superoxide Radical-Induced Oxidative Stress

H. Yanagisawa and T. Kido. Department of Public Health and Environmental Medicine, The Jikei University School of Medicine, Tokyo, Japan. Sponsor: M. Tsunoda.

In recent years, foods and tablets with addition of the essential trace element, zinc (Zn), have been sold for the maintenance of good health and for health promotion. However, Zn toxicity due to Zn-intake excess has not been fully established. Using rats fed 22 g/day of a control diet containing 0.005% (1.1 mgZn/day) Zn or two Zn-excess diets containing 0.05% (11 mgZn/day) or 0.2% (44 mgZn/day) Zn for 4 weeks, we examined whether or not Zn-excess intake affected systemic blood pressure (BP) and renal function. An increase in Zn intake elevated systolic BP, diastolic BP and mean arterial pressure (MAP), and reduced renal blood flow (RBF) and inulin clearance in a dose-dependent manner. This decline in inulin clearance may be the result of a fall in RBF. Administration of the nitric oxide (NO) synthase inhibitor, L-NAME, markedly increased MAP and significantly decreased RBF in the three groups of rats. Inversely, administration of the exogenous superoxide radical scavenger, tempol, significantly increased MAP and substantially increased RBF in the three groups of rats. Resultantly, tempol dramatically restored MAP and RBF levels in rats fed two Zn-excess diets to levels comparable to those observed in rats fed a control diet. These observations suggest that both an elevation in systemic BP and a reduction in RBF seen in the two Zn-excess diet groups result from a decrease in the action of the vasodilator, NO through the formation of peroxynitrite based upon the non-enzymatic reaction of NO and increased superoxide radical. Indeed, the activity of the endogenous superoxide radical scavenger, Cu/Zn-superoxide dismutase, was significantly reduced in the vesicular wall of rats fed two Zn-excess diets vs. a control diet. Thus, Zn-excess intake increases systemic BP and deteriorates renal function through the oxidative stress caused by superoxide radical. In addition, the lowest observed adverse effect level (LOAEL) of Zn appears to be approximately 11 mg/day.

**2050** Epigenetic Changes in p21 Expression in Renal Cells after Exposure to Bromate

N. E. Scholza, X. Zhang and B. S. Cummings, Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.

This study tested the hypothesis that bromate (KBrO3)-induced renal cell death is mediated by epigenetic mechanisms. Global DNA methylation, as assayed by 5-methylcytosine staining, was not changed in normal rat kidney cells treated with acute cytotoxic doses of KBrO3 (100 and 200 ppm), as compared to controls. However, KBrO3 treatment did increase p58, p53 and histone 2AX (H2AX)
phosphorylation, and p21 expression. Treatment of cells with inhibitors of DNA methyltransferase (5-azacytidine or 5-Aza) and histone deacetylase (trichostatin A or TSA) in addition to KB03 increased cytotoxicity, compared to cells exposed to KB03 alone. 5-Aza and TSA co-treatment did not alter p38 or p53 phosphorylation, but slightly decreased H2AX phosphorylation, and significantly decreased p21 expression. We also assessed epigenetic changes in cells treated under sub-chronic conditions with environmentally relevant concentrations of KB03. Under these conditions (0-10 ppm KB03 for 28 days), we detected no increases in cell death or DNA damage. In contrast, slight alterations were detected in the phosphorylation of H2AX, p38 and p53. Sub-chronic low dose KB03 treatment also induced a biphasic response in p21 expression, with lower concentrations increasing expression, but higher concentrations decreasing expression. Methylation specific PCR demonstrated that sub-chronic KB03 treatment decreased the methylation of cytosine bases in the p21 gene, as compared to controls. Decreases in cytosine methylation correlated to alterations in p21 protein expression. Collectively, these data show the novel finding that KB03-induced renal cell death is altered by inhibitors of epigenetic modifying enzymes and that KB03 itself induces epigenetic changes in the p21 gene.

**2051 Effects of Proguanil Hydrochloride on Selected Hematological, Liver, and Kidney Function Indices in Rats**

Proguanil is a prophylactic antimalarial drug often used in combination with other drugs, such as atovaquone. However, the toxicity of this compound has not been fully elucidated. In this study, effects of sub-chronic administration of proguanil on selected haematological, liver and kidney function indices were investigated. Forty rats were randomly divided into four groups (i.e. A, B, C and D). Rats in group A (control) were orally administered distilled water while rats in groups B, C and D were orally administered 2.86, 5.71 and 11.43 mg/kg body weight of proguanil hydrochloride respectively for 28 days. The rats were then sacrificed and the full blood count with selected liver and kidney function indices were determined. The results revealed that the drug, at all doses, caused no significant alteration (P>0.05) to platelet count, total white blood cell count, percentage neutrophils, percentage lymphocytes and serum urea, uric acid and creatinine concentrations compared to controls. Moreover, the drug at all doses did not significantly alter (P>0.05) γ-glutamyl transferase activity compared to control. However, the haemoglobin concentration, red blood cell count, mean corpuscular volume, mean corpuscular haemoglobin concentration, mean corpuscular haemoglobin, packed cell volume and serum albumin concentration were significantly reduced at the highest dose of the drug administered compared to controls. The results suggest that proguanil may cause haemolysis and inhibit albumin synthesis in the liver at higher doses; thus, its abuse should be avoided.

**2052 Proteomic Biomarkers for Early Detection of Acute Kidney Injury (AKI) in Rats**

H. Kim1, T. Kim1, E. Lee2, E. Park2, B. Jung1, M. Shin1 and B. M. Lee1.

1School of Pharmacy, Sungkyunkwan University, Suwon, Republic of Korea and 2College of Pharmacy, Pusan National University, Suwon, Republic of Korea.

Traditional urinary biomarkers for the diagnosis of acute kidney injury (AKI) are insensitive and nonspecific. Our studies were carried out to evaluate whether ald-o-keto reductase subfamily (Akr7a1) and selenium-binding protein-1 (SBP-1) might be used as early biomarkers for the detection of AKI. In this study, urinary Akr7a1 and SBP-1 levels were significantly decreased in the nephrotoxicants-treated groups when compared to control group. In contrast, urinary Kim-1, MMP-9, and NAG release were the inflammatory markers.

- BPA at non-cytotoxic concentrations is capable of increasing the expression/secretion of COX-2/PGE2 and cytokines in MMC, and imply that BPA may cause inflammatory response in renal glomeruli and influence the renal function.
- The interleukin-1β (IL-1β) levels were also increased in MMC culture medium after BPA treatment. BPA could also activate the AMP-activated protein kinase (AMPK), which plays an inflammation regulator. Taken together, these results indicate that BPA at non-cytotoxic concentrations is capable of increasing the expression/secretion of COX-2/PGE2 and cytokines in MMC, and imply that BPA may cause inflammatory response in renal glomeruli and influence the renal function.

**2053 Deficiency in Mdr1/MDR1 Increases Paraquat Accumulation and Toxicity in Mice and Human Renal Proximal Tubule Cells**

X. Wen1, C. J. Gibson2, I. Yang3, B. Buckley2, J. Richardson1, 2, 3, M. J. Gooden1 and E. M. Aleksunes1, 2.

1Pharmacology and Toxicology, Rutgers Univ, Piscataway, NJ, 2Environmental and Occupational Health Sciences Institute, Rutgers Univ, Piscataway, NJ, 3Environmental & Occupational Medicine, Rutgers Univ, Piscataway, NJ and 4Pathology, Merck Research Laboratories, Kenilworth, NJ.

Paraquat is a highly toxic herbicide that targets the lungs and kidneys following acute exposures. Prior studies demonstrated that the organic cation transporter 2 and multidrug and toxin extrusion 1 protein contribute to the urinary excretion of paraquat in the kidneys. The purpose of this project was to determine whether the multidrug resistance protein 1 (MDR1/Mdr1, Abc1) also participates in the efflux of paraquat from the kidneys and protects against renal injury. Paraquat transport and toxicity were quantitated in human renal proximal tubule epithelial cells (RPTEC) that endogenously express MDR1. Inhibition of MDR1 function by PSC833 or siRNA increased the cellular accumulation of paraquat in RPTEC cells by > 50%. Reduced efflux was accompanied by enhanced cytotoxicity of paraquat (50% decrease in the LC50 value) in PSC833-treated cells. To determine the role of Mdr1 in vivo, renal paraquat accumulation and subsequent nephrotoxicity were assessed in wild-type and Mdr1a/-/b-null mice administered paraquat (10 or 30 mg/kg, i.p.). The kidneys of Mdr1a/-/b-null mice had a 750% higher paraquat concentration compared to wild-type mice at 4 h. This was accompanied by significantly greater mRNA induction of kidney injury-responsive genes Kim-1 and Npg1 in paraquat-treated Mdr1a/-/b-null mice. Histopathological analysis confirmed the enhanced paraquat toxicity, as more extensive tubular degeneration was observed in Mdr1a/-/b null mice compared to wild-type mice. In conclusion, Mdr1/MDR1 contributes to the elimination of paraquat from the kidneys and protects against toxicity (Supported by DK093903, ES020522, ES050522, ES007148).

**2054 Bisphenol A Induces Inflammatory Response and Cytokine Release in Renal Mesangial Cells**

B. Chen1, C. Wu1, S. Liu1, C. Chiang2, C. Huang4 and Y. Chen4.

1Institute of Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan, 2Department of Integrated Diagnostics & Therapeutics, College of Medicine and Hospital, National Taiwan University, Taipei, Taiwan, 3Graduate Institute of Chinese Medical Science, School of Chinese Medicine, China Medical University, Taichung, Taiwan and 4Department of Physiology and Graduate Institute of Basic Medical Science, China Medical University, Taichung, Taiwan.

Bisphenol A (BPA) is a common ingredient of plastic products, which wildly exists in daily life. In addition to reproductive toxicity, renal toxicity has also been implicated during BPA exposure. BPA exposure has been demonstrated to be associated with low-grade albuminuria in adults. Mesangial cells play an important role in renal glomerular filtration rate. However, the detailed action and mechanism of BPA-induced renal toxicity are still unclear. Here, we investigated the effect and possible mechanism of BPA on glomerular mesangial cells. In this study, mouse mesangial cell (MCC) were treated with 0–100 μM BPA. Cell viability was not affected by 25 and 50 μM BPA after 24 h treatment, but cell viability was decreased to 90% under treatment with 100 μM BPA. BPA 100 μM did not increase the cell apoptosis by PI-Annexin V staining. BPA treatment also did not change the caspase-3 and PARP cleavages in MCC. In renal cells, cyclooxygenase (COX-2) prostaglandin (PG) E2 and interleukin-1β release were the inflammatory markers. After BPA treatment, COX-2 protein expression and PGE2 secretion and nuclear factor κ-B (NFκB)-p65 phosphorylation in MCC were increased in a dose-dependent manner. The interleukin-1β levels were also increased in MCC culture medium after BPA treatment. BPA could induce the AMP-activated protein kinase (AMPK), which plays an inflammation regulator. Taken together, these results indicate that BPA at non-cytotoxic concentrations is capable of increasing the expression/secretion of COX-2/PGE2 and cytokines in MMC, and imply that BPA may cause inflammatory response in renal glomeruli and influence the renal function.

**2055 Cell-Based Approach to Predict Kidney Toxicity**

M. Adler1, 2, E. M. Gortwald1, 2, A. K. Aiyar3, X. Lu4, M. Hafner2, A. Subramanian1, P. Sorger1 and V. S. Vaidya1, 2, 3.

1Brigham and Women’s Hospital, Boston, MA, 2Harvard Medical School, Boston, MA and 3Broad Institute of MIT and Harvard, Cambridge, MA.

Kidney toxicity due to drugs and environmental contaminants accounts for significant patient mortality and morbidity. Current approaches to conduct safety and risk assessment of compounds rely predominately on animal studies and ex-
trapolation of the dose effects to humans although the typical response of animal models and humans can differ greatly. The objective of this study was to develop a cell-based high-throughput assay to identify potential nephrotoxic compounds using primary human proximal tubular epithelial cells (HTPEC). We show that HTPECs grown on a monolayer possess structural (e.g. expression of zonula occludens-1, cytokeratin 18) and functional characteristics (transport and glutathione activity) that are more representative of human kidney than immortalized kidney cell lines. To identify a biomarker of kidney toxicity in vitro, we treated HTPECs with known nephrotoxicants (cyclosporin A, cisplatin, tacrolimus, gentamicin, tobramycin, aristolochic acid, cadmium chloride, ochratoxin A, doxorubicin) as well as a non-toxicant (carboplatin) in at least 6 concentrations for 3, 6, 12 and 24 h. We measured 1,000 selected transcripts, which are a reduced representation of the genome and from which the remainder of the transcriptome can be computationally inferred. Here oxygenase-1 (HO-1) was identified as one of the most differentially expressed genes after incubation with kidney toxicants, confirming in vivo reports of its significant increase in mice, rats and humans during kidney injury. Increases in the HO-1 mRNA (RT-PCR) and protein (ELISA) levels correlated well with morphological changes in the cells. We then developed and optimized a homogenous time-resolved fluorescence (HTRF) assay that allows high-throughput measurement of HO-1. Alterations in the HO-1 levels measured by HTRF correlated with ELISA (r2=0.97). We demonstrate an alternative approach to pre-screen a large number of compounds for kidney toxicity, thus reducing and replacing the use of animals in preclinical toxicity studies.

2056 Cyclosporin A-Induced Apoptosis in Renal Proximal Tubular Epithelial Cells Is Associated with Trb3 Induction

D. Germano, M. Uteng, S. Chibure, P. Pognan and A. Wolf, Discovery & Investigative Safety, Novartis Pharma AG, Basel, Switzerland.

Cyclosporine (CsA) is currently the primary immunosuppressant for the prevention of allograft rejection in solid organ transplantation. However, chronic treatment with CsA results in nephrotoxicity. Tubular cell apoptosis contributes to the pathogenesis of renal injury, but the molecular mechanisms are poorly understood. CsA is known to provoke endoplasmic reticulum (ER) stress, but the role of mediators involved in the processes leading to apoptosis remains elusive. In this study, the immortalized human renal proximal tubular epithelial cell line (RPTEC/TERT1) was used. Occurrence of reactive oxygen species (ROS), dephosphorylation of mitochondrial membrane potential (AMF), apoptosis by caspase 3/7 activation and necrosis were measured with the use of specific fluorescent dyes by high content imaging (HCl) microscopy technology. Exposure of RPTEC/TERT1 to CsA for 48 hours resulted into dose-dependent ROS production, increased apoptosis and necrosis. The expression of ER stress-related genes CHOP, ATF4 and Trb3 together with pro-apoptotic genes was markedly increased. Silencing of Trb3 with specific siRNA resulted into decreased dissipation of mitochondrial membrane potential and protected significantly from CsA-induced apoptosis and necrosis. In addition, Trb3 silencing promoted the activation of the AKT-dependent pro-survival pathway following CsA exposure. Thus, our data suggest that Trb3 has a crucial role during ER stress-induced apoptosis upon treatment with CsA, and therefore serve as a potential target for nephroprotective treatments.

2057 MiR-27b Regulates Podocyte Function by Targeting Adenosine Receptor

Z. Li, B. L. Homer, S. O’Neill and R. Nassipour, Pfizer, Andover, MA.

MicroRNAs (miRNAs) have been shown to be crucial not only in kidney development and normal renal function but also in various kidney diseases. In this study, we investigated the potential role of miRNAs as key regulators of podocyte injury. We first characterized the miRNA expression patterns in glomeruli as well as in primary podocyte cultures isolated from three different mammalian species: mouse, rat, and non-human primate (NHP). Profiling miRNA expressions led to the identification of a list of highly-conserved glomerulus-enriched and podocyte enriched miRNAs. We then examined if podocyte injury induced by application of a nephrotoxicant, puromycin aminonucleoside (PAN), alters the expression pattern of miRNAs in vitro. As reported previously, PAN not only induced apoptosis but also significantly down-regulated several podocyte enriched miRNAs, including miR-27b. By manipulating the expression level of this miRNA, we found that overexpression of miR-27b in vitro enhanced PAN-induced apoptosis in podocytes while its inhibition promoted survival. Target identification analysis identified Adora2b as a potential target for miR-27b. In fact, ectopic expression of miR-27b suppressed both Adora2b mRNA and protein expression in primary podocyte cultures. Not surprisingly, inhibition of miR-27b increased the transcript and protein expression levels of Adora2B.

2058 Inhibitors of Ceramide Synthesis Protect Mice from Cisplatin-Induced Acute Kidney Injury

T. Dupre, A. R. Mather and L. J. Siskind. Pharmacology and Toxicology, University of Louisville, Louisville, KY.

Acute kidney injury (AKI) resulting from cisplatin administration remains to be an obstacle in chemotherapeutic treatments. Cisplatin-induced AKI involves apoptotic and necrotic cell death of the proximal tubules (PT). Pathways known to be regulated by the sphingolipid ceramide, PT cells grown in culture elevate ceramides when treated with apoptotic or necrotic doses of ceramide as a result of the activation of ceramide synthase (CerS) and acid sphingomyelinase (aSMase), respectively. Thus, we hypothesize that inhibitors of ceramide synthesis will protect mice from cisplatin-induced nephrotoxicity. To test this hypothesis, we used cisplatin-induced (25 mg/kg) AKI in C57BL/6 mice. At twenty-four hours C16, C20, and C24:1-ceramides were increased in the kidney cortex of cisplatin treated mice, concomitant with elevated CerS and aSMase activities. Mice pretreated for 3 days with the de novo synthesis inhibitor myriocin and the aSMase inhibitor amiprityline were protected from cisplatin-induced AKI. At 72 h post cisplatin injection, serum creatinine and BUN levels were measured, showing a significant decrease in mice treated with cisplatin inhibitors as compared to the levels observed in vehicle control mice. In conclusion these data indicate that inhibitors of aSMase and de novo ceramide synthesis protect mice from cisplatin-induced nephrotoxicity. As amiprityline is already FDA approved for use in humans and myriocin is well tolerated in multiple mammalian models, these data these data show high potential for translational use for the prevention of AKI during chemotherapy treatment. This work was supported by R01 DK093462 (to L.J.S.).

2059 Methyl Isobutyl Ketone (MIBK) Induces an Exposure-Related Increase in Measures of α2u-Globulin (α2u) Nephropathy in Male but Not Female F344 Rats

S. Berghoff1, G. G. Hard2, T. S. Page1, J. Davis1, S. M. Green3, B. J. Hughes4, T. Mensing1 and S. S. Sarang4, ToxStrategies, Inc, Cary, NC, 2Private Consultant, Taurua, New Zealand, 3Summit Toxicology, Richland, WA, 4ILS Inc, Morrisville, NC, 5Eastman Chemical, Kingsport, TN, 6Dow Chemical, Midland, MI, 7Sasol Solvents, Moer, Germany and 8Shell International, Houston, TX.

Chronic exposure to MIBK caused an increased incidence of renal tubular adenomas and occurrence of renal tubular carcinomas in male, but not female rats. A number of chemicals have been shown to cause male rat renal tumors through the α2u nephropathy-mediated mode of action (MOA). The objective of this study was to evaluate the ability of MIBK to induce measures of α2u nephropathy in male and female F344 rats following exposure to the same inhalation concentrations used in the cancer bioassay (0, 450, 900, or 1800 ppm). Rats were exposed 6 hours/day for 1 or 4 weeks and kidneys excised approximately 18 hours post exposure to evaluate hyaline droplet accumulation (HDA), α2u nephropathy, sustained increase of α2u concentration at 6 hours post exposure, α2u nephropathy, sustained increase of α2u concentration at 6 hours post exposure, α2u nephropathy, sustained increase of α2u concentration at 6 hours post exposure. At 18 hours post exposure to evaluate hyaline droplet accumulation (HDA), α2u staining of hyaline droplets, renal cell proliferation, and to quantitate renal α2u concentration at both 1 and 4 weeks. There was an exposure-related increase in all measures of α2u nephropathy in the male, but not female rat kidneys. The hyaline droplets present in the male rat kidney stained positively for α2u. The changes in HDA and α2u concentration were comparable to d-limonene, an acknowledged inducer of α2u nephropathy, sustained increase of α2u concentration at 6 hours post exposure, α2u nephropathy, sustained increase of α2u concentration at 6 hours post exposure. At 18 hours post exposure to evaluate hyaline droplet accumulation (HDA), α2u staining of hyaline droplets, renal cell proliferation, and to quantitate renal α2u concentration at both 1 and 4 weeks. There was an exposure-related increase in all measures of α2u nephropathy in the male, but not female rat kidneys. The hyaline droplets present in the male rat kidney stained positively for α2u. The changes in HDA and α2u concentration were comparable to d-limonene, an acknowledged inducer of α2u nephropathy, sustained increase of α2u concentration at 6 hours post exposure, α2u nephropathy, sustained increase of α2u concentration at 6 hours post exposure.
Aristolochic acid (AA)-induced renal lesions are related to increased renal levels of methylglyoxal (MGO) and N-[(carboxymethyl)lysine (CML) which is an advanced glycation end product (AGE). Metformin is a generally accepted drug for the treatment of type 2 diabetes mellitus, and is considered as an MGO scavenger and AGE inhibitor. This study investigated the renal MGO and CML scavenging ability of metformin, and its effect on renal function in C57BL/6 mice with AA-induced renal lesions. Mice were treated with metformin orally (12 or 24 mg/kg BW/day) for 15 days, and injected intraperitoneally with AA (5 mg/kg BW/day) for 8 days since day 8. Following injection of AA into mice for 8 days, decreased renal function was observed according to biochemical indexes and histopathological test results. Administration of metformin ameliorated the renal lesions, especially at a dose of 12 mg/kg BW. The concentration of renal MGO in AA-injected, untreated mice (without metformin) was approximately 6-fold higher than that in the control mice (37.33 ± 7.98 vs. 5.89 ± 2.64 μg/mg of protein, p < 0.01, respectively). CML was also observed in the renal tubules of AA-injected, untreated mice by immunohistochemistry. Administration of metformin at the two tested doses reduced renal MGO levels to 9.81 ± 5.04 μg/mg of protein in the 12 mg/kg BW-treated mice and 17.79 ± 7.80 μg/mg of protein in the 24 mg/kg BW-treated mice, and attenuated the accumulation of CML in the kidney. In this study, we found that metformin decreased renal MGO and CML levels, and improved renal function in AA-injected mice, which confirmed that metformin may be a suitable therapy for AA nephropathy due to its ability to control MGO and CML accumulation.

2061 Altered Expression of Renal Drug Transporters in Multiple Rodent Models of Nonalcoholic Steatohepatitis

M. Canet, R. N. Hardwick, A. D. Lake, A. L. Dziereenga, J. Clarke and N. J. Cherrington. Pharmacology and Toxicology, University of Arizona, Tucson, AZ.

Nonalcoholic fatty liver disease (NAFLD) is the most common form of chronic liver disease in Western society. NAFLD represents several stages of liver damage ranging from simple steatosis to the more advanced nonalcoholic steatohepatitis (NASH). Current experimental models of NASH include diet-induced models such as the mouse models of diet-induced obesity, such as high-fat diet, ob/ob and db/db mice, and fa/fa rats. Previous investigations have demonstrated alterations in the expression and activity of multiple hepatic drug transporters in human NASH, but little information is currently known regarding extra-hepatic regulation of drug transporters in NASH. The purpose of the current study was to characterize and investigate the regulation of renal drug transporters across multiple experimental rodent models of NASH. Both rat and mouse NASH models were utilized in this investigation and included the MCD diet, atherogenic diet, ob/ob and db/db mice, and fa/far rats. Histologic and pathological evaluations confirmed that the MCD and atherogenic rats as well as the ob/ob and db/db mice all developed NASH. In contrast, the fa/far rats did not develop NASH; however, despite a lack of liver damage; renal histology suggests that the fa/far rats develop significant renal injury in comparison to the NASH-confirmed models. Investigation into the kidney mRNA expression of drug transporters showed that among the rodent models, the animals with confirmed NASH such as the rat MCD diet model and the ob/ob and db/db mice developed more, total alterations in miRNA and protein expression. In general, the majority of drug efflux transporters are induced by NASH while drug uptake transporters are both induced and repressed; at the mRNA and protein level. These results suggest that NASH alters the expression and possibly function of renal drug transporters, which would disrupt drug elimination mechanisms in the kidney.

2062 Resveratrol Reduces Doxorubicin Cytotoxicity in Human Kidney (HK-2) Cells

L. K. Vu‡, G. O. Rankin†, H. Hedrick, J. G. Ball and M. Valentić†

1Pharmacology, Physiology and Toxicology, Marshall University School of Medicine, Huntington, WV and 2University of West Virginia, Charleston, WV.

Doxorubicin (DOX), or Adriamycin, is a cancer chemotherapeutic agent used in treatment of breast cancer, ovarian, small cell lung cancer, acute and chronic lymphoid leukemia. DOX is both cardiotoxic and nephrotoxic. Resveratrol (RES) is a phytochemical found in grapes, berries, and nuts. RES possesses antioxidant and anticancer properties. This study tested the hypothesis that RES will reduce DOX cytotoxicity in human noncancerous renal proximal tubular epithelial cells (HK-2) and RES will attenuate DOX mediated oxidative stress. HK-2 cells were grown for 48 h. Cells were then pre-incubated for 1 h with 0 (DMSO), 5, or 7.5 μM RES followed by a 24 or 48 h co-incubation with 0, 1, or 2 μM DOX. Cell viability was assessed using the AlamarBlue assay. Results showed that DOX decreased cell viability in a concentration dependent manner and RES increased cell viability in cells exposed to DOX. Protein carbonyls, an indicator of oxidative stress and detected by Oxyblot Western analysis, were increased by DOX and reduced by RES. Additionally, RES decreased protein carbonyls in cells exposed only to RES. ADP/ATP and GTP and RES pretreatment of cells following DOX exposure. RES reduced DOX cytotoxicity in HK2 cells at DOX concentrations that are clinically relevant. (Supported by NIH Grant 5P20RR016477 to the West Virginia IDeA Network for Biomedical Research Excellence).

2063 Inhibition of TGF-β1-Induced Renal Epithelial Mesenchymal Transition by Chrysin

R. Nagavally and S. M. Ford. Toxicology Program, St. John’s University, Jamaica, NY.

Epithelial mesenchymal transition (EMT) has been suggested as mechanism in the development of fibrosis, such as occurs in the response to certain toxicants. It is a process in which a polarized epithelial cell is converted into a motile mesenchymal cell. Mesenchymal-specific proteins required for movement, invasion and fibrosis are acquired as the epithelial cell proteins necessary for the function of epithelial tissue are lost. In the current study, we tested the effect of a flavonoid in a cell-culture model of EMT. To induce EMT, we use transforming growth factor-β1 (TGF-β1) which is a cytokine activated in most cases of fibrotic injury. Chrysin, a flavonoid extracted mainly from passion flowers, was examined for its ability to inhibit EMT induced by TGF-β1 in the LLC-PK1 cell line. Cells were treated with TGF-β1 alone or TGF-β1 + chrysin. Effects on the mesenchymal markers collagen, α-skeletal muscle actin, and vimentin were evaluated as indicators of EMT. The amount of collagen in the cells was determined by the Sirius red assay. Collagen content was significantly increased from 93 ± 8 μg collagen/mg total protein in the control group to 127 ± 8 μg collagen/mg total protein in the TGF-β1 treated group. In the group treated with both TGF-β1 + chrysin, collagen was significantly reduced to 104 ± 6 μg collagen/mg total protein. The expression of α-smooth muscle actin and vimentin was determined by immunocytochemistry. Mouse primary antibodies were tagged using an anti-mouse IgG conjugated with FITC. The specimens were evaluated by widefield microscopy at 20X magnification. Treatment with TGF-β1 increased the expression of mesenchymal markers, whereas in the presence of TGF-β1 + chrysin the expression of both α-smooth muscle actin and vimentin resembled the untreated controls. These results demonstrate that chrysin can inhibit TGF-β1-induced EMT in LLC-PK1 cells.
in 3,4,5-TCA nephrotoxicity in vitro, and that these oxidative species arise from biotransformation by cyclooxygenase activity or via CYP isozymes inhibited by PiBS but not metyrapone.

2065 Renal Epithelial Hyperplasia Caused by Urinary Crystals of a Novel GKA and Its Metabolites after Acute Dosing in Sprague-Dawley Rats

Renal toxicity caused by crystal formation in the urine is well-established for some drugs, industrial chemicals, food additives, and naturally occurring toxins but toxicity typically requires long term dosing to cause measurable changes in urinary system morphology and/or function. Compound A, a novel glucokinase activator (GKA), caused crystal formation in the urine with accumulation in the collecting ducts accompanied by renal transitional epithelial hyperplasia with neutrophil infiltration after only 4 consecutive daily doses in female Sprague Dawley rats. A second study dosing Compound A at 600mg/kg/day for 1, 2 or 4 consecutive days was performed to explore the unusually rapid progression of the hyperplasia and identify the crystals. Findings after a single dose included crystals in urine and kidneys and clinical pathology changes indicating inflammation and decreased renal function. Additional findings after 2 doses included renal transitional epithelial hyperplasia with neutrophil infiltration. No changes were observed in urinary bladder epithelium. Crystals in the kidneys were identified as Compound A and two major metabolites by MALDI mass spec imaging. Urinary system findings observed with Compound A have not been seen with other internally tested GKAs of similar structure nor GKA reported in the literature, suggesting that it is unrelated to the biology of glucokinase activation. The renal toxicity caused by Compound A highlights possible rapid onset of such effects and acute toxicity studies could benefit from additional endpoints to more clearly define the nature of such findings if the potential exists for renal toxicity to occur.

2066 Are Succinate and Diglycolic Acid Taken Up into Human Kidney Proximal Tubule Cells by the Same Sodium Dicarboxylate Transporters?

C. N. Robinson, G. M. Landey, C. Dunning and K. McMartin. Pharmacology, Toxicology & Neuroscience, LSU Health Sciences Center, Shreveport, LA.

Diglycolic acid (DGA) is now considered to be the primary toxic metabolite of diethylene glycol (DEG), leading to the acute kidney injury from DEG overdose. DGA is a four-carbon dicarboxylic acid, with structural similarity to the TCA cycle intermediate, succinate. We hypothesize that DGA and succinate are taken up by the same sodium dicarboxylate transporter (NaDC) located in the proximal tubule cells of the kidney. This study compared the intracellular uptake of DGA and succinate, via apical (NaDC-1) and basolateral (NaDC-3) transporters. Human kidney proximal tubule cells were cultured until confluent, then subcultured onto membrane inserts in 24 well plates, that allow for distinct apical and basolateral uptake. Using 14C-substrates, uptake was measured at increasing time points and concentrations for both succinate and DGA, along with measurements of sodium dependence of the NaDC transporters. Cellular uptake of succinate from both the apical and basolateral membrane demonstrated sodium dependence, suggesting mediation via NaDCs, with somewhat higher uptake by the apical NaDC-1. Uptake of DGA was not sodium dependent from the apical direction and was not saturable, suggesting a transporter-independent mechanism. Basolateral uptake of DGA was sodium-dependent and was saturable with a Km of about 16 mM/L. The magnitude of DGA uptake at non-toxic concentrations was greater from the basolateral side than the apical. These results suggest that DGA and succinate transport have differing characteristics in human kidney cells.

2067 Transporter Function and Response to Nephrotoxins in a p16-Mutated Human Renal Proximal Tubule Epithelial Cell Line

T. Steiner, N. Venkatraman, Y. Xiao, J. Blasberg, M. Bourner and D. C. Thompson. Sigma-Aldrich, St. Louis, MO.

Kidney toxicity is a continuing concern during drug development. Although primary human kidney cells are available and a handful of immortalized kidney cell lines currently exist, there is a need for improved assay systems. We modified human primary renal proximal tubule epithelial cells by knocking out p16, a cyclin dependent kinase inhibitor, thereby enabling extended cell proliferation. The resulting cell line was characterized for the presence of proximal tubule cell markers as well as several functional properties, including transporter activity and response to known human nephrotoxins. Two uptake (OAT1, OCT1) and two efflux (MDR1, MRP2) renal transporters were studied. Transporter assays were carried out on poly-D-lysine coated 24-well plates at a seeding density of 0.5 million cells/well for 10 (uptake) or 30 min (efflux). Concentration-dependent uptake of the OCT1 substrate taurocholic acid (TEA) and the OAT1 substrate p-aminohippuric acid (PAH) were observed. Verapamil and probenecid inhibited TEA and PAH uptake by 33 and 66%, respectively. For the efflux transporters, MRP2-mediated efflux of carbonyldichlorofluorescein (CDCF) was inhibited using MK571, leading to a 3.25-fold increase in intracellular CDCF. Similarly, MDR1-mediated efflux of calcine was inhibited with cyclosporin A, leading to a 7-fold increase in intracellular calcine. The cell line was also tested for sensitivity to several nephrotoxins. Concentration-dependent cytotoxicity (48 hr, MTT assay, IC50) was observed with each of the test compounds, including gentamicin (3 mM), cisplatin (20 μM), tacrolimus (75 μM), potassium dichromate (25 μM) and diglycolic acid (7.5 μM), the proposed nephrotoxic metabolite of diethylene glycol. The presence of functional uptake and efflux transporters coupled with toxicant sensitivity suggest that the cell line may be useful for drug-transporter interactions and the early detection of renal toxicants.

2067a Development and Characterization of a Novel Cell-Based Model to Study MATE1- and MATE2K-Mediated Drug Uptake and Interactions

Transporter involved drug-drug interactions (DDIs) in the kidney can prolong the drug elimination half-life, leading to accumulation of victim drugs in the body, consequently causing pharmacological problems or renal toxicity. Multidrug and toxinn extrusion transporters (MATEs), e.g. MATE1 and MATE2K, localized on the apical membrane of proximal tubule cells are major transporters which mediate the excretion of important medications into the urine. Several studies have demonstrated that apical efflux by MATEs is one of the sites of DDI in the kidney. Therefore, the International Transporter Consortium (ITC) recommends studying the potential interaction of new molecular entities (NMEs) with MATE1 and 2K. A new “Thaw and Go” cell-based transporter model has been developed to evaluate MATE1 and MATE2K-based interactions, which enables early in vitro evaluation of potential MATEs involvement in drug induced renal toxicity. In the presence of oppositely directed H+ gradient or ammonium chloride-induced intracellular acidification, the transport activity of various cations, such as tetaethylammonium (TEA), mertformin and 1-methyl-4-phenylpyridinium (MPP) were significantly stimulated in hMATE1 and hMATE2K expressing cells for more than 10 fold compared to the control cells expressing the empty vector. The concentration dependent uptake of TEA and mertformin in hMATE1 and hMATE2K demonstrated “simple” Michaelis-Menten kinetics with Km value of 260μM and 355μM in MATE1, and 755μM and 1.2mM in MATE2K respectively. The inhibitory parameters of known drug inhibitors for MATEs verapamil, quindine, cimetidine and ritonavir were also determined using this model, which are comparable to literature reports. The study demonstrates the model is a compliant and useful in vitro tool to screen hMATE1 and hMATE2K involved drug interaction and/or drug induced renal toxicity in early stages of drug development.

2068 Exploring the Interface between Air Pollution and Metabolic Syndrome: The Bittersweet Dilemma

U. P. Kodavanti1 and I. G. Wagner. 1 EPHD, NHEERL, US EPA, Research Triangle Park, NC and 2Cardiorespiratory Toxicology, Michigan State University, East Lansing, MI.

The metabolic syndrome (MetS) affects approximately 32% of the US population and is expected to grow to 34% by 2020. The conventional risk factors, such as diet and sedentary lifestyle, do not fully explain this rising epidemic. Multiple lines
of epidemiological evidence show associations of high ambient air pollution with the incidence of metabolic disease, such as diabetes, and risk factors that comprise the metabolic syndrome. Coincident with uncontrolled air pollution in developing countries is improved lifestyle (less physical activity) and calorie-rich diets. These imply that there is likely an interaction between diet, metabolic processes, and injuries induced by inhaled pollutants. While new research on the contribution of air pollution to cardiometabolic derangements is emerging, the mechanisms by which airborne materials can affect multiple cardiovascular and metabolic pathways are unknown. The goal of this session is to present new data from both animal and human studies that shed light on the interaction of air pollutant exposure with both the incidence and exacerbation of diabetes, obesity, and cardiovascular disease. Some key issues to be addressed by presentations in this session include: What behavioral, dietary, and environmental factors contribute to the development of MetS and, subsequently, to type 2 diabetes and cardiovascular disease? How do obesity and other metabolic abnormalities interact to promote cardiovascular disease? How do air pollutant exposures alter cardiometabolic outcomes during controlled versus natural exposures in humans? How does diet-induced metabolic syndrome alter cardiovascular responses to single and multipollutant exposures? How does obesity predispose for exaggerated airway responses to pollutants? Lastly, how do air pollutants alter stress pathways and energy expenditure? Together, the presentations begin to answer these critical questions and provide some seminal examples of the toxic interface between diet, metabolic homeostasis, and air pollutant exposure.

### 2069 The Role of Overweight and Obesity in the Diabetics and Cardiorenal Syndrome

J. R. Sowers, Department of Internal Medicine, Diabetes and Cardiovascular Center, University of Missouri, Columbia, MO. Sponsor: U. Kodavanti.

The presence of a group of interactive maladaptive factors including hypertension, insulin resistance, metabolic dyslipidemia, obesity, microalbuminuria, and/or reduced renal function constitutes the cardiorenal metabolic syndrome (CRMS). Overweight, obesity, diabetes and chronic kidney diseases (CKD) have grown to pandemic proportions in industrialized countries during the past decade. The fact that these interactive factors promote heart and renal disease has been documented in large population-based studies. Obesity seems to be the driving force behind the development of heart disease, diabetes and CKD and therefore the CRMS. The relationship between overweight/obesity, insulin resistance and kidney disease begins in early childhood and appears to be related to overconsumption of high-fructose corn syrup and insufficient physical activity. Today, 13 million children are obese, and over 70% of these children are likely to become obese adults. Indeed, approximately 30% of male and 34% of female adults in the United States are obese. This lifestyle-related epidemic will be a major societal medical and economic problem that will accentuate the current epidemic of CRMS in the United States and other industrialized and emerging industrialized countries. This presentation will review the potential mechanisms by which obesity and other metabolic abnormalities interact to promote diabetes and cardiovascular disease. Some of the potential mechanisms might explain the role of air pollutants in exacerbating cardiometabolic disease.

### 2070 The Effects of Air Pollution Exposures on Aspects of the Metabolic Syndrome in Humans

R. Brook, Division of Cardiovascular Medicine, University of Michigan, Ann Arbor, MI. Sponsor: U. Kodavanti.

Particulate matter (PM) air pollution is associated with an increased risk of cardiovascular (CV) events over periods of both short and long-term exposures. While PM is capable of promoting CV morbidity by a variety of mechanisms, an important pathway may be via the potentiation of facets of the metabolic syndrome (MetS) including hypertension and insulin resistance. We have undertaken a series of human studies in the US and China that evaluated the acute and sub-acute effects of PM exposures upon several aspects of the MetS in humans. First, we performed a series of randomized double-blind cross-over studies of acute exposures to rural coarse concentrated ambient PM (CAP). Systolic (0.32 ± 0.74 mm Hg, p = 0.021) and diastolic (0.27 ± 0.77 mm Hg, p = 0.05) blood pressure (BP) linearly increased during the inhalation of coarse CAP (76.2 ± 51.5 μg/m-3) compared to filtered. Heart rate was higher and the ratio of low-to-high frequency heart rate variability increased together with circulating endothelial progenitor cells during CAP exposures. Second, the homeostasis model assessment of insulin resistance (HOMA-IR) was measured in 25 healthy adults living in rural Michigan were transported to an urban location for 5 consecutive days of daily 4-5-hour-long ambient air pollution exposures. A 10 μg/m-3 increase in sub-acute fine PM exposures was associated with increased HOMA-IR (p=0.7, p=0.023) and reduced heart rate variability (standard deviation of normal-to-normal intervals). Lastly, we evaluated the association between personal exposure to combustion-related BC [median=4.1 μg/m-3] with ambulatory BP and autonomic function in Beijing, China. An interquartile range increase in BC during the previous 10 hours was associated with an increase in systolic BP of 2.20 mmHg and diastolic BP of 1.55 mmHg. This series of experiments demonstrates that exposures to fine and coarse PM, as well as BC, are capable of increasing BP and impairing metabolic insulin sensitivity in humans. PM air pollution may be an important environmental factor contributing to global epidemic of the MetS.

### 2071 Cardiometabolic Interactions of Diet and Air Pollution: Field Studies with Multipollutant Atmospheres

J. G. Wagner, Cardiorespiratory Toxicology, Michigan State University, East Lansing, MI.

Metabolic conditions such as diabetes, insulin resistance and metabolic syndrome (MetS) might predispose an individual to adverse cardiovascular responses to air pollutant exposures. While health complications from exposure to various airborne pollutants have been modeled in rodents with hypertension and various cardiac diseases, comparable studies in animal models of metabolic disorders have not been conducted. This presentation will briefly survey the use of relevant animal models that study cardiovascular and metabolic outcomes, and will then focus on new results from a series of studies that use the high fructose-fed (HFr) rat model of diet-induced CMS. HFr- rats were exposed to ozone, fine particulate matter (PM2.5) or their combination, to test the hypotheses that: 1) adverse cardiovascular effects of air pollution would be exacerbated by the MetS and 2) coexposure to multipollutants would induce greater toxicological responses than to single pollutants. Prior to exposures, HFr rats had dyslipidemia, hepatic lipodisosis, and elevated blood pressure (BP) and heart rate (HR), but had depressed heart rate variability (HRV). Reductions in BP and HR by air pollutant exposures were exacerbated and prolonged in HFr rats. Interestingly, insulin resistance and lipid derangements were less severe in HFr rats after exposures. Results using this novel model of CMS will contribute to the development of prevention and intervention strategies to protect this susceptible population from the adverse cardiovascular effects of multipollutant atmospheres.

### 2072 Augmented Pulmonary Responses to Acute Ozone Exposure in Obese Mice: Roles of TNFR2, IL-13, and IL-17A

Acute ozone exposure results in more inflammation, greater changes in pulmonary mechanics, and greater airway hyperresponsiveness (AHr) in obese than lean mice. These obesity-related differences in ozone responses are observed both in genetically obese mice and in mice with diet induced obesity. Because obese mice have increased circulating TNF-α, and because TNF-α has been shown to play a role in responses to acute ozone in lean mice, we examined the role of TNF-α in the augmented responses to acute ozone exposure of obese mice. Lean wildtype (WT) and TNFR2 deficient (TNFR2-/-) mice, and obese Cpefat and TNFR2 deficient Cpefat mice (Cpefat/TNFR2-/-) were exposed to ozone (2 ppm for 3 h) or air. Ozone-induced increases in pulmonary mechanics, airway responsiveness, and cellular inflammation were greater in Cpefat than WT mice. In lean mice, TNFR2 deficiency ablated ozone-induced AHR, without affecting pulmonary inflammation, whereas in obese mice, TNFR2 deficiency augmented ozone-induced AHR but reduced inflammatory cell recruitment. Interestingly, ozone caused pulmonary expression of IL-13 in Cpefat but not WT mice. In Cpefat mice, anti-IL-13 attenuated ozone-induced increases in pulmonary mechanics and inflammation, but not AHR. There was no effect of anti-IL-13 in WT mice. Ozone also caused greater IL-17A expression in lungs of obese versus lean mice, and anti-IL-17A treatment attenuated ozone induced AHR and inflammation in obese but not lean mice. CD4+ cells were the source of both the IL-13 and the IL-17A induced by ozone in obese mice. These results indicate that pulmonary responses to ozone are not just greater, but qualitatively different in obese versus lean mice. In particular, in obese mice, ozone induces activation of CD4+ T cells, causing release of IL-13 and IL-17A that exacerbate the pulmonary effects of ozone, in part via synergism with TNF-α. The majority of the population of the US is either obese or overweight. Our results emphasize the need for improved understanding of the effects of ozone in this population.
Recent evidence suggests that air pollutant exposure impacts key metabolic processes and is linked to metabolic syndrome. Because ozone (O3) does not translocate systemically, neuronal pathways and/or systemic mediators released from lung injury are proposed to account for the metabolic impairment. Our studies provide evidence that short-term O3 exposure induces reversible metabolic alterations, including glucose intolerance and increases in blood leptin, glucose, fatty acids, and amino acids in rodent models. These metabolic alterations are reflected in transcriptional changes in the liver, consistent with increased catebolism (i.e., increased energy expenditure and reduced lipid synthesis). Liver metabolic processes are likely coordinated with changes in adipose and muscle metabolism. Because these O3-induced systemic changes are accompanied by large increases in circulating catecholamine (i.e., stress response), derangement of neurohormonally-mediated metabolic processes likely play a key role. Experiments using adrenalectomized rats confirm the role of circulating adrenal hormones for the induction of the acute metabolic response after acute O3 exposure. Collectively, data show that short-term air pollution exposure results in increased energy expenditure. Conversely, the hypothermic and bradycardia responses noted in rodents exposed to air pollutants suggest reduced energy demand. Currently systems approaches such as transcriptomics, proteomics, and metabolomics are being used to determine how these acute metabolic responses induced by O3 might relate to adaptation, and when elicited chronically, may result in disease (e.g., obesity, insulin resistance, and/or type 2 diabetes). (This abstract does not reflect USEPA policy).

We conducted a large-scale forward genetic screen in mice with chemical mutagenesis to elucidate the genetic etiology of structural birth defects. For this study, we developed a sophisticated mouse phenotyping pipeline entailing the combined use of noninvasive in utero fetal ultrasound imaging of pregnant dams, with follow up analysis of the abnormal fetuses and neonates using a combination of micro-CT, micro-MRI and histopathology examination by confocal epifluorescence image capture (EFIC). Confocal EFIC imaging is a histological imaging technique ideally suited for the analysis of complex anatomy associated with structural birth defects, as it allows any standard paraffin embedded sample to be imaged using native tissue autofluorescence, generating high resolution registered 2D image stack of the specimen suitable for seamless digital rescanning in any orientation and also rapid 3D rendering. Using this combined approach, we have screened over 70,000 fetal mice encompassing 4X genome coverage, and have recovered over 2,000 mutants exhibiting a wide spectrum of birth defects, including eye/craniofacial/brain malformations, limb and other skeletal anomalies, neural tube closure defects, congenital heart disease, and visceral organ defects such as multiple organ cysts, polycystic kidney disease, biliary atresia, intestinal malrotation/obstruction, kidney agenesis, hydrenephrosis, hydrourtourinary and bladder obstructions, thymus aplasia, and other visceral organ anomalies. Using whole mouse exome sequencing analysis, we have recovered the disease causing mutations in over 100 of the mutant mouse lines recovered from the screen. Together, these studies show the efficacy of our phenotyping pipeline for the diagnosis of birth defects in fetal/neonatal mice. Supported by NIH grant HL098188.

The lightsheet microscope uses cylindrical lenses to create laser sheets that illuminate a single z-plane at a perpendicular to the collection objective(s). This narrow plane of excitation reduces sample phototoxicity and allows capture of an entire z-plane at once, which greatly speeds collection of 3- and 4-dimensional imaging. Rapid imaging of entire zebrafish larvae at single time-points or over extended periods of time provides insight into biological responses throughout development. This presentation will provide an overview of the basic principles of Lightsheet microscopy, describe our glucocorticoid-responsive BioBanner fish, and provide sample Lightsheet images obtained from these fish.
reconstruction, visualization, segmentation, and registration. Examples of analyses using segmentation and registration of skeletal elements and visceral organs, which required contrast staining, will be presented. It will be evident that these latter techniques offer the potential for automated analysis of morphology. The use of micro-CT in other laboratories to assess developmental biology will be briefly reviewed. Conduct of positive control studies and studies with new drug candidates show that micro-CT evaluation of the fetal skeleton is equal to conventional evaluations after alizarin red staining. Relative to alizarin red evaluations, micro CT evaluations have not changed the NOEL and/or LOEL of a study. The incidences of a few minor skeletal abnormalities are either increased (e.g., incomplete ossification of sternebra 5 in rats and of metacarpal 1 in rabbits) or decreased (e.g., trace supernumerary ribs in rats) across all groups including controls by micro-CT compared to alizarin red evaluation. These differences are mainly due to the slightly lower resolution of the current scanner; however, a different scanner with higher resolution is under evaluation. Results of a study that scanned postnatal rat pups to assess skeletal changes in the same animals over time will be discussed. Such procedures will be useful in performing longitudinal studies. The ready availability of electronic images provided ample material for development of a web-based atlas. Discussion will conclude with our current efforts directed toward automated segmentation and analysis of all fetal rabbit skeletal elements in order to flag potentially abnormal fetuses for manual micro-CT evaluation.

2079 Imaging Data for Scientific Decision-Making in a Regulatory Context
S. L. Makris, ORD, NCCEA, US EPA, Washington, DC.

Imaging technologies that facilitate high resolution evaluation of the developing fetus and/or neonatal individual have been utilized with outstanding success in developmental research and clinical practice for many years. Innovative application of current technologies has historically been used to resolve complex scientific issues. In the research and clinical communities, there is a high degree of confidence in the derived information. Yet, there are likely to be many challenges that arise in bridging the gap between these widely accepted applications and regulatory decision-making for pharmaceuticals and environmental chemicals. This presentation will address the ways in which imaging technologies have been utilized in a regulatory context to date, and how they might be utilized in the future, particularly in the field of developmental toxicology. The pathway to achieve this goal remains under discussion. There are recognized benefits of implementing an organized and collaborative effort to address the collection, interpretation, and application of developmental toxicology imaging data. Establishing technical standards for imaging hardware and software, as well as methodological best practices for technological processes and procedures, would be useful in standardizing imaging within and across laboratories. Validation of developmental imaging technologies would need to include a demonstration of such inter- and intra-laboratory consistency in the detection of morphological alterations during development, the ability to detect effects from known developmental toxicants (positive reference chemicals), and evidence that imaging techniques provide, at the very least, a similar level of sensitivity and specificity as conventional developmental toxicity testing methods. Additionally, issues of increased efficiency, and cost vs. benefit would need to be explored. In spite of the many challenges, there is widespread consensus on the potential usefulness of imaging data for the characterization of developmental hazard.

2080 Beyond hERG: Novel Cardiovascular De-Risking Strategies and Their Regulatory Acceptance
J. Davis and T. Brabham, Pfizer, Andover, MA.

Whether drug development is prosecuting small molecule or biologic programs, cardiovascular safety is still one of the leading causes of compound attrition. The rationale for attrition has gone far beyond the traditional drug-induced long QT syndrome associated with inhibition of the human Ether-a-go-go Related Gene (hERG). Pharmaceutical companies have built-in greater controls for eliminating this hurdle by using sensitive high-throughput in vitro screens around this and other important cardiac ion channels that have significantly reduced arrhythmogenic risks. Despite these advances, adverse effects on the cardiovascular system remain a multifactorial risk, difficult to discern, especially during early drug discovery stages. Recent comprehensive preclinical attrition data has demonstrated that hemodynamic alterations, vasculitis, and left ventricular cardiac hypertrophy are increasing in incidence in short- and long-term animal studies. Unlike the well-established mechanistic link between hERG and QT prolongation, these unique pathologies either lack suitable investigative tools and models, or have a lack of confidence in the underlying mechanisms preclinically. This challenge is compounded by the advancement of molecules that act as novel targets for which limited safety data are available. However, in the past couple of years promising advances have been made in in vitro and ex vivo assay development, which have the potential to impact industry cardiovascular safety de-risking standards much as hERG screening did. Investigators are exploring more integrative tactics, by effectively employing predictive in vivo tissues baths as well as stem cell-derived human cardiomyocytes to rank-order and/or advance suitable drug candidates. While developing innovative tools is important, it’s also clear, as the diversity of pharmaceutical drug products evolve into a more challenging target space (i.e., kinase inhibition), these inherent risks need to be evaluated on par with regulatory expectations.

2081 Study of Cardiovascular Safety of Small Molecules and Biologics: The State of Science, Challenges, and Gaps
A. S. Bass1 and F. Sannajust2. 1Discovery Sciences Support, Merck & Co., Boston, MA and 2Safety and Exploratory Pharmacology, Merck & Co., West Point, PA.

The search for innovative approaches allowing early prediction of cardiovascular toxicity of small molecules or biologics is urgently needed. Despite significant efforts to identify new methodologies and assays that accurately predict the risk of cardiovascular toxicity, everyone recognizes that validation of these test systems is only evident from the number of new molecules safely brought to the marketplace. The story of the hERG channel assay and the impact that it has had on removing development those molecules that pose a risk of proarrhythmia exemplifies both the science and strategy that goes into validation of an assay. Possessing data which describing a molecule’s profile on other established mechanisms of cardiovascular toxicity, e.g., effects on receptors, ion channels, transporters, kinases and intracellular organelles (e.g., mitochondria), sets up a “theoretical” concern, a hypothesis, amendable to further testing. In the case of these simple biologic targets and those associated with more complex cardiovascular toxicities, quantitative translation and predicting adverse events remain to be established. Translational biomarkers, testing in viable organs or tissues harvested from patients and study of pluripotent stem cells offer hope of resolving some of the challenges of translational biology. However, considered as steps in the lead optimization phase, in vitro assays do not fully represent the integrated physiology of animals or patients. Furthermore, there are adverse cardiovascular events for which the underlying pathophysiology is not well understood. These latter cases are emblematic of challenges faced by the scientific community. For those investigators, a “line of sight” to de-risking the potential for cardiovascular toxicity of a promising new drug begins in early discovery and continues through to the post-marketing phase.

2082 Regulatory Expectations for Submission of Novel In Vitro Assays Addressing Cardiovascular Risk
T. Papoian, US FDA, Silver Spring, MD. Sponsor: J. Davis.

The potential for bio-pharmaceuticals to possess unintended clinical effects on the cardiovascular system during the drug development process is an important regulatory concern. Although in vitro and in vivo preclinical models have been designed to predictive screen bio-pharmaceuticals for specific cardiovascular liabilities, such as QT interval prolongation and other proarrhythmic effects, failure to prevent cardiovascular risk in humans continues to occur, particularly with compounds that do not specifically interfere with cardiac ion channels. Examples for improvement in screening for potential cardiotoxicity would be development of more human-specific models, such as human induced pluripotent stem cell-derived (iPSC) cardiomyocytes. Although this and other in vitro models are gaining acceptance among bio-pharmaceutical companies for initial screening of candidate compounds for further development, the predictivity, reliability and regulatory acceptance of submitted data generated from such newer in vitro models requires proper validation and qualification, so that appropriate decisions regarding human risk assessment during subsequent clinical testing can be made with an acceptable degree of confidence. Regulatory agencies, such as the FDA, clearly have been supportive of such efforts to develop better predictive in vitro models that can improve drug safety for subsequent testing and therapeutic use in humans. Some of the regulatory expectations for the future of novel in vitro assays to address non-proarrhythmic cardiovascular risk will be discussed.
Hemodynamic effects of non-cardiovascular compounds continue to be a challenge in drug development. Early compound selection employing a robust cardiovascular ex vivo/in vivo screening funnel can lead to improved decision making and project efficiencies. To this end, understanding of the cross model and cross-species translation can significantly inform decision making and compound advancement. The translational relationship between in vitro and in vivo such as the isolated rat aorta and conscious rat heart telemetry has been explored and defined for select chemical series and mechanisms. These assays have optimized detection/differentiation of compounds with potential hypertensive risk associated with a mechanistic structure-activity-relation (SAR). Key relationships in this strategy included the establishment of in vitro concentrations relevant to observed in vivo effects. Several case studies will be shared demonstrating key impacts and decision making criteria. Additionally, the understanding cross species in vivo translation and effects can strengthen decision making and improve the ability to achieve the ultimate goal of predicting human outcomes.

Cardiac hypertrophy is initiated and maintained by a wide array of endocrine, paracrine, and autocrine growth factors in response to increased work load, injury, or defects in contractile performance. Cardiac hypertrophy is clearly double-edged, where under exercise or pregnancy it is beneficial and referred to as physiologic, but under sustained hypertension or aortic stenosis cardiac hypertrophy is pathologic. Both types of hypertrophy are characterized by an increase in cardiomyocyte size, but only pathological hypertrophy is associated with increased apoptosis and fibrosis as well as functional changes such as altered cellular Ca2+ homeostasis, ion channel remodeling, reduced contractile force and relaxation velocity. While initially an adaptive response that attempts to maintain cardiac output, sustained cardiac hypertrophy induced by pathological stimuli is a leading predictor for the development of heart failure. Drug-induced cardiac hypertrophy often manifests in the later stages of preclinical safety testing. In response to this late stage risk, an early safety assessment screening paradigm has been developed using iPS derived human cardiomyocytes, which are phenotypically and functionally more reflective of cardiac myocytes in vivo. Upon treatment with molecules associated with the induction of cardiac hypertrophy we have characterized these cells using endpoints that represent the hallmarks of cardiac myocyte hypertrophy including; cytoskeleton remodeling, induction of the fetal reversion gene expression program, and secretion of natriuretic peptides. In addition, new approaches that leverage high content imaging and computational systems biology have been applied to the model, which allow for a more thorough characterization and deeper understanding of drivers of cardiac myocyte hypertrophy.

Within the basic science community, in vitro models and approaches that improve the early understanding of compound’s beneficial or deleterious effects as well as accurately reflect diseased tissues are sorely needed. Breakthroughs that enable research to make faster, more accurate, human relevant decisions would be embraced by regulatory agencies as well as companies who make products (be it chemical, food, drugs, etc). Recent advancements in the ability to manufacture stem cell-derived tissues has enabled drug discovery scientists to create relevant models for pharmacology and toxicology investigations using pluripotent stem cells of human origin. Specifically to benefit drug-induced cardiotoxicity, stem cell-derived cardiomyocytes have been made in high quality, purity, and quantity and confirmation of their expression, function, and response to cardiotoxic molecules has occurred. Across a set of nearly 80 compounds, stem cell-derived cardiomyocytes were shown to respond in a clinically meaningful manner to drugs that induce arrhythmia. This approach is being adopted by pharmaceutical companies as a means to better assess drug-induced arrhythmia at early stages of drug development and is in the early stages of consideration by regulatory agencies as a surrogate for extensive clinical data. In addition, mechanistic studies in stem cell-derived cardiomyocytes have been conducted to investigate potential kinases that mediate sunitinib-induced cardiotoxicity. While the utility of stem cell-derived cardiomyocytes as a model for cardiotoxicity has not been broadly studied, a real opportunity exists to evaluate effects in a human cell system that is stably beating and maturing in vitro. A higher level of opportunity exists since stem cell-derived cardiomyocytes are being made from a genetically diverse set of individuals which will allow interrogation of the relationship of genetics and drug-induced cardiotoxicity in an in vivo manner.

Biopharmaceutical (BP) drugs are innovative medicines that have revolutionized the treatment of human disease, and offer the opportunity to develop new therapeutics with high specificity for their human target, long half-life and target coverage, and low risk for “off-target” pharmacology. While BP attrition due to safety concerns is generally considered to be low, especially for risks like QTc prolongation, these novel therapeutics may have functional cardiovascular effects that require evaluation during nonclinical drug development. The cardiovascular evaluation of BP products requires a science-based, case-by-case approach, as each biological modality will have unique pharmacological characteristics that influence the testing strategy. The integration of safety pharmacology endpoints into general (repeat-dose) toxicity studies is a rational paradigm for assessing potential changes in the cardiovascular system, but requires thoughtful planning. In some cases, dedicated and optimally-designed nonclinical cardiovascular safety studies may be needed to assess a functional risk triggered by target-pharmacology concerns. For example, implant telemetry studies may be needed to detect small changes in arterial blood pressure after acute and chronic exposure. This presentation will cover some examples of cardiovascular strategies used to evaluate novel biopharmaceuticals.

Dissemination of scientific results drives innovation and productivity in all fields, including toxicology. It is critical to effectively communicate findings to colleagues, peers and trainees in written and oral forms and most of us are comfortable in this arena. However, it is more difficult to communicate results and translate risk to the lay public that listens to messages through an emotional lens—especially in the world of social media that defines “experts” based upon frequency and volume of communication rather than demonstrated expertise. Certainly, the public faces a barrage of environmental health issues associated with alleged hazards due to contamination of food, water, air and soils. To make appropriate decisions, the public, media and legislators need information in a readily understandable format presented in a way that resonates with them. In general, communicating and engaging with the lay public is not addressed as part of graduate training, and, therefore, even accomplished toxicologists who are effective scientific communicators find themselves underprepared. Communication directed at “lay” audiences, even that which uses appropriate terminology, is often ignored and does not “stick” with the target audience. Moreover, it is now clear that effective public communication must exceed simple dissemination of results; all stakeholders, including affected communities and populations, should be engaged by toxicologists in bidirectional discussions that facilitate learning by both scientists and the public on an emotional and transparent level. Four actors from four different vantage points will present on the role scientists should play in communication and engagement with the public about toxicology. A discussion panel will follow.
To Speak or Not to Speak. That Is the Question. And the Challenge
M. P. Holsapple, Battelle, Columbus, OH.

Practically every member of the SOT has been given an opportunity to speak about their research in a scientific setting—highlight their hypothesis, describe methods, present results, make interpretations, defend their conclusions. Because the above is centered on THEIR work, it is generally a comfortable experience, and there is no question that these presentations highlight the values and impacts of the science of toxicology. Far fewer members of the SOT are called upon to provide a non-scientific perspective on what it means to be a toxicologist, or on why the science of toxicology should be viewed by the public as value-added. The focus of this presentation will be on the challenges inherent in serving as a spokesperson for science and our Society. The first question is—Should the SOT enlist its members to occasionally communicate on behalf of science, toxicology and the Society? The short answer is ‘yes’ based on past practices—there are examples of how the SOT has reached out to its members for this type of communication. The second question is—What are the challenges inherent in communicating on these subjects? One of the strengths of the SOT is the diversity of its membership, and any message offered needs to leverage that diversity. Even though toxicology is one of the most integrated sciences currently being practiced, and there is an increasingly greater emphasis on the need for multi-disciplinary research teams, toxicology continues to struggle with an ‘identity crisis’ that is common across the sciences today. Societal perceptions are changing and must be anticipated. The impacts of ‘chemophobia’, and the perception that all toxicologists do is ‘tell us that everything is harmful’ can impact our effectiveness and credibility. There are also examples of the “good guy/bad guy” syndrome, as in “bad guys” are in industry or government, and “good guys” are in academia. Ultimately, we must recognize that in spite of the challenges, the failure to speak about the value of the SOT, and of the science that exists at its core, could marginalize our discipline, and indeed all of science, in the eyes of the public.

The New Universe of “Knowledge”
S. J. Hermansky, Research and Quality Innovation, ConAgra Foods, Omaha, NE.

Information availability, whether accurate or not, is rapidly evolving and continuing to change how we perceive and interact with the world in which we live. The definition of “expert” is no longer based on education and training but on the frequency and passion of communication. How this new universe of knowledge affects our world cannot be ignored when a single person has the power to initiate movements that rapidly and completely demonize finely textured ground beef (“pink slime”) or cause major companies to reformulate products to eliminate a specific ingredient. As scientists, we must adapt our communication style to this new world or be drowned out or, worse, become irrelevant. This is no easy task as we work to protect integrity and credibility for ourselves and our employers. Accomplishing real and persistent change in our approach to communication requires a commitment of time and resources on our part, and an effort to use new tools and techniques in this new universe of “knowledge.” Not only does our ability to influence our stakeholders and public behavior depend on it, the very role of science in society depends on it.

Values, Trust, and Science
C. Arnot. Center for Food Integrity, Gladstone, MO. Sponsor: S. Hermansky.

All organizations operate through social license or the privilege of operating with minimal formalized restrictions (regulation or legislation). A social license is granted when you operate in a way consistent with the ethics, values and expectations of your stakeholders (customers, employees, community, regulators, legislators, the media). Once lost, either by reducing or eliminating public trust, social license is replaced by various levels of control designed to compel performance consistent with expectations. Operating with a social license is flexible and low cost while operating with a high degree of social control increases costs and reduces flexibility. A radical example of lost social license is Arthur Anderson and Enron. After the collapse of Enron, the accounting profession lost its social license. Freedom enjoyed by scientists is in jeopardy as stakeholders raise questions about the trustworthiness of today’s science-based industries. Our research, focused on the food industry, demonstrated that three primary elements drive trust: competence, confidence, and influential others. Competence is about skills and technical ability. Historically, we as scientists have focused our communication on this believing stakeholders will make logical data based decisions. However, with today’s social media, competence no longer ensures public trust. Thus, consumers focus on other aspects of communication including confidence: the perception that the communicator has shared values and ethics and a belief they will do the right thing. Similarly, consumers turn to other sources of information or their “influential others” (family and friends).

Our research also demonstrated that confidence, or shared values, is much more important than competence for consumers. This research should be relevant to today’s crisis of science communication. New ways of engaging communicating are required if we want to build trust and maintain social license. A major driver of trust in today’s world is a non-negotiable focus on transparency. To succeed, we need to demonstrate our commitment to practices that are ethically grounded, scientifically verified and economically viable.

Databases Facilitating Systems Biology Approaches to Toxicology
S. M. Bello1 and M. Shimoyama2. 1Mouse Genome Informatics, The Jackson Laboratory, Bar Harbor, ME and 2Rat Genome Databases, Medical College of Wisconsin, Milwaukee, WI.

The application of systems biology approaches to toxicology promises discovery of new molecular and genetic connections, the ability to draw novel inferences about mechanisms and modes of actions, and the ability to build better predictive models. However, a systems biology approach first requires identifying appropriate data from a vast array of possible data types and resources. By using multiple high-quality databases, researchers can pull together the required gene, pathway, chemical relationship, and other information needed to build their predictive model. To best use these resources, one first needs to know what resources exist, what the strengths and limitations of the resources are, and how to efficiently retrieve data from them. This session will provide an introduction to several types of resources, including model organism (Mouse Genome Informatics, Rat Genome Database), pathway (Reactome), and toxicology (Comparative Toxicogenomics Database, EPA Dashboard) databases. The goal of this session is to familiarize participants with the power and limitations of publicly available databases that may be used to build and refine models of biological systems that can be applied to toxicology research. Talks will present content overviews for each database and demonstrate data retrieval and analysis capabilities. Speakers also will be available for interactive demonstration sessions during the meeting (see the US EPA booth for dates and times).

Mouse Genome Informatics: Using Data Integration to Facilitate Discovery of Relationships Among Genes
S. M. Bello, M. Ringwald, J. E. Richardson, J. A. Kadin, C. J. Bult, J. A. Blake and J. T. Eppig. Mouse Genome Informatics, The Jackson Laboratory, Bar Harbor, ME.

The Mouse Genome Informatics Database (MGI, www.informatics.jax.org) is the free international resource for the genetics, genomics, and biology of the laboratory mouse. MGI integrates biological data about the laboratory mouse, including mutant phenotypes, human disease associations, developmental gene expression, gene functions, and tumor biology, from a variety of different sources. MGI uses multiple ontologies and vocabularies including the Gene Ontology (GO), Mammalian Phenotype Ontology (MP), and Mouse Anatomical Dictionary, to annotate data from direct submissions, high throughput projects, and published literature. Data integration and use of ontologies allows users to identify and retrieve annotated data sets with varying levels of specificity. For example, using the recently created MouseMine resource at MGI (www.mousemine.org) a user can generate a list of genes associated with iron homoestasis, binding and/or transport, refine this list to only those genes with mutations resulting in neurological or behavioral defects then export the final list in a variety of formats. Or a user can exploit specific MGI query forms to identify genes known to be expressed in the developing autonomic nervous system, then export this list to the batch query tool to retrieve all phenotypes associated with mutations in these genes. This talk will describe some of the ways data are brought in and integrated into MGI, how ontologies can be used to facilitate identification of specific data sets, and how MGI tools may be used for bulk data entry and retrieval. An emphasis will be placed on data types that may be useful in building mechanistic or predictive models for use in toxicology.

The Mouse Genome Database (MGD) at MGI is supported by NIH/NHGRI grant HG000330. MouseMine is supported by NIH/NHGRI grant HG004834.

Chemical Connections at the Rat Genome Database
M. Shimoyama. Rat Genome Database, Medical College of Wisconsin, Milwaukee, WI. Sponsor: S. Bello.

The Rat Genome Database (RGD) is the premier site for genetic, genomic, physiological and phenotype data for the laboratory rat. RGD provides an integrated research platform for investigators through the integration of multiple datasets and software tools. To meet the needs of the many investigators who use rat in tox-
The Comparative Toxicogenomics Database (CTD): Facilitating Mechanistic Understanding of Chemical Effects

C. J. Mattingly. Biology, North Carolina State University, Raleigh, NC.

The Comparative Toxicogenomics Database (CTD; http://ctdbase.org) is a publicly available resource that informs hypothesis development about mechanisms of chemical actions and the impact of environmental exposures on human health. CTD contains manually curated data describing chemical-gene-interactions and chemical-disease and gene-disease relationships. Curated data are integrated with external data sets (e.g., Gene Ontology and pathway data) and tools that allow users to navigate and analyze biological relationships relevant to environmental health. This presentation will describe CTD functionality and highlight several new analysis and data visualization features. It will also include information about emerging projects, including the modifications to chemical representations, text-mining workflows for identifying chemical-gene-disease data, novel pathway development tools, and exposure data curation.

Interactive Web Application (Chemical Safety for Sustainability Dashboard) for Computational Toxicology Data Exploration

M. T. Martin. US EPA, Research Triangle Park, NC.

The USEPA has developed a web-based interface (Dashboard) to synthesize data from the ToxCast and ExpoCast project in the federated Aggregated Computational Toxicology Resource (ACToR) database into customized information displays. The Chemical Safety for Sustainability (CSS) Dashboard is built upon a flexible infrastructure, allowing multiple views of ACToR data organized to support user-specific needs. The users select sets of chemicals and data to focus on for data exploration and analysis. The data are organized into data classes to present all relevant information for a given pre-defined grouping of data such as hazard and exposure or in vivo and in vitro data. The CSS Dashboard provides data class views relevant to the data types and will continuously expand the viewing options. Within the Data Explorer mode, the user can view summarized information for the various data classes across all selected chemicals. In contrast, the Chemical Explorer mode permits viewing of the highly detailed data including concentration response plots and curve-fitting parameters across hundreds of high-throughput screening assays and chemicals. Chemical-specific scores that consider all information in each data class is presented in a dynamic summary table with a default score (e.g., average AC50 across assays within the in vitro hazard data class). Users can adjust default score criteria or apply expert knowledge to modify particular scores, with all decisions saved for sharing or later consideration. The scores are carried over into the Prioritization Mode where the chemicals are ranked in a weight-of-evidence scheme including an implementation of the Toxicological Prioritization Index (ToxPi). The ToxCast Dashboard will serve as the primary portal for ToxCast and ExpoCast data and model release and public user-interaction. This abstract does not necessarily reflect U.S. EPA policy.

Genomics in Toxics Regulation and Litigation in the Era of Whole Genome Sequencing

A. R. Schatz and G. E. Marchant. College of Law, Arizona State University, Tempe, AZ and Global Safety & Environment, Merck & Co, Whitehouse Station, NJ.

Genomic and other ‘omic data are increasingly being used in both toxic tort litigation and environmental standard-setting. For example, defendants are beginning to request genetic testing of toxic tort plaintiffs to demonstrate alternative causation, while plaintiffs are using genomic biomarkers in appropriate cases to buttress their proof of specific causation. On the regulatory side, the US Environmental Protection Agency is increasingly using genetic susceptibility data to identify susceptible subgroups in setting ambient air quality standards, while using toxico-genomic data to evaluate and characterize the toxicology of pesticides and chemicals. These initial applications of genomic data are setting the precedents and creating the pathways for much broader use of genomic data in both the toxic tort litigation and environmental regulation contexts as we rapidly move into the era of whole genome sequencing. This year, tens of thousands of people will have their genome sequenced. That number is expected to rapidly climb to the millions and perhaps even hundreds of millions over the next few years. This session will discuss current applications of genomic data, and how whole genome sequencing will greatly increase the availability and use of genomic data, in both the litigation and regulatory domains. It will also discuss the complex ethical, legal, and social issues the increased use of genomic data will present in these contexts, including informed consent, disclosure and access issues, the “right not to know,” privacy and confidentiality issues, and the rights and responsibilities of those that produce and are harmed by toxic substances with differential genetic susceptibility.

Incorporating Genomic Data into the Risk-Analysis Paradigm

H. I. Clewell. The Hammer Institutes For Health Sciences, Research Triangle Park, NC.

Genomic data are increasingly being used to assess and manage potential health risks from drugs and environmental chemicals. Gene array data can provide information on the mode of action for toxicity of a compound and, when coupled with Benchmark Dose modeling, can be used to determine acceptable exposures and evaluate population variability. In addition, whole-genome or whole-exome sequencing can help to identify individuals with known genetic susceptibility factors for a particular adverse health outcome. This presentation will discuss how genomic data are now, and are likely to be in the future, incorporated into risk assessment and risk management, and some of the scientific challenges and policy/ethical issues that this category of data present.

Regulatory Applications and Implications of Whole Genome Sequencing

M. A. Rothstein. Institute for Bioethics, Health Policy and Law, University of Louisville School of Medicine, Louisville, KY. Sponsor: G. Marchant.

This presentation will review the various applications and implications of WGS data for regulation of toxic chemicals, including how to regulate for individuals with genetically-variable sensitivities; setting uncertainty factors based on genetic susceptibility data, relationships between genetic susceptibilities and ethnic background, whether genetically-at-risk individuals be able to accept increase risk in the workplace, and the appropriate role for warnings, labels, and self-help with respect to genetic susceptibilities.
Validated biomarkers of exposure, effect and susceptibility obtained from toxicogenomics studies are potentially very powerful tools to establish or negate causation in toxic tort. For example, increased “chromosomal abnormalities” in plaintiffs might be used to establish that exposure to DNA damaging agents has occurred, but cannot be used for establishing general causation due to lack of chemical specificity. On the other hand, genetic polymorphisms that affect DNA repair may impact an individual’s response to genotoxic agents, (i.e. more susceptible to exposure) or indicate that an individual carrying that biomarker will have an increased “baseline” of chromosomal abnormalities, altering the biomarker dose-response curve in establishing or negating causation criteria and suggesting an alternate cause of elevated genotoxic biomarkers. The use of biomarkers in toxic tort is increasing; however, in many cases, the biomarkers in question have not been sufficiently validated to demonstrate that reported changes in gene expression patterns or changes in circulating cytokines/proteins levels are indeed causally related to overexposure to a specific chemical or class of chemicals. Proper validation of a defensible biomarker developed from toxicogenomics data includes reproducibility by one or more independent scientific investigators, demonstration of dose-response and specificity, development of a blind test set as confirmation of the methodology, data transparency, and the absence of non-specific or confounding responses. This presentation will discuss the potential use of WGS sequence data in toxic tort litigation, beginning with current uses and applications of genomic data in toxic tort litigation. It will then evaluate the implications of much greater availability and use of genetic data as WGS becomes more prevalent, and some of the issues this will create for the litigation system and the individual participants.

The role of the dopaminergic system in the clinical syndrome associated with Mn has been controversial. PET imaging with [18F]fluorodopa (FDOPA) is a noninvasive measure of nigrostriatal dopaminergic neuron integrity. Ultimately, neuropathologic examination of brains of exposed workers is the most definitive approach to identify causative pathways. To assess the pre- and post-synaptic dopaminergic system in humans with occupational Mn exposure, we conducted molecular neuroimaging with FDOPA PET in 40 Mn-exposed welders and neuropathologic assessment of the corpus striatum in eight Mn miners and compared both to matched controls. None of these workers had a diagnosis of a Mn-related clinical syndrome. For the PET studies, basal ganglia volumes of interest were identified for each subject and the uptake of FDOPA, Ki, was generated for each region. For the pathologic assessment, we compared mean cell density of neurons, astrocytes, and microglia in the caudate, putamen, and globus pallidus interna and externa in Mn miners with non-Mn miners. In the FDOPA PET study, repeated measures general linear model (GLM) analysis demonstrated a strong interaction between diagnostic group and region. The regional pattern of uptake in welders was most affected in the caudate > anterior putamen > posterior putamen. Histopathology of Mn miner brains revealed a trend towards lower mean neuron and astrocyte density compared to non-Mn miners in the caudate nucleus and putamen. There was higher mean microglia density in Mn miners than non-Mn miners in the globus pallidus interna and externa. The ratio of astrocytes to microglia in each brain region was lower in Mn miners as compared to non-Mn miners. The FDOPA PET studies in Mn-exposed welders indicate dysfunction in the presymptomatic nigrostriatal dopaminergic system. The neuropathology studies in Mn miners suggest that chronic, low-level Mn exposure may be associated with selective toxicity to astrocytes and neurons and microglial response in the corpus striatum.

Methcathinone abuse is a new cause of manganism. This psycho-stimulant is prepared from pseudoephedrine using potassium permanganate as an oxidant. The final mixture contains high concentrations of manganese (Mn). Methcathinone abuse is an important cause of parkinsonism among young Estonian patients. We describe the clinical, biological, neuroimaging characteristics and follow-up results in a large cohort of intravenous methcathinone users. The most prevalent symptoms are symmetrical bradykinesia, dystonia, early postural, gait and speech impairment; rest tremor is rarely present and rigidity is mild. The syndrome is irreversible after cessation of exposure and there is a trend of worsening. Plasma Mn concentrations in active uses are significantly higher than those in former users; so are the hair Mn levels. By MRI T1-weighted images, all active users show a symmetric hyper-intensity in globus pallidus, substantia nigra, periaqueductal grey matter and cerebral pedunculi, less in putamen, caudate nucleus, dentate nucleus and white matter. Whether these changes are mainly Mn induced, as the clinical syndrome, or correspond to the effect of long-term methcathinone abuse cannot be concluded. DAT SPECT results indicate that the presynaptic dopaminergic system in the nigrostriatal pathway are intact in former methcathinone abusers. Further, the data show no decrease in the level of postsynaptic D2 receptors in striatum. Evidence from our neuroimaging studies support the hypothesis that the accumulation of Mn in the brain is not associated with the degeneration of dopaminergic neurons as in PD, instead the dopaminergic system could be dysfunctional.

Methcathinone is a synthetic stimulant drug that is related to amphetamines, and it is primarily used in the form of a white crystalline powder. It is often referred to as "Ice" or "Crystal Meth," and is commonly smoked or injected intravenously. The effects of methcathinone abuse can be severe and include neurological symptoms such as tremors, rigidity, and bradykinesia, which are characteristic of Parkinson's disease. The study by K. Sikk et al. describes the clinical, biological, and neuroimaging characteristics of methcathinone abuse and highlights the importance of recognizing this emerging health issue.
It has long been recognized that chronic manganese (Mn) exposure in humans produces a neurological syndrome comprising psychiatric, cognitive and movement abnormalities that resemble some aspects of idiopathic Parkinson’s disease (PD). However, examination of the literature also indicates significant differences between Mn-induced parkinsonism and PD. For example, Mn-induced parkinsonism does not seem to be responsive to l-dopa therapy, an effective treatment for PD. Our laboratory has been examining the effect of chronic exposure to moderate levels of Mn in non-human primates in order to assess the effects on the nigrostriatal dopaminergic system using Positron Emission Tomography (PET) as well as other neuropsychological endpoints. Recent results indicate that the most affected parameter of the dopaminergic synapse is the ability to release dopamine.

No significant changes were measured in dopamine transporter levels indicating that dopamine terminals do not degenerate as a result of Mn exposure. A small but significant decrease was also measured in the level of D2-dopamine receptors in the striatum. These findings indicate that chronic exposure to moderate levels of Mn does not result in the degeneration of dopamine neurons but it results in dopamine neuron dysfunction since they cannot release dopamine more. Recent evidence indicates that a similar decrease in dopamine release measured by PET is present in dopamine terminals innervating the frontal cortex. In general, dopamine neuron dysfunction may be a common mechanism to explain cognitive and motor function deficits associated with Mn neurotoxicity. [Supported by NIEHS grant number ES010975]

Numerous studies on manganese (Mn)-induced parkinsonism indicate an interaction between Mn and dopaminergic neurotransmission. However, the lack of distinct T1 signal by MRI in substantia nigra (SN) in Mn-exposed human brain, along with other study results, has led to the assumption that Mn toxicity may take place in brain regions other than the dopamine (DA) neuron-enriched SN.

To better characterize Mn toxicity, we developed a high spatial resolution synchrotron X-ray fluorescence imaging technique (XRF) as a new quantitative tool to study Mn transporters and deciphering mechanisms of Mn-induced neurodegeneration. Distinct T1 signal by MRI in substantia nigra (SN) in Mn-exposed human brain, along with other study results, has led to the assumption that Mn toxicity may take place in brain regions other than the dopamine (DA) neuron-enriched SN. For the 75 CDs for which both rodent and non-rodent studies were conducted, new target organs were identified in non-rodents for 43 of the CDs and the changes in organ toxicities that was largely similar across most therapeutic areas although the dose can continue beyond the duration of toxicology cover according to the participant’s request (ICH Guideline M3(R2), 2009), although for oncology Phase I trials in advanced cancer, dosing can continue beyond the duration of toxicology cover according to the patient’s response (ICH Guideline 59; 2009). An analysis of target organ toxicities in these studies for 77 AstraZeneca candidate drugs (CDs) revealed a pattern of target organ toxicities that was largely similar across most therapeutic areas although the oncology/infection therapeutic area differed with a larger range of organs affected. For the 75 CDs for which both rodent and non-rodent studies were conducted, new target organs were identified in non-rodents for 43 of the CDs and the changes seen only in non-rodents included organ systems of high relevance for human risk assessment such as the liver, male reproductive tissues and CNS. Overall, these data on small molecule target organ toxicities provide new insights into drug toxicity profiles in preclinical species and additionally confirm the value of using non-rodents as a second species in toxicity testing to support human safety. As such, these approaches have been successful in supporting robust decisions around risk assessment for traditional pharmacological targets and small molecule chemistries, but how have these regulatory strategies fared when applied to more challenging targets and more sophisticated chemistries? In order to address this, speakers will cover the four key areas of small molecules, traditional biologics, innovative biologics, and nucleotide constructs.

The presentations will include specific discussion of the science and technology and the experiences of individuals and organizations. In this context, this workshop will consider the key question: Are these ‘diversities’ complementary and working expeditiously to bring important new (and safer) medicines to patients? In order to address this, speakers will cover the four key areas of small molecules, traditional biologics, innovative biologics, and nucleotide constructs. Overall, the presentations will provide clear information illustrated by examples on the different strategies employed for the different types of chemistry with an emphasis on relevance and outcome. The session will be of broad interest to academic, industry, regulatory, and consultant toxicologists who wish to be updated in this critical and evolving area.

Preclinical toxicology studies of up to 1 month duration are frequently used to support single or multiple dosing for a similar duration in Phase I clinical trials (ICH Guideline M3(R2), 2009), although for oncology Phase I trials in advanced cancer, dosing can continue beyond the duration of toxicology cover according to the patient’s response (ICH Guideline 59; 2009). An analysis of target organ toxicities in these studies for 77 AstraZeneca candidate drugs (CDs) revealed a pattern of target organ toxicities that was largely similar across most therapeutic areas although the oncology/infection therapeutic area differed with a larger range of organs affected. For the 75 CDs for which both rodent and non-rodent studies were conducted, new target organs were identified in non-rodents for 43 of the CDs and the changes seen only in non-rodents included organ systems of high relevance for human risk assessment such as the liver, male reproductive tissues and CNS. Overall, these data on small molecule target organ toxicities provide new insights into drug toxicity profiles in preclinical species and additionally confirm the value of using non-rodents as a second species in toxicity testing to support human safety. As such, these approaches have been successful in supporting robust decisions around risk assessment for traditional pharmacological targets and small molecule chemistries, but how have these regulatory strategies fared when applied to more challenging targets and more sophisticated chemistries? In addition, what recent innovations have been made to enhance regulatory success?
clination of safety pharmacology endpoints into general toxicology studies; these can provide useful data and are resource efficient. A further notable trend is a shared aim across the Pharma industry of reducing attrition in the GLP toxicology phase of candidate drug testing. Our data have shown that failures in this phase can be significantly reduced by extending the dose range finding studies and also by front loading the non-rodent telemetry.

### W 2111 Risk Assessment of “Traditional” Biologics
L. Andrew, Sanofi, Waltham, MA.

This presentation will address the issues and challenges presented in preclinical risk assessment of pharmaceutical targets and molecular constructs produced by recombinant technologies such as hormones and cytokines where multiple pre-clinical test species may be inappropriate. As the activity of the biologic therapeutic is frequently species specific, the selection of appropriate animal models or surrogates is crucial to generating useful data. Some animal test systems have been refined to alleviate the inter-species issues, and alternative in vitro strategies have also been identified which could significantly reduce or eliminate testing. However the cost benefit of approaching the development of a “non-traditional” biologic either through the use of a surrogate or the use of an animal model still raises many questions. The focus of this presentation is to discuss and disseminate the problems and potential solutions associated with the development and safety testing of biologics-based products. Considerations will be given to the use of transgenic animals, homologous molecules and in vitro systems that may be more predictive of safety and translatable than traditional species/tests. In addition, review of the recent regulatory guidelines including 36 addendum, 39 and other relevant guidelines will be highlighted as to their impact on the development of large molecules. Specific examples will be given to illustrate the utility of many of these alternative strategies. Case examples will include the use of a transgenic animal for a development program (including DART), the use of a surrogate antibody and the potential challenges of relevance and translatable and a unique development program using an animal model of disease and the predictivity of this model to the clinic.

### W 2112 Risk Assessment of Humanized Monoclonal Antibodies, Antbody-Drug Conjugates, and Novel Antibody Constructs
M. Hinrichs, L. A. Icicke, K. P. McKeeve and P. C. Ryan, MedImmune, Gaithersburg, MD.

Rapid advances in the field of protein engineering have led to the development of novel biologic drug platforms such as targeted nanoparticles, antibody drug conjugates (ADC), bispecific antibodies, and Fc mutated monoclonal antibodies. These emerging drugs continue to present new regulatory safety assessment challenges despite decades of practical experience with more traditional biologic agents. While the basic principles outlined in the recent addendum to ICH S6(R1) Preclinical Safety Evaluation of Biotechnology-Derived Pharmaceuticals can be applied to regulatory safety testing of novel biologics, the unique characteristics of each platform necessitates a science-based case-by-case approach often involving the use of safety testing methods that have not yet been standardized. This presentation will cover the scientific aspects of safety study design and species selection for two types of novel biologic platforms, bispecifics and ADCs. Case examples will be presented to highlight the strategic thinking and individualized approach required when evaluating the safety of new biologic technologies. The presentation will conclude with a discussion of the clinical relevance and current limitations of nonclinical testing strategies to focus on areas that could be improved in the future.

### W 2113 Safety Assessment of Oligonucleotide Constructs

This presentation will address the strategy, issues and challenges presented in risk assessment of oligonucleotide constructs such as antisense inhibitors and microRNAs. The basic principles of safety testing generally apply to oligonucleotide based therapeutics, but there are unique considerations related to targeting RNA expression in terms of general tolerability and exaggerated pharmacologic assessments. These considerations with regards to the site of action, interspecies cross-reactivity, and nonspecific effects influence the choice of animal models and the design of toxicology studies. Existing guidance’s for traditional drugs or biotherapeutics makes the use of surrogate inhibitors relatively straightforward. This talk will focus on strategies to deal with the challenges to ultimately provide meaningful safety assessment for new drugs that translate to patients. An example of a safety/pharmacodynamics relationship for an antisense inhibitor of Factor XI that incorporates mouse, monkey and human data will be presented.

### W 2114 Regulatory Authority Experience with Diverse Molecular Chemistry and Preclinical Safety Assessments Supporting First Time in Humans
D. Jacobson Kaat, US FDA, Silver Spring, MD.

Novel pharmacologic targets and new molecular chemistries raise challenging regulatory issues. A balance must be struck between supporting innovation in drug discovery while insuring volunteer/patient safety. For healthy volunteers there is no risk/benefit paradigm and the bar for safety is high. The lack of historical information on clinical toxicities for novel pharmacologic targets argues for conservatism in selecting a safe start dose and dose escalation scheme. FDA’s guidance “Estimating the Maximum Safe Starting Dose in Initial Clinical Trials for Therapeutics in Adult Healthy Volunteers” discusses situations where the start doses based on animal toxicology NOAELs should be lowered; one of the listed reasons is “novel therapeutic target.” For biologic drugs in this category a MABEL (minimal anticipated biological effect level) approach has been proposed. The need for such an approach was largely triggered by the cytokine release syndrome seen after the first dose in the Tegenero 1412 phase 1 study. This paradigm may have to be altered when the patient population has a serious and life threatening indication such as cancer. In these instances, patients should not be repeatedly exposed to drug doses that are not expected to have pharmacological effects. Other approaches could include microdose testing when investigating pharmacokinetics and bioavailability and the use of surrogate molecules when the drug only binds to the human target. In general, selection of the start dose for first in man studies with novel pharmacologic targets and/or new molecular chemistries should err on the side of safety i.e. lower start doses, slower dose escalation, protracted timing between dosing of participants and careful monitoring.

### W 2115 A History of the 3Rs in Toxicology Testing: From Russell and Burch to 21st Century Toxicology
M. L. Stephens1 and N. Mak2, 1CAAT, Johns Hopkins University, Baltimore, MD, 2Alternatives Research and Development Foundation, Jenkintown, PA.

The 3Rs—replace, reduce, and refine—have become the internationally established framework guiding the development of alternatives to animal experimentation in toxicology. Yet this framework languished for two decades after it was first proposed in 1959 by British scientists William Russell and Rex Burch. Then, as the animal experimentation controversy intensified in the 1980s, the concept of alternatives became politically charged, with some arguing that in vivo experiments could be replaced readily and others arguing that they were irreplaceable. A generation or so later, following the 2007 publication of a US National Research Council (NRC) report Toxicity Testing in the 21st Century, a Vision and Strategy, prominent scientists began predicting the near elimination of animal use in toxicity testing through the development of “21st-Century Toxicology.” Have we gotten from Russell and Burch to the beginnings of 21st-Century Toxicology? In this session, we will present results from comprehensive citation and literature searches that track the influence of Russell and Burch’s 3Rs framework and the prevalence of 3Rs-related research in toxicology over time. We will also draw on timelines of various 3Rs activities, including the founding of 3Rs organizations, centers, journals and websites, funding sources, the organization of workshops and conferences, the enactment of animal welfare/alternatives laws, and other milestones, to inform our historical analysis. We will present a historical narrative framed around four phases of activity: incubation (1959–1979), increasing acceptance and spread (1980–early 1990s), maturation (early 1990s–2007), and paradigm shift (2007–present). The impact of more than 50 years of 3Rs activity will be measured in part by focusing on the validation and regulatory acceptance status of alternative methods and trends in animal-use statistics, concluding with a discussion of remaining challenges to the development, validation, regulatory acceptance, and implementation of 3Rs methods.
In the 21st century, more than any other time in history, science is a team sport and requires cross-disciplinary/cross-functional interaction to meet the objectives and gain results. These interactions across multiple disciplines often require careful management and skillful leadership. Often times we fall prey to the belief that "a leader is always born". However, all of us "lead" in everyday life consciously or rather unconsciously. A question that begs to be asked is, "Why should anyone be led by me?" The answer can be elusive and requires the recognition that not all leaders are born. Good leaders can be developed. This, of course, leads to question, "How?" That again has to be addressed directly in terms of tangible competencies and behaviors. Is this due to the perception that the scientific ladder and management ladder are parallel, and one cannot support the other? The 21st century demands that each of us "own" our careers as well as the contributions towards society in a variety of ways. The time has arrived to spur the enthusiasm to "lead" in all fronts—the classroom to the boardroom and beyond. This informational session will include presentations by key leaders from academia, industry, government, and consulting. The speakers will introduce the concept of leadership as it relates to the current and emerging work environment, followed by a testimonial of core skills and styles required to be an effective leader. The testimonials will be individual but will provide set of tangible core qualities that are key to succeed and lead—at all levels. The session is designed for presentation and includes time for questions and discussion.

For ophthalmic medications, phototoxicity is one of the toxicities which would be a concern during drug development. Although there are several in vitro phototoxicity assays, no in vivo studies have been established to assess ocular phototoxicity. The purpose of this study was to develop appropriate study conditions to evaluate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu- rate ocular phototoxicity for intravitreal injective solutions by using Porphyrin [4,4',4'',4'''-(Porphine-5,10,15,20-tetrayl) tetrakis (benzenesulfonic acid) tetrascu-
Development of a murine gammaherpesvirus 68 (MHV-68) infection model was performed to facilitate identification of pharmaceutical agents that cause reactivation of latent viral infections, such as Epstein Barr Virus (EBV) in humans. Both MHV-68 and EBV are B-lymphotropic, establish latency after acute lytic infection, and are associated with the development of lymphomas. The model was developed using cyclosporine A as a positive immunomodulatory control. Cyclosporine A blocks calcineurin activity, which prevents activation of cytokine genes in T cells, leading to decreased T cell growth and activity. Cytoxic T lymphocytes are critical for control of latent MHV-68 infection in the spleen. C57BL/6 mice were tested against nearly 10,000 T MHV-68 and treated with 50 mg/kg cyclosporine A by the intraperitoneal route. Primary infection and viral reactivation in the spleen were measured by plaque assay for cell-free infectious virus, and qRT-PCR for latent and lytic mRNA viral transcripts. Infected splenocytes were quantified by infectious center assay. MHV-68 was detected in spleens of C57BL/6 mice treated with cyclosporine A 31 days following primary infection.

In summary, (1) the majority of plasma BAs in dogs was taurine conjugates, (2) feeding increased plasma BAs by about an order of magnitude, due primarily to increased taurine-conjugated BAs, (3) basal concentrations of BAs were higher in F than M dogs, (4) and there were large inter-individual differences in plasma BAs. These findings demonstrate that physiological BA concentrations in plasma of dogs are influenced markedly by prandial status, and slightly by gender. These physiological variations may complicate the interpretation of plasma BA concentrations in pathological conditions.

Intracisternal A Newcastle Summers virus was used as a control virus. Infected rabbits were randomized to treatment at the first observation of secondary lesions. Treatment regimens consisted of 3 oral doses spaced at 48 hours beginning at randomization. Doses of 5/5/5, 20/5/5 and 20/20/20 mg/kg BCV were evaluated. Compared to placebo, a statistically significant, dose dependent increase in survival was observed at the 20/5/5 and 20/20/20 mg/kg doses; demonstrating that BCV is effective for treatment of lethal poxvirus infection when administered after appearance of clinical signs of disease, specifically appearance of secondary lesions remote from the inoculation site.

An independent cohort of rabbits was added to study the PK of the 20/5/5 mg/kg regimen of BCV, when dose was initiated Day 4 post-infection. The concentration of cidofovir-diphosphate (CDV-PP), the active antiviral, was assessed in plasma, spleen, liver, lung, kidney and eye infected rabbit tissues. CDV-PP was detected in these tissues with the highest concentrations observed in the liver. Treatment of animals with BCV resulted in increased survival at doses of 20/5/5 mg/kg; demonstrating that BCV is effective for treatment of lethal poxvirus infection when administered after appearance of clinical signs of disease compared to placebo. Recurrent copy number alterations were identified by defining altered segments of DNA and calculating their frequency. We found considerable variation in the frequency of alterations between the tumors and the matched non-tumor tissues. Several regions of gain or loss observed in the tumors were also detected in non-tumor tissues, but at a lower frequency. This indicates that genomic instability increases with disease progression, and demonstrates genomic changes in pre-neoplastic tissues. Collectively, these data show that genomic instability plays a role in the development of fibrosis-associated HCC. This copy number data can also be used to identify genes that play a functional role in cancer development. Importantly, DNA copy number data is an endpoint used by The Cancer Genome Atlas project, and can be used to explore the human relevance of our model of HCC.
Assessment, SNBL USA, Everett, WA and Corporate, Shin Nippon Biomedical First Hospital, Jilin University, Changchun, Jilin, China and KCHRI at Department of Pediatrics, University of Louisville, Louisville, KY.

Infertility is a common complication in diabetic men due to the loss of germ cells. Our previous study had demonstrated that repetitive exposures to low dose X-rays radiation (LDR) can attenuate type 2 diabetes-induced testicular apoptotic cell death. To define whether repetitive exposures to LDR can also attenuate type 2 diabetes (T2DM)-induced testicular apoptotic cell death, T2DM rats were established by high fat diet feeding, followed by a small dose of streptozotocin. After diabetes onset, diabetic and age-matched control rats were treated with or without LDR at 25 mGy for 4 weeks every other day. Western blotting assay revealed that testicular apoptosis was significantly increased in T2DM rats by detecting AIF, along with increased oxidative and nitrosative damage, by detecting 3-NT and 4-HNE, and increased ER stress, by detecting CHOP and caspase 12. All these effects were attenuated by repetitive exposures to LDR. Mechanistic studies showed that Akt-mediated GSK-3β was down-regulated, but Akt negative regulators PTPIB and TRB3 were up-regulated in T2DM group. T2DM-induced the above testicular Akt related changes were partially prevented by repetitive exposures to LDR. Expression of Nrf2 and its downstream gene NQO-1 was up-regulated in T2DM group, and further up-regulated by exposures to LDR. Nrf2-related downstream anti-oxidants, such as SOD activity and catalase content were decreased in T2DM group by quantification assays, and these effects were attenuated by exposures to LDR. Therefore, the attenuation of T2DM-induced testicular apoptotic cell death by repetitive exposures to LDR is likely mediated by up-regulation of Akt/Nrf2-mediated anti-oxidative pathway.

2125 Repetitive Exposures to Low Dose X-Rays Radiation Attenuates Testicular Apoptotic Cell Death in Type 2 Diabetic Rats via Akt-Mediated Nrf2 Activation

Y. Zhao1, X. Chen1, J. Dai2, Y. Tan2, L. Cai2 and W. Li1, 1Cancer Center, First Hospital, Jilin University, Changchun, Jilin, China and 2KCHRI at Department of Pediatrics, University of Louisville, Louisville, KY.

Iron is an essential element that is required for many cellular functions. Multiple symptoms of iron deficiency have been reported in humans, including anemia, hair loss, stunted growth, and reduced oxygen transport. Mammalian iron intake is mediated in two different ways, across the placenta during fetal growth, and through the intestine during postnatal growth and development. We previously identified hephaestin (Hp), a copper-iron ferroxidase, which plays a key role in intestinal iron transport. Hephastin oxidizes iron and works in conjunction with ferroportin to facilitate iron export from enterocytes and its efficient binding to plasma transferrin. Null mutations in the Hp gene cause an accumulation of intracellular iron, specifically in the intestine. During analysis of the Hp null mice, we discovered that neonates born to Hp knockout (Hp KO) dams developed truncal hair loss (the “mask” hair loss phenotype) that resolved after weaning. The same phenotype was also observed in pups born to mothers with intestine-specific knockout of Hp (even WT (flooded) pups born to these mothers), suggesting that lack of maternal Hp in the intestine alone is responsible for the mask phenotype. In order to determine the stage (ante and/or post natal) at which lack of maternal Hp leads to pup hair loss, we performed cross-fostering studies. Wild-type pups fed by Hp KO dams presented with the “mask” phenotype, whereas, all pups fed by the WT dams had normal hair growth. Histology of the affected skin of pups fed by Hp KO dams demonstrated disorientation and keratinization of the follicles, follicular infundibular plugging and some tortuosity to the hair canals. Our findings suggest the involvement of a “toxic milk” phenotype involving low levels of iron in the milk causing this phenotype.

2128 Toxic Milk Leads to the “Mask” Phenotype in Hephastin Knockout Mice

Millions of Americans suffer from dry eye. The symptoms include: ocular surface discomfort, often described as feelings of dryness, burning, a sandy/gritty sensation, itchiness, visual fatigue, sensitivity to light, and blurred vision. The environmental (e.g. smoke, dust, low humidity, light etc.) and occupational (e.g. CO, CS2) stressors can induce or exacerbate dry eye by reducing ocular mucous cells and mucin production. In one of the dominant dry eye diseases - Sjögren syndrome, the patients have markedly reduced conjunctival goblet cells and the goblet cell-specific mucin-MUC5AC. However, there is no experimental evidence causally linking the mucin deficiency and the pathogenesis of dry eye. In the present study, a Muc5ac knockout (KO) mouse model was created so that one major ocular mucin-Muc5ac is deleted. The mice was subject to various physiological measurements as compared to wild-type (WT) growth and development, but the tear break up time (TBUT) values were significantly lower and corneal fluorescein staining scores were significantly higher in KO mice as compared to WT. But the tear volume was not changed. Despite the lack of Muc5ac expression in the conjunctiva of KO mice, Muc3b expression was significantly increased in these mice. Corneal opacification, varying in location and severity, was found in a few KO mice but not in WT mice. The present results suggest a significant difference in the quality, but not the quantity, of tear fluid in the KO mice compared to WT mice. Therefore, we, for the first time, demonstrate that the lack of a major ocular mucin-Muc5ac causes dry eye.

2129 Alterations of Contractile Gene Expression (Mypt1, CPI-17, and Myosin Kinase) in RUPP, L-NAME, and Adriamycin Rodent Models of Preeclampsia

L. Toot1 and J. Reho2.
1WIL Research, Ashland, OH and 2Department of Medicine, Division of Cardiology, University of Maryland, Baltimore, MD.

Preeclampsia (PE) is a pregnancy disorder that is characterized by a variety of complications, including high systemic blood pressure and deficits in renal hemodynamics. These PE related changes result in the characteristic reduction in placental perfusion pressure and compromised vascular function. In particular, this altered vascular reactivity is potentially due to a complex mechanism involving endothelial dysfunction and changes in vascular smooth muscle (VSM) contractile properties. The VSM of the microvasculature (i.e., mesenteric arteries) is distinct both phenotypically and functionally from that of the large conduit arteries, with many of the associated hemodynamic factors responsible for these differences still remaining undefined. Therefore, the objective of this study was to investigate and characterize the expression of several key contractile genes (Mypt1, CPI-17, and Myosin

556 SOT 2014 ANNUAL MEETING
Kinase) in various rodent models of PE (i.e., RUPP, L-NAME, and Adriamycin). Of particular interest is myosin phosphatase (MP), which acts as a central mediator of vascular function and can be used as a model to determine the VSM phenotype. Alternative splicing of exon 24 (E24) of the MP targeting subunit (Mypt1) generates isoforms that determine the VSM response to GCMP mediated vaso-relaxation. Fast contracting (E24+) isoforms are predominant in mesenteric artery VSM while slow contracting (E24-) isoforms are expressed in large artery VSM. Control and SHAM operated pregnant rats expressed the E24+ isoform of Mypt1 in mesenteric arteries. Hypertension during pregnancy resulted in a moderate shift in Mypt1 isoforms in L-NAME and RUPP mesenteric arteries, while Adriamycin treatment lead to a significant shifting of the Mypt1 from the E24+ to E24- isoform (p<0.05) in mesenteric arteries. These data indicate a potential compensatory mechanism of the VSM involved in the pathology associated with PE.

**2129a Variability in Neurotoxicity: Who Is Susceptible and Why**

G. Alam1, D. B. Miller1, L. P. O’Collaghan2, L. Lu3, R. W. Williams3 and B. C. Jones1. 1Biobehavioral Health, The Pennsylvania State University, University Park, PA, 2CDC-NIOSH, Morgantown, WV and 3University of Tennessee Health Sciences Center, Memphis, TN.

There is increasing interest in differential susceptibility among humans to toxicants, as well as a growing appreciation that multiple gene variants, exposure history, and complex gene-environment interactions (GXE) are critical determinants of disease and risk. For example, individuals who carry a mutation in the glutathione S-transferase gene have far higher risk for developing Parkinson’s disease when exposed to paraquat (PQ) (Goldman et al. Mov Disord 27:1652, 2012). More refined animal models, in particular genetic reference families of mice, now make it practical to replicate, extend, and mechanistically validate findings from epidemiologic and genetic studies of humans. In fact, Liang and colleagues validated the findings of Goldman in glutathione deficient mice (Toxicol Sci 134:366, 2013). These families, including the BXD and the Collaborative Cross, provide tight experimental control, but incorporate a very high level of genetic diversity. They are ideal for mechanistic studies of GXE and can now be reliably exploited to define single gene polymorphisms, important biochemical, and molecular mechanisms of toxicity. To illustrate, we studied the neurotoxicity of PQ and MPTP in BXD recombinant inbred mouse strains. Toxicity of PQ is highly variable among these strains and covaries with PQ-related disruption of iron regulation in the midbrain. We also studied effects of MPTP on striatal dopaminergic neurotoxicity among 10 BXD lines and found that 12.5 mg/kg MPTP s.c. caused a variation of 20–90% in neurotoxicity as determined by reductions in dopamine and its metabolites, tyrosine hydroxylase protein and elevations in GFAP, an astrocyte marker of neurotoxicity. Furthermore, the variation in dopaminergic neurotoxicity among strains was not due to altered metabolism of MPTP to MPP+, the proximal neurotoxicant. Genetic reference panels can provide valuable information on potential genetic differences in susceptibility and GXE.

**2129b Nuclear Receptor Small Heterodimer Partner (SHP) Modulates Circadian Clock Control of ER Stress Signaling in Alcoholic Liver Disease (ALD)**

[Purpose] In the past decade, our research has focused on elucidating the molecular mechanisms by which SHP (N4062) regulates liver and metabolic diseases. Highlights of our findings include revealing the role of SHP in fatty liver, liver cancer, and microRNA regulation. In this study, we use SHP-/- mice and the alcohol binge model to investigate how the liver circadian clock regulates ER stress and fatty liver.

[Methods] The NIAAA binge model was established using 8 weeks old, male C57BL/6 (WT) and SHP-/- mice (Nat Protoc 2013; 8:627–637). The mice were acclimatized to a control liquid diet for 5 days, then fed with 5% Lieber-DeCarli diet or pair-fed for 10 days. On day 11, mice were gavaged with maltose (control) or alcohol solutions at zeitgeber time (ZT) 3 (9 am) and sacrificed at ZT12, 18, 0, and 6. Serum and liver were collected. GC/MS and RNA-sequencing (RNA-seq) were used to identify clock regulated metabolites and genes, respectively. Transient transfection, luciferase reporter assay, ChIP assay, gel-shift assay, Co-IP, Western blots, adenosine overexpression, siRNA knockdown, and qPCR were used to elucidate the molecular mechanisms. Metabolomics revealed a global alteration by alcohol in the oscillation of intermediate metabolites in pathways of glucose, lipid, and amino acid metabolism in SHP-/- mice. Liver SREBP-1c protein cleavage and TGF content exhibited a rhythm pattern of changes. The rhythmity of core clock genes (Clock, Bmal1, Npas2) and nuclear receptors (Rorα, Rorγ, Rev-erbα) was disturbed by alcohol. Hepatic lipid metabolic genes and ER stress markers exhibited strong oscillations, which were perturbed by alcohol binge. We identified Chop as a circadian clock controlled gene that involves the Rorα/Rorγ/Rev-erbα/SHP regulatory cascade. [Conclusions] We provide a unique model for future investigation of the role of environmental chemical exposures in the development of metabolic diseases. [Grant Support] NIH DK080440 and AHA GIA (L.W.).

**2129c Mammary Gland Tumor Promotion by IGFI and an Insulin Analogue in the p53+/R270HWAPCre Mouse Model**

B. ter Braak1, K. Siezen2, B. van de Water2 and J. van der Laan1,2,3. 1Toxilogie, LACDR, Leiden University, Leiden, Zuid-Holland, Netherlands, 2National Institute of Public Health and the Environment, Bilthoven, Netherlands and 3Medicines Evaluation Board, Utrecht, Netherlands.

Insulin analogues are chemically modified molecules with improved pharmacokinetic parameters compared to regular human insulin. Although these compounds have been tested for carcinogenic side-effects with the standard two-year in vivo assays in rodents, there are some concerns raised by several epidemiological studies in which an association is suggested between the use of some insulin analogues and the cancer incidence in these diabetic patients. In this study the new p53R270H+/WAPCre mouse model, which will develop spontaneous human relevant mammary gland specific tumors, was used. We frequently injected this model with insulin NPH, insulin glargine, insulin X10 (AspB10) or IGFI. We hypothesized that injections with possible carcinogenic compounds would increase the number of tumors that are formed, decrease the latency time for tumor development, lead to different types or more aggressive tumors. We found that both X10 and IGFI significantly decreased the latency time for tumor development (for glargine a slight, non-significant effect was observed). A Western blot analysis was done on all primary mammary gland tumors (n=170) to investigate the IR/IGF1R/HER2/ESR/p-Ekt/p-Akt/ and Catherin status. Hierarchical clustering of this data revealed that X10 and IGFI induced tumors showed a distinct protein-expression profile that was characterized by high p-Erk levels, suggesting an important role of MAPK signalling cascade in tumor progression/initiation in insulin analogue induced tumors. These results also indicate that the use of a tissue specific cancer model, like the p53R270H+/WAPCre mouse model, can be used to discriminate between mitogenic and non-mitogenic compounds.

**2129d Characteristics of IgG Deposit and Neurodevelopmental Protein Expression in Brain of BTBR T+tf/J Mouse Females**

Y. Heo1, S. Hwang1, C. Kim1, H. Kim1, K. Shin1 and J. Jo1. 1Occupational Health, Catholic University of Daegu, Gyeongsan, Republic of Korea and 2Preventive Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Autism is a brain developmental disorder with social interaction defects, communication faults, and repetitive behaviors. The cause of autism is not clearly defined. Since the presence of autoantibodies against brain antigen was reported in autistic children and their mothers, autoimmunity is considered being involved in pathogenesis of autism. BTBR T+tf/J (BTBR) mouse was recently reported as a model for investigation of autism because of its similarity in behavioral abnormalities with human autistic subjects. Neuro-inflammation could mediate generation of autoantibodies to brain antigen resulting in altered brain development. To evaluate the presence of brain autoantibodies and expression status of proteins related with brain development at fetal stage, fetus of BTBR mice were obtained at day 18 of prenatal period. IJVB mice were used as a control strain because of its positive social behaviors. Thirty one and twenty seven fetuses were obtained from three pregnant BTBR and FVB dams, respectively. Deposit of IgG isotype in fetal brain was evaluated using brain homogenates by ELISA. Expression of glial fibrillary acidic protein (GFAP), brain-derived neurotrophic factor (BDNF), nerve growth factor (NGF), and myelin basic protein (MBP) was examined using the fetal brain homogenates. Level of brain IgGa, IgG2b, and IgG3 deposit was significantly higher in BTBR fetus than FVB fetus, but no difference was found for IgG1 between the two strains. Expression of GFAP, NGF, and MBP was significantly lower in BTBR fetus than FVB fetus, but level of BDNF was not different between the two strains. Overall, this study suggests that pre-natal alteration in expression of various proteins related with brain development could lead to occurrence of autism. In addition, accumulation of autoantibody against brain antigen at fetal stage could result in pathogenesis to brain development. [supported by National Research Foundation of Korea 2010-0022169]
The availability of historical data for survival and tumor incidences can be useful in the overall interpretation of lifetime carcinogenicity bioassays. Survival data and incidences of neoplastic lesions were compiled for CD-1 mice from the same supplier used as control animals in nine carcinogenicity studies of 104 weeks. All studies, terminated between 2005 and 2011, were performed in our facility, with standardized environment, housing, feeding, necropsy, tissue sampling and trim- ming procedures, application of common diagnostic criteria and peer review. The mean survival rate of male and female mice was similar (respectively 45% and 43% at terminal sacrifice). The most common causes of unscheduled death or moribundity in males during the course of the studies were, by decreasing order, tumors (mostly from hemolymphoreticular system, lung or liver), atrial thrombo- sis, amyloidosis, skin lesion, various inflammatory processes or nephropathy. In females, the most common causes were tumors from the hemolymphoreticular system or from another origin (mainly lung or uterus), amyloidosis, skin lesion or nephropathy. In males, the most common neoplasms originated from lungs (ade- noma and carcinoma: >25%), liver (adenoma and carcinoma: >25%) and lympho- reticular system (10% malignant lymphoma) while females had mostly malignant lymphoma (>25%). The other common tumors seen with an incidence above 1% were found in various organs, i.e. Harderian gland, uterus, ovaries, adrenal gland, pituitary gland, mammary gland, testis and kidney or testis, in addition to systemic tumors (mainly histiocytic sarcoma and hemangiosarcoma). The incidences of the principal tumors were compared to published data. There were no marked differ- ences with the exception of the slightly higher incidence of malignant lymphoma in the males and females from our facility. These data were also compared study per study, revealing no major differences. This suggested that major tumor types were stable during this 6-year period with no evidence of strain drift.

The aim of this study was to obtain historical background data in Wistar rats collected over a period of 2 years as an essential prerequisite of carcinogenicity studies with this rat strain. Specific pathogen free Crl:WI(Han) Wistar rats obtained from Charles River, Germany were maintained untreated and provided ad libitum rodent diet. A 104-week study was conducted with 50 males and 50 females to investigate the survival, body weight development, health condition, clinical pathology and incidences of major MNU-induced tumors in rasH2 mice such as forestomach pap- illoma and carcinoma, malignant lymphoma, skin papilloma and lung adenoma. At study completion a high survival rate of 86% in males and 74% in females was observed. Body weights developed as expected, but reached extremely low mean values (<500g in male and <300g in female animals). Clinical findings and clinical pathology results were within the expected range. When compared to other rat strains, a low number of spontaneous lesions were observed at necropsy.

The general tumor profile was within the range of expected lesions (pituitary ad- enoma, mammary tumors, hepatocellular, thyroid and adrenal gland neoplasms, Leydig cell tumors). In contrast, the Wistar specific thymoma, but also skin and ovarian neoplasms were of very low incidence. Rare tumors included cases of hiber- noma, two nasal cavity tumors (adenoma, hemangiosarcoma), and parotid gland adenoma. Amongst pre-neoplastic and nonneoplastic lesions, there was a low inci- dence of foci of hepatocellular alteration, especially for basophilic cell foci, a com- mon finding in Wistar rats. The severity degrees of other findings were significantly lower than noted in other rat strains.

These results show that this Wistar rat strain maintained on Altromin 1324 diet at BSL offers a reliable model for the evaluation of carcinogenic potential of com- pounds especially in studies that are designed to exceed the standard duration of 2 years.
Effectiveness of New Drugs When Human Efficacy Studies Are Not Ethical or Feasible (21 CFR 314.600 for drugs; 21 CFR 601 Subpart H for biological products), nonhuman primates, including cynomolgus macaques, have also become essential animal models to address product efficacy.

A comprehensive set of well-documented reference values for hematology, clinical chemistry and coagulation parameters can assist in interpreting clinical pathology data from cynomolgus macaques. These values provide data essential for the characterization of the cynomolgus macaque, as is required of an animal model in support of product development under the 'Animal Rule'. In addition, reference ranges are useful in evaluating the overall health status of each animal as well as serving as a baseline for evaluation/interpretation of any changes that occur due to disease and/or toxicity.

The values summarized and presented in this poster are intended to provide veterinary clinicians, researchers and toxicologists with reference ranges for hematology, clinical chemistry and coagulation parameters commonly evaluated in toxicology and/or efficacy studies. Analyses were performed using samples collected from clinically normal, healthy, naive, young adult, cynomolgus macaques of Asian origin. Methods of collection, sample handling and analysis are described. Samples were collected and analyzed as part of multiple studies across multiple sites sponsored by the National Institute of Allergy and Infectious Disease (NIAID).

**2136 Comparison of Rodent Euthanasia Using Carbon Dioxide (CO2) by Pre-Filled, Slow-Filled, and Rapid-Filled Methods in Mice**

J. K. Herman, J. Seeman, B. Joachim, T. Richner, M. Logan and L. W. Dochterman. Taxology, Covance Laboratories, Madison, WI. LabDiet and Covance Laboratories, Madison, WI. *Toxicology, Covance Laboratories, Madison, WI.* LabDiet and Covance Laboratories, Madison, WI. *Pathology, Covance Laboratories, Madison, WI.*

The AVMA Guidelines for the Euthanasia of Animals (2013) states that pre-filled CO2 chambers are unacceptable and a slow-fill method with a rate of approximately 10% to 30% per minute is optimal due to lower potential for pain or distress. To evaluate the proposed procedure, three methods of CO2 delivery for euthanasia were compared in mice: fully charged chamber (Group 1, n=5; 100% CO2), rapid fill (Group 2, n=8; 80% CO2 per minute) and slow fill (Group 3, n=8; 30% CO2 per minute). Blood was collected via cardiac puncture for analysis, necropsy was performed and histological changes were assessed. Mean onset of tachypnea was 11, 15 and 20 seconds while mean time to respiratory cessation was 35, 56 and 141 seconds for Groups 1, 2 or 3, respectively. Ataxia, tachypnea, open-mouth breathing, and recumbency occurred in all groups but onset was more rapid in Group 1 while overall durations were longest in Group 3. Mean pH of the mixed venous samples was 7.10, 7.05 and 6.88 for Groups 1, 2 and 3, respectively, although the partial pressure of oxygen and hemoglobin oxygen saturation were consistent across groups. Additionally, Group 3 animals had macroscopic observations of dark red discoloration of all lung lobes correlating microscopically to lung congestion and hemorrhage. In conclusion, based on shorter time to respiratory cessation, milder clinical pathology changes and lack of microscopic changes, the fully charged chamber is considered to be more humane than using a slow fill technique. However, given the recent guideline changes, we propose utilizing the rapid-fill method for the euthanasia of rodents via CO2 as this method appeared more humane compared to the slow-fill method. Given the variability in the blood pH, toxicokinetic evaluation may also be affected based on variability in plasma protein binding when using the slow filled method.

**2137 Effects of Blood Collection via Catheter on Hematology and Coagulation Parameters in Rats**

A. M. Brooks, A. N. Alexander, L. Hurdges and R. Hall. Toxicology, Covance Laboratories Inc., Madison, WI.

The purpose of this study was to determine the optimum blood collection method in rats treated with Alteplase (Activas®, an on-the-market anticoagulant, and compare clinical pathology data after various collection methods. Five groups of male rats (3/group in 3 treated groups, 3/group in 2 control groups) were catheterized via femoral vein for intravenous (IV) dosing. Animals in 5 of those groups (1 control and 2 treated) were also catheterized in the jugular vein; this second catheter was connected to an injection port and used for blood collections. Alteplase (20 mg/kg, 1 mg/mL) was administrated IV to treated groups over approximately 1 hour. Control groups received sterile saline at the same dose volume and duration. Blood for hematology and coagulation were collected approximately 10 minutes after the end of infusion. Samples were collected directly from the jugular vein (JB) or via catheter with (CBH) or without (CB) heparin lock. Alteplase administration produced pharmacologically expected mildly prolonged PT (30% higher), moderately prolonged APTT (49% higher), and moderately lower fibrinogen concentration (58% lower) for JB animals (compared to JB controls). However, coagulation data from samples collected via catheter showed significant artifact compared to data from JB samples, even in untreated animals. Virtually no APTT data could be obtained from CBH or CB animals; the few samples that did produce data showed abnormally extended times (67.9-80.3 seconds vs. 17.1-18.1 seconds for JB controls). Plasma samples also showed slight hemolysis for animals bled by CB (2/5 samples) or CBH (2/3 control and 3/5 Alteplase samples) techniques. Hemolysis was not present in plasma samples from control or treated JB animals, and APTT was measurable in all of these plasma samples. Between control groups, CBH collection resulted in lower platelet counts than did JB collection (28% lower).

In conclusion, direct venous blood collection is preferred when assessing coagulation and hematology endpoints in rats; collection via catheter should be avoided in this model.

**2138 Characterization of Background Routine and Specialization Ocular Endpoints Used in Juvenile NHP Toxicology Studies**

K. Tennesen, S. Wise and M. Vézina. Ocular and Neuroscience, Charles River, Montreal, QC, Canada.

In recent years there has been an increased emphasis on non-clinical testing of pharmaceutical and biopharmaceutical products for the pediatric population. With larger numbers of new chemical entities undergoing toxicity testing, ocular changes may also be detected. Ophthalmologic examinations are a common endpoint on toxicity studies and can detect unanticipated ocular effects; however, other parameters may also provide relevant information. As the non-human primate (NHP) is often the most appropriate species for the testing on biologics, we characterized the full battery of standard and specialized ocular endpoints in juvenile non-human primates (18 to 23 months; n=4 animals) to determine whether they exhibited significantly different profiles than observed in older animals. No abnormal findings were observed during examinations, which consisted of a bio- microscopic (slit lamp) examination for evaluation of the adnexa and anterior portion of the eye, funduscopic (direct and indirect ophthalmoscopy) examination to evaluate the ocular fundus. Effects on intraocular pressure (IOP) can occur in young animals, mean IOP values were 15 ± 4 mmHg; approximately 14% lower than background ranges in older animals (2 to 5 years; n=172 eyes). Mean corneal thickness measured using a handheld pachymeter (451 ± 25 μm) or specular microscope (457 ± 15 μm) were slightly higher than those measured in older populations (422 ± 21 μm; n=12 eyes). Corneal endothelial cell density was overall higher in juvenile animals (mean = 3519 cells/mm² vs. 2936 cells/mm²), however, fewer of these consisted of the typical hexagonal shape compared to older animals (61% vs 71%). In conclusion, background ocular characteristics are generally similar between juvenile and older
animals, however, there are some differences which should be taken into consideration when evaluating the results in toxicology studies to facilitate the recognition of test article-related changes.

**2139 Data Comparison of the Respiratory Parameters during the Acclimatization Phase of Rat Snout-Only and Whole-Body Plethysmography Studies**

Prior to the exposure phase of a snout-only plethysmography (SOP) or whole-body plethysmography (WBP) study, the animals are trained to the restraint procedure over a period of days. The aim is to minimise any stress-related elevations in respiratory minute volume (RMV) values, which may mask potential effects of the administered test material. Measurements of tidal volume (TV), respiration rate (RR) and RMV were conducted over a number of consecutive days. For SOP, the animals were held in restraining tubes and for WBP they had freedom of movement in a small chamber. Mean data (n=8) for the SOP study gave elevated RMV values of up to 637 mL/min on Day 1 after 10mins, which decreased to 229 mL/min by 30mins and 200 mL/min by 60mins. For Day 3 to 5, the RMV had decreased to between 405 and 420 mL/min after 10mins, 185 and 198 mL/min by 30mins and 189 and 203 mL/min by 60mins. The values from the period 30 to 60mins are similar to published data (1). These changes in RMV were due to increases in the RR (up to 399 breaths per minute (bpm) as only a marginal effect on TV was observed. Mean RMV data (116 to 138 mL/min) for the WBP study gave little change with acclimatisation number and duration. Comparing the two approaches, RR values were initially considerably higher for SOP (up to 399bpm) but after 30mins were similar (123bpm for SOP and 124bpm for WBP). There was also a marked difference in mean TV values, 1.75mL/min for SOP and 1.06mL/min for WBP. In conclusion, the method of restraint has a marked effect on RR, TV and RMV and additional study design considerations needs to be given prior to conducting SOP studies.

**2140 Comparison of 4DCT-Derived Ventilation Maps to Deposition Patterns of Inhaled Particulates in Healthy and Diseased Rat Lungs**

R. E. Jacob1, W. J. Lamm2, D. R. Einstein1,3, M. Kueger2, R. W. Glenn2 and R. A. Corley2. 1Pacific Northwest National Laboratory, Richland, WA, 2Pulmonary and Critical Care Medicine, University of Washington, Seattle, WA and 3Mechanical Engineering, University of Washington, Seattle, WA.

Changes in lung mechanics due to disease can strongly impact airflow dynamics and ventilation patterns. We have demonstrated that non-invasive, in vivo 4DCT imaging (3D imaging at multiple time points in the breathing cycle) can be used to map heterogeneities in ventilation patterns of rats under healthy and disease conditions. To validate such maps we exposed rats to fluorescent microspheres (FMS) by inhalation and examined 3D particle deposition patterns using cryomicrotome imaging. In these studies, eleven male Sprague-Dawley rats (231 ± 7g) were given an intratracheal dose of either 10 U/kg elastase or 0.2 mL saline or 0.2 mL saline only to a single lobe. Four weeks after dosing, rats were surgically intubated, mechanically ventilated with a tidal volume of ~2.0 mL, and imaged at 100 ms temporal resolution over the full breathing cycle by 4DCT. Immediately following imaging, rats were transferred to another ventilator with the same tidal volume and exposed to an aerosol of ~1 micron FMS for 5 minutes. After the exposure, the lungs were removed, filled with an embedding medium, and frozen for cryomicrotome sectioning. The cryomicrotome captured images of inhaled particle deposition throughout the entire lung, where the fluorescent signal intensity indicates ventilation. Comparisons between 4DCT ventilation maps and FMS deposition patterns showed strong correlations (r=0.75, p<0.0005) in ventilation patterns, where gross ventilation defects due to the disease were observed. By comparison, control rats showed few, if any, ventilation anomalies. We conclude that ventilation maps derived from non-invasive 4DCT imaging can be useful for predicting aerosol deposition in inhalation studies, evaluating lung disease and disease progression, and assessing treatment efficacy.

**2141 Development of an Impedance-Based Model For Assessment of Cardiopulmonary Function in Rabbits**

M. Horsmon1, N. M. Vincelli2 and R. Kristovich1. 1US Army Edgewood Chemical Biological Center, Gunpowder, MD and 2Leidos, Gunpowder, MD. Sponsor: S. Hulet.

Improving the quality of physiologic data collected from research animals in toxicology studies is paramount. This is most easily accomplished by collecting as much data as possible from a single animal, thereby reducing animal use and error associated with satellite groups. The present study investigates the feasibility of applying a large animal implantable telemetry device capable of providing data on animal activity, core body temperature, blood pressure (BP), electrocardiogram (ECG), and impedance-based respiratory parameters in the rabbit. Six New Zealand white rabbits were implanted with a modified TL11M-D70-PCTR device from data sciences international. The first task was to develop an optimal implantation technique that allows calibrated tidal volume (Vt) measurements that are within 10% of those obtained simultaneously from a pneumotachograph (PNT), low noise ECG, and stable BP. The second task was to challenge with a known respiratory stimulant (doxapram HCl, 5.0mg/kg i.v.) to assess linearity of the calibration across a range of Vt. Of the three electrode placements attempted, only one resulted in calibrations consistently under 10% error. Optimal electrode placement results in calibrated Vt measurements within 1.7% (±1.6%) of those obtained from a PNT during normal tidal breathing, 6.0% (±3.6%) following doxapram HCl injection and 7.3% (±4.4%) following saline injection. Vt range for normal tidal breathing and saline injection was 9-15 mL, and following doxapram injection was 25-30 mL. Similar error ranges were associated with derived flow parameters. Increases in mean BP of 25.0mmHg (±6.82mmHg) and decreases in heart rate of 56.3bpm (±6.82bpm) were associated with doxapram injection only. No departure from normal body temperature was observed in any group. The development of this model offers a solution to monitoring cardiopulmonary function the rabbit.

**2142 Comparison of Cardiovascular Parameters Recorded via Radio-Telemetry in Göttingen and Chinese Bama Minipigs**

S. Mason, L. Qu, R. Wu, S. McPherson and Q. He. WuXi AppTec, Suzhou, China.

Introduction: Minipigs are routinely used for regulatory toxicity testing, including assessment of cardiovascular effects of a drug via telemetry. In the USA and Europe, the Göttingen minipig is often selected for such studies, while in China, the Bama minipig is usually the species of choice. The objective of this study was to compare the hemodynamic and electrocardiographic parameters of the Göttingen and Chinese Bama minipigs, using the standard telemetry methodology.

Method: Six Bama minipigs were surgically implanted with radiotelemetry transmitters (DSI TL11M-D70-PCTR). Systemic blood pressure, modified Lead II ECG intervals, and heart rate were recorded continuously for repeated intervals of approximately 24 hours using the DSI Ponomah software (version 5.00). The control cardiovascular data for Göttingen minipigs were obtained from literature (Markert et al, 2008).

Results and discussion: The mean systolic and diastolic pressures for Bama pigs were 134 and 95 mmHg, respectively, compared with the published values of 122 and 86 mmHg for Göttingen animals. Baseline heart rates were slightly higher for the Bama pigs (88 btm) compared with the Göttingen pigs (71 btm). Associated with the difference in heart rate, there were some small differences in quantitative ECG parameters, most notably for the QRS duration (39 ms for Bama and 56 ms for Göttingen) and QT-interval (295 ms for Bama and 320 ms for Göttingen). Much of the difference in heart rate and derived ECG intervals may be attributable to variations in housing and husbandry practice. In particular, the timing of feeding relative to data collection is an important factor as postprandial increases of 8-10% in heart rate have been demonstrated in minipigs. In summary, the cardiovascular parameters collected from telemetry-instrumented Bama minipigs were broadly similar to those reported from Göttingen animals, and this strain of animal is considered suitable for assessment of effects of new drugs on the cardiovascular system.
Comparative Sensitivities of the Rat, Dog, and Monkey Larynx and Tracheal Bifurcation in Inhalation Toxicity Studies

A. M. Pilling1, V. Mowat1 and D. J. Alexander1. 1Pathology, HLS, Huntington, United Kingdom, 2Toxpath Consultancy Ltd, Stradbroke, Suffolk, United Kingdom and 3DDA Nonclinical Safety Ltd, Godmanchester, Cambs, United Kingdom. Sponsor: D. Mitchell.

Introduction

In this review, a comparative assessment of the larynx and carina from rat, dog and cynomolgus monkey is undertaken, to compare sensitivities and to assess their relevance for man. In inhalation toxicity studies, the authors have observed that drug induced lesions are frequently reported in the larynx and tracheal bifurcation (carina) in the rat, but less so in the dog or primate. This review is based on observations made by the authors over several years, and on data from inhalation studies compiled at one site. Histopathological sections of the upper respiratory tract tissues, including the larynx and carina, were prepared and evaluated according to the protocols in use at the different sites, in accordance with best practice guidelines. Data from several inhalation studies run at one site on different rodent and nonrodent species were collated and tabulated. They indicated that some test articles which induce lesions in the upper respiratory tract in rodents, notably in the larynx, do not cause histopathological changes in the dog or primate, supporting the authors’ observations. The rat larynx is far more sensitive than the dog and monkey in its response to inhaled xenobiotics, due to the relatively thin epithelial lining, in association with increased mucosal deposition of aerosol particles. The carinal ridge in the tracheal bifurcation is also a well-defined point of impaction for inhaled particles, and is more frequently injured in rodents than in dogs and primates, due to its relatively thin epithelium and airflow dynamics.

Conclusion

Personal observations and available data indicate that drug induced lesions are more frequently reported in the larynx and tracheal bifurcation (carina) in the rat than in the dog or primate, bringing into question the relevance of these rodent findings for humans. These observations suggest the human larynx is closer to the beagle dog and cynomolgus monkey in its response to inhaled xenobiotics.

Species-Related Differential Sensitivity for Assessing Hemodynamics and Respiratory Function Using Combined Telemetry-Plethysmography Model

Simultaneous monitoring of cardiovascular and respiratory parameters in conscious non-restrained animals could be useful in safety evaluation. However, the choice of the animal species may be crucial.

We investigated the sensitivity of the 3 commonly used rodent species to the effects of clonidine (1 mg/kg, i.p.), verapamil (30 mg/kg, p.o.) and theophylline (100 mg/kg or 50 mg/kg in mice, m.p.) on cardio-respiratory function using combined telemetry and plethysmography. Telemetered rats, guinea-pigs and mice were placed into plethysmography chambers to simultaneously assess hemodynamics (Heart Rate, HR; Mean Arterial Blood Pressure, MAP) and respiratory function (Minute Volume, MV).

Clonidine decreased HR in rats (-38%, p<0.001) and mice (-31%, p<0.01) but not in guinea-pigs. Clonidine also increased MAP (+35%, p<0.01) and tended to reduce MV (-22%, NS) in rat only. In rats and mice, verapamil decreased MAP (-27% and -25%, p<0.01) and increased HR (+16% and +12%, p<0.05). Hemodynamic parameters were not modified in guinea-pigs. Verapamil had no effect on ventilation in the 3 species. Theophylline increased HR in rats, mice and guinea-pigs (+59%, +39% and +32%, p<0.001) but had no effect on MAP. Theophylline exhibited respiratory stimulant properties in rats (MV, +68%, p<0.05) and mice (MV, +203%, p<0.01) but not in guinea-pigs.

These findings suggest that, in contrast to cardiac risk assessment with regards to evaluation of QT interval prolongation, both rats and mice are more sensitive than guinea-pigs in the combined telemetry-plethysmography model for assessing hemodynamics and respiratory function in early safety pharmacology studies.

Effect on Dosimetry of Altered Respiratory Minute Volume During Inhalation Exposure

X. Li, S. Oag, P. McDonald and P. Smith. Inhalation Toxicology, Charles River Edinburgh, Edinburgh, United Kingdom. Sponsor: W. Harvey.

For most rodent inhalation studies, the achieved dose is estimated based on the calculated respiratory minute volume (RMV) according to animal body weight using one of the commonly accepted algorithms, like Guyton, McMahon, Bide or ATF formula. However, such estimates will not be accurate if the inhaled material has a local irritating effect on the respiratory system, with consequent effects on the respiratory pattern and RMV. Under such circumstances, the inhalation dose may be miscalculated by use of standard algorithms. The current study was designed to investigate the effect of a known respiratory irritating agent (Code: SA) on the RMV of rats. SA was aerosolised and administered to the rat via the nose-only inhalation route for 10 min at three different aerosol concentrations using a flow past system. Animal RMV was assessed using a head out plethysmography system before, during and after inhalation exposure. Our investigations revealed that the RMV values decreased significantly during inhalation exposure to SA compared with the values obtained before inhalation exposure in the same animals. The reduction was mainly due to decreased tidal volume and was largely concentration-dependent. At the high concentration, the measured RMV value was less than 50% of the RMV value estimated according to the McMahon formula. The investigation justifies our approach of using the measured RMV value rather than calculated RMV (based on animal body weight) for a better estimate of achieved doses during inhalation exposure to test items which may have an irritant effect on the respiratory system.

Implantation of Left Ventricular Pressure Telemetry with Solid Tip ECG in the Cynomolgus Macaques: Surgical and Anaesthetic Considerations

Objectives: Implantation of a D70-PCTP transmitter allows measurement of cardiovascular parameters for safety pharmacology and toxicology studies. Historically, we have implanted ECG electrodes subcutaneously over the thorax in the primate, resulting in a variable signal with a large noise-signal ratio. The solid-tip negative ECG electrode configuration aims to eliminate muscle noise and movement artefact from the ECG waveform.

Method: A balanced anaesthetic technique is used and multimodal analgesia is provided. The dual pressure catheters are surgically implanted into the apex of the left ventricle via a midline laparotomy and incision in the diaphragm, and into the abdominal aorta via the left femoral artery. The device body is anchored in the abdominal cavity to measure core body temperature. The positive ECG electrode is positioned on the diaphragm close to the apex of the heart, and the negative ECG electrode advanced into the superior vena cava via the right internal jugular vein. The final position of the negative ECG electrode is ascertained at surgery by monitoring ECG morphology.

Results: The solid-tip ECG configuration ensures the procedure for implantation is reproducible and simplified compared to subcutaneous placement. Waveforms from these implants are considered good, and all animals recovered well without complications. Our peri-operative protocol provides stable anaesthesia and suitable analgesia for this procedure. To date none of our macaques implanted with this device have required surgical repair.

Conclusions: The solid-tip ECG D70-PCTP device provides improvements in ECG waveform quality in the primate, and also animal welfare due to decreased surgical/anaesthesia time and fewer surgical repairs.

Onset of Sexual Maturity in Female Göttingen Minipigs

B. Peters1, E. de Rijk1, H. Lorentsen2, A. Zeltner2 and H. Emmen1. 1Toxicology, WIL Research, Den Bosch, Netherlands and 2Elevegard Göttingen Minipigs A/S, Dalmose, Denmark.

In drug development minipigs may be used as a non-rodent alternative to dogs or non-human primates. For general toxicity studies, the animals should be sexually mature at start of the study. Based on breeding experience, female Göttingen minipigs are considered to reach sexual maturity at 4-5 months of age. To investigate this further, a study with young sows at 3-4 months of age (housed in the same room as adult boars) was performed. Twice weekly, they were observed for signs of heat (vulva redness/swelling, mounting) and blood samples were taken for progesterone analysis. In addition, body weights were recorded every 2 weeks. After the completion of 1-2 cycles of progesterone release, females were sacrificed. To check
whether the female minipigs were actually sexually mature, the reproductive organs (ovaries, uterus, pituitary gland) were weighted and histopathological examination of reproductive-related organs (ovaries, uterus and cervix, vagina, mammary gland and pituitary) was performed.

Before reaching sexual maturity, very low concentrations of progesterone (< 1 ng/mL) and/or signs of heat were detected sporadically. The first cycle of progesterone release, indicative of a functional corpus luteum, was noted in 7/13 sows at 3.7–4.2 months (8.4–12 kg) and for another 6/13 sows at 6.1–6.5 months (12.1–16 kg) of age. The estimated cycle length was 17–22 days. Signs for heat were not always noted around expected ovulation. Histopathological examination of the reproductive organs confirmed that all 13 sows were sexually mature.

In conclusion, the age range when female Göttingen minipigs reach sexual maturity (3.7–6.5 months) is much longer than anticipated. Hence, care should be taken when designing toxicity studies with young sows and interpreting data hereof. Progesterone analysis proved to be a reliable method to detect sexual maturity during in-life.

A. Mitchell1, C. M. Luetjens2, S. M. Henwood1 and G. F. Weinbanger1, 1Covance Laboratories, Madison, WI and 2Covance Laboratories GmbH, Muenster, Germany.

Social housing of macaques is a standard and common requirement of up-to-date primate husbandry. Unlike in male animals, social housing can have profound effects on ovarian cyclicity and potentially on female fertility. Among these effects are interruptions or irregularities of the ovarian cycles. However, these cycle disturbances vanish as animals are socially housed over prolonged periods of time. Since this laboratory has long-lasting experience in ovarian cycle monitoring/social housing, a retrospective analysis of cycle patterns was undertaken. Beyond that, a comparison of menstrual cycle data was conducted for two locations (US vs. Europe) with highly comparable husbandry approaches/vaginal swabbing collection and criteria. Daily vaginal swab data were available from 5447 ovarian cycles of Asian origin animals. Animals were housed socially for a period of at least 3 months. The swabs were rated from no to heavy menstruation. Menstrual cycle length was categorized (C1, C2, and C3) depending on the cycle length difference between consecutive cycles with C1 being a regular cycle, C2 a prolonged cycle and C3 a comparatively irregular cycle. Cycle durations below 20 days and over 50 days between consecutive cycles with C1 being a regular cycle, C2 a prolonged cycle and C3 an Old World monkey. New World monkeys, e.g. the marmoset monkey (Callithrix jacchus) are also being used occasionally. Within the primate pedigree Old World monkeys are more closely related to humans compared to New World monkeys. In many instances, safety assessment of biopharmaceuticals requires evaluation of the immune system. In this work, relevant differences between cynomolgus and marmoset monkeys are compared. Functional immunotoxicology tests are easier to be performed in cynomolgus monkeys due to better functionality of human assays or blood volume limitations in marmosets. On the other hand some leukocyte CD markers better resemble the human distribution in marmosets. Development of anti-drug antibodies (ADA) is often a critical limitation for the evaluation or maximum duration of preclinical studies with biopharmaceuticals. Based upon the phylogenetic distance a higher risk of ADA development in marmosets can be assumed. However, data from approx. 200 animals/species exposed to human antibodies reveal 6% of cynomolgus and only 2% of marmosets developed detectable ADA responses impacting toxicokinetics. In conclusion, whilst cynomolgus monkeys are the preferred non-human primate model, marmosets provide a relevant alternative in certain instances.

E. Higoshi1, A. Ando1, S. Iwano1, N. Murayama2, H. Yamazaki2 and Y. Miyamoto2, 1Toxicology and Pharmacokinetics Laboratories, Toney Industries, Inc., Kanagawa, Japan and 2Laboratory of Drug Metabolism and Pharmacokinetics, Showa Pharmaceutical University, Tokyo, Japan.

Microminipig, a small minipig (< 10 kg body weight in adult) is developed as a novel experimental animal for nonclinical pharmacology/toxicology studies in Fuji Micra Inc. (Shizuoka, Japan). To understand the results of nonclinical studies, we need to comprehend species differences in drug metabolism between human and microminipig. It has been reported that there is some overlap in microminipig and human cytochrome P450 substrate specificity, with high P450 2D-mediated activity in liver microsomes. Glucuronidation catalyzed by UDP-glucuronosyltransferase (UGT) is a predominant phase II biotransformation reaction in the metabolism. The purpose of the present study is to identify the characteristics of hepatic UGT activity of microminipig by a comparison with those of human and other experimental animals.

In vitro UGT activities in liver microsomes from microminipig, human, mouse, rat, dog, monkey and minipig were investigated. Glucuronidases of estradiol, imipramine, serotonin, propofol and 3'-Azido-3'-deoxythymidine (AZT), a selective substrate of human UGT1A1, 1A4, 1A6, 1A9 and 2B7, respectively, were measured by LC/MS/MS. Estradiol glucuronidation activity of microminipig was higher than that of human and other animals. Imipramine-N-glucuronidation, a distinctive conjugation by human UGT1A4, was catalyzed by microminipig liver microsomes, but not by dog liver microsomes. Serotonin and propofol glucuronidation activities in microminipig were similar to those in human. Low AZT glucuronidation activity in microminipig was observed as similar to that in rodents or dog. UGT activities in microminipig were similar to those in minipig. It is suggested that microminipig is useful for nonclinical studies as one of non-rodent species on UGT activity.

S. Jana, V. Goyal, S. Pandey, A. Gotri, S. Kakade and R. Nirogi, Discovery Toxicology, Suren Life Science Ltd, Hyderabad, Andhra Pradesh, India.

Clinical chemistry is an essential analytic tool in many areas of research, drug assessment and development. In research involving mice or other small animals, limited amount of blood that can be collected pose a challenge and limit the prac-
tical utility of clinical chemistry analyses on serum or plasma. To overcome this problem, multiple cohort of animal are being used for different activities at different time leading to extra animals and additional resources, and limit the suitability of interpretation of results which are derived from different animals. The aim of this study was to prove the hypothesis that diluted plasma can be used in toxicity studies involving mice to determine various clinical chemistry parameters from the same animal without compromising the quality of data. Blood samples were collected from the mice; two aliquots were prepared, one used for dilution and other one kept undiluted. First aliquot was diluted 2, 3, 5 and 10-fold with water for injection. Analysis was carried out using automated clinical chemistry analyzer. Results were compared with the results from non-diluted plasma of same mice.

Most of the clinical chemistry parameters were well within the range of undiluted samples except electrolytes. For electrolytes, we tried dilution with different diluent like reagent grade water type I, Cal A (Random), plasma, normal saline and water for injection albeit without any success. Nevertheless, when specimen dilution will permit essential testing on small, valuable or fewer animals, all specimen dilutions should be performed identically throughout the study.

Conclusions: The Sinclair lineage had the lowest average basal cortisol level. The stressor increased cortisol from a range of 14% to 129% (means) across the four lineages. All lineages responded to the stressor as reflected by increased plasma cortisol but the Sinclair increase was very modest. The Sinclair lineage was essentially a non-responder to the short-term stressor (food denial).

D. M. Abney1, K. Harding2, J. Toscano1, L. Poor1, E. Moreua2, H. Moomaw1, D. Reim3 and C. Winnicker1. 1Charles River Laboratories, Reno, NV, 2Charles River Laboratories, Houston, TX, 3Charles River Laboratories, Seneville, QC, Canada and 4Charles River Laboratories, Wilmington, MA. Sponsor: R. Kaiser.

At Charles River Laboratories (CRL), we are committed to ensuring all our animals have the highest level of care and welfare. To this end, our social housing program includes placing all animals in pairs or groups. We have a rate of almost 100% success social housing juvenile and sub-adult animals as well as adult females. Social housing of sexually mature males can be a challenge. Some publications suggest that it is not advisable to attempt adult male introductions in mixed sex rooms of rhesus macaques (Macaca mulatta). However separating animals into single sex rooms introduces a potential scientific confound as well as operational inefficiencies, and to our knowledge this data has not been published for cynomolgus macaques (Macaca fascicularis). Data was collected from two CRL sites which are actively social housing mature males. For the purposes of data collection, sexually mature males were defined as 5 years of age and 5kg or greater. As is common in toxicology research, all animals had a narrowly defined weight range. A pair/group was considered successful if they had maintained compatibility for a minimum of two weeks. All social housing attempts were made in rooms with females present and visible to the males. A total of 21 rooms were analyzed, and 81% of the rooms surveyed had success in pairing the majority of males in the room. Fifteen rooms had a success rate of 75% - 100% (median 92%) with over 280 male animals being socially housed. This data shows that mature males can be successfully socially housed in rooms with females. The ability to compatibly socially house mature males in mix sex rooms does not compromise welfare and allows for greater flexibil-

ity of vivarium space usage.

2152 Surgical and Nonsurgical Options for Dosing of Cen-
trally Administered Compounds and CSF Sampling in Toxicity Studies Using Cynomolgus Monkeys

In preclinical toxicology, the cynomolgus monkey represents the predominant non-human primate species. In terms of drug delivery, crossing the blood-brain barrier is often an important need in pharmaceutical development. This work gives an overview about available techniques and our experience. Opt.A: Under sedation, in juv. (11 months and 0.8 kg) to mature (≥5 kg) animals, lumbar spinal needle in-

jection was feasible at 3 times within 24 hrs (n=1000) for dosing (1-3mL) or CSF sampling (1-3mL). Opt.B: Animals of the same age range underwent intrathecal administration (0.02 mL/kg/hour) with a surgically implanted lumbar port system (n=480) for a duration of 13 wks, with 50% port patency for CSF. Opt.C: Dual port surgery with implantation (n=3) of a cisterna magna and lumbar port allowed multiple CSF samplings with chair-restrained and non sedated animals, while dos-

ing continuously through the lumbar port. The cisterna magna port showed a 100% port patency for 4 wks, hence required precaution when handling the ani-

mals to avoid catheter blocking or relocation. Opt.D: So far 9 months patency was achieved for an implanted intraventricular port (n=1) to allow a more robust and practicable CSF withdrawal (daily: 8 times, each 0.3mL). For the proper location of the lateral ventricle, a template atlas of the macaque brain for digital imaging and quantitative neuroanatomy was used. Non-stereotactic surgeries were conducted using SoloPort™ MID LOVO; 3 Fr polyurethane catheter; round tip; 60cm, 2 movable beads (Solomon Scientific, USA) as also performed in clinical settings. Post surgery the animal received an antibiotic and flunixin as analgesic for 5 days. A wash out period, was scheduled prior to start of first dosing. In conclusion, all described techniques were successfully conducted with juvenile and mature group housed cynomolgus monkeys in accordance with European requirements. It is now possible to perform the full range of clinical settings in this species for withdrawal of CSF, as well as for administration of centrally active drugs.
2153 Selection of Ocular Histology Tissue Sections Based on Ophthalmic Examination Findings

M. C. Colling. Preclinical Services, Charles River Laboratories, Reno, NV.

Standard procedures for collection and sectioning of eyes may not be sufficient when ocular findings are noted during ophthalmic examinations. Routine histologic sections of the eye are collected cutting by a section parallel to the ciliary artery to include cornea, iris, lens, retina, macula, optic disc, and optic nerve. While this process provides a tissue section that includes the most important ocular structures, this section may be insufficient if ocular findings have been noted in regions that are not centrally-located or if the test article targets the eye. Data from ophthalmic exams can be used to determine the best location to collect histologic sections of the eye.

Cynomolgus monkeys with pre-existing ophthalmic findings such as lens opacity, optic disc pallor, and retinal changes were selected for evaluation. An ophthalmic examination via slit lamp biomicroscopy and indirect ophthalmoscopy was conducted. Detailed information regarding the location of the ocular finding was recorded. For lens and fundus findings, a photograph was collected at the time of ophthalmic examination. At necropsy, the globes were collected separately. A standard histologic section and additional sections were collected based on location information from the ophthalmic data.

The routine section rarely included affected regions of the eye. Only in cases of optic disc findings was there a good likelihood of seeing the affected region on the routine slide. Non-central retina findings and lens findings were less often visible in routine sections. Using detailed descriptions from ophthalmic examination and photographs, the likelihood of collection a tissue section that included the region of ophthalmic findings was improved.

The routine section only provides the opportunity to evaluate ophthalmic findings if they are present in the region that is sectioned. For non-central findings, data from ophthalmic exams (including photographs) can be used to hone in on a tissue section more likely to include the affected region.

2154 Dermal Administration in Toxicity Studies Using the Cynomolgus Monkey

The cynomolgus monkey represents an important primate model for preclinical safety evaluation, and in rare cases drugs must be administered topically (epicutaneous administration). The current work describes the conduct and practicability of long duration administration (4-8 hours) of a gel-like test item (0.5 mL/kg/dose) over a period of 4 weeks. Following calculation of the required body surface area, the application site was shaved (e.g. 15 times 10 cm), so that the area was clearly separated from the remaining coat. Vehicle or appropriate concentration of the formulated test article was uniformly applied with a plastic card in equal thickness to the shaved area at the animals back, covered with a soft cloth and fixed with tape. In addition, a thin elastic tape was rolled around the animal’s body thickness to the shaved area at the animals back, covered with a soft cloth and fixed with tape. In addition, a thin elastic tape was rolled around the animal’s body. A jacket was used for further protection of the dosing site.

The animals underwent a 3 day jacket training to ensure comfort when wearing the jacket and to reduce the risk of manipulation by cage partners. At the end of the exposure period and after the skin assessment all application sites were cleaned with water for injection and additionally back and hands/feet were washed with an anti-allergic olive-based soap. Hereby, possible contamination should be further reduced. Great care was given to ensure protection of the dosing area to avoid accidental exposure or cross contamination with other group housed monkeys. All animals were examined for signs of erythema, edema formation and oedema at the dosing site(s) according to a modified Draize scheme (Draize, 1944). At necropsy, skin samples were taken from (a) application site (back), (b) non-dosed area (lower back, adjacent to application site), and (c) non-dosed area (abdomen), for comparison. In conclusion, the described technique was successfully conducted with group housed cynomolgus monkeys. However, some incidences of cross contamination did occur. Future work therefore shall evaluate the practicability of a thin body coat partly also covering legs and arms.

2155 Comparative Analysis of Cynomolgus Monkeys Behaviour by 24 Hour Time-Lapse Video Monitoring in Toxicity Studies

The cynomolgus monkey represents the predominant non-human primate species when it comes to preclinical safety evaluation of new medical products but rarely rely on behavioural aspects of undisturbed animals. Therefore, a video monitoring study was conducted with 12 animals divided in three animals per group. Repeated monitoring in a longitudinal study on three different occasions was performed in an interval of six weeks. The grouped animals were acquainted to each other and to the European style cages which are equipped with separating steel bar boxes. A video system monitored the animals for 24 hours in a light/dark regime of 12/12h adapted biweekly in a dark phase to red-light, with weak light emission. The videos were captured with software to monitor three animals on a single data file. To keep the total analysis time manageable all analyzed videos were only observed for six hours in total, always in the same daily time frames for all observed animals: Four hours at day light and two hours during the night. A qualitative behavioural scoring was utilized by timing the actions of the individual monkeys, divided into the following five different categories: 1) moving slowly, 2) sitting or lying calmly, 3) sitting on the water tap at the back, 4) wandering or climbing, and 5) the total number of behavioural changes. The observations demonstrated a high intra- and inter-variation of behavioural actions. The total number of behavioural changes was similar for the simultaneously monitored animals compared to the animals repeatedly monitored: 57.3 ± 18.0 compared to 53.3 ± 15.1 changes, respectively. The longest observed category (over 2 hours) was the mean time of sitting or lying calmly (which is mainly during the night) followed by sitting on the wateripple for almost two hours. In conclusion, this study demonstrated the feasibility of video recording of undisturbed cynomolgus monkeys over 24 hours. The results of this study will help detection and comparison of clinically relevant or adverse treatment effects normally not seen by short cage side observations.

2156 Investigation of a Suitable Method for Monkey Semen Collection

The cynomolgus monkey (Macaca fascicularis) is routinely used in preclinical toxicity testing. For certain drug indications it is important to have sexually mature animals on the studies. For males the presence of sperm in the ejaculate is one of the criteria for determination of sexual maturity. The intent of this study was to evaluate a reliable and repeatable method of semen collection. A total of 36 male cynomolgus monkeys, approximately 5 years of age or older and weighing 4.4 to 6.9 kg, were individually housed in stainless steel cages elevated off the floor, in HEPA-filtered rooms with a 12-hour light cycle. Semen was collected using a modified penile electroejaculation method (Mattison, et al., 2011). Semen collection was attempted in normal restraint chairs using minimal restraint. A gauze strip moistened in 0.9% saline was wrapped around the penis. Two electrodes from the stimulator were attached to the gauze. The stimulator settings were 10 to 30 pulses per second, and 1 to 3-ms duration. The voltage was varied from 0 to 50 V. The head of the penis was held inside an appropriate volume tube opening to catch the entire ejaculate, which was immediately transported to the laboratory for sperm count. The semen weight was also recorded. If no ejaculation occurred the animal was allowed to rest for at least 1 min and the stimulation was repeated. If no ejaculation occurred within 10 min, the animal was returned to his cage. Semen collection was attempted from the animal again with a minimum of 24-hour of rest between collection attempts. The success rate for semen collection was 86% at the first attempt and 100% within 2 days. The ejaculate parameters results obtained (weight 0.02 to 1.9 g and sperm count 2.7 x 107 to 5.8 x 108 ) were comparable to the literature (Niehoff, et al. 2010). The results demonstrated that this semen collection method may be used during the conduct of preclinical toxicity testing and the results can support the determination of the sexual maturity of the male non human primate.

2157 Collection of Semen Samples from Rabbits in Drug Disposition Studies

J. D. Stuhler1, J. Relph1, M. Jenson2, T. Eckhoff2, F. Thulacker1 and V. Tedesco3. 1Metabolism, Covance Laboratories, Madison, WI and 2Novartis Pharmaceuticals Corporation, East Hanover, NJ. Sponsor: V. Dinkel.

The rabbit semen collection model is a useful tool for the investigation of drug distribution into semen. Rabbits are relatively low cost, easy to manipulate in this application, and provide adequate sample volumes for analysis. This study describes a relatively simple and convenient method for collecting semen from rabbits for quantification of drug levels in drug disposition studies. The method used in this study is a modification of the procedures reported by Naughton et al. (2003) and Brederman et al. (1964).

In two studies with separate groups of rabbits (acclimated to laboratory conditions for 1 to 3 weeks before study initiation), 10 of 11 rabbits on test produced semen samples over an 8-day sample collection period. Postdose sample weights ranged
from 0.111 to 0.541 grams (mean 0.320 ± 0.148 grams) in the first study, and from 0.220 to 1.54 grams (mean 0.483 ± 0.324 grams) in the second study. All sample weights met the minimum sample size criterion for analysis.

The results demonstrate that multiple intranasal dosing sessions to achieve high total daily intranasal dose volumes can be tolerated by rats and dogs, two commonly used test species, provided there is a suitable interval between sessions.

For laboratory animal species, the total amount of blood withdrawn depends upon the weight of the animal and the time between successive collections. Withdrawal of too much blood, without intravenous fluid replacement can result in hypovolemic shock. Withdrawal of smaller volumes at intervals too frequent to allow for blood cell replacement can result in anemia. In general, for rats, it is recommended to collect no more than 3 samples, at a volume less than 20% of the total blood volume over a 24-hour period. This approach necessitates combining data across animals for the purposes of toxicokinetic/pharmacokinetic analyses. In order to allow serial blood sampling from adult rodents, WIL Research has recently established the technique of packed cell rejections. While this method has been used in academia, to the best of our knowledge, it has not been used previously in regulatory toxicology. Adult female rats were surgically implanted with femoral vein catheters with SAF Quick Connect harnesses with injection caps and jacket adaptors. Catheter patency was maintained by use of a heparinized saline lock. Blood samples were collected at 6 timepoints over two 24-hour periods in one week. Between collection and reinsertion, catheters were flushed with saline and a heparin lock was maintained. Samples were centrifuged, plasma was removed and the cell pellet was resuspended in sterile saline to make a cell suspension, which was reintroduced back into the animal. Catheters were flushed with saline and a heparin lock was reapplied. Subsequently, catheter patency was monitored on a twice-weekly basis for 4 weeks to facilitate inclusion of additional sampling intervals. Thirteen (13) of 15 females survived the packed cell reinsertion procedures, with patent catheters. Over the course of 4 weeks, gradual reduction in percentage of patent catheters was noted, with >50% patent at termination. These newly established procedures allow us to collect up to 12 serial samples (0.4-0.5 mL/sample) during one week period.

Toxicology studies in suckling rats often include satellite animals (3/sex/timepoint) for toxicokinetic (TK) purposes where blood is collected (typically >200μL) as a terminal procedure. Blood microsampling using a tail vein, capillary tube method has been used for TK profiling of satellite pups in an oral gavage repeat dose toxicology study where 5x32μL blood samples were collected from Postnatal day (PND) 14 pups (weighing ca 34g) and again at end of study on PND35. There were no clinical observations in the sampled pups and their weight gain matched that of unsampled control pups. Use of microsampling at PND14 and PND35 reduced the number of satellite pups from 60 to only 6 pups. Numbers of animals could be reduced even further if (limited) TK sampling could be done in main study pups. However there is concern that this might affect critical toxicological endpoints. An experiment was performed to emulate studies that finish at the end of the suckling period. 3 x 32μL blood samples were taken from 10 pups/sex within a 24 hour period at PND19 (ca 40-43g) and the following were measured at termination on PND20: clinical pathology, spleen and liver weights plus histopathology. There was an equal sized unsampled concurrent control group. There were no in-life observations or histopathological differences but there was a slight (non statistically significant) increase in spleen weight. In the terminal blood samples, females showed a slight but statistically significant decrease in red blood cell count (to 0.94x of control) plus slight (non significant) decreases in haemoglobin and haematocrit. The males showed a slight (non significant) increase in reticulocyte counts (to 1.05x of control). However, all values were within the concurrent control range. It was concluded that the nature and severity of the effects of microsampling 96μL blood in a PND19 suckling rat does not preclude the microsampling of main test pups provided care is taken to match blood loss in the control and judgement is used in the interpretation of findings.
PS 2162 Quantified Electroencephalography (qEEG) in Safety Pharmacology

Quantified Electroencephalography (qEEG) is a highly relevant translational technique able to measure the global effects of drugs on brain electrical activity. The aim of this study was to investigate the effects of 4 drugs with well-known side-effects, scopolamine, clozapine, ketamine and amphetamine on qEEG in the conscious rat. Fourteen telemetered rats were implanted with two surface electrodes over the fronto-parietal cortical area. After post-surgical recovery, animals were administered with vehicle or a drug and EEG was recorded over 60 minutes, starting 15 or 30 minutes after systemic injection. The differences of the spectral power between vehicle and the different treatments were assessed for each frequency band.

Scopolamine (0.5 mg/kg) clearly increased theta and alpha frequencies over 60 minutes with similar effects on delta frequencies from 0 to 10 minutes. A significant increase of alpha and beta frequencies was observed with clozapine (2 mg/kg). Ketamine (30 mg/kg) globally increased total spectral power with marked effects on delta, beta and gamma frequencies. Amphetamine (4 mg/kg) tended to increase alpha frequencies but significantly decreased beta to gamma frequencies. The increase of slow waves (delta to theta) potentially relates to the amnesic effects reported for scopolamine. Hyperactivity induced by amphetamine or ketamine potentially relates to the increase of theta to beta frequencies. An increase of intermediate frequencies is characteristic of a sedative-like effect, as observed with clozapine on beta frequencies. These results suggest that qEEG is a sensitive and reliable translational tool to predict potential adverse effects induced by new compounds on the central nervous system.

PS 2163 Serotonin Reuptake Impairs Executive Function and Induces Submissive-Like Behavior in Mice: A Validation Study of a New Cognitive Test for Chemical Risk Assessment

T. Endo1, S. Benner1, W. Ling1, N. Endo2, E. Kimura1 and M. Kakeyama1, 2. Laboratory of Environmental Health Sciences, Center for Disease Biology and Integrative Medicine, Graduate School of Medicine, the University of Tokyo, Tokyo, Japan and 2Department of Neurobiology and Behavior, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan.

Environmental chemical exposure has been suspected to be responsible for a recent increase in the incidence of pervasive developmental disorders. To study the possible causal relationship, we recently developed a new behavioral test method, using an apparatus named IntelliCage, which can analyze the executive function and social behavior in group-housed mice in a highly reproducible manner (Endo et al., Behav. Brain Res., 2011; PLOS ONE, 2012). In the present study, we have validated the reliability of this method by applying it to an assessment of chemically-induced serotonin reuptake model mice as a widely accepted model of executive function and social behavioral impairments. C57BL/6j male mice were administered 4-chloro-6-phenylalanine (PCPA), a tryptophan hydroxylase inhibitor, at a daily dose of 0 or 25 mg/kg for 4 weeks using osmotic mini-pump. Throughout this period, the two groups of mice were housed together in an IntelliCage and subjected to the behavioral flexibility test that consists of acquisition of place learning and its serial reversals. As a result, the PCPA group was found to perform less well in both periods, the two groups of mice were housed together in an IntelliCage and subjected to the behavioral flexibility test that consists of acquisition of place learning and its serial reversals. As a result, the PCPA group was found to perform less well in both periods.

In conclusion, the present behavioral test was validated as a reliable method for assessing abnormality in higher brain function and social behavioral impairments. C57BL/6j male mice were administrated 4-chloro-6-phenylalanine (PCPA), a tryptophan hydroxylase inhibitor, at a daily dose of 0 or 25 mg/kg for 4 weeks using osmotic mini-pump. Throughout this period, the two groups of mice were housed together in an IntelliCage and subjected to the behavioral flexibility test that consists of acquisition of place learning and its serial reversals. As a result, the PCPA group was found to perform less well in both periods.

PS 2163a A Simple Method of Cerebrospinal Fluid Collection from Conscious Beagle Dogs and Its Application As a Surrogate for the Assessment of CNS Exposures

V. Goyal, S. Pagnut, S. Pandey, S. Jana, A. Gothi, S. Kakade, G. Bhryapuneni and R. Nivogi. Discovery Toxicology, Suen Life Science Ltd, Hyderabad, Andhra Pradesh, India.

Many central nervous system (CNS) drug discovery programs require the successful collection of cerebrospinal fluid (CSF) for assessing CNS penetration and distribution of new chemical entities. Evidence from preclinical and clinical studies suggests that drug concentration in CSF appears to be reasonably accurate in predicting unbound drug concentration in the brain. Therefore, CSF can be used as a useful surrogate for in vivo assessment of CNS exposure and provides an important basis for the selection of drug candidates for entry into development. For repeated collection of CSF from dog, either dog has to be surgically cannulated or anesthetized several times which may interfere the pharmacokinetic (PK) property of the drug of interest. The objective of the present investigation was to develop a systematic approach to simplify the technique for collecting CSF from cisterna magna of the conscious Beagle dog. Dogs is placed either in lateral recumbency with the head flexed ventrally to 90 degree or alternatively in standing position comfortably and bent the neck at 90 degree to the table with the help of an assistant. Neck should be flexed so that space of insertion can be visible. A 20 - 24 gauge needle is inserted into depression just behind the pointed occipital prominence; direction of needle should be first slight transverse then obliquely into cistern magna. A slight popping sensation is observed when needle in subarachnoid space. CSF will come out with pressure inside the space as well as by gravity into collection tube. Multiple sampling can be done by this method using same animals to determine PK parameters.

The same animal can be used again after appropriate wash out period. In our laboratory we have used this technique several times to determine the drug CSF concentrations successfully. This method can be used for CSF PK without use of anesthesia or any surgical intervention.

PS 2163b Phosgene-Induced Lung Injury in the Conscious Pig

S. Graham1, A. J. Smith1, R. L. Perrott1, B. J. Jug1 and A. M. Schiut1. Detl Salisbury, United Kingdom and 2USAMRICD, Aberdeen Proving Ground, MD.

Currently no medical countermeasures exist for phosgene poisoning and treatment is supportive in an intensive care setting. Small animal models have been used to screen candidate therapies, however, extrapolation of therapeutic benefit to man requires verification in a larger animal model e.g. the pig. Therefore, a requirement to test the efficacy of treatments against a consistent, well characterised injury.

Animals were surgically implanted with a telemetry transmitter and exteriorised catheters to enable venous and arterial blood samples to be taken. After recovering from surgery (1 week) and baseline measurements (1 week), animals were exposed to either air or phosgene under anaesthesia, then recovered and monitored, fully conscious for 24 h.

Air exposed and phosgene exposed (Mean inhaled dose ± S.E.M., 0.793 ± 0.03 mg/kg) animals were successfully recovered and monitored to 24 h post-exposure. The phosgene exposed animals had a moderate/severe lung injury at 24 h compared to the air exposed animals.

Phosgene produced an increase in the amount of protein in the terminal broncho-alveolar lavage (BAL) fluid of the phosgene exposed animals (Mean ± S.E.M., 0.82 ± 0.3 mg/ml). The lung wet weight to body weight ratio (LWW:BW) and lung wet weight to dry weight ratio (LWW:DW) are measures of extravascular lung water and indicate the degree of alveolar permeability. There was an increase in the LWW:BW ration in the phosgene exposed animals when compared to the air exposed animals (Mean ± S.E.M., 16.16 ± 1.81 versus 8.01 ± 0.13). There was also an increase in the LWW:DW ration in all the lung lobes sampled in the phosgene exposed animals compared to the air exposed animals. Phosgene increased the number of neutrophils recruited to the lungs compared to the air exposed animals. The feasibility and reproducibility of the dose of phosgene producing a severe, but non-lethal lung injury at 24 h in which to test therapeutic candidates has been demonstrated.

PS 2163c LC50 Determination of Sarin and Soman in Conscious Guinea Pigs (GP) Using a Nose-Only Vapor Inhalation Model

Sarin and soman are organophosphorus compounds that pose both a military and a civilian threat. Because of the volatility of these agents, inhalation is likely the primary route of exposure. The toxicology of these inhaled agents has been under-investigated to date. This study was conducted to evaluate the dose–relationship curve and establish the lethal concentration of 50% of the exposed population (LC50) for both sarin and soman in unanasthetized GP using a newly developed nose-only vapor exposure system. GP were placed in a double compartment Plexiglas chamber separated by rubber neck and rubber nose seals which was then mounted to a 12-port nose-only inhalation tower. Respiratory parameters were monitored with a pneumotach and transducer during the exposure. GP were exposed to sarin or soman vapor via a Brooks vapor-generating system for 20 min in the concentration range of 13.1 to 21.8, and 13.7 to 24.5 mg/m3, respectively. LC50 estimates (± 95% confidence intervals [CIs]) were determined using a stage-wise adaptive dose design analysis. The LC50 for sarin was calculated to be 14.3 mg/m3 (CI:14.0-
14.6) and 18.4 mg/m³ (CI:16.7-20.2) for soman. Acetylcholinesterase (AChE) activity was measured in whole blood (WB) and from red blood cells (RBC) immediately following death. AChE activity was greatly depressed in both RBC and WB with maximal levels of activity being 15.5% and 10.5% of baseline, respectively, and means of 6.39% and 5.53% of baseline, respectively. This model provides a precise, accurate and realistic nerve agent vapor inhalation exposure system that can be used to test potential therapeutic compounds against these volatile nerve agents. The views expressed in this poster are those of the author(s) and do not reflect the official policy of the DoD, DOD, or the U.S. Government. The experimental protocol was approved by the USAMRICD IACUC and all procedures were conducted in accordance with the principles stated in the Guide for the Care and Use of Laboratory Animals and the Animal Welfare Act of 1966 (P.L. 89-544), as amended.

2164 The Endogenous Arylhydrocarbon Receptor Ligand 6-Formylindolo[3,2-b]Carbazole (FICZ) Is a Phototoxic UVA-Sensitizer in Epidermal Keratinocytes and Reconstructed Human Skin

Pharmacology and Toxicology, College of Pharmacy and Arizona Cancer Center, University of Arizona, Tucson, AZ.

6-Formylindolo[3,2-b]carbazole (FICZ) is a physiological high affinity ligand for the mammalian aryl hydrocarbon receptor (AhR) regulating expression of AhR target genes including cytochrome P450 1A1 (CYP1A1). Cutaneous formation of FICZ occurs through ultraviolet (UV)-driven photo-oxidation of its precursor L-tryptophan, and FICZ is thought to potentiate the UVB-induced stress response in human skin through AhR activation. Here we demonstrate for the first time that FICZ displays nanomolar sensitivity as a phototoxic UVA-sensitizer targeting human skin cells through photodynamic induction of oxidative and prototoxic stress. In human HaCaT keratinocytes, induction of apoptosis was observed in response to the combined action of solar simulated UVA (3,3 J/cm²) and FICZ (10 nM), but not in HaCaT keratinocytes in the absence of UVA or FICZ only. FICZ-toxicity was also observed in an epidermal tissue reconstruct (Epiderm®) exposed to FICZ and UVA, as evident from sunburn cell formation and proteolytic activation of caspase 3. Gene expression array analysis revealed that FICZ caused upregulation of CYP1A1 independent of UVA exposure. In contrast, induction of cellular heat shock (HSP70, HSP90), ER stress (DDIT3), and oxidative stress (TXNRD1, HMOX1, ARR82, SPI1R) response gene expression was observed solely upon combined exposure to UVA and FICZ, further substantiated by immunoblot detection (p-eIF2α, p-p38, HO-1). FICZ photosensitization was associated with induction of pronounced intracellular photosensitizing stress that could be antagonized by single oxygen quenchers (sodium azide, DABCO). Taken together, our data demonstrate that the endogenous AhR ligand FICZ displays pronounced photodynamic activity in epidermal keratinocytes and reconstructed human skin, representing a novel mechanism of UVA photoactivity that may be operative in human skin. Supported by grants from NIH (R01CA122484, R03CA167580, R21CA166926, ES007091, ES06694).

2165 Linalool and Limonene in Fragranced Products: Stability and Quantification of Potentially Sensitizing Hydroperoxides

G. Adams1, S. Kern1, H. Dkhil2 and A. Natsch1.

Givaudan Schweiz AG, Duedorfendorf, Switzerland, 1Givaudan France SA, Argenteuil, France and 2Givaudan US, East Hanover, NJ.

Upon exposure to air, linalool and limonene can form sensitizing hydroperoxides. Positive patch tests to the hydroperoxides in dermatitis patients were reported. Due to a lack of analytical evidence it is unclear under which conditions, and from which sources, the public might be exposed to sufficient quantities of these oxidized products for induction of skin sensitization to occur. We developed analytical methods using mass spectrometry in combination with gas chromatography (GC-MS) and liquid chromatography (LC-MS) for the oxidation products. We performed stability studies to follow the fate of linalool and limonene in fine fragrances and antiperspirants, since these product types lead to highest consumer exposure to these ingredients. We found a high stability of linalool and limonene in the products investigated. We detected very low levels (around 0.07%) of linalool hydroperoxide in linalool obtained from natural sources. This level remained constant upon storage. Low levels of linalool hydroperoxide were detected in a commercial fragrance but degraded at elevated temperature to non-sensitizing secondary oxidation products. Aged fine fragrances retrieved from consumers contained a median of 19.43 mg/l of linalool and 7 μg/g of linalool hydroperoxide. Corrected for matrix effects, concentrations are twofold higher. In antiperspirants, we detected no oxidized products. A novel method for linalool hydroperoxide detection is presented, but limonene hydroperoxide levels stay below limit of detection of this method (≤ 0.5 µg/g) in tested products. In conclusion, low levels of linalool and limonene hydroperoxide in fragranced products may originate from raw materials, but we found no evidence for hydroperoxide formation during storage of representative perfume-containing consumer products. The typical concentrations found in the fragrance samples are around three orders of magnitude below the experimental concentration inducing skin sensitization in animal tests.

2166 Vetiveryl Acetate Evaluated for Potential Phototoxicity Utilizing a Human Epidermal Model and Patch Testing

Vetiveryl acetate is utilized as a fragrance ingredient in a variety of consumer and personal care products, being appreciated for its woody note in perfumery. The UV spectrum for this material demonstrates absorption in the region of 290 – 700nm, and therefore has the potential to be photactivated. In order to determine the potential for phototoxic effects, a phototoxicity test in a three dimensional human epidermal model (EST1000) was conducted. This assay is based upon a comparison of the cytotoxic effects of the test material following exposure to a non-toxic dose of UV light. Cytotoxicity is expressed as a reduction in the mitochondrial conversion of MTT [(3-4,5-dimethyl thiazole 2-yl) 2,5-diphenyl-tetrazoliumbromide] to formazan. A material is considered to have a phototoxic potential if one or more concentrations +UVA (60 min with 6 J/cm²) results in a decrease in relative cell viability of ≥ 30%, when compared to the identical concentration –UVA. Vetiveryl acetate was tested at five concentrations ranging from 0.1 to 10% (v/v) in 1:3 Ethanol:Diestyl phthalate (EstOH:DEP). In the EST1000 model, no phototoxicity was observed to vetiveryl acetate over the range of concentrations tested. Additionally, historical studies conducted in animal models indicate a lack of phototoxicity up to 100%. A confirmatory phototoxicity patch test was conducted in a group of human volunteers with a concentration series of 2.5%, 7.5% and 25%. These concentrations of vetiveryl acetate were confirmed as having no phototoxic effects in humans following the phototoxicity patch test.

2167 In Vivo Phototoxicity Evaluation in Hairless Mice followed by 8-Methoxypsoralen, Lomeloxacin, and Ofloxacin

Purpose: The ICH S10 draft consensus guideline “Phototoxicity Evaluations of Pharmaceuticals” is in the Step 3 consultation period in Sept 2013. However, this draft guideline does not currently specify species/strain selection or test procedures for in vivo phototoxicity studies. Therefore, in order to select a suitable positive control compound and animal strain, we examined in vivo phototoxicity in 2 strains of hairless mice after administration of 3 known phototoxicants, 8-methoxypsoralen (8-MOP), lomeloxacin HCl (LMFX), and ofloxacin (OFLX). Methods: Seven-week-old HR-1 and SKH-1 hairless mice (Hoshino Laboratory Animals, Inc., Japan, and Charles River, NC, respectively) were orally given 8-MOP (10 and 20 mg/kg), LMFX (50 and 100 mg/kg), and OFLX (300 and 1000 mg/kg), and irradiated with ultraviolet A at 20 J/cm² (≥ 352 nm) from a Dermaray M-DMR-50 (Tokyo Electric Co., Ltd., Japan) apparatus 30 min later. The expression of phototoxicity was evaluated in each strain with the following items: auricle thickness, skin reactions at the auricle and on the back with the Draize method at 0.5, 24, 48 and 72 hr after irradiation, and ophthalmology and histopathologic changes in the auricular and back skins, eyeballs, and optic nerves (HE staining) at 72 hr. Result: Male HR-1 mice given 8-MOP showed very slight erythema and edema at the auricle and back at 24 hr and an increased edema score (3; moderate) at 72 hr, auricle thickening and eyelid edema. Histopathology revealed inflammation, degeneration and necrosis in the skin and eyelids. These reactions were also observed, but to a lesser extent, after other phototoxicant treatments (order of severity: 8-MOP > LMFX > OFLX). No marked sex or strain (HR-1 vs. SKH-1-E) differences were noted. Discussion: We judged that both investigated strains were appropriate, and 8-MOP was the most appropriate positive compound, for phototoxicity tests in hairless mice.
2168 Development of an Alternative Method for Assessment of Skin Sensitization Using the In Vitro IL-18 Reconstructed Human Epidermis (RHE) Model

Several efforts are underway, in line with the 3Rs philosophy, to develop and validate in vitro testing methods for sensitization, as alternatives to the traditional in vivo models. The first living cells of the skin to encounter sensitizing chemicals are mainly keratinocytes. Of the cytokines produced by keratinocytes, IL-18 plays a key role in skin sensitization induction. The use of keratinocytes and skin cultures provides a valuable, simplified in vitro model to evaluate the sensitization potential of topical applied compounds. An IL-18 assay has been found to have advantages of decreased variability, better representation of human exposure and the ability to test water insoluble/undissolveable compounds as well as final product formulations. The IL-18 RHE protocol was adapted using EpidermTM and three known contact sensitizers (resorcinol, weak; cinnamaldehyde, moderate; 2,4-dimethylthiourea, strong). Chemical dilutions were made and applied topically to the RHEs for 24 hours. Cell viability (MTT) and IL-18 levels (ELISA) were used as measures of sensitization. Criteria were established as an IL-18 Stimulation Index (SI) value >1.6x with a cell viability between 5%-50% for at least one concentration. Results indicated the test was simple to perform with slight modifications for the type of cultures used. Reproducible results were obtained for the moderate and strong sensitizers with varying results for the weak sensitizer, resorcinol. The variability in results may stem from differences in stratum corneum barriers between types of RHE cultures. In conclusion, IL-18 production by RHE represents a promising and easily adaptable model for the screening of chemicals for sensitization potential and reducing the use of animals for testing.

2170 Differential Induction of DUOX Isosforms by Arsenite and Vanadate: A Novel Role for Reactive Oxygen?

T. Hille1,2 and R. H. Rice1. 1Environmental Toxicology, University of California at Davis, Davis, CA and 2School of Nursing, University of Northern Colorado, Greeley, CO.

Dual oxygenase (DUOX) 1 and 2 are membrane bound proteins of the NOX superfamily that have been linked to specific inflammatory or cellular repair functions. Our previous work has demonstrated selective inductionswitching of DUOX isosforms by the cytokines IFN-γ and IL-4 in cultured human keratinocytes and bronchial epithelium. Similarities between the biochemistry of keratinocyte differentiation and DUOX regulation suggest DUOX perturbation could be a source of epidermal barrier defects that enhance toxicant penetration. Arsenic toxicity is characterized by ROS generation and is reported to involve NOX activity. Water pollutants from mining activity that contain metal ions such as vanadate also generate ROS at high concentration. We examined the effects of these known water contaminants on DUOX induction using an established exposure model for heavy metals in spontaneously immortalized human keratinocyte (SK) cultures and real time QPCR. We find that most metal/metalloid compounds suppress the cytokine induction of both DUOX isosforms. However, arsenite exposure causes incomplete suppression of DUOX2, while vanadate amplifies DUOX2 induction by IFN-γ beyond its normal efficacy. DUOX2 inductions by IFN-γ, as well as its amplification by vanadate, are completely suppressed in the presence of 30 mM dimethylthiourea, a known ROS scavenger. Similarly, glutathione depletion using 0.5 mM buthionine sulfoxime replicated the increased efficacy of DUOX2 induction by IFN-γ seen with vanadate. These findings suggest a novel role for ROS in DUOX2 gene induction and provide additional insight into arsenic toxicity as well as the mechanistic contribution of DUOX biology to differentiating epithelium. Future studies on the role of DUOX in keratinocytes may provide a novel mechanistic approach to assess the effects of environmental and industrial toxicants on healthy skin and wound healing.

2171 Involvement of Reactive Oxygen Species (ROS) and Gene Expression Profile in Response to p-Phenylenediamine and Components of Permanent Hair Dyes in Human Keratinocytes (HaCaT) Cells and Human Skin Explants

T. Zanoni1, A. Bast1,2, G. Hagen1,2, S. S. Maria-Engler1 and D. P. de Oliveira1. 1Environmental Toxicology, University of Sao Paulo-USP, Ribeirao Preto, Brazil and 2Toxicology, University of Maastricht, Maastricht, Netherlands.

Para-phenylenediamine (PPD) is an amine amine present in about 70% of all hair dyes worldwide. PPD is primarily used as a dye intermediate after reaction with H2O2 (oxidizing agent) and Resorcinol(R) (coupler). It penetrates the hair shaft permanently modifying the hair colour. Sensitization to PPD is known to cause of allergic contact dermatitis. However, the molecular mechanism of PPD-induced skin toxicity remains unclear. We investigated the induction of Reactive Oxygen Species (ROS) and the involvement of gene expression of certain genes that appear to be involved in toxicity of PPD. We tested the ROS induction potential of PPD in presence and absence of the coupler Resorcinol and oxidizing agent H2O2 in monolayer using immortalized keratinocytes (HaCaT) that are the first contact point after dermal exposure, as well as human skin explants. For HaCaT cells in monolayer, the dose of 100μg/mL increased the intracellular levels of ROS after 1 hour of incubation. After 24 hours of incubation the dose of 20 μg/mL was able to increase the levels of 8-oxo-4G and malonaldehyde (MDA) was formed. Besides, we observed that the addition of H2O2 decreased the intracellular levels of ROS and the levels of 8-oxo-dG, while the levels of MDA were not decreased by the addition of H2O2. Using the human skin explants, we demonstrate that the exposure to PPD, PPD-H2O2-R and PPD-R on commercial concentration, upregulates the expression of genes involved in inflammatory responses, responses to oxidative stress and metabolism of xenobiotics by cytochrome P450 on human epidermis. Our results indicate that oxidative stress is involved in the mechanism of PPD-epidermis toxicity in monolayer and in skin explants. This study helps to elucidate the toxic effects in response to PPD and components of hair dyes on human skin.

2172 Dermal Absorption In Vitro and Its Influencing Parameters

K. Guth, E. Fabian, S. Wölk, B. van Ravenzaag and R. Landsiedel. Toxicology, BASF SE, Ludwigshafen/Rhein, Germany.

Skin absorption is an in vitro method described in OECD guideline 428 and the technical guidance GD 28. Since study design dependent parameters can be varied, we performed systematic parameter variations under defined experimental conditions to understand their potential influence.
We investigated dermal absorption with skin preparations of rats, pigs and humans in Franz like diffusion cells. Experiments were performed to address the following parameters: ex vivo skin preparations (gender, age, localization, preparation), reconstructed skin models, storage and freezing-cycles, static versus flow through, concentration of test compounds, donor vehicle and receptor fluids. We used different model compounds, e.g. testosterone, caffeine which were analyzed by liquid scintillation counting, HPLC or photometry. Absorbed dose (%), permeation rates and permeability constants (Kp) were calculated.

Variations in skin preparation and testing in static or in flow-through systems had no remarkable influence on Kp. Main impacts on Kp were observed for ex vivo vs. reconstructed skin preparations, thickness of SC, test-substance concentration, donor vehicle and receptor fluid: In our experiments the barrier function of reconstructed skin was inappropriate for absorption testing. Since the test substance, its concentration and donor vehicle are reflected by the applied formulated product these parameters have to parallel the real exposure scenario and will intentionally predetermine the study results. The influential effect of the receptor fluid was related to the solubility of the test substance in the chosen solvents. This relation was obvious e.g. for the lipophilic compound testosterone where a higher Kp and absorbed dose was observed for ethanol-water (1:1 / v/v) in comparison to 5% aqueous BSA.

Taken together, the results of the current investigations can be taken into account for the establishment of a standardized experimental set up for dermal absorption studies in vitro, whereby the identified major influential parameters should be carefully addressed.

**Evaluation of Age, Storage, and Skin Preparation Technique on Dermal Absorption in Rat Skin**

Dermal uptake is a common route of exposure for chemicals and can have a substantial impact on exposure and risk assessments. Accurate in vitro dermal penetration data from rat skin is critical for triple pack studies where these data are used in conjunction with in vitro human and in vivo rat results to correctly extrapolate to human in vivo absorption levels. The present study evaluated the quantitative impact of age, storage and skin preparation technique on dermal absorption of three test chemicals (benzoic acid, caffeine and testosterone) in rat skins. Juvenile (4-5 wk old) rat skin was compared to mature adult rat skin (12-15 wk old). The data indicated that flux and absorption were consistently increased by approximately two-fold in juvenile rats compared to adult rats with all 3 test materials. Storage of rat skins at -80°C did not significantly affect flux or absorption values, compared to fresh skin samples, however, there was an overall 30% decrease in the number of viable skins when frozen, compared to fresh skins. The extent of hair clipping for preparation of the skin samples is also critical in dermal absorption experiments. Data indicated that extensive clipping (7-8 passes), to remove most of the epidermal hair, resulted in 2-fold higher flux rates, with 87% of skin samples failing integrity tests. In contrast integrity was maintained in 100% of the skin samples that were subject to moderate clipping (2-3 passes). Flux and absorption were increased approximately 2-3 fold in skin samples subject to more extensive clipping compared to those treated more moderately with all the 3 test materials. Collectively, the data suggest that age of rats and clipping technique substantially affect the rate of dermal absorption during in vitro dermal experiments, while prolonged storage may lead to material wastage due to loss of integrity in skin samples. As a result, appropriate experimental design is critical for an accurate assessment of this major exposure route.

**In Vitro Human Skin Permeation: Example of CMI/MI and Tolylfluanid, Two Irritant, and Sensitizer Biocides**

A. Berthet1, P. Spring2, N. Charriere1, D. Vernez1 and N. B. Hopf1. 1Institute for Work and Health, Lausanne, Switzerland and 2Dermatology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.

Every year, ten million workers are exposed to metalworking fluids (MWFs) which may be toxic, especially to the respiratory system and the skin. There are four types of MWFs: neat oils and three water-based MWFs (soluble oil, semi-synthetic and synthetic) which are diluted with water and whose composition varies according to the mineral oils ratio. MWFs also contain various additives such as biocides and corrosion inhibitors. The absorption of six amines used as corrosion inhibitors and biocides in MWF was determined in porcine-skin flow-through diffusion cell experiments using three radiolabeled ethanolamines (MEA, di- and tri-ethanolamine, MEA, DEA and TEA respectively) and a mixture of three GC-amenable amines (dibuty lethanolamine, dicyclohexylamine and diphenylamine). The test compounds were dosed in four vehicles (water and three generic water-based MWF formulations) and analyzed using a scintillation counter or a gas chromatography/mass spectrometer. The six compounds were significantly (p<0.05) more absorbed in water (e.g. 1.15±0.29 %dose (DEA in Water)) compared to other formulations (e.g. 0.13±0.01 %dose (DEA in semi-synthetic MWF)) and absorption was greatest for dibutylethanolamine in all the formulations. Generic soluble oil formulation tended to increase the permeability and the absorption of MEA, DEA and TEA. Permeability coefficients were significantly higher (p<0.05) with TEA relative to the other test compounds (e.g. 4.22±0.45±3.0±0.5 cm/h (TEA in synthetic MWF) VS 1.23±0.4±1.0±0.5 cm/h (MEA in synthetic MWF)), except for MEA in generic soluble oil formulation. Future research will confirm these findings with in vivo studies in pigs and dermatotoxicity studies will be conducted to compare the relative safety of these compounds in MWF. With this data, the MWF industry would be able to alter their MWF formulation to protect the metalworkers’ health.

**The Effect of Coformulants on Dermal Uptake—A Raman Study**

T. Patel1, D. Salazar2, G. Bell3, J. Wright4, B. Parr-Dobranski5, A. Ghaemmaghami2, P. Williams1, C. J. Roberts1 and F. R. Rose1. 1School of Pharmacy, University of Nottingham, Nottingham, United Kingdom, 2School of Life Sciences, University of Nottingham, Nottingham, United Kingdom and 3Syngenta Ltd, Jealott's Hill International Research Centre, Berkshire, United Kingdom. Sponsor: P. Botham.

The Organisation for Economic Co-operation and Development (OECD) guidelines on the conduct of in vitro dermal absorption investigations have attempted to standardise global practices. However, the methods used to evaluate epidermal accumulation such as ‘tape stripping’ have yet to be formalised and can give rise to large sources of variability. Thus, there is a strong need to develop alternative methods to investigate compound localisation within skin samples. Confocal Raman spectroscopy (CRS) is a radiolabelfree, rapid, optical, non-invasive method which allows compounds to be identified within dermal tissue. In this study, CRS was used to determine testosterone localisation with ex vivo 300 μm dermatropped pig skin samples treated with the compound in solutions (1:1 w/v) containing either; Emulsogen EL360, propylene glycol, or Tween 20. A LabRAM HR (Horiba Scientific) imaging spectrometer was employed for the analysis of the treated skin samples (n=6), using an IR laser at 785 nm coupled with a Synapse CCD detector. Spectra were obtained from the surface of the skin to a maximum depth of 150 μm at 0, 1, 2, 3, 4, 5, 6 and 24 hour time points to mimic real-time exposure. CRS spectra for the pig skin samples demonstrated good reproducibility with some spectral differences noticed. Spectral intensity decreased with increasing depth, as expected. Emulsogen EL360, Tween 20 and propylene glycol all appeared to influence the absorption of 30.0 mg/mL testosterone through the skin. The spectra obtained also suggested that the stratum corneum was the main barrier to testosterone absorption. These findings show that the CRS method has the potential to determine epidermal compound accumulation, which will help to inform the likely systemic bioavailability of residues within skin, providing an alternative tool for standardised dermal risk assessment.

**Skin Absorption of Performance Amines Used in Metalworking Fluids**

L. Roux, J. Brooks, J. Yeatts and R. E. Baynes. NCsu, Raleigh, NC.

We investigated dermal absorption with skin preparations of rats, pigs and humans in Franz like diffusion cells. Absorbed dose (%), permeation rates and permeability constants (Kp) were calculated.
Skin irritation and skin corrosion refer to localized toxic effects resulting from a topical exposure of the skin to a substance. The Globally Harmonized System of Classification and Labeling of Chemicals (GHS) define skin irritation as "the production of reversible damages" and skin corrosion as "irreversible damage" to the skin following the application of a substance. A number of validated, non-animal methods to determine skin corrosion and irritation are available. As such, the SkinEthic Reconstructed Human Epidermis (RHE) test method has been adopted within the context of OECD TG 431 (skin corrosion) and OECD TG 439 (skin irritation).

Updated approaches to the use of tiered and integrated testing strategies for predicting skin corrosion/irritation potential without the use of animals are discussed in the present study. Illustration is provided by combining both SkinEthic RHE skin corrosion and irritation test methods for evaluating the stepwise testing strategy (Top down and Bottom-Up approaches).

All 50 reference chemicals listed in either OECD TG431 or 439 were evaluated in both skin irritation and corrosion SkinEthic RHE validated methods. Amongst the 22 known in vivo corrosive chemicals, 95% were correctly predicted amongst the 35 in vivo non irritants, 85% might be correctly classified in vitro as non corrosives. Therefore those 21 chemicals were also defined as irritants. The substances were well classified by using the top-down approach which consists of conducting primarily skin corrosion test method.

Considering the non irritant chemicals, 100% (10/10) of the correctly classified substances were well classified by using the top-down approach which consists of conducting primarily skin corrosion and irritation test methods for evaluating the stepwise testing strategy (Top down and Bottom-Up approaches).

The OECD adopted a tiered approach for dermal testing described in the revised TG 404. Data from structurally related chemicals (e.g. pH extremes), human data and experience (weight of evidence) are sometimes sufficient for classifying the skin irritation/corrosion potential of chemicals. If this information is not sufficient, validated in vitro methods can then be used e.g. in vitro EpiSkin methods accepted in both OECD TG 431 (skin corrosion) and TG439 (skin irritation).

The aim of the study is to present the Top-Down and Bottom-Up approaches to predicting skin corrosion/irritation potential without the use of animals. For such purpose, 98 chemicals (partially from EURL-ECVAM validation studies and OECD TG431 & TG439) were evaluated in both skin corrosion and irritation EpiSkin methods.

Amongst the 35 in vivo non irritants, 85% might be correctly classified in vitro as irritants (I). Therefore those 35 chemicals were also defined as non corrosives (NC). Thus, when applying the bottom-up approach the GHS classification of those substances was accurately defined by performing the skin irritation evaluation.

In conclusion, the results suggest that testing strategy is not a strict sequence and that stepwise procedure, weight of evidence and testing should be considered as acceptable approaches to structure relevant information of the substance used for hazard assessment.

**2178 In Vitro Skin Corrosion and Irritation Assessment of Ingredients Using EpiSkin Model: Top-Down and Bottom-Up Approaches**

The OECD adopted a tiered approach for testing described in the revised TG 404. Data from structurally related chemicals (e.g. pH extremes), human data and experience (weight of evidence) are sometimes sufficient for classifying the skin irritation/corrosion potential of chemicals. If this information is not sufficient, validated in vitro methods can then be used e.g. in vitro EpiSkin methods accepted in both OECD TG 431 (skin corrosion) and TG439 (skin irritation).

The aim of the study is to present the Top-Down and Bottom-Up approaches to predicting skin corrosion/irritation potential without the use of animals. For such purpose, 98 chemicals (partially from EURL-ECVAM validation studies and OECD TG431 & TG439) were evaluated in both skin corrosion and irritation EpiSkin methods.

Amongst the 35 in vivo non irritants, 85% might be correctly classified in vitro as irritants (I). Therefore those 35 chemicals were also defined as non corrosives (NC). Thus, when applying the bottom-up approach the GHS classification of those substances was accurately defined by performing the skin irritation evaluation.

In conclusion, the results suggest that testing strategy is not a strict sequence and that stepwise procedure, weight of evidence and testing should be considered as acceptable approaches to structure relevant information of the substance used for hazard assessment.

**2179 The Usefulness of the Validated SkinEthic RHE Method to Identify Skin Corrosive UN GHS Subcategories**

The SkinEthic Reconstructed Human Epidermis (RHE) test method has been adopted within the context of OECD TG 431 for distinguishing corrosives and non-corrosives. The EU CLP classification system requires subcategorising of corrosive chemicals into the three UN GHS subcategories 1A, 1B and 1C. Since the SkinEthic RHE method was originally validated to discriminate corrosives from non-corrosives, the present study was undertaken to investigate its usefulness to discriminate skin corrosive UN GHS subcategories.

In total 84 substances were tested in three independent runs and two prediction models (PM) were assessed, representing a pre-defined validated prediction model (PM-A) and an alternative one defined post-hoc (PM-B). The results obtained with both PM were reproducible, as shown by the > 92.9% concordance of classification between runs for discriminating corrosives versus non-corrosives, and the > 85% concordance for discriminating the GHS subcategories versus non-corrosives. Moreover these results confirmed a high sensitivity of the SkinEthic™ RHE method to predict corrosives (94.9%) and good specificity (> 73.7%) independent of the PM applied.

Regarding the identification of UN GHS corrosive subcategories, when considering the 30 reference chemicals as recommended in the recently revised OECD TG 431 (2013), PM-A and PM-B achieved 78.9% and 83.3% accuracy respectively for the identification of GHS subcategories and non-corrosives. They correctly predicted 90% of GHS subcategory 1A and 80% of GHS non-corrosive substances independent of the PM used.

In conclusion, the SkinEthic RHE test method is highly reproducible and sensitive for discriminating corrosive from non-corrosive substances. Furthermore it allows reliable identification of skin corrosive GHS subcategory 1B-and-1C substances using the PM-A and PM-B, and of GHS subcategories 1A using the PM-B. Due to its high sensitivity, the test method provides high safety standards for skin corrosion testing.
Solar ultraviolet (UV) radiation is known to have deleterious effects on human skin. The UVB (280-320 nm) and UVA (320-400 nm) spectrum of solar radiation have been shown to affect keratinocytes, the major cellular constituent of the epidermis, by causing direct DNA damage and/or indirect DNA damage and cytotoxicity through the formation of reactive oxygen species. In the present study, a commercially available human skin equivalent (HSE) (Epiderm-FITM) and excised human skin was exposed to solar-simulated light to gain insight into the temporal UV-induced response of human epidermal tissue. In vitro HSEs were irradiated with a single UVR dose approximately equivalent to either 6 or 9.5 minimal erythema doses (MEDs) for an individual of EPA skin phototype 2. Cutaneous damage and recovery were then monitored for a period of seven days. Histological analysis showed a dose dependent formation of apoptotic sunburn cells in epidermal KCs at 24 hrs post-irradiation. By day 3 post-irradiation, a thinning of the viable epidermal cell layers was evident with maximum epidermal degeneration observed at day 4. Resumption of epidermal proliferation and differentiation was evident in both 6 and 9.5 MED tissues by days 5-7, leading to regeneration of viable epidermal layers. Excised human skin tissues irradiated with the same UV doses displayed responses very similar to those observed in the in vitro HSEs. DNA damage indicated by cyclooxygenid e dimer (CPD) formation was assessed by immunohistochemistry. CPD positive basal KCs decreased steadily in number each day, and were almost completely undetectable seven days post-irradiation. CPD formation could be completely blocked through topical application of OTC sunscreens. Finally, elevated levels of IL-8 and MMP-1 were induced following UV-irradiation demonstrating an early inflammatory response followed by an extended period of matrix remodeling activity. These results demonstrate that HSEs are useful for UV-induced photocarcinogenesis studies and evaluation of sunscreens.

The aim of this study was to develop and test different skin toxicity Modes of Action (MOA). MOA describes the key events and processes starting with interaction of an agent with the cell leading to different biological response. MOA can be looked at as a representation of existing knowledge concerning the linkage(s) between initial chemical binding, defined as the molecular initiating event (MIE), intermediate events on cell, tissue and organ level and biological outcome. MOA can be used to identify key events for which non-animal tests can be developed, thereby facilitating mechanism-based, predictive toxicological assessments with low uncertainty and high human relevance.

We focused on 5 well studied skin toxicants and based on the present knowledge, created their biological network. In addition we created a computational model of biological pathways describing cellular processes activated by these chemicals by manually annotating and processing molecular information from the literature from the public domain (PubMed articles and FDA reports) and made the data computable. Moreover, we created bioinformatics analysis tools for assessing chemical structure similarity, allowing us to group the compounds based on their chemical structure in addition to their MOA. We tested this database for other known skin toxicants that are not covered by the database. Based on their structure similarity to other skin toxicant and/or known biological interaction partners we were able to predict skin toxicity of these compounds and suggest possible MOA.

Retention exposure to a chemical agent can induce an immune reaction in susceptible individuals leading to skin sensitization. We have developed computational models capable of accurately assessing the skin sensitization potential of environmental chemicals. To this end, we have (i) compiled, curated, and integrated the largest publicly-available database of skin-sensitizing chemicals; (ii) used this data to generate and validate QSAR models for skin sensitization; and (iii) employed these models to identify putative sensitizers among chemicals in the Scorecard and Tox21 databases. A random forest method was employed for QSAR modeling of compounds characterized by SiRMS and Dragon descriptors, and the OECD-Tox21 databases. The aim of this study was to develop and test different skin toxicity Modes of Action (MOA). MOA describes the key events and processes starting with interaction of an agent with the cell leading to different biological response. MOA can be looked at as a representation of existing knowledge concerning the linkage(s) between initial chemical binding, defined as the molecular initiating event (MIE), intermediate events on cell, tissue and organ level and biological outcome. MOA can be used to identify key events for which non-animal tests can be developed, thereby facilitating mechanism-based, predictive toxicological assessments with low uncertainty and high human relevance.

We focused on 5 well studied skin toxicants and based on the present knowledge, created their biological network. Putative skin sensitizers in the ScoreCard and Tox21 databases as primary hits for structural optimization of chemicals of interest. Using these models, we have identified putative sensitizers with 94% and 71% certainty, respectively. Statistically significant accuracy of 68-88% when evaluated on several external validation sets. When compared to the OECD QSR toolbox skin sensitization module, our models afforded significantly higher Positive and Predictive Rates. When applied to chemicals within the applicability domains, however, the models could reliably identify positive and negative sensitizers with 94% and 71% certainty, respectively. Statistically significant descriptors from high-accuracy models yielded SAR rules that could guide structural optimization of chemicals of interest. Using these models, we have identified putative skin sensitizers in the ScoreCard and Tox21 databases as primary hits for

Cyclophosphamide (CPA) is used to treat cancer in children and women. Cyclophosphamide mustard (PM), the ovotoxic metabolite of CPA, destroys rapidly dividing cells by forming NOR-G-OH, NOR-G, and N-O-G adducts with DNA, which can ultimately lead to DNA damage. DNA repair processes are constantly active and cell death can occur when normal repair processes fail. Previous studies have shown that PM induces DNA damage in rat oocytes. This study was designed to investigate PM-induced DNA adduct formation and induction of the DNA repair response using rat spontaneously immortalized granulosa cells (SIGC). Cells were treated with vehicle control (1% DMSO) or PM (3 or 6 μM) for 24 or 48 hrs. Cell viability was reduced (P < 0.05) after 48 hrs in cells treated with 3 or 6 μM PM. The NOR-G-OH DNA adduct was detected by treatment with 6 μM PM after 24 hrs (8%±0.15 relative abundance) compared to control (1.0±0.1). The NOR-G-OH DNA adduct was formed after 48 hrs by both 3 (4.5±0.1) and 6 μM PM (4.5±0.15) compared to control (2.0±0.15) treatments. Phosphorylated H2AX (γH2AX), a marker of DNA double-stranded break occurrence, was increased by exposure to 6 μM PM after 24 hrs. After 24 hrs of PM exposure, 3 μM PM decreased mRNA expression of the DNA repair gene Atm (0.6±0.09 p<0.01), Parp1 (0.7±fold ±0.01), Brcal (0.5±fold ±0.07), Rad51 (0.9±fold ±0.04) Xcc6 (0.7±fold ±0.06) and Pkdc (0.6±fold ±0.07) while, in contrast, mRNA levels of Atm (1.2±fold ±0.5), Parp1 (1.16±fold ±0.03) and Brcal (1.0±fold ±0.3, Rad51 (2.3±fold ±0.7). Xcc6 (1-fold ±0.3) and Pkdc (1.1±fold ±0.1) were increased (P < 0.05) by 6 μM PM compared to control. After 48 hrs, both PM concentrations increased (P < 0.05) Atm (3 μM: 2.1±fold ±0.6, 6 μM: 1.3±fold ±0.3) and Parp1 (3 μM: 4±fold ±0.8; 6 μM: 1.2-fold ±0.4) mRNA levels relative to control-treated cells. These data support that PM induces DNA adduct formation in ovarian granulosa cells causing DNA damage and eliciting the ovarian DNA repair response in a dose- and time-dependent manner (Supported by ES016818 to AFK).

Genistein is an isoflavone phytoestrogen found naturally in a variety of plant structures, including soybeans, lentils, sunflower seeds, and chickpeas. However, the majority of human genistein exposure originates from soy-based dietary products such as soy milk and soy protein. Phytoestrogens have the potential to mimic, enhance, or impair the components of the estradiol biosynthesis pathway, which could alter follicle growth. Though some studies have inconsistently indicated that genistein affects granulosa cell proliferation and hormone production, no studies could alter follicle growth. Though some studies have inconsistently indicated that genistein affects granulosa cell proliferation and hormone production, no studies could alter follicle growth. Though some studies have inconsistently indicated that genistein affects granulosa cell proliferation and hormone production, no studies could alter follicle growth.
to PM is largely unknown, thus this study investigated whether PM might impact ovarian energy production by evaluating potential changes in glucose metabolism gene expression. Postnatal day 4 (PND 4) F344 rat ovaries were cultured in media and treated on alternate days with vehicle control (DMSSO; CT) or PM (60 μM). Following 2 or 4 days (d) of culture, RNA was isolated and a drug response RT2 Profiler PCR array was performed. Relative to CT treated ovaries there was no impact of PM exposure on mRNA levels of glucose metabolism genes investigated after 2 d. However, following 4d of PM exposure, mRNA levels of three glycolytic genes decreased (P < 0.05): glucose-6-phosphate isomerase (Gpi; 29% decrease), hexokinase-2 (Hk2; 57% decrease) and lactate dehydrogenase A (Ldh, 39% decrease). Hk2 and Gpi are the first two enzymes of glycolysis, while Ldh catalyzes the final step. The mRNA level of aryl hydrocarbon receptor nuclear translocator (Ahr/Hif1α), a transcription factor regulating glycolytic gene expression, was also decreased (P < 0.05; 25% decrease) at 4d and unchanged at 2d, compared to CT. These results suggest that glycolysis may be decreased or slowed by PM, reducing the ovarian capacity to convert glucose to pyruvate, which could potentially be involved in PM-induced ovotoxicity. (Supported by ES016818 to AFK).

2189 Temporal Impact of Obesity on Expression of Genes Encoding Enzymes Involved in Ovarian Xenobiotic Biotransformation

I. Neeba and A. Keating, Department of Animal Science, Iowa State University, Ames, IA.

Obesity is associated with type 2 diabetes, compromised reproductive health and birth defects in offspring. Obesity is also allied with elevated blood glucose and insulin levels, altering insulin’s action on various organs including the ovary. In extra-ovarian tissues, insulin regulates xenobiotic biotransformation enzymes, potentially through phosphatidylinositol 3-kinase (PI3K) signaling. Xenobiotic chemicals can target the ovary and destroy the primordial follicles as well as other follicle types, leading to premature ovarian failure, infertility and other health impairments. Despite strong association between obesity and elevated plasma insulin, whether obesity influences ovarian xenobiotic biotransformation remains poorly understood. This study therefore, investigated the temporal effect of obesity on ovarian expression of genes encoding cytochrome P450 isofrome 2E1 (Cyp2e1) and microsomal epoxide hydrolase (Epoxide). 4 weeks old female wild type normal non-agouti (a/a; designated lean; n = 20) and agouti lethal yellow (KK.Cg-Ay/J; designated obese; n = 20) mice were utilized. Glucose tolerance testing followed by euthanization and ovary collection was performed at 6, 12, 18 or 24 weeks (n = 5 per group) of age. Total RNA was isolated and cDNA (1:25) were amplified using primers specific for mouse Cyp2e1 and Epoxide. Relative mRNA expression of each gene was normalized using Gapdh as a housekeeping gene. Statistical analysis was performed using the T-test function of GraphPad Prism 5.5 software with a statistically significant level set at P < 0.05. Obesity had a differential effect on ovarian Cyp2e1 and Epoxide expression over time. Relative to their lean counterparts, in a time-dependent manner, ovaries from obese mice displayed decreased (P < 0.05) Cyp2e1 on one hand and increased (P < 0.05) Epoxide mRNA levels, supporting that Cyp2e1 and Epoxide may have some common transcriptional regulator. These results indicate that obese females may have increased susceptibility to ovotoxicant-induced reproductive health impairments. This work was supported by ES016818 to AFK.

2190 Examining Triclosan-Induced Potentiation of the Estrogen Uterotropic Effect

G. W. Louis, 1, 2, D. Hallinger1 and T. E. Stoker, 1 Endocrine Toxicology Branch, US Environmental Protection Agency, Research Triangle Park, NC and 2Oak Ridge Institute for Science and Education, Oak Ridge, TN.

Triclosan (TCS), a widely used antibacterial, has been shown to be an endocrine disruptor. We reported previously that TCS potentiated the estrogenic effect of ethinyl estradiol (EE) on uterine growth in rats orally administered 3 μg/kg EE and TCS (2 to 18 mg/kg) in the uterotropic assay, whereas TCS alone had no effect. We further characterized this potentiation by evaluating the effect of co-exposure with lower doses of EE (0.125 to 2 μg/kg) that are comparable to the concentrations in hormone replacement therapies. We found that TCS correspondingly potentiated the uterotropic effect (both in uterine weight and epithelial cell height), but at significantly lower doses of EE (LOEL = 0.25 μg/kg). In the current study, we evaluated the effects of TCS with a xenostrogen in the uterotropic assay to determine whether the effect is specific to only co-administration with EE. Female rats were exposed to 100 and 200 mg/kg of nonylphenol (NP), a pesticide with ER agonist activity, in addition to an EE-treated positive control group. NP induced a significant increase in uterine weight, but to a lesser extent than the EE-induced response. Animals co-treated with TCS and NP also had a significant increase in uterine weight compared to vehicle controls, but this difference was not significantly different from NP alone. To examine the cellular mechanism by which TCS potentiated the EE uterotropic effect, we conducted an in vitro estrogen receptor (ER) transactivation assay, which revealed that TCS alone does not activate the ER. Cotreatment of TCS with estradiol did not alter the maximal response suggesting that TCS does not antagonize nor potentiate the ER. These results provide evidence that the potentiation of the estrogenic response by TCS is not at the level of the ER. Further studies are needed to evaluate the role of TCS in altering estrogen metabolism. This work does not necessarily reflect EPA policy.

2191 Propylparaben Has No Estrogenic Activity When Administered for 3 Months in Juvenile Rats

L. Sivaranjan1, L. Poulod1, Y. Zhao1, G. Liu1, H. Shen1, B. Wang1, C. Parrula1, T. Brodie1, M. J. Graziano1 and M. E. McNerney1 Bristol-Myers Squibb Co., New Brunswick, NJ and 2Charles River Laboratories Preclinical Services, Montreal, QC, Canada.

BACKGROUND: Parabens, esters of p-hydroxybenzoic acid, are used as antimicrobial preservatives in pharmaceuticals. There has been considerable controversy regarding the potential of parabens for estrogen-mimetic activity, and widespread concern regarding their use in pediatric medicinal formulations. The scientific literature contains conflicting results from several studies. We designed and conducted a comprehensive study to determine the potential of propylparaben (PB) to elicit estrogen-mimetic effects. OBJECTIVES: 1). Determine the potential estrogen-mimetic effects of PB in juvenile rats; 2). determine the systemic exposures to PB and metabolites; and 3). evaluate the reversibility of any observed changes. METHODS: PB was administered by oral gavage once daily to groups of Crl:CD(SD) rats at doses of 0 (vehicle), 10, 100, or 1000 mg/kg from Postnatal Days (PNDs) 4 through 90. Evaluations included clinical observations, body weight, food consumption (after weaning on PND 21), evidence of sexual maturation (vaginal opening and preputial separation), clinical pathology, anatomic pathology of male and female reproductive tracts, and toxicokinetic profiles on PND 7, 21 and 83. Recovery phase evaluations additionally included estrus cyclicity, mating (PND 91) and fertility assessments. Evaluations of the offspring included viability, birth weight, litter size, clinical observations, and examinations of pups for evidence of dysmorphology. RESULTS: PB was well tolerated by neonatal, juvenile, and adult rats when administered from PND 4-90 at doses ≤1000 mg/kg/day. There were no effects of PB on sexual maturation or reproductive function in male or female rats, nor changes in organ weights or microscopic pathology of reproductive tissues suggestive of estrogen mimetic effects of PB or its metabolites. Exposures to PB and metabolites were confirmed in toxicokinetic evaluations. CONCLUSION: Propylparaben is not an estrogen-mimetic in juvenile rats.
Perfluoroalkyl carboxylic acids (PFCAs) are environmental pollutants which are of concern due to their possible effects on human health. Although many toxicological researches have been performed, there is little information about the toxicity of PFCAs with a carbon chain length C11 and above. In order to obtain initial toxicological information for such long-chain PFCAs, combined repeated dose toxicity studies with the reproduction/developmental toxicity screening tests were conducted in the Japanese safety examination of existing chemicals and safety programmes. Presented here are the results for perfluorotetradecanoic acid (PFTeDA, C14) and perfluorohexadecanoic acid (PFHxDA, C16) concluded recently. Male and female rats were administered by gavage with PFTeDA at 1, 3 or 10 mg/kg/day or with PFHxDA at 4, 20 or 100 mg/kg/day, and each female was mated with a male in the same dose group after 14-day administration. Males were dosed for a total of 42 days and females were dosed throughout the gestation period until day 5 after parturition. PFTeDA and PFHxDA mainly affected the liver, causing hypertrophy of hepatocytes and fatty change, at middle and high doses. PFTeDA also induced follicular cell hypertrophy in the thyroid at middle and high doses. The only observed reproductive/developmental effect was an inhibition of postnatal body weight gain of pups at a maternal toxic dose of PFTeDA. The NOAELs for the repeated dose and reproductive/developmental toxicity were concluded to be 1 and 3 mg/kg/day for PFTeDA and 4 and 100 mg/kg/day for PFHxDA, respectively.

Epidemiologic studies suggest a strong causal link between exposure to airborne particulate matter (PM) during pregnancy and preterm birth (PTB) and low birth weight (LBW). However, these studies are often in disagreement regarding which particular time points are most sensitive or whether such effects are cumulative. Previously, we showed that inhalation exposure of timed-pregnant mice to concentrations of particulate matter (PM) from mother to offspring both in utero and through lactation using accelerated reproductive/developmental Toxicity Screening Tests (RTTs) to Zer produces transgenerational effects on sexual development and if these effects are dose dependent.

It has been demonstrated that a variety of chemicals are not removed after wastewater treatment, which results in their release back into the water supply and environment. These chemicals may act as endocrine disrupting compounds (EDCs), which can affect the function of the endocrine system and adversely affect progeny and/or (sub)-populations. To date, studies evaluating the effects of EDC during periods of development are lacking, including quantitative measures of accumulation after exposure. We are measuring the transfer and accumulation of the EDC, triclocarban (TCC), from mother to offspring both in utero and through lactation using accelerator mass spectrometry (AMS). The high sensitivity of AMS allows for assessment of environmentally relevant concentrations of TCC (pmol·mL⁻¹).

14C-labeled TCC was administered to pregnant female mice through their drinking water (100nM) during gestation and lactation using custom made water bottles. In utero, detectable quantities of TCC were found in fetal (~0.02%ID) and placental tissue (~0.02%ID). An increase in accumulation of TCC was observed through lactation (~6 pmol TCC/gm) compared to the gestation only exposure group (~2 pmol TCC/gm). Taken together, these data indicate that TCC is transferred from mother to offspring through two routes: across the placental barrier and through lactation. While low levels of TCC transfer were observed in mice, these findings suggest that if TCC is similarly transferred in humans, there may be implications after exposure on human health. Further studies are needed to identify whether low levels of TCC accumulation can interfere with reproduction and development and if these effects are dose dependent.

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
Microsampling-coupled bioanalytical techniques are becoming powerful tools for use in pre-clinical studies, particularly with rodents, where optimizing blood use is paramount to try and avoid or reduce the need for satellite animals. In a series of intravenous (bolus) single and repeat dose pharmacokinetic investigations in the mouse with IgG antibodies, serial blood microsamples (30 μL each) were taken from the non-anesthetized adult female using K2-EDTA Microvette tubes via the saphenous vein and single microsamples from the gestation day 15, 16.5 or 18 fetus by cardiac puncture using insulin syringes. The fetal samples were pooled by litter (approximately 30 μL) into K2-EDTA microtubes. Adult and fetal plasma (approximately 10 μL each) was obtained by centrifugation. Amniotic fluid was also sampled using insulin syringes. All samples were stored frozen in cryotubes (between -15 and -25 °C) until analysis.

For quantifying the test item in the plasma and amniotic fluid, highly selective and sensitive ligand-binding assays were developed using Electro-Chemo-Luminescence (ECL) detection. Based on the characteristics of the test item and its target antigen, assay plates were either coated indirectly using biotin labeled recombinant antigen captured via streptavidin, or directly using idiotypic anti-drug antibodies. Only 2 μL of the plasma or 4 μL of amniotic fluid were diluted in assay buffer to analyze each sample in duplicate within the assay plate. The bound test item was detected by ECL-labeled secondary detection antibodies (e.g. anti-Fc or Fab antibodies). Bioanalysis of IgG antibodies was feasible with microsamples using the described assay setup and provided a precise, accurate and specific quantification of the test item with low limits of quantification between 10-100 ng/mL back calculated for undiluted plasma/amniotic fluid samples.

We conclude that microsampling-coupled bioanalytical techniques provide ethical, undiluted plasma/amniotic fluid samples.

Bioanalysis of IgG antibodies was feasible with microsamples using the described assay setup and provided a precise, accurate and specific quantification of the test item with low limits of quantification between 10-100 ng/mL back calculated for undiluted plasma/amniotic fluid samples.

We conclude that microsampling-coupled bioanalytical techniques provide ethical, undiluted plasma/amniotic fluid samples.
analysis of whole mounts, microarrays, qPCR, Western blots, histology, immuno-histochemistry, and serum PFOA and steroid hormone analysis. Developmental scoring of mammary whole mounts indicated PFOA-induced mammary delays persisted into adulthood. These morphological alterations were characterized as increased collagen density, active terminal end buds and reduced side branching changes were observed even though serum PFOA concentrations had reached control levels. Ppar, Wnt, and Esr1 (Esr2) were identified as candidate gene pathways by microarray analysis; RNA post-transcriptional modification and lipid metabolism were top molecular functions. Updated array analysis predicted Ppar and γ-dihydroprogesterone and estradiol were potentially induced. Additional compound-related renal metabolism was observed, including reduced expressions of genes with Ppar and γ predicted to be inhibited and dihydrotestosterone and beta-estradiol predicted to be activated. qPCR validated changes in Ppar targeted and steroid related genes. Western blot analysis of selected genes revealed increased protein expression of Ppar and Ert in whole cell lysates at PND 7 with non-significant increases in Ppar and Ppar/β-Er protein expression was reduced by PND 21. Results from blots coincided with H&E stained sections for Er that were reduced at PND 21 and 56. No change was observed in serum estradiol or progesterone, however testosterone levels were reduced at PND 21 and DHEA levels were reduced at PND 56. Changes in hormone levels over time were different in PFOA-treated animals compared to controls for estradiol, testosterone, and DHEA, suggesting that PFOA may have an overarching effect on sex steroid hormone synthesis. Collectively, these data show prenatal PFOA exposure disrupts the endocrine system to have localized effects on the maturation of the mammary gland at serum levels that overlap with human exposures.

**2196e** Mode of Action and Human Relevance Assessment of Male CD-1 Mouse Renal Adenocarcinoma Associated with Lifetime Exposure to Empagliflozin

J. A. Phillips1, M. E. Taub1, N. Ishiguro2, S. Van Tongeren1, B. Knight1, E. C. Ludwig-Schwellinger1, J. Yuan1, J. D. Smith1, H. Yu1, P. A. Escobar2, W. T. Loging3 and W. W. Ku1.

Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT. 2Kobe Pharma Research Institute, Kobe, Japan and 3Boehringer Ingelheim Pharmaceuticals, GmbH, Biberach, Germany.

In the 2-year carcinogenicity study with empagliflozin (dose levels of 100, 300 and 1000 mg/kg/day) in CD-1 mice, an increased incidence of renal tubular adenomas and carcinomas was identified in the male high dose (1000 mg/kg/day) group. Renal tumors were preceded by a number of renal degenerative/regenerative findings that overlap with human exposures. Specifically, membranous glomerulopathy, tubular atrophy, tubular cell necrosis, cystic hyperplasia and hypertrophy (mouse), renal mineralization and tubular nephropathy and interstitial nephritis (dog). Empagliflozin is non-genotoxic in a standard battery of gene mutation and chromosomal damage assays. In rat and mouse carcinogenicity studies, empagliflozin induced no tumors in females. Benign hemangiomata of the mesenteric lymph node and Leydig cell tumors were observed in male rats, both of which are common to the SGLT2 class, strain of rat, or may be of secondary relationship to treatment. Renal tumors were observed in male mice at 1000 mg/kg/day, an exposure approximately 45- and 113-fold above the therapeutic doses of 25 and 10 mg, respectively. In humans, tumor promotion by empagliflozin is not relevant to humans. Evaluations of photosensitivity spectrum and distribution of 14C-labelled empagliflozin to eye and skin coupled with the results of general toxicology studies revealed no potential for phototoxicity.

**2196f** General Toxicology and Carcinogenicity Assessment of Empagliflozin, an SGLT2 Inhibitor for the Treatment of Type 2 Diabetes Mellitus

Empagliflozin selectively inhibits sodium glucose co-transporter SGLT2 thereby reducing renal reabsorption of glucose as a therapeutic modality for type 2 diabetes mellitus. In pivotal toxicity studies in CD-1 mice, Wistar (Han) rat, and Beagle dogs, most toxicity was consistent with secondary pharmacology related to urinary glucose loss and electrolyte imbalances including decreased body weight and body fat, increased food consumption, diarrhea, dehydration, decreased serum glucose and increases in other serum parameters reflective of increased protein metabolism and glucosuria, urinary changes such as polyuria, and glycosuria. At high multiples of the therapeutic exposure, microscopic changes were observed in kidney and some soft and vascular tissues, and included tubular karyomegaly, single cell necrosis, cystic hyperplasia and hypertrophy (mouse), renal mineralization (rat), and tubular nephropathy and interstitial nephritis (dog). Empagliflozin is non-genotoxic in a standard battery of gene mutation and chromosomal damage assays. In rat and mouse carcinogenicity studies, empagliflozin induced no tumors in females. Benign hemangiomata of the mesenteric lymph node and Leydig cell tumors were observed in male rats, both of which are common to the SGLT2 class, strain of rat, or may be of secondary relationship to treatment. Renal tumors were observed in male mice at 1000 mg/kg/day, an exposure approximately 45- and 113-fold above the therapeutic doses of 25 and 10 mg, respectively. As described in relevant studies, the mode of action for these tumors is dependent on the natural predisposition of the male mouse to renal pathology and a metabolic pathway not reflective of humans. The male mouse renal tumors are considered not relevant to humans. Evaluations of photosensitivity spectrum and distribution of 14C-labelled empagliflozin to eye and skin coupled with the results of general toxicology studies revealed no potential for phototoxicity.

**2196g** A Predominant Oxidative Renal Metabolite of Empagliflozin in Male Mice Is Cytotoxic to Mouse Renal Tubular Cells but Not Genotoxic

J. D. Smith1, Z. Huang1, H. Maw1, R. Nardi1, P. Foppiano1, L. Her1, W. Loging1, P. A. Escobar1, J. A. Phillips1, H. Yu1, M. E. Taub1, W. W. Ku1, Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT.

In a mouse 2 year carcinogenicity study with the SGLT2 inhibitor empagliflozin (dose levels of 100, 300 and 1000 mg/kg/day), an increased incidence of renal tubular adenomas and carcinomas was identified only in the male high dose group. Renal tumors were preceded by a number of renal degenerative/regenerative findings that overlap with human exposures. Specifically, membranous glomerulopathy, tubular atrophy, tubular cell necrosis, cystic hyperplasia and hypertrophy (mouse), renal mineralization and tubular nephropathy and interstitial nephritis (dog). Empagliflozin is non-genotoxic, which supports a nongenotoxic mode of action. Cross species in vitro studies in mRTE cells demonstrated exposures comprising >75% of M380/1, implying a stoichiometric release of reactive 4-OH cromonoldehyde (4-OH CTA). In vitro toxicity studies were conducted to evaluate the cytotoxic and genotoxic potential of empagliflozin and synthesized M466/2. M466/2 was tested in both the bacterial reverse mutation test and mammalian clonogenic assays to evaluate genotoxic potential. A primary mouse renal tubular epithelial (mRTE) cell model was used to assess the cytotoxic potential of empagliflozin and M466/2, showing that M466/2-derived in vitro 4-OH CTA exposure is cytotoxic to mRTE cells but is not genotoxic. In vitro genotoxicity testing was conducted to evaluate the cytotoxicity and genotoxicity of empagliflozin suggestive of alternative modes of action. In conclusion, a male mouse predominant renal metabolite M466/2 is associated with the male mouse specificity in renal injury and tumor response. These in vitro data showed that M466/2-derived 4-OH CTA exposure is cytotoxic to renal tubule cells and can contribute to additional compound related renal metabolic stress and further chronic low level renal injury that support a nongenotoxic mode of tumor pathogenesis.

**2196h** Pathogenesis of Renal Injury in the Male CD-1 Mouse Associated with Exposure to Empagliflozin

B. Knight1, S. Ermich Hart1, J. A. Phillips1, S. Koegler1, J. Hall1 and W. W. Ku1, Boehringer Ingelheim Inc., Ridgefield, CT.

An increased incidence of renal tubular adenomas and carcinomas was identified in the 2-year CD-1 mouse carcinogenicity study with empagliflozin (SGLT2 inhibitor) in high dose (1000 mg/kg/day) male mice. A 13-week mouse renal pathogenesis study was conducted with empagliflozin to evaluate dose-dependency and temporal onset of non-neoplastic degenerative/regenerative tubular changes which precede neoplasia. Male and female CD-1 mice were given daily oral doses of 0, 100, 300, or 1000 mg/kg, (corresponding carcinogenicity study dose levels) for 1, 2, 4, 8 or 13 weeks. The maximum expected pharmacology with secondary osmotic diuresis was observed by Week 1 at > 100 mg/kg/day in both genders. Histopathologic kidney changes were first detected after 4 weeks of dosing in the male high dose group. Changes detected starting on Week 4 consisted of minimal single cell necrosis and minimal increases in mitotic figures. These changes persisted throughout the study period and were associated with male mouse specificity in renal injury and tumor response. These changes were additionally supported by a predominant oxidative pathway of empagliflozin metabolism in the mouse, compared to a predominant conjugative pathway (O-glucuronidation) in humans.
adverse. Similar changes were not identified in lower dose groups in males nor were they present in females of any dose group. Overall, the study results support early compound-related degenerative/regenerative changes only in high dose male CD-1 mice as a key contributing feature to a nongenotoxic mode of renal tumor pathogenesis.

**2196i** RNA-Seq Reveals Molecular Changes in Renal Injury Associated with Exposure to Empagliflozin in the Male CD-1 Mouse

J. Yuan1, P. Pande1, J. Hill1, Y. Wang2, D. Hall1, J. Mikl2 and W. W. Ku1, 
1Nonclinical Drug Safety, Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT, 2CT, Scientific Knowledge Discovery, Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT and 3Biometrics and Data Management, Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT.

In the CD-1 mouse 2-yr carcinogenicity study with empagliflozin, an increased incidence of renal tubular adenoma/carcinomas was observed in the high dose (1000 mg/kg/day) male group. To gain better understanding of the molecular changes in mouse kidney to support a tumorigenic mode of action, we have utilized RNA-Seq to evaluate gene expression changes in mice dosed with empagliflozin at 1000 mg/kg/day in a 13-week renal pathogenesis study. Enriched renal cortex was collected at 1, 2, 4, 8 and 13 weeks and the whole transcriptome in kidney was profiled. The transcriptome was compared between vehicle and empagliflozin treated male and female mice. Data showed male mouse-specific changes in kidney over 13 weeks of dosing. Consistent with the expected pharmacologic activity of SGLT2 inhibition and compound related renal metabolic stress, early treatment-related male-specific expression changes were noted in osmolality regulation, drug metabolism and transport at Weeks 1 and 2, followed by changes in immunity and complement system genes at Week 4. Treatment-related changes in genes and pathways related to p53 regulated cell proliferation, oxidative stress and renal injury were observed in high dose males at Week 8 and the number of genes with significant expression change dramatically increased at Week 13. The later expression changes were consistent with the increased appearance of degenerative/regenerative renal tubular changes only in high dose male. In contrast to males, observed expression changes were less apparent in female mice. Consistent with a nongenotoxic tumorigenic mode of action, no expression changes in DNA damage/repair pathways were identified. Overall, observed molecular changes in the male mouse complement the renal pathological changes in supporting a nongenotoxic tumorigenic mode of pathogenesis for empagliflozin.

**2196j** Nonclinical Safety Assessment of Exendin (9-39) in Juvenile Rats and Dogs

K. E. Elssas1, N. Bordelon2, M. Lynch3, M. Hawk1, T. Arndt2, P. Hong2, K. Knostman3, D. DeLeon1 and P. S. Teres4, National Center for Advancing Translational Sciences, Bethesda, MD, 2Battelle, Columbus, OH and 3The Children’s Hospital of Philadelphia, Philadelphia, PA.

Exendin (9-39) is being developed for the treatment of congenital hyperinsulinism, the most common cause of persistent hypoglycemia in children. Toxicology studies were conducted in Sprague-Dawley rats (7±1 days of age) and beagle dogs (13 days of age) to support its clinical evaluation. In 14-day non-GLP studies, TID subcutaneous (SC) doses of 15, 50, and 150 mg/kg/dose were administered to rats and 5, 15, and 40 mg/kg/dose were administered to dogs. Based on the lack of toxicologically significant findings, TID doses for GLP 28-day studies were increased to 20, 80, and 300 mg/kg/dose for rats and 10, 30, and 100 mg/kg/dose for dogs. Toxicological endpoints evaluated included: clinical observations, body weight, food consumption, clinical pathology, CNS assessment (rats), electrocardiography (dogs), toxicokinetics, and histopathology. The only Exendin (9-39)-related observations noted were increased serum glucose in female rats, decreased serum triglycerides in male rats, and increased urine volume in male dogs. In the cardiac vascular safety pharmacology study, beagle dogs (7 to 8 months old) were administered a single SC dose of vehicle or 5, 20, or 80 mg/kg Exendin (9-39) in a 4 x 4 Latin-square design. No toxicologically significant findings were observed. A dose proportional increase in Exendin plasma exposure was observed; combined average AUClast on Day 28 in male and female rats at the 300 mg/kg/dose was 249,000 ng.h/mL and at the 100 mg/kg/dose in dogs was 340,500 ng.h/mL. In conclusion, based on the available data, no observed adverse effect levels were 300 mg/kg/dose in rats and at 100 mg/kg/dose in dogs using TID subcutaneous dosing schedule. 

(Supported by NCI-SAIC Contract No. HHSN261200800001E, NICHD and NINDS under BrIDGs Program).

**2196k** ETI-204 Nonclinical Safety Assessment of CNS Findings from Inhalational Anthrax Animal Studies

B. Yamamoto1, M. T. Butt2, N. Serbina1, H. Tang1 and A. Shadiack1, 1Eluys Therapeutics, Pine Brook, NJ and 2Tox Path Specialists, Frederick, MD.

Inhalational anthrax (IA) can result in progressive hemorrhagic meningoencephalitis and death. Antibodies against Bacillus anthracis (Ba) toxin components (antitoxins) are strategies to treat IA. ETI-204 is a mononclonal antibody against the protective antigen component of Ba toxins currently in development for IA disease treatment. No Ba antitoxin-related changes are typically observed in the CNS of IA study survivors (monkeys, rabbits), however, in IA infected non-survivors, Ba antitoxins have been associated with extravascular bacteria and higher incidence of acute inflammatory reactions in leptomeninges compared to controls that tend to die with no CNS changes or with just intravascular bacteria. Because of a putative Ba antitoxin CNS effect, ETI-204 CNS safety was assessed in dogs. Cynomolgus monkeys or NZW rabbits were aerosol exposed with ~200 LD50 of Ba spores and dosed with ETI-204 (1-32 mg/kg, IV) and the brains from 78 monkeys and 86 rabbits were examined microscopically. Brains of 15 non-Ba-exposed rabbits dosed with ETI-204 (16-32 mg/kg/dose x 4, IV) were also examined. There were no ETI-204-related changes in IA study survivors or in ETI-204 exposed, non-infected rabbits, indicating no direct ETI-204 CNS effect. In IA infected monkeys and rabbits, there was a higher incidence of meningitis and extravascular bacteria in ETI-204-treated non-survivors (all doses) compared to controls that tended to die with no CNS changes or had just intravascular bacteria. CNS findings in ETI-204-treated non-survivors were consistent with IA and an immune response to extravascular bacteria. One hypothesis is in non-survivors, Ba antitoxins do not reach the brain in sufficient quantities or in time to prevent bacterial extravasation, inflammatory reactions, and death, or the Ba infection is too severe to save the host with Ba antitoxin treatment alone. ETI-204 has not been shown to be toxic to the CNS, and ETI-204 IA survival benefit appears to outweigh any potential CNS risk. Federally supported by ASPR/BARDA under Contract No. HHSO100201000026C.

**2196l** Nonclinical Assessment of NRX-1074, an Orally Bioavailable NMDAR Partial Agonist

G. W. Wolfe1, M. M. Veyragus2, C. S. Goodin1, D. Houck1 and J. Sidda2, Smithsere Ance, Gaithersburg, MD and 2Natures, Inc, Evaston, IL.

NRX-1074, a partial agonist of the NMDAR receptor, is an orally bioavailable molecule that is being developed for major depressive disorders. Studies have shown promising ketamine-like efficacy signatures without apparent safety issues. As part of an IND, studies were conducted included in vitro genotoxicity, blood compatibility, safety pharmacology, and repeat-dose studies. NRX-1074 did not result in genotoxicity or hemolysis. No adverse effects were noted on the respiratory or central nervous systems in rats at 700 mg/kg, PO and in the cardiovascular systems in dogs at 70 mg/kg, PO. In the Repeat-Dose Studies, animals were dosed daily for 28 days via oral gavage at 0, 30, 200 or 600 mg/kg/day (rats) or 0, 30, 20, 200 mg/kg/day (dogs) or daily for four weeks by IV injection at doses of 100 (200) mg/kg/day (rats) or 70 mg/kg/day (dogs). Parameters evaluated in both studies included mortality, physical examinations, cageside observations, body weight, food consumption, ophthalmology, clinical pathology, gross pathology, absolute/relative organ weights, histopathology, EC50s (dogs only) and toxicokinetics. In the oral gavage studies up to 600 mg/kg/day (rats) and 200 mg/kg/day (dogs) and in the intravenous studies up to 100 mg/kg/day (rats) and 70 mg/kg/day (dogs), no treatment-related effects were noted during the dosing or recovery period. IV administration of NRX-1074 at 200 mg/kg resulted in mortality in rats. The no-observed-effect level (NOEL) for NRX-1074 when administered orally for at least 28 days to rats and dogs was 600 and 200 mg/kg/day for the oral route, respectively, and 100 and 70 mg/kg/day, respectively for the intravenous route. The oral HED’s were 97 and 108 mg/kg in rats and dogs, respectively and intravenous HED’s were 16 and 38 mg/kg in rats and dogs, respectively, suggesting the rat as the most sensitive species.

**2196m** Comparative Prolactin Study in Mouse and Rat Using CNS Drugs: Melindone, Haloperidol and Reserpine

S. Ganiger1, H. Krishnappa1, S. Sulaiman1, S. God1 and G. Krishna2, 1Safety Assessment, Advinus Therapeutics Ltd, Bangalore, Karnataka, India and 2Supernus Pharmaceuticals, Inc, Rockville, MD.

Typical antipsychotics have high affinity for dopamine D2 receptors and known to increase blood prolactin in both rodents and humans. Two independent studies were conducted to investigate and compare the prolactin and its reversal to basal

---

**SOT 2014 Annual Meeting 577**
levels over a 24h postdose (PD) in Wistar rats and 32h PD in Swiss albino mice. Groups of rats and mice were treated with single doses of molindone (5 and 60 mg/kg; oral), haloperidol (20 and 100 mg/kg; oral), or reserpine (10 and 50 mg/kg; subcutaneous). These drugs were selected based on their potential to increase prolactin. Blood samples were drawn over 6 time points and prolactin levels were measured using validated ELISA method. Molindone resulted in peak prolactin levels at 0.25h PD and returned to baseline by 24h in both species. In general, haloperidol and reserpine showed treatment related increase in prolactin, though at a slower rate compared to molindone in rats and mice. The prolactin levels reached basal levels in males and rats by the last sampling time studied. However, in females the prolactin was decreased but remained elevated by last sampling time compared to controls. This study demonstrates, rodents experience prolactin surges that are physiologically required for reproductive effects of test-drugs. The changes in prolactin correlated with plasma drug levels and were higher in females than in males for all three drugs. Rapid reversal of prolactin in molindone treated animals compared to haloperidol and reserpine correlated with short half lives. These data are considered to be of significant value in comparative human risk assessment of test drugs.

2196n Assessment of Prolactin-Mediated Changes and Their Reversal in Molindone-Treated rasH2 Mice
G. Krishna1, S. Ganiger2 and S. Goel1.1
Superpharm Pharmaceuticals, Inc., Rockville, MD and Advicis Therapeutics Ltd., Bengaluru, India.

Molindone, an antipsychotic, is known to modulate prolactin levels linked with reproductive changes in rodents. Such effects were further investigated in 6-month mouse study with a reversible phase to better characterize risks assessment. Groups of rasH2 mice were dosed daily by gavage with molindone at 5, 15 and 50 mg/kg. Blood samples were analyzed for molindone on Day 180 and prolactin on Days 1, 180 and at a 2-month reversal period. Histopathology was performed on reproductive tissues. Results showed that plasma levels of molindone were more than dose proportional with Tmax at 0.25h postdose (PD). Prolactin levels peaked within 0.5h PD and were 257 and 272ng/mL in males and 1313 and 2454ng/mL in females, respectively, for Days 1 and 180. Prolactin levels remained elevated up to 250h PD and were 255 and 272ng/mL in males and 1313 and 2454ng/mL in females, respectively, for Days 1 and 180. Prolactin levels remained elevated up to 1h PD in males and 3h in females but returned to basal levels by 24h PD. Further, after 2-month recovery, prolactin levels were at basal levels, suggesting complete reversibility. Histopathologically, on Day 180, changes in ovaries included retention of eosinophilic corpora lutea and interstitial atrophy of diffuse tissue in all of the treated groups. Atrophy of uterus and vagina were observed in these groups. At the end of recovery, these changes were completely reversed at 5 and 15 mg/kg, with signs of reversal at 50 mg/kg. In males, there was no histopathology changes noted. Reversibility of prolactin levels and histopathology seen in this study confirms the pharmacologically mediated effects of molindone and corroborate with the known role of prolactin in hormonal homeostasis and reproductive physiology. These changes are considered rodent-specific, similar to those seen with other antipsychotics in this class of drugs. It is concluded that the transient prolactin-mediated changes seen in this mouse study are of negligible risk, if any, to humans, because such changes have not been reported in humans taking molindone as a therapeutic.

2196p De-Risking Potential Infection Risk with Anti-CSF-1
Genentech, South San Francisco, CA.

Colonoly-stimulating factor-1 (CSF-1) promotes differentiation, proliferation and migration of monocytes/macrophages, which are involved in innate and adaptive immunity. Macrophages are implicated in a variety of inflammatory diseases; therefore, anti-CSF-1 therapeutic antibodies can be beneficial in several indications such as rheumatoid arthritis (RA). A safety concern when targeting this pathway is increased infection risk due to the role of monocytes/macrophages in immunity; therefore, 2 mouse studies were conducted to evaluate the anti-CSF-1 safety profile and infection risk.

The overall safety profile of anti-CSF-1 was evaluated in an 84d repeat dose study, where administration of anti-CSF-1 (twice weekly; i.p.; 200ug/mouse) resulted in decreased macrophages in spleen, lung, kidney and liver. There was a minimal to mild increase in ALT, AST and CK, consistent with the role of liver macrophages in clearing serum enzymes. No anti-CSF-1-related anatomic pathology findings were observed. Collectively, these findings are consistent with pharmacology of anti-CSF-1.

Infection risk with anti-CSF-1 was interrogated by evaluating the response to Listeria monocytogenes challenge in a head-to-head comparison to a TNFa inhibitor (TNFRII-IgG). The biology standard of care for RA, A mouse Listeria infectious challenge model was chosen because the primary response to Listeria is driven by macrophages and RA patients treated with TNFa inhibitors are at an increased risk of infections with Listeria. While anti-CSF-1 treatment (twice weekly; i.p.; 200ug/mouse; up to 42d) did result in increased mortality compared to isotype antibody-treated controls, the onset and rate of mortality was significantly later and lower than that observed with TNFRII-IgG (twice weekly; i.p.; 150ug/mouse; up to 14d). These data suggest that anti-CSF-1 may be associated with less risk of infection compared to TNFa inhibitors.

2196q A Method Validation for the Screening and Confirmation of Neutralizing Antibodies (Nab) against PEG-IL-29 in HCV Human Sera Using a Cell-Based Assay with a Bioluminescent Detection Platform
J. Hantash.
Biotechnology Services, Tandem Labs Inc., West Trenton, NJ. Sponsor: Z. Radi.

A cell based assay for the determination of PEG-IL-29 neutralizing antibody in human HCV positive sera was developed and validated in support of bioequivalence studies. The assay utilized a cell line that was engineered to over-express the IL-29 receptor containing a Luciferase reporter construct with ISRE and STAT binding elements directly upstream of a luciferase reporter gene. Positive Quality Control and test HCV positive serum samples containing Anti-PEG-IL-29 antibodies (antibody/PEG-IL-29) mix was added to an overnight seeded cell culture plate and incubated. ONE-Glo solution was added and the signal was measured. Samples were determined to be “positive” or “negative” for neutralizing activity based on a comparison of the mean response of the positive control to the mean response of the negative control. Samples are considered positive if the % Neutralization value is greater than or equal to the assay cut point. 25 HCV positive Human Sera lots were tested to determine the neutralization cut point of the assay, which was found to be ≥26%. For quality control samples tested at two concentrations (1000 and 500 ng/mL), precision (%CV) ranged from 0.1 to 25.7% and 0.0 to 23.7%; respectively. The assay sensitivity was 250 ng/mL with a drug tolerance ≥2ng/mL. For selectivity, 10 out of the 10 HCV positive Human Sera lots tested showed neutralization (%) ≤26%. Positive control samples showed bench top stability for 20 hours (neutralization ranged from 34 to 38%) and freeze thaw stability for up to 8 cycles (neutralization ranged from 44 to 65%). Long term stability at -80°C was proven for up to 182 days (neutralization ranged from 30 to 57%). The validated Nab cell based assay in HCV positive Human Sera successfully met all standard assay-validation parameters and was suitable for use in bioequivalence studies.

2196o The Role of Receptor Occupancy Analysis during Preclinical Development of Biologics

Pre-clinical safety assessment of biopharmaceuticals provides many challenges, including the potential for the production of anti-drug antibodies (ADA) when a human (or humanised) protein is administered to an animal system. ADA production may lead to loss of exposure and activity of the biotech derived protein (Bio-A) specific for receptors on a sub-set of lymphocytes, during a 26 week regulatory study in the mouse. Prior to starting the 26 week study an RO method was validated to determine the proportion of bound and free target receptors on lymphocytes in the presence / absence of Bio-A. Both evaluations established good reproducibility (CV ≤27%), whilst requiring minimal quantities of blood. At Week 13 of the 26 week mouse study, ADA production and a drop in systemic levels of Bio-A suggested loss of exposure, especially in the low dose group, RO analysis on a sub-set of animals indicated that the majority of low dose mice had reduced levels of bound Bio-A and high levels of free receptors. However, in the remaining mice, Bio-A was still bound to the surface of lymphocytes. Based on the possibility that exposure still persisted in some animals it was decided that additional blood be taken from the toxicology animals at necropsy to evaluate the level of free receptors in each. This additional analysis was possible in the mouse as the RO validation had established a method where this could be evaluated in blood samples of 50uL. Evaluation of free receptors in the low dose group, contradicted the ADA and TK data, suggesting that the majority of mice were still exposed and rendering these animals valid for assessment of toxicity over the 26 week period.

In conclusion, establishment of a robust method to measure RO provided vital information regarding exposure levels that allowed a proportion of the low dose animals to be used to for histopathology evaluation, when the TK and ADA data suggested otherwise.

2196r SOT 2014 Annual Meeting
Testing of biological drug products for safety and efficacy in animal models has been difficult to assess because common models such as rodents, canines and non-human primates do not necessarily share common biological receptors with humans. A new animal model, the human immune system mouse, has recently emerged in widespread use for infectious disease pathogenesis and vaccine testing research. We utilize human immune system mice that have human thymus and liver implanted underneath the kidney capsule and are engrafted with human hematopoietic stem cells. To test the ability of this model assess the efficacy and safety of biological drug products in vivo, we tested the anti-C2D2 product rituximab.

Mice were pretreated with anti-histamines and anti-inflammatory products, as recommended per package label. A single treatment was administered at three different doses: 2 mg/kg (low), 8 mg/kg (middle), and 15 mg/kg (high). The drug was diluted in saline to concentrations of 0.2 – 0.75 mg/ml prior to i.v. administration to reduce the likelihood of immediate hypersensitivity reaction. Samples for flow cytometric assessment and serum were taken immediately prior to administration and then at 1, 2, 5, 8, 11, 16, and 21 days post-treatment. Mice were euthanized at days 8, 11, 16 and 21 post-administration to determine the completeness and durability of B-cell depletion in blood, spleen and bone marrow. Results showed that human immune system mice experienced full B-cell depletion in a dose-dependent manner, with the low dose group substantially reconstituted at day 8 and the high-dose group still depleted at day 21 post-administration. Adverse effects observed included off-target depletion of T-cells that was donor dependent, which has also been shown to occur in some human patients. These results demonstrate that human immune system mice can respond biologically in a dose-dependent manner to anti-C2D2 drug products and recapitulate the pharmacodynamics and adverse events observed in humans.
Administration of SCH A produced increased salivation and emesis at doses equal to or greater than 300 mg/kg and mild to severe tremor at doses equal to or greater than 600 mg/kg. Tremor occurred 30-60 minutes post-dose and increased in magnitude with increasing dose. Two animals appeared to be more sensitive to these effects, showing more severe findings and findings at lower doses than the other two animals. EEG analysis showed no evidence of seizure-related waveforms in any animal. TK analysis showed that mean AUC values increased with increasing dose, and mean Cmax values increased from 300-1000 mg/kg, with no further increase at 2000 mg/kg. Individual inter-animal variability made difficult the determination of a PK-PD relationship. It did not appear that there was a strong correlation between plasma concentration and clinical signs following oral administration of SCH A. Oral administration of SCH A was not accompanied by adverse changes in brain activity, as assessed by EEG.

**The Effect of Anesthetic on QT Interval Measurements in Guinea Pigs**

L. A. Neves, H. Wang, J. Huang, P. B. Senese and M. R. Gralinski, CoreDynamics, Inc., Chicago, IL.

Anesthetized guinea pig is a widely used model for early screening of drug-candidate effects on cardiovascular function. This species is gaining traction for use in conscious screening telemetry studies. For unanesthetized work, the majority of published studies use sodium pentobarbital (NaP) as the anesthetic of choice. However, NaP is an antagonist of the inward rectifying cardiac potassium channel IKs. Since the IKs is a component of the guinea pig cardiac repolarization sequence, this species can be exquisitely sensitive to IKs blockade. In this study we investigated the baseline vulnerability of the anesthetized guinea pig for safety pharmacology screening of drugs with potential to prolong the QT interval. Male guinea pigs (400-550g) were anesthetized with ketamine/xylazine (87.5/7.5 mg/kg, KET) or NaP (15-30 mg/kg) and surgically instrumented with a Millar catheter to measure arterial pressure. Electrocardiograms were recorded and PR interval, QRS duration, QT/QTc interval and arrhythmogrames were monitored. Monitored parameters were compared with measurements obtained previously in conscious guinea pigs (CON). NaP anesthetized guinea pigs exhibited baseline QTcB intervals (342±3 ms, p<0.05) that were significantly increased compared to CON cohort (256±6 ms). QTcB intervals in the KET group (307±7 ms, p<0.05) were also increased as compared to CON group, but the changes were significantly less robust. Lower HR was observed in the KET group (215±29 bpm, p<0.05) as compared to CON (258±13 bpm) and NaP (250±6 bpm) groups. QRS duration was increased in the KET (45±2.8 ms) and NaP (44±3.3 ms) groups as compared to CON guinea pigs (29±1.3 bpm, p<0.05). No change in mean arterial pressure was observed between the groups. In summary, the choice of anesthetic appears to influence the QT interval in anesthetized guinea pigs compared to conscious animals. It is possible that anesthetics with additional inherent IKs blockade may overly sensitize the animal to agents that prolong the electrocardiographic QT interval. Consideration should be taken when selecting anesthetics for this model.

**IG-001 Suppressed Hypersensitivity Reactions versus Taxol® in Beagle Dogs**

O. J. D’Cruz, J. Hsu and V. Trieu, Sorrento Therapeutics, Irvine, CA.

Study Purpose: Hypersensitivity reactions (HRs) are known adverse effects of Taxol® chemotherapy. Taxol® is formulated in Cremophor EL (Cr-EL) which triggers HRs requiring premedication. Abraxane®, a Cr-EL-free albumin-bound formulation (nab-Pac), has low incidence of HRs. IG-001 is a novel Cr-EL-free, non-biologic nanoparticle formulation being developed as an alternative to nab-Pac. We report the suppressed HRs for IG-001 vs Taxol® in beagle dogs as the most sensitive species.

Methods: Sixty-five beagle dogs (33 M and 32 F) were evaluated in 3 GLP studies. In a dose-escalation study, 9 dogs received a 30 min intravenous (iv) infusion of IG-001 (1.1-4.5 mg/kg) or Taxol® (0.1-1.1 mg/kg). In the single (n = 24) or repeated 5-cycle (n = 32) dosing studies, dogs received IG-001 (1.5-4.5 mg/kg for 3 hr) or Taxol® (0.1-2.5 mg/kg for 30 min), the latter group with antihistamine premedication. Measurements included clinical observations, body weight, food consumption, hematology, blood chemistry, and histopathology. Results: Minimal clinical signs were noted at IG-001 doses of 1.1 to 2.2 mg/kg, but 4.5 mg/kg was associated with morbidity. Taxol® produced HRs at 0.1 mg/kg and above, necessitating premedication and shortening of infusion time from 3 hr to 30 min. The MTD was >2.2 mg/kg for IG-001 and 0.2 mg/kg for Taxol®. HRs to IG-001 was limited to only 2 of 32 (6.25%) dogs from the dose-escalation study. The HRs occurred after 3 or 4 doses within 3 or 5 weeks. No HR was noted with the IG-001 vehicle or those treated with IG-001 in the single- and repeated-dose studies. Excluding the severe HRs observed in the Taxol® group, body weight, food consumption, clinical signs, and hematology responses were comparable between IG-001 and Taxol®.

Conclusions: Taxol® infusion in the canine model resulted in severe HRs requiring >2.2 mg/kg premedication and a reduction in infusion time. IG-001 was better-tolerated without premedication at substantially higher doses and with a low potential to produce HRs. IG-001 could potentially be a safe and effective alternative to nab-Pac.

**2196b**

**Repeat-Dose Rabbit Vaginal Tolerance/Toxicity Study of Diindolylmethane Cream for Topical Treatment of Cervical Intraepithelial Neoplasia**

T. L. Horn1, M. Muzzio1, C. J. Detrisac2, M. A. Zelig3, D. L. Boring1 and D. L. McCormick1, 1IIT Research Institute, Chicago, IL, 2Pathology Associates, Chicago, IL, 3BioResponse Nutrients, LLC, Boulder, CO and 4National Cancer Institute, Bethesda, MD.

Cervical Intraepithelial Neoplasia (CIN) is a premalignant condition characterized by dysplastic changes in the cervix. Because it can be identified by screening and may progress to invasive malignancy, CIN is an attractive target for cancer prevention. Indole-3-carbinol and its condensation product, diindolylmethane (DIM), have chemopreventive activity in several carcinogenesis models. As a result of its superior stability, DIM is being evaluated in clinical trials for cancer prevention in several sites, including the cervix. A preclinical study was performed to characterize the local and systemic effects of intravaginal administration of DIM (DIM Vaginal Cream, BioResponse LLC, Boulder, CO [BR-DIM-VC]). Groups of 5 NZW rabbits received intravaginal instillation of the maximum feasible volume (4.0 ml) of BR-DIM-VC (0% [placebo], 2%, 4%, or 6%) on alternate days for two weeks. Exposure to BR-DIM-VC induced no mortality and had no effect on body weight. The results of clinical and physical observations, chemical analysis, hematology, and coagulation assays were comparable in all groups. Vaginal pH was unchanged by exposure to BR-DIM-VC. Vaginal irritation scoring demonstrated dose-related vaginal edema and erythema in rabbits treated with BR-DIM-VC. At 2%, 4% rabbits were normal; 1 rabbit demonstrated very slight edema (no erythema). At 4%, 2/5 rabbits were normal; 3 rabbits demonstrated very slight edema with barely perceptible erythema. At 6% 1/5 rabbits was normal, 2 rabbits demonstrated very slight edema with very slight erythema, and 2 rabbits demonstrated slight edema with well-defined erythema. No vaginal edema or erythema was seen in placebo-treated rabbits. Repeat-dose intravaginal administration of BR-DIM-VC on alternate days for two weeks induced no systemic toxicity in rabbits. BR-DIM-VC did induce very slight to slight vaginal irritation in a dose-related fashion. (HHSN261201200025F)

**A Retrospective Analysis of the Effect of Housing Conditions on Body Weight, Food Consumption and Survival in Rat Carcinogenic Rat Studies**

D. Zhao1, C. N. Papagiannis2, D. W. Pouge3, R. L. Yeager1, D. R. Davila1, J. Hiner1 and L. Shu1, 1Preclinical Safety, AbbVie Inc, North Chicago, IL, 2MPI Research, Mattawan, MI and 3Statistics, AbbVie Inc, North Chicago, IL.

Rodent toxicity studies have historically been performed in wire-bottom cages. However, both the National Research Council (NRC) and Association for the Assessment and Accreditation of Laboratory Animal Care (AAALAC) International, recommend housing rats in solid-bottom cages with bedding to prevent development of foot lesions and/or stress responses. A retrospective analysis of Sprague-Dawley rat carcinogenicity study data (n=25 control groups) compared the effects of individual vs. pair housing and wire-bottom vs. solid-bottom caging on body weight, food consumption and survival. Survival was analyzed by the Cox proportional hazards model; body weight was analyzed by the Gompertz non-linear model. For rats housed individually in solid-bottom cages, average body weights were higher compared to rats housed individually in wire-bottom cages. The body weight differences become significant around Week 25 in males and Week 45 in females, and continued until the end of study. At Week 104, the average difference in males was about 50 g or 5% and in females was about 55 g or 11%. The differences in average body weight did not correspond with a significant difference in average food consumption or in survival rates. For pair-housed rats in solid-bottom cages, average food consumption was lower (~7% in males; ~8% in females) than rats housed individually. This difference in average food consumption corresponded with a slightly lower average body weight (Week 104, ~3% in males; ~9% in females) and a marginal improvement in survival (in females only, Week 104, ~15%). In conclusion, this analysis demonstrates that housing conditions (individ-ual vs. paired and wire-bottom vs. solid-bottom) may affect body weight, food consumption, and survival on two-year rat carcinogenicity studies.
An international expert group which includes 32 organisations (pharmaceutical and biotechnology companies, contract research organisations and regulatory bodies) has shared data on the use of recovery animals in the assessment of pharmaceutical safety for early development. The group has used this data as an evidence-base to make recommendations on the inclusion of recovery animals in toxicology studies to best assess human safety, while reducing animal use. The initiative is led by the NC3Rs in collaboration with the Medicines and Healthcare products Regulatory Agency (MHRA).

Recovery animals are used in pharmaceutical development to provide information on the potential for a toxic effect observed in animals to translate into long-term human risk. They are included on toxicology studies to assess whether effects observed during dosing persist or reverse once treatment ends. It is a regulatory requirement to assess recovery at some point during drug development.

The group devised a questionnaire to collect information on the use of recovery animals in general regulatory toxicology studies to support first-in-human clinical studies. Questions focused on study design (e.g. species, recovery duration and the number of animals used), the rationale behind inclusion or exclusion (case-specific vs. default inclusion), and the impact this had on internal and regulatory decisions. Data on 137 compounds (53 biologicals and 78 small molecules) from 259 studies was provided by 22 companies and showed that there was wide variation in where, when and why recovery animals were included. We found that recovery animals were included on all studies for 85% biologicals and 65% small molecules.

Recovery animals were included on more than one dose group for 70% biologicals and 25% small molecules. The number of recovery animals used per compound ranged from 0 to over 100. An analysis of individual study and programme design shows that there are opportunities to reduce the use of recovery animals in certain circumstances which would not impact drug development.

Alkaline phosphatase (ALP, EC 3.1.3.1.) in serum is measured frequently in toxicity studies. ALP isoenzymes in serum are important items for the evaluation of organ toxicity, but they are also informative on underlying environmental contaminants-induced diabetes and identify AhR signal transduction as a potential therapeutic target.

Epidemiological studies have shown that exposure to persistent organic pollutants (POPs) is associated with increased risk of type 2 diabetes. Most of POPs function through activation of the aryl hydrocarbon receptor (AhR), and our previous studies have shown that AhR knockout (AhRKO) mice exhibit enhanced insulin sensitivity.

In this study, we explored the effects and mechanisms of AhR agonists on the insulin signaling pathway using wild-type (WT) and AhRKO mice, as well as hepatic tumours. Hepa-1c1c7 (C7). In C7 cells, AhR agonists 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) and beta naphthoflavone (BNF) decreased insulin receptor substrate 1 (IRS-1) protein expression and inhibited Akt phosphorylation, but did not change IRS-1 mRNA, TNF-α or phospho-JNK levels. AhR knockdown with specific siRNA partially reversed the BNF or TCDD-mediated IRS-1 protein decrease. Furthermore, the proteasome inhibitor, MG132, partially restored AhR agonist-mediated IRS-1 protein degradation. In addition, AhR activation by its agonists compromised the insulin signaling pathway and caused hyperglycemia in WT mice, but not in AhRKO mice. Taken together, these data indicate that AhR activation induced IRS-1 ubiquitin-dependent degradation leading to insulin resistance and hyperglycemia. Our findings provide an insight into the mechanisms underlying environmental contaminants-induced diabetes and identify AhR signaling as a novel therapeutic target.
the mechanism causing these effects and their relevance to human disease is not well understood. In this study, we have used unique immortal human preadipocytes that can be differentiated into adipocytes to evaluate the effects of PCBs on adipocyte biology. Exposure of the preadipocytes to PCB126 at concentrations of 0.1 - 10 μM caused a dose-dependent decrease in subsequent differentiation to adipocytes. Reduced differentiation was marked by significant decreases in accumulation of lipids, mRNA expression of adipocyte differentiation markers (PPAR/2, CEBP/α, p2 and adiponectin; P < 0.05) and genes in the insulin signaling pathway (IRS-1 and GLUT4). Strikingly, the decrease in adipocyte differentiation was more profound in preadipocytes exposed to PCB126 before differentiation compared to exposure during differentiation, the latter being the treatment regimen used in previously reported studies. These results indicate that PCB126 may maintain pre-adipocytes in an undifferentiated state, possibly leading to expansion and metabolic disruption that can initiate metabolic syndrome. These interesting observations warrant further research in order to understand the mechanism by which PCB126 causes inhibition of adipocyte differentiation and the roles of adipose tissue in PCB126 induced toxicity.

2200 TCDD Treatment Enhances Hepatic Stellate Cell Activation during Experimental Liver Fibrosis

C. L. Lamb, W. A. Harvey and K. A. Mitchell. Biological Sciences, Boise State University, Boise, ID.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) and related chemicals are widely spread environmental pollutants that elicit toxicity through the aryl hydrocarbon receptor. It was recently shown that exposure to TCDD enhances gross markers of liver damage during experimental liver fibrosis. Liver fibrosis is a wound healing response characterized by the deposition of excessive or abnormal extracellular matrix by myofibroblasts, namely hepatic stellate cells (HSCs). Previous studies in our laboratory revealed that TCDD treatment enhances activation of a human HSC line in vivo. The goal of the present study was to determine if TCDD increases HSC activation in vitro using two mouse models of liver fibrosis: bile duct ligation (BDL) and carbon tetrachloride (CCL4) administration. For the BDL model system, C57Bl/6 mice were treated with TCDD (20 μg/kg) or peanut oil (vehicle) one day prior to surgery and euthanized 3 and 7 days later. For the CCL4 model system, C57Bl/6 mice was administered twice a week for 6 weeks and TCDD (20 μg/kg) or vehicle was given during the last 2 weeks. In BDL mice, TCDD treatment elicited a 3- to 6-fold increase in plasma alanine aminotransferase levels and caused marked expansion of periportal bile ducts. Immunofluorescence staining revealed that TCDD treatment increased expression of the HSC activation marker, alpha-smooth muscle actin (αSMA), in areas surrounding the bile ducts, which coincided with a three-fold increase in αSMA transcript levels in the whole liver. In the CCL4 model, a 50% increase in liver-body weight ratio was observed in TCDD-treated mice compared to mice that received CCL4 alone. TCDD treatment also elicited a 5-fold increase in hepatic αSMA transcript levels and enhanced collagen deposition, as revealed by increased Sirius red staining. These results indicate that TCDD treatment enhances HSC activation in vivo, which may contribute to the exacerbation of liver damage observed in TCDD-treated mice during experimental liver fibrosis.

2201 Congener- and Species-Specific Differences in Relative Effect Potencies of Dioxin-Like Compounds between In Vitro-Exposed Human Peripheral Blood Lymphocytes and Mouse Splenic Cells

Human risk assessment for dioxin-like compounds is typically based on the concentration measured in blood serum multiplied by their assigned toxic equivalence factor (TEF). Consequently, the actual value of the TEF is very important for accurate human risk assessment. In this study we investigated the effect potencies of 3 polychlorinated dibenzo-p-dioxins (PCDDs), 6 polychlorinated dibenzofurans (PCDFs) and 10 polychlorinated biphenyls (PCBs) relative to the reference congener 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in vitro exposed primary human peripheral blood lymphocytes (PBLs) and mouse splenic cells. REPs were determined based on cytotoxicity in 96-well plates using CellTiter96® Aqueous One Solution assay (Promega). The aryl hydrocarbon receptor repressor (AhRR) gene expression as well as the TCF3 and REL gene expression. These factors interfere with understanding the toxic potential of this class of compounds, particularly in mixtures. Characterizing the non-carcinogenic toxicity of PAH compounds will contribute to toxicity assessments, understanding mixture interactions, and the management of human health risks. The objective of this study was to observe cellular responses from PAH concentrations. Clone-9 rat liver cells were grown in culture and tested to observe acute toxicity. In paired trials, cells were exposed to 15 parent and methylated PAHs for a period of 24 hours, with concentrations ranging from 0.25-20 parts per million (ppm). At 100% confluence, Janus green B staining was performed to observe cellular viability and proliferation. Many of the tested compounds displayed minimal toxicity, with no observed inhibition of proliferation or viability except at the highest concentration. Benzo[a]pyrene (BaP) displayed slight toxicity, with a decline in proliferation only at 20 ppm. There was no observed response from benzo[c]pyrene, benzo[b]fluoranthene, chrysene and phenanthrene. 3,6-dimethylphenanthrene, 7,12-dimethylbenz[a]anthracene and 9,10-di-menthylanthracene displayed severe toxicity, impairing both proliferation and viability in a dose-responsive manner. The results for the parent compounds concur with available literature, which acknowledge carcinogenesis as the primary health concern rather than non-carcinogenic toxicity at environmentally-relevant concentrations. However, our findings suggest that methylated PAHs can be much more toxic than the parent compounds. Further research will compare these results to trials using binary PAH mixtures for the purpose of characterizing mixture effects.

2202 Measurement of Protein Adducts Formed by Quinoid Metabolites of Polychlorinated Biphenyls (PCBs)

M. Li1, W. H. Robertson1,2, A. P. Kapke3 and G. Ludewig1, 2. Interdisciplinary Graduate Program in Human Toxicology, The University of Iowa, Iowa City, IA.

2Department of Occupational and Environmental Health, The University of Iowa, Iowa City, IA and 3HybriNova Facility, Iowa State University, Ames, IA.

Recently unexpected high levels of indoor PCB air concentrations were found in a large number of public elementary school classrooms. Most of the airborne PCBs are lower chlorinated congeners, from mono- to tri-chlorinated PCBs. Lower chlorinated biphenyls can be metabolized to dihydroxy metabolites and further oxidized to quinoid metabolites both in vivo and in vitro. Quinoid metabolites of PCBs may form adducts at nucleophilic sites of proteins. Using radioactively labeled PCB3, we previously had observed hemoglobin adducts in vivo and covalently bound adducts with nuclear protein in liver. Our current objective is to establish the methodologies to quantitatively measure the adducts formed by PCB3 quinones, and to determine the distribution of protein adducts and the target proteins in cells treated with PCB3 and metabolites. Monoclonal antibodies against PCB3 quinone protein adducts may be employed to screen tissues for such adducts and to isolate adducted proteins. Two types of immunogens of PCB3 quinones were synthesized. PCB3 quinones were linked with keyhole limpet hemocyanin (KLH) or N418 through N-succinimidyl 3-(2-pyridyldithio)-propionate (SDPD). These antigens were injected repeatedly into mice. Four hybridoma lines with strong antibody production were chosen for further analysis of antibody specificity. In addition a method is being developed to quantify protein adduction by detachment bound quinone molecules from the proteins, isolating and quantifying them. To establish this method, PCB3-para-quinone was incubated with bovine serum albumin (BSA). Protein adducts were hydrolyzed under mild acidic conditions and extracted with hexane. Quinoid PCB3 residues in the extracts were determined by HPLC and confirmed by mass spectrometry. In future experiments GC/MS or LC/MS will be used to increase detection limits. (Supported by NIEHS Superfund Program P42 ES013661)

2203 The Effects of Polycyclic Aromatic Hydrocarbons on Cellular Proliferation and Viability in Clone-9 Rat Liver Cells

S. I. Gray and E. D. Bruce. Environmental Science, Baylor University, Waco, TX.

Polycyclic aromatic hydrocarbons (PAHs) have been labeled contaminated of concern due to their carcinogenic potential, insufficient toxicological data, ubiquity, and common presence in the environmental media. These factors interfere with understanding the toxic potential of this class of compounds, particularly in mixtures. Characterizing the non-carcinogenic toxicity of PAH compounds will contribute to toxicity assessments, understanding mixture interactions, and the management of human health risks. The objective of this study was to observe cellular responses from PAH concentrations. Clone-9 rat liver cells were grown in culture and tested to observe acute toxicity. In paired trials, cells were exposed to 15 parent and methylated PAHs for a period of 24 hours, with concentrations ranging from 0.25-20 parts per million (ppm). At 100% confluence, Janus green B staining was performed to observe cellular viability and proliferation. Many of the tested compounds displayed minimal toxicity, with no observed inhibition of proliferation or viability except at the highest concentration. Benzo[a]pyrene (BaP) displayed slight toxicity, with a decline in proliferation only at 20 ppm. There was no observed response from benzo[c]pyrene, benzo[b]fluoranthene, chrysene and phenanthrene. 3,6-dimethylphenanthrene, 7,12-dimethylbenz[a]anthracene and 9,10-di-menthylanthracene displayed severe toxicity, impairing both proliferation and viability in a dose-responsive manner. The results for the parent compounds concur with available literature, which acknowledge carcinogenesis as the primary health concern rather than non-carcinogenic toxicity at environmentally-relevant concentrations. However, our findings suggest that methylated PAHs can be much more toxic than the parent compounds. Further research will compare these results to trials using binary PAH mixtures for the purpose of characterizing mixture effects.
2204 Biotransformation of BDE-100 to Potentially Toxic Metabolites: Predominant Role of Human CYP2B6

M. S. Gross1, D. M. Butryn1, B. P. McGarrigle2, D. S. Aga1 and J. R. Olson2.
1Chemistry, University at Buffalo, Buffalo, NY and 2Pharmacology and Toxicology, University at Buffalo, Buffalo, NY.

Polybrominated diphenyl ethers (PBDEs) are additive flame-retardants used in numerous consumer products, resulting in their presence as widespread environmental contaminants. Recent studies have suggested that hydroxylated metabolites of PBDEs accumulate in human serum at levels similar to or greater than their parent PBDEs. Furthermore, it has been suggested that bioactivation through oxidative metabolism may add to the neurotoxic potential of PBDEs, however, insufficient data exists on the metabolism of PBDEs in humans. The purpose of this study was to characterize the in vitro metabolism of 2,2',4,4',6,6'-hexabromodiphenyl ether (BDE-100), one of the most abundant PBDEs found in humans, by recombinant human cytochrome P450s (CYPs) and pooled human liver microsomes (HLMs). Recombinant CYPs (1A1, 1A2, 2A6, 3A4, 2B6, 2C8, 2C9, 2C19, 2D6, and 2E1) were individually incubated with 20 μM BDE-100 to monitor CYP-specific metabolism. For kinetic studies, recombinant CYP2B6 and HLMs were incubated with BDE-100 (0-60 μM). Analysis was completed by gas chromatography-mass spectrometry after derivatization of the hydroxylated-BDE metabolites (OH-BDEs) to their methylated derivatives using (trimethylsilyl) diazomethane. CYP2B6 was found to be the predominant CYP responsible for the formation of five mono-OH-BDE and two di-OH-BDE metabolites observed for BDE-100. One metabolite was identified as 6-OH-BDE-100 through use of an authenticated standard. Utilizing fragmentation characteristics of methoxylated-BDEs (MeO-BDEs), it is hypothesized that two meta-OH-BDEs and one para-OH-BDE are among the remaining OH-BDE metabolites. Kinetic studies of BDE-100 metabolism by CYP2B6 and HLMs were confirmed by Km values ranging from 3.7-5.9 μM and 4.7-5.6 μM, respectively, suggesting a high affinity towards the formation of OH-BDEs. These results will ultimately better inform future studies investigating the potential of PBDEs and their metabolites to produce neurotoxic and other health effects. (NI-EHS grant #ES021554)

2205 Enantioselective Disposition of 2, 2’, 3, 5’, 6-Hexachlorobiphenyl (PCB 95) and Its Metabolites in Mouse Dams Dosed during Pregnancy

L. Kania-Korwel1, C. Barnhart1, K. M. Traoung2, P. Lein2 and H. Lehmler1.
1Department of Occupational and Environmental Health, Univ of Iowa, Iowa City, IA and 2School of Veterinary Medicine, University of California, Davis, CA.

Racemic PCB 95 has been implicated as a developmental neurotoxicant. Although studies in adult female mice show a dose-dependent enantiomeric enrichment of PCB 95 and its hydroxylated metabolites (OH-PCBs), the effect of pregnancy on the enantioselective disposition of PCB 95 in laboratory animals has not been investigated. This is an important question since pregnancy-related changes in cytochrome P450 and enantioselective transfer of PCBs and OH-PCBs to the fetus and neonate could potentially modulate enantiomeric enrichment of PCB 95 and its metabolites. This study investigates dose-dependent differences in the enantioselective disposition of PCB 95 and OH-PCBs in female C57Bl/6 mice (8 weeks old) fed daily with racemic PCB95 (0.1, 1 or 6 mg/kg) or vehicle (peanut oil) in peanut butter, starting two weeks before mating and continuing throughout gestation and lactation. The levels and enantiomeric enrichment of PCB 95 and OH-PCBs were determined in adipose, blood, brain and liver. There was an increase in PCB 95 and OH-PCB levels with increasing dose in all tissues. Adipose had the highest level of the parent compound; blood had higher OH-PCBs levels than liver, and no metabolites were detected in brain or adipose. PCB 95 displayed clear enantiomeric enrichment in all tissues, with enantiomeric fractions (EF) ranging from 0.26 ± 0.01 (adipose) to 0.11 ± 0.02 (liver). These EF values are comparable to observed previously in PCB 95-treated adult mice. Our findings suggest that pregnancy-related changes in P450 enzyme levels and transfer to the offspring do not significantly change the enantiomeric enrichment of PCB 95 in adult female mice. Future studies are needed to better understand the toxicological implications of the enantiomeric enrichment of PCB 95 and its metabolites in mice and, ultimately, PCB exposed humans. [Supported by NIH grants, ES014901, ES017425 and ES007059]

2206 Decreased Hepatocyte Nuclear Factor 4alpha Activity As A Mechanism of Hepatomegaly Induced by PFOA and PFOS

S. McGreal1, A. McCarthy3, C. Walsey1, M. Manley1, C. S. Lau1, B. Hagenbuch1 and U. Apte1.
1Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS and 2National Health and Environmental Effects Research Laboratory, U.S. Environmental Protection Agency, Research Triangle Park, NC.

Perfluorooctanoate (PFOA) and Perfluoroctanesulfonate (PFOS) are synthetic perfluorinated carboxylic acids and are persistent organic pollutants with significant reproductive, hormonal and hepatic effects. PFOA and PFOS induce hepatomegaly in rodents, mechanisms of which are not completely clear. Recent in vitro studies indicate that PFOA and PFOS can bind and inhibit HNF4α activity in hepatic cell lines. Previous studies in our laboratory have shown that inhibition of HNF4α results in hepatomegaly. Based on these data, we investigated whether loss of HNF4α function is involved in hepatomegaly induced by PFOA and PFOS. Male CD1 mice treated with PFOA (3 mg/kg) and PFOS (10 mg/kg) once a day for seven days by oral gavage exhibited significant increase in liver to body weight ratio along with increased PCNA positive cells in the liver. PFOA and PFOS treatment decreased in HNF4α protein levels in the liver without affecting its mRNA levels. Western blot analysis showed increase in Cycillin D1 protein levels upon PFOA and PFOS treatment. Further, Real Time PCR analysis of several known and novel HNF4α target genes revealed that PFOA and PFOS exposure resulted in a significant increase in the expression of pro-mitogenic genes normally down regulated by HNF4α including cdkn3, egfr1, cyp2c37, ccdn1, akt1, bcl7a, myc, and uqcrbl1. Consistent with these observations, human hepatocyte treated for 48 hours with 100 μM PFOS showed an increase in mRNA of Cdon1, Ognin1, Cdkn3, Cds3, genes that are negative targets of HNF4α and a decrease in Apoa2, Fpol1, E2 genes which are positive targets of HNF4α. Taken together, these data indicate that PFOA and PFOS-induced decrease HNF4α protein and activity, may be involved in hepatomegaly induced by these chemicals.

2207 Low-Dose Perfluorooctanesulfonic Acid (PFOS) Induces Hepatic Lipid Accumulation and Dampens Caloric Restriction-Induced Lipid Loss in Mice

D. Saltiel, J. Xu, W. Wei, I. Armstrong and A. L. Slitt. Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.

A combination of caloric restriction (CR), dietary modification, and exercise is the recommended therapy to reverse nonalcoholic fatty liver disease. The ability to mount an effective response to caloric restriction required to effectively shift hepatic metabolism to fatty acid oxidation depends upon induction of Sirtuins, AMP-activated kinase, and Peroxisome proliferator-activated receptor-γ coactivator 1α (PGC-1α). PFOS, a fluorosurfactant previously used as a stain repellent and anti-stick material, is persistent in the environment and considered an “emerging contaminant” by the EPA. PFOS (1-10 mg PFOS/kg/day) induced hepatic lipid accumulation associated with altered lipid metabolism gene and protein expression in mice. We hypothesized that PFOS interferes with the beneficial effects of CR on hepatic lipid utilization and glucose homeostasis. Adult male C57BL/6 mice were fed ad libitum or 25% reduced calorie diet concomitant with 100 μg PFOS/kg/day for 6 weeks. PFOS significantly increased percent body weight after 4 weeks of administration, but did not significantly alter CR-induced percent weight loss over 6 weeks. Further studies indicated that PFOS (50 nm, 1, 5, 10, and 50 μM) increased adipogenesis in 3T3-L1 cells through induction CEBPs and PPARγ. PFOS also increased hepatic triglyceride accumulation and lipid loss after CR was lower in PFOS treated mice but not associated with significant changes in lipoprotein gene expression. We also evaluated PFOS effects on glucose tolerance and found that it interfered with CR-induced improvement of glucose tolerance. This was further associated with suppression of hepatic Glut-2 and IRS-1 mRNA expression and PFOS stimulation of glucose production in isolated hepatocytes. Overall, a relatively low sub-chronic administration of PFOS had disruptive effects for lipid and glucose homeostasis under ad libitum and CR conditions.

2208 Bile Salt Transporters Are Involved in the Disposition of Perfluoroalkyl Sulphonates in Rats and Humans

W. Zhao1, L. Ziatou1, D. L. Ehresman2, S. Chang1, J. B. Butenhoff2, W. Wei, L. Armstrong and A. L. Slitt.
1Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI and 2Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.

Perfluoroalkyl sulphonates (PFSAs) are persistent environmental contaminants present in human serum. Pharmacokinetic studies in animal models suggest that the long half-lives of certain PFSAs such as perfluorohexanesulfonate (PFHxS) and
perfluorooctanesulfonate (PFOS) are in part, due to strong hepatic accumulation and slow renal elimination. Studies in rats have indicated that PFOS undergoes enterohepatic circulation and in humans, cholestyramine treatment appeared to enhance its fecal excretion. Given that the sodium dependent bile acid uptake transporters such as sodium-dependent bile acid transporter (ASBT) mainly expressed at the apical membrane of enterocytes and the bile salt efflux pump (BSEP) expressed at the apical membrane of hepatocytes are essential for the enterohepatic circulation of bile acids, we tested whether PFSAs are substrates of these transporters in rats and humans. We used CHO Flp-In cells stably expressing human NTCP and HEK293 cells transiently expressing rat NTCP, as well as rat and human ASBT to measure the uptake of perfluorobutanesulfonate (PFBS), PFHxS, and PFOS in the presence or absence of sodium. In addition, SP vesicles expressing human BSEP were used to test whether PFBS, PFHxS or PFOS would inhibit taurocholate transport by human BSEP. The results demonstrate that both rat and human NTCP can transport PFBS, PFHxS and PFOS. However, human ASBT only transports PFOS while rat ASBT transports none of the PFSAs. Transport of taurocholate by human BSEP was inhibited by both PFHxS and PFOS. We further characterized transport by performing time and concentration dependent uptake studies. In conclusion, these results suggest that the long half-life and the hepatic accumulation of PFOS in humans are, at least in part, due to transport by NTCP, ASBT and BSEP.

**2209 Evaluation of 6-Week Dietary Exposure to 100 ppm Perfluorooctane Sulfonate (PFOS) and Normal Choline or High Choline in Sprague-Dawley Rats**

B. D. Bagley, S. Chang, D. J. Fluresman and J. L. Burenhuff. 3M Company, St. Paul, MN.

Perfluorooctane sulfonate (PFOS) is a bioaccumulative and environmentally persistent chemical that has been detected in the serum of occupationally exposed workers as well as the general population. In toxicology studies, PFOS administration (at doses several orders of magnitude greater than the general population exposure) has produced hepatocellular hypertrophy, hepatocellular vacuolation, increased liver triglycerides, and decreased serum cholesterol. Many of these observations are similar to those reported in choline deficient animal models used to investigate non-alcoholic hepatic steatosis. Choline is a nutrient used as the essential phospholipid building block and as a precursor of phosphorylcholine. PFOS creates an ion complex with choline in solution and in ex vivo liver which may constitute a choline sink leading to a choline deficient phenotype. The central hypothesis is that at high doses PFOS makes an ion complex with choline in the liver and produces a choline deficient phenotype in the treated animals which may be exacerbated by increased lipid β-oxidation. To investigate this hypothesis, Sprague Dawley rats (6/sex/group) received diets containing normal choline, high choline, 100 ppm PFOS with normal choline or 100 ppm PFOS with high choline for 6 weeks. The total consumed PFOS dose achieved approximately 200 mg/kg which approximates the acute oral LD50 in rats (i.e., 251 mg/kg). As such, moribund animals, i.e. those to light and touch were noted in PFOS-exposed animals. Hepatocellular vacuolation and microscopic evidence of peroxisome proliferation were noted in PFOS-exposed animals. The hepatic vacuoles were a result of lipid accumulation based on Oil Red O staining. Choline supplementation showed a trend towards decreased hepatic lipid concentration in PFOS-treated male rats. Additional studies are needed to further investigate this potential relationship between PFOS and choline.

**2210 Perfluoroalkyl Acids in River and Sea Water of Japan**

N. Saito1, N. Shimizu 2 and S. Tsuda 1. Institute of zoology, University of Tsukuba, Japan.

Environmental waters such as river water (RW) and sea water (SW) are expected to be the major exposure sources of Perfluoroalkyl acids (PFAA) to humans via tap water and food fish. At the 2013 Annual Meeting of SOT, we reported that perfluorooctanoic acid (PFOA); a chemical that has an environmental presence with uncertain human health effects. We evaluated the mortality experience of employees of an APFO manufacturing plant. Methods: This cohort mortality study followed 9,027 employees including 4,668 from a site that produced PFOS from 1947-2000 and 4,359 from a non-APFO facility in the same geographic area. Yearly APFO exposure was estimated using a job and task-based APFO exposure matrix developed from industrial hygiene monitoring data, expert judgment, and production information. APFO production workers were categorized into quartiles of cumulative exposure with those from a non-APFO plant as a non-exposed reference population. Standardized mortality ratios (SMR) and 95 percent confidence intervals (95% CI) were estimated using state reference mortality data from 1960-2008. Standardized rate ratios (SRR) and 95% CI were estimated for the exposed population and each APFO exposure quartile in comparison to the non-exposed worker population. Study was approved by Univ of MN IRB. Results: We observed 2,954 deaths (SMR = 0.93 (95% CI=0.89-0.96)). Cancers of a priori interest (Obs total, Obs expected, SRR (95% CI)) included liver (15, 8, (1.5 (0.5-4.2)), pancreatic (48, 18, [0.8 (0.4-1.5)), kidney (24, 6, [0.4 (0.1-0.9)), bladder (16, 8, [1.3 (0.5-3.6)), and prostate (72, 23 [10.6 (4.1-10.0))]. There was little evidence of an exposure response association comparing exposure quartiles to the referent population. The SRR for prostate cancer in the highest exposure category was elevated, but imprecise (obs 6, SRR=2.2 (95% CI=0.6-7.7)). The SRR for heart disease was 0.81 (95% CI=0.70-0.94), with a SRR of 1.2 (95% CI=0.6-2.2) in the highest exposure category. Conclusion: In this study, occupational exposure to APFO was not associated with a greater risk of death from all causes or specific causes of death.

**2211 Mortality Experience of APFO Production Workers**

Background: The ammonium salt of perfluorooctanoic acid (APFO) is used in fluoropolymer production. APFO dissociates in biologic media to perfluorooctanoate (PFOA); a chemical that has an environmental presence with uncertain human health effects. We evaluated the mortality experience of employees of an APFO manufacturing plant. Methods: This cohort mortality study followed 9,027 employees including 4,668 from a site that produced PFOS from 1947-2000 and 4,359 from a non-APFO facility in the same geographic area. Yearly APFO exposure was estimated using a job and task-based APFO exposure matrix developed from industrial hygiene monitoring data, expert judgment, and production information. APFO production workers were categorized into quartiles of cumulative exposure with those from a non-APFO plant as a non-exposed reference population. Standardized mortality ratios (SMR) and 95 percent confidence intervals (95% CI) were estimated using state reference mortality data from 1960-2008. Standardized rate ratios (SRR) and 95% CI were estimated for the exposed population and each APFO exposure quartile in comparison to the non-exposed worker population. Study was approved by Univ of MN IRB. Results: We observed 2,954 deaths (SMR = 0.93 (95% CI=0.89-0.96)). Cancers of a priori interest (Obs total, Obs expected, SRR (95% CI)) included liver (15, 8, (1.5 (0.5-4.2)), pancreatic (48, 18, [0.8 (0.4-1.5)), kidney (24, 6, [0.4 (0.1-0.9)), bladder (16, 8, [1.3 (0.5-3.6)), and prostate (72, 23 [10.6 (4.1-10.0))]. There was little evidence of an exposure response association comparing exposure quartiles to the referent population. The SRR for prostate cancer in the highest exposure category was elevated, but imprecise (obs 6, SRR=2.2 (95% CI=0.6-7.7)). The SRR for heart disease was 0.81 (95% CI=0.70-0.94), with a SRR of 1.2 (95% CI=0.6-2.2) in the highest exposure category. Conclusion: In this study, occupational exposure to APFO was not associated with a greater risk of death from all causes or specific causes of death.

**2212 iTRAQ Protein Profile Analysis of Mouse Tissues after Perfluorooctanoate (PFOA) Exposure**

H. Zhang 1, L. Yin 1, L. Bie 1, Y. Shengmin 1 and J. Dai 1. Institute of zoology, Beijing, China and Arab University, Heife, China.

Perfluorooctanoic acid (PFOA) is a stable man-made compound with many industrial and commercial uses. Concern has been raised that it may induce hepatotoxicity, immunotoxicity, developmental effects and some other toxicological effects. However, the testicular toxicity of PFOA and its underlying mechanism is not well known. In this study, male mice were exposed to 0.08, 0.31, 1.25, 5 and 20 mg/kg/day of PFOA for 28 days. Absolute testis weight was diminished at the highest dose, as well as testosterone and progesterone levels in serum and testis were all increased in a dose range of 1.25,5 and 20 mg/kg/day. In addition, the seminiferous tubules were damaged in a different degree after PFOA exposure. After iTRAQ labeling combined with two-dimensional liquid chromatography and tandem mass spectrometry (2DLC–MS/MS) analysis, 93 differentially expressed proteins between the control and the 5 mg/kg/d PFOA treated mice were successfully identified. These proteins were mainly involved in cell proliferation, lipid metabolism, steroid metabolism and spermatogenesis, nucleic acid metabolism, stress response and apoptosis, and others. In addition, serum and testis cholesterol were all reduced after PFOA exposure, and the mRNA and protein expressed levels of genes involving in cholesterol transport and testosterone synthesis were all inhibited by PFOA. Thus, we speculated that the decrease of serum cholesterol might play an important role in testicular toxicity of PFOA.
2213 Effects of Perfluorooctanoate (PFOA) and Perfluorooctanesulfonate (PFOS) on Cholesterol Efflux in Macrophage-Derived Foam Cells

J. Vanden Heuvel1,2, J. A. Garhan and J. T. Thompson1. 1Veterinary and Biomedical Sciences, Penn State University, University Park, PA and 2Indigo Biosciences, Inc., State College, PA.

Cholesterol metabolism and efflux from peripheral cells, such as macrophages and foam cells, is a critical part of reverse cholesterol transport (RCT), a metabolic process that has implications for atherosclerosis and cardiovascular diseases. There have been several conflicting studies that suggest environmental and occupational exposure to Perfluorooctanoate (PFOA) and Perfluorooctanesulfonate (PFOS) affects RCT and cholesterol metabolism. However, the data from animal studies and from examination of potential mechanisms of action raise questions as to whether there is a direct causality of PFOA and PFOS exposure and hypercholesterolemia. In these studies, we have directly examined the effects of PFOA and PFOS on cholesterol efflux and in genes involved in this process. PFOA and PFOS are agonists for nuclear receptors that increase cholesterol efflux, such as the peroxisome proliferator-activated receptors (PPARs). Importantly, in THP-1 differentiated into macrophage-derived foam cells, PFOA and PFOS increased cholesterol efflux to either HDL or apoA. Comprehensive gene expression analysis by microarray is being pursued to determine the key genes being regulated by these perfluorinated compounds in foam cells that impact RCT. These studies will also assist in the identification of genes that are sensitive to PFOA and PFOS exposure that can be utilized in biomonitoring studies. Taken together, these studies suggest that PFOA and PFOS exposure affects cholesterol efflux, but not in a manner consistent with a negative health impact.

2213a Tetramethylbisphenol A versus Bisphenol A: Excitation-Contraction Coupling Impairment through Divergent Mechanisms

R. Zhang and J. N. Pesalaj. Department of Molecular Biosciences, School of Veterinary Medicine, University of California, Davis, Davis, CA.

Bisphenol A (BPA) and its brominated derivative tetramethylbisphenol A (TBBPA) are high production volume chemicals utilized in the manufacture of various consumer products. While these chemicals share the same chemical backbone, the halogenation on TBBPA may produce activity on a distinct set of molecular targets versus BPA. The targets we investigated are those involved with skeletal muscle excitation-contraction (EC) coupling and relaxation, namely 1) the dihydropyridine receptor (DHPR), 2) the type 1 ryanodine receptor (RyR1), and 3) the sarcoplasmic/endoplasmic reticulum Ca2+ ATPase (SERCA). TBBPA indeed had concentration-dependent interactions with these targets: 1) it inhibited specific [3H]ryanodine binding to RyR1, achieving >1500% of vehicle control at 30 μM, and induced rapid efflux of Ca2+ from actively loaded microsomes; 3) it inhibited the biochemical activity of SERCA with an IC50 of ~13.3 μM. TBBPA did not modify baseline Ca2+ levels, and induced rapid efflux of Ca2+ from actively loaded microsomes; 2) it elicited an increase in specific [3H]ryanodine binding to RyR1, achieving >1500% of vehicle control at 30 μM, and induced rapid efflux of Ca2+ from actively loaded microsomes; and 3) it inhibited the biochemical activity of SERCA with an IC50 of ~13.3 μM. In contrast, BPA had no influence on specific [3H]PN200 binding, SERCA activity, and Ca2+ efflux. However, surprisingly, both TBBPA and BPA impaired EC coupling in primary skeletal myotubes. In field stimulated myotubes loaded with the Ca2+ indicator fluo-4, 10 μM TBBPA rapidly diminished evoked Ca2+ transient amplitudes, achieving complete transient abrogation within 15 min of exposure, and increased baseline intracellular Ca2+ levels. BPA did not modify baseline Ca2+ levels, and while BPA did diminish Ca2+ transient amplitudes, complete abrogation was not achieved. These results indicate that while TBBPA is able to potently modify Ca2+ dynamics in myotubes via interactions with DHPR, RyR1 and SERCA (which are indeed detrimental to muscular function), such interactions are not necessary for impairing skeletal EC coupling. The mechanism(s) by which BPA impairs skeletal EC coupling warrant further investigation. Sponsored by NIH P42 ES06099, P01 11269, U.S. EPA R833292, R829388, T32 HL 86350, and T32 ES 7099.

2213b An Evaluation of Gestational Exposure to Perfluorooctanoic Acid (PFOA): Effects on Body Composition and Physiological Factors

Exposure to environmental pollutants can be a factor for induction of metabolic disorders. This study examined if exposure to PFOA during development could alter body composition and other physiological outcomes. Study 1: Pregnant CD-1 mice were gavaged with BPA at 0, 0.001, 0.01, 0.1, or 0.3 μg/kg body weight (bw) from gestation day (GD) 1 – 17. At weaning, pups were fed a high fat (HFD) or control (CD) diet. Body composition, blood pressure (bp), and gene expression in tissues of offspring were examined. Male- BW increased in 0 mg PFOA+HFD vs 0 mg PFOA+CD and 0.01 mg PFOA+HFD vs 0.01 mg PFOA+CD. In HFD, bw decreased in 0.3 vs 0 mg PFOA. There were no effects on percent of body fat. At postnatal day (PND) 90, diastolic bp was decreased in 0.1 and 0.3 mg PFOA+HFD vs 0 mg PFOA+HFD and increased in 0.3 mg PFOA+HFD vs 0.3 mg PFOA+CD. The bp effects of 0.1 mg PFOA+HFD persisted to PND 180. Female- At 0 and 0.001 mg PFOA+HFD had increased weight gain vs CD. The %fat increased in 0.001 vs 0 mg PFOA+HFD. At PND 180, diastolic bp decreased in 0.01 and 0.3 mg PFOA+CD vs 0 mg PFOA+CD. Differential gene regulation was produced by HFD and PFOA in white fat and liver at 52 weeks of age. At 0.01 mg PFOA+HFD vs 0.01 mg PFOA+CD, 3 genes in white fat and liver were under-expressed while 14 genes in white fat and 19 in liver were over-expressed. At 0.01 mg PFOA+HFD vs 0.01 mg PFOA+CD, 3 genes in white fat and 4 genes in liver were under-expressed while 14 genes in white fat and 15 in liver were over-expressed. Study 2: Pregnant mice were fed NIH-31 (low phytoestrogen) diet and dosed with PFOA at 0.01, 0.1, or 1 mg/kg from GD 1 – 17. Pups remained on the NIH-31 diet. There were no age- or dose-related differences in bw or %body fat in either sex. In summary, exposure to PFOA and HFD produced sex-dependent changes in bw, body composition, and bp response in mouse offspring exposed to the chemical during perinatal development. This abstract does not necessarily reflect USEPA policy.

2214 Cardiovascular Effects of Lead, Inorganic Mercury, and Methylmercury: Potential Risk to Humans

T. Wildemann1,2, S. D. Siciliano3 and L. P. Weber1,3. 1Toxicology Graduate Program, University of Saskatchewan, Saskatoon, SK, Canada, 2Soil Science, University of Saskatchewan, Saskatoon, SK, Canada, 3Veterinary Biomedical Sciences, University of Saskatchewan, Saskatoon, SK, Canada.

Humans are exposed to lead, inorganic Hg and methylmercury in the environment. The European Food Safety Authority (EFSA) estimated average human exposures of 0.68 μg Pb/kg-bw/d, 0.08 μg Hg(II)/kg-bw/d and 0.039 μg MeHg/kg-bw/d. Epidemiological studies show an association between exposure to Pb or Hg and hypertension. The study objective was to explore cardiovascular effects of sub-chronic Pb or Hg exposure in rats to determine NOAELs for human health risk assessments. Male rats (n=3-6) were exposed for 4 weeks to lead acetate (Pb: 4 – 45000 μg/kg-bw/d), mercuric chloride (Hg(II): 7 – 4000 μg/kg-bw/d) or mono-methylmercury chloride (MeHg; 4 – 1607 μg/kg-bw/d) in the drinking water. Echocardiography, carotid artery ultrasound and intra-arterial blood pressure were performed after 4 weeks.

Dose-response curves for most cardiovascular effects were U-shaped. Blood pressure was significantly increased for Pb ≥ 2000 μg/kg-bw/d (Δ20 mmHg systolic) as well as for MeHg ≥ 7 μg/kg-bw/d (Δ40 mmHg systolic and diastolic), while Hg(II) had no effect on blood pressure. MeHg ≥ 7 μg/kg-bw/d also increased pulse pressure and heart rate, while Pb and inHg had no effect. Pb ≤ 57 μg/kg-bw/d decreased blood pressure and increased carotid diameter (vasodilation) with compensatory increase in stroke volume. In contrast, Hg(II) ≤ 29 μg/kg-bw/d reduced carotid diameter (vasoconstriction) with compensatory decrease in stroke volume, while MeHg showed no effect.

Cardiovascular responses to Pb, Hg(II) and MeHg were U-shaped, but both Pb and MeHg increased blood pressure at higher doses. Based on the increased blood pressure response, NOAELs (safety factor of 100) for humans were estimated as 0.57 μg Pb/kg-bw/d, 0.29 μg Hg(II)/kg-bw/d and 0.04 μg MeHg/kg-bw/d. Thus, risk of cardiovascular disease might be increased by Pb in the general European population and by MeHg for high fish consumers.

2215 Stainless Steel Leaches Nickel and Chromium into Foods during Cooking

K. A. Hobbie, K. L. Kamerud and K. Anderson. Department of Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR. Sponsor: G. Sower.

Toxicological studies show that oral doses of nickel and chromium can cause cutaneous adverse reactions such as dermatitis. Additional dietary sources, such as leaching from stainless steel cookware during food preparation, are not well characterized. This study examined stainless steel grades, cooking time, repetitive cooking cycles, and multiple types of tomato sauces for their effects on nickel and chromium leaching. While a dose of only 67 μg of nickel was associated with cutaneous reactions in 40 percent of nickel sensitive participants, we found depending on cooking conditions 88 to 1,000 μg Ni per serving of tomato sauce cooking in stainless steel. Like nickel, we found chromium leached from stainless steel into tomato sauce, from 86 to 900 μg Cr in a single serving of tomato sauce. All tomato sauce samples that were cooked in the presence of stainless steel using typical cooking conditions.
procedures showed significantly elevated Ni and Cr concentrations. In addition to other natural dietary sources, stainless steel cookware can significantly contribute to overall nickel and chromium consumption.

2216  Oxidative Stress and Heavy Metal Toxicity in Work Place Exposure to Heavy Metals in Nigeria

O. M. Akinosun and O. S. Adeleye. *Chemical Pathology, University of Ibadan, Nigeria; Ibadan, Oyo, Nigeria.*

Heavy metals contamination of the environment is of major concern because of their toxicity and threat to human life and the environment. Studies have shown that the air in the work environment usually contains a number of chemicals, which when inhaled and absorbed by the body, pose a potential risk for workers’ health. Though, most metals are essential for proper functioning of the human biological system, humans are not adapted to dealing with them at concentrations higher than the reference values.

Presence of elevated concentrations of heavy metals can result in induction of oxidative stress via production of reactive oxygen species or reduction of antioxidant defenses, disruption of calcium homeostasis, induction of DNA damage, interaction with sulphydryl groups, disturbances in the heme biosynthetic pathway, and some are known human carcinogens.

Accumulating evidence also indicates that workplace exposure leading to generation of free radicals, accompanied by inadequate antioxidants in the body leading to oxidative stress on the increase. This study assesses workplace exposure to heavy metals in thirty-seven metal workers and thirty-six age and sex matched office workers serving as controls. Ten (10) ml of venous blood was collected from each subject into lithium-heparin bottle and this was used to determine Total Plasma Peroxides (TPP) by the FOX2 method while Cadmium (Cd), lead (Pb), zinc (Zn), Manganese (Mn), Ferritin were determined by atomic absorption spectrophotometer. There was significant increase p<0.05 in Lead (0.0159 ± 0.0029 µg/L and Mn (31.92 ± 7.79 µg/dl in the exposed group than the controls and significant positive correlation between TPP and Pb. Significant decrease p<0.05 in Ferritin (56.38 ± 8.22 µg/L in the exposed was also observed. Occupationally exposed workers are prone to heavy metal toxicity with increased free radical generation which may lead to increased chronic disease manifestations and even cancers. Increase intake of antioxidant supplements may be beneficial as well as using safety/protection apparels.

2217  Gene Expression Profiling in Saudi Individuals Exposed to Environmental Heavy Metals

J. M. Attaie1, S. A. Al Bukkeh1, K. S. Famulski1 and H. M. Korashy2. 1Poison Control Center, Jazan Health Affairs, Jazan, Saudi Arabia; 2Albertha Transplant Applied Genomics Center, University of Alberta, Edmonton, AB, Canada and 3Pharmacology and Toxicology, King Saud University, Riyadh, Saudi Arabia.

The aim of this study was to evaluate the effects of long-term exposure to environmental heavy metals on the gene expression profile of individuals live near to mining areas at Mahd Ad-Dahab region, Saudi Arabia. For this purpose, microarray analysis was conducted in an attempt to evaluate the alteration of gene expression profile of gene-regulated diseases and to identify potential biomarkers that may be involved in the response to heavy metals toxicity. Sixty healthy volunteers were divided to two groups; exposed group consisted of 40 male residents in the heavy metal-polluted area, whereas the control group consisted of 20 male residents in a non-polluted area (Riyadh). Our results showed that the plasma levels of Pb, Cd, and Hg were found to be significantly high in the heavy metal-exposed group. Total RNA was isolated from whole blood using PAXgene Blood RNA tubes and reversed transcribed and hybridized to the gene array using the Affymetrix U219 GeneChip. Microarray analysis identified 425 genes that are differentially expressed in heavy metal-exposed groups. The alteration of many genes of interest revealed by microarray analysis suggests that these genes play a role in heavy metal-induced toxicity. Some of these genes were confirmed by RT-PCR analysis. The commonly significant differentially expressed genes in the heavy metal-exposed groups were analyzed for network, functional, canonical pathways, and upstream regulators using the Ingenuity Pathway Analysis (IPA) software. Renal and urological diseases, developmental disorders, and hematological diseases were the most significant diseases that are associated with heavy metal-exposed groups. The following genes participate in renal disease induction (such as SNRPG, UQCRB and AIF1) could be used as early biomarkers for renal toxicity. IPA also indicated that MYC might be a sensitizer, corrosive or irritant.

2218 Are Metals in Rolling Tobacco Less Risky Than Cigarettes?

M. C. Rubio-Armendáriz1, C. Silva2, D. González-Weller1, Á. J. Gutiérrez1, G. Luis-González1, A. Hardisson2 and A. Anadón3. 1Toxicología, Universidad de La Laguna, La Laguna, S/C de Tenerife, Islas Canarias, Spain and 2Toxicología y Farmacología, Universidad Complutense, Madrid, Madrid, Spain; Sponsors: A. Anadón.

Smoking is a major public health problem and an important source of exposure to toxic elements, including metals. The presence of metals in tobacco depends mainly on where the tobacco was grown and the production process.

Objectives: a) to quantify the concentrations of metals (Al, B, Ba, Ca, Cd, Co, Cr, Cu, Fe, K, Li, Mg, Mn, Mo, Na, Ni, Pb, Si, V, Zn) in 23 brands of rolling tobacco and to compare them with the concentrations previously found in cigarettes, b) to compare metals levels across different brands and producers, and with/without additives.

Materials and Methods: 34 samples from 23 different brands of rolling tobacco sold on the island of Tenerife (Spain) were analyzed by Inductively Coupled Plasma-Optical Emission Spectrometry (ICP-OES).

Results: Mean concentrations of metals in rolling tobacco were (mg/kg): Al (207.97); B (9.20); Ba (31.91); Ca (9189.74); Co (0.23); Cr (0.62); Cu (8.65); Fe (167.23); K (9767.13); Li (14.66); Mg (2257.74); Mn (56.29); Mo (0.09); Na (458.99); Ni (0.75); Si (644.28); V (0.29); Zn (17.45). Mean levels in rolling tobacco with/without additives were (mg/kg): Al (223.3/181.7); B (8.499/7.735); Ba (28.97/21.50); Ca (829/817873); Co (0.196/0.182); Cr (0.793/0.259); Cu (8.619/9.524); Fe (164.5/141.8); K (7567/10260); Li (19.05/13.69); Mg (1945/2449); Mn (42.54/53.71); Mo (0.075/0.171); Na (497.3/497.1); Ni (0.776/0.638); Si (649.7/629.5); V (0.358/0.434); Zn (12.92/20.12). Average Cd levels (mg/kg) were 0.396 (range 0.129–0.035); levels with/without additives were 0.2080/0.484. Average Pb levels (mg/kg) were 0.327 (range 0.131–0.759); levels with/without additives were 0.3390/0.326.

Conclusions: The levels of Al, Cr, Co, Mn, Ni, Pb and Cd in rolling tobacco are roughly half of those previously detected in tobacco cigarettes (mg/Kg; Al (428); Pb (0.56); Cr (1.442); Mn (112.026); Ni (2.238); Cd (0.810); and Pb (0.602).

The objective of this study is to identify the metals that are not well known in the production of rolling tobacco does not affect the level of metals significantly.

2219 Evaluation of Electric Arc Furnace-Processed Steel Slag for Dermal Corrosion, Irritation, and Sensitization

M. Sahu1, J. J. Yzenas2 and D. Proctor1. 1ToxStrategy, Mission Viejo, CA and 2Edw. C. Levy Company, Valparaiso, IN.

Electric arc furnace (EAF) steel slag is alkaline (pH of ~11-12) and contains metals that are known dermal sensitizers, most notably chromium and nickel. As such, EAF slag has potential to cause dermal irritation and sensitization at sufficient dose, but no published study has characterized the potential for dermal effects associated with EAF slag. To assess dermal irritation, corrosion, and sensitizing potential of EAF slag, in vitro and in vivo dermal toxicity assays were conducted following Organisation for Economic Co-operation and Development (OECD) guidelines. In vitro dermal corrosion and irritation testing (OECD 431 and 439) of EAF slag was conducted using human epidermal model. In vivo dermal toxicity and delayed contact sensitization testing (OECD 404 and 406) were conducted in rabbits and guinea pigs. Chemical properties of EAF slag were also characterized. Calcium, iron, silicon and magnesium oxides were the major constituents of EAF slag, each contributing more than 10% of the slag composition. Other elements measured in the EAF slag at higher concentrations were manganese, aluminum and chromium, but nickel was measured at relatively low concentrations. Barium and chromium were the only constituents detected in the TCLP extraction leachate, and they were measured concentrations of 0.798 and 0.250 mg/l, respectively. EAF slag was not corrosive and not irritating in any in vitro and in vivo dermal toxicity tests. The results of the delayed contact dermal sensitization test indicate that EAF slag is not a dermal sensitizer. These findings are supported by the observation that metals in EAF slag occur as oxides of low solubility with leachates that are well below TCLP limits. Metals in slag are tightly fused to the physical matrix limiting the mobility of metal constituents that may be of concern for dermal effects. Based on these results and in accordance to the OECD guidelines, EAF slag is not considered a dermal sensitizer, corrosive or irritant.
Butte, Montana, a town of approximately 35,000 residents, is a part of the largest superfund site in the United States. One of the unique aspects of Butte’s history is that surface mining and smelting activities occurred, and continue today, in close proximity to Butte’s historically dense urban population. This has resulted in homes and neighborhoods in Butte with high concentrations of a variety of toxic metals (and metalloids) including arsenic, lead, copper, zinc, mercury and cadmium. Therefore it is likely that people living near areas of active mining, or the numerous areas of uncovered smelter wastes, may have been chronically exposed through air, water or soil to this suite of potential toxins. In this study, volunteers were recruited based upon mapping and demographic data to determine if potential chronic exposure to these metal mixtures could lead to changes in miRNA expression patterns. Human hair and nasal cell samples were collected from individuals of various ages, living within close proximity to current surface mining as well as near historic mine tailings (n=16). Control samples were collected from individuals living in Bozeman, MT (n=8) a town without historical or current mining practices. Elemental analysis was performed on the hair samples by ICP-MS and several metals were found to be elevated in the Butte population, including copper and molybdenum. Preliminary miRNA data show a number of up-regulated micro RNAs that are putative oncomirs (mir-93-5p, mir-106b-5p). There is also a down-regulation in the Butte population of miRNAs known to participate in regulation of inflammatory responses (mir-146b-5p and mir-146a-5p). These preliminary data illustrate the need for additional study and data collection of samples from individuals living downwind of an active open-pit copper mine.

**2221 Initial Characterization of Metal Exposures in Community Residents Living Adjacent to the Black Leaf Pesticide Manufacturing Complex**

I. Kirsch1, M. Mohammad1, K. C. Falkner1, G. E. Arredondo1, R. Barnett1, J. C. States2, R. A. Prough3 and M. Cave1, 4. 1Pharmacology & Toxicology, University of Louisville, Louisville, KY, 2Biochemistry, University of Louisville, Louisville, KY and 3Pharmacy, University of Louisville, Louisville, KY, and 4Robley Rex VAMC, Louisville, KY.

Black Leaf is an abandoned industrial site in Louisville, KY with exceptionally high-level soil contamination by organochlorine pesticides (OCP) – exceeding the Residential Screening Level (RSL) by up to 18,000-fold. However, the site is also contaminated to a lesser degree with arsenic, lead, and polycyclic aromatic hydrocarbons. Black leaf is surrounded by the Park Hill Neighborhood, and in 2013 EPA began remediating residential yards with soil contamination. The aim of this study was to determine if adult Park Hill residents living adjacent to Black Leaf had elevated levels of arsenic and lead; and to determine if levels correlated with soil mapping and pro-inflammatory cytokine elevation. Blood lead and creatinine (Crea) nine-adjusted random urine arsenic levels were determined by inductively coupled Plasma/Mass (ICP/MS). Serum pro-inflammatory cytokines were measured by Luminex analysis. The mean age of voluntary participants (n=53) was 52±14.6 years with 18.6±19.4 years of residence near Black Leaf. Participants were predominately female (66.0%) and African American (79.2%). Two participants living adjacent to an on-site arsenic “hotspot” had very high urine arsenic levels (175 and 60 mcg/g creat). These residents also had marked elevation in serum IL-8 levels.<ref>2222 Influence of Light/Dark Condition on Bioaccumulation and Toxic Severity of Heavy Metals in Mice**

We recently reported that cadmium (Cd)-induced mortality was markedly different by injection timing meaning light/dark cycle affect the severity of Cd-induced toxicity. In this study, we report further evidences for the diurnal variation of toxicities induced by heavy metals such as chromium and nickel in mice. Male C57BL/6J mice adapted for 14 days with assigned to 6 groups of 5 animals were administrated intraperitoneally (i.p.) with potassium dichromate (50 mg/kg) or nickel sulfate (60 mg/kg) at different hours in the day (10:00, 14:00, 18:00, 22:00, 2:00 and 6:00 h), describing as zeitgeber time (ZT); ZT2, ZT6, ZT10, ZT14, ZT18 and ZT22. The mortality was observed until 14 days after the injection. As a result, mice were more sensitive to Ni during light phase (ZT6) while more resistant during dark phase as same as the result of Cd. In case of Cd, however, mice were more sensitive at late-night to mid-dark phase (ZT10 to ZT18). Therefore, 1) mice had clear diurnal variation to metal-induced toxicity, and 2) the daily fluctuation of metal sensitivity differed depending on metal compounds, probably depending on the valence of metal ion. We further investigated that Cd accumulation in the liver was significantly rose at light-phase exposure compared to dark-phase exposure. Our results clearly indicate that light/dark condition affects on severity of metal-induced toxicity and metal bioaccumulation.
Electronic cigarettes (EC) are novel nicotine delivery devices. Based on our earlier data, we hypothesized that new models of EC will vary in their performance characteristics and have heavy metals in their aerosol. We investigated this hypothesis using 10 brands of cartomizer EC and three approaches that included dissections, performance, and elemental analysis of EC aerosols. All 10 brands had the same basic design components, which consisted of wires, solder joints, air-tubes, a mouthpiece, fluid, and fibers. Four brands had been used prior to packaging, while six were in pristine condition. The flow rate required for aerosol production ranged from 4–21 mL/s. During “smoke out”, flow rate was constant for 5 brands, but had to be increased periodically to produce aerosol in 5 brands. Within the brands, pressure drop was relatively stable, but varied between brands (12-330 mm H2O). The elemental composition of EC aerosol and smoke from conventional cigarettes was compared using inductively coupled plasma optical emission spectroscopy. Of 62 elements screened, 21 were present in EC aerosols. Eight (Al, Ba, Na, Pb, Si, Sr, Zn) were, in general, less abundant in EC aerosol than in conventional cigarette smoke. In contrast 12 (Ag, Ca, Cr, Cu, Fe, Mg, Mn, Ni, Se, Sn, Ti, Zn) were more abundant as much silicon as the conventional brands and a different leading brand of EC had about 3.4 times as much tin in its aerosol than in smoke. One major selling brand had about 500 times as much tin in its aerosol than the conventional cigarette smoke.

Electronic cigarettes (EC) are novel nicotine delivery devices. Based on our earlier data, we hypothesized that new models of EC will vary in their performance characteristics and have heavy metals in their aerosol. We investigated this hypothesis using 10 brands of cartomizer EC and three approaches that included dissections, performance, and elemental analysis of EC aerosols. All 10 brands had the same basic design components, which consisted of wires, solder joints, air-tubes, a mouthpiece, fluid, and fibers. Four brands had been used prior to packaging, while six were in pristine condition. The flow rate required for aerosol production ranged from 4–21 mL/s. During “smoke out”, flow rate was constant for 5 brands, but had to be increased periodically to produce aerosol in 5 brands. Within the brands, pressure drop was relatively stable, but varied between brands (12-330 mm H2O). The elemental composition of EC aerosol and smoke from conventional cigarettes was compared using inductively coupled plasma optical emission spectroscopy. Of 62 elements screened, 21 were present in EC aerosols. Eight (Al, Ba, Na, Pb, Si, Sr, Zn) were, in general, less abundant in EC aerosol than in conventional cigarette smoke. In contrast 12 (Ag, Ca, Cr, Cu, Fe, Mg, Mn, Ni, Se, Sn, Ti, Zn) were more abundant as much silicon as the conventional brands and a different leading brand of EC had about 3.4 times as much tin in its aerosol than in smoke. One major selling brand had about 500 times as much tin in its aerosol than the conventional cigarette smoke.

In Vietnam, pollution caused by small-scale smelting of automobile batteries into lead ingot is a growing concern. The smelting craft village of Ngïa Lo, Vietnam, has attracted the attention of health and environmental experts due to its extremely high lead levels in water, soil, dust, and foods. Despite the threat of toxic metal exposure, biomonitoring among susceptible populations, such as children, has not been previously conducted. In this pilot study, twenty children from Ngïa Lo ages 18 months to four years were selected for capillary whole blood and toenail biomonitoring. Blood lead levels and toenail levels of arsenic, cadmium, chromium, lead, manganese, and mercury were measured. All 20 children had detectable levels of blood lead and every child had levels that exceeded the CDC guideline level of 5 μg/dL. Eighty percent of tested subjects had blood lead levels higher than 10 μg/dL. Five children (25%) had lead levels greater than 45 μg/dL, the level of recommended medical intervention. Average toenail lead, manganese, and mercury levels were 157, 7.41, and 2.63 μg/g, respectively, well above levels previously reported in children. Significant correlations were found between toenail metal levels including chromium and manganese and lead and cadmium (r>0.65, p<0.001). Linear regression showed that closer residential distance to a smelter was associated with increased blood lead levels (p<0.07). Results support the urgent need to control toxic metal exposure sources related to domestic smelting and seek treatment for children residing in these villages with the highest blood lead levels.

The heavy metal residues of Fe, Zn, Cu, Ni and Mn were assessed in three food crops, barley Hordeum Vulgar (grain crop); broad beans Vicia faba (legume) and rape seed Brassica napus (oil crop) irrigated with municipal wastewater. Results showed that Mn and Ni were significantly higher at all crops irrigated by municipal wastewater. However, the effect of municipal wastewater irrigation was insignificant on Zn and Cu residues when compared to groundwater irrigation. The residues of Fe and Mn in straw of all wastewater irrigated crops were significantly higher than in grain and seeds. However, there were no significant differences between the residues of the heavy metals Cu, Zn and Ni in all crops irrigated by municipal wastewater or groundwater. The study approved the need of proper regulations for disposal, recycling and application of municipal wastewater due to agricultural lands.
2230 Novel Oral Detoxification of Mercury, Cadmium, and Lead with Thiol-Modified Mesoporous Silica

T. Sanyanich1, D. Castro2,3, W. Njamcherthrakul4, J. Morry2, W. Yantasee1,2 and G. Fryxell1.1PDex Pharmaceuticals, Portland, OR, 2Biomedical Engineering, Oregon Health and Science University, Portland, OR and 3Pacific Northwest National Laboratory, Richland, WA.

Thiol modified mesoporous silica (SH-SAMMS) was developed as an oral drug for the prevention and treatment of heavy metal poisoning. SH-SAMMS was first evaluated for the removal of methyl mercury (MeHg(II)), inorganic mercury (Hg(III)), lead (Pb(II)), and cadmium (Cd(II)) in terms of binding capacity and rate in synthetic matrices mimicking conditions of gastric and intestinal fluids. SH-SAMMS was found to be superior to SAMMS with carboxylic and phosphonic acid based ligands as well as other commercially available chelating sorbents. Furthermore, SH-SAMMS could effectively remove soluble mercury from digested fish without significantly affecting the levels of most essential minerals found in fish. SH-SAMMS retained Hg(II) and MeHg(I) tightly inside the nano-size pores, preventing micron-size bacteria from converting the mercury species to more mobile forms. Rats fed with diet containing MeHg(I), Cd(II), and Pb(II) and SH-SAMMS for two weeks had blood Hg levels that were significantly lower than rats fed with the metal rich diet containing metals only. Upon cessation of the metal rich diet, continued administration of SH-SAMMS for two weeks facilitated the clearance of Hg faster and greater than those not fed with SH-SAMMS. Rats receiving SH-SAMMS were also protected from body weight loss associated with the metal poisoning. Retention of Hg and Cd in major organs was lowest in rats fed with SH SAMMS throughout the entire study of 4 weeks. For Pb, while its retention in most tissues of rats was negligible (with the exception of bone), the reduction of blood Pb by SH-SAMMS, but not more than that of rats receiving metal diets alone, was observed due to SH-SAMMS, but not more than that of rats receiving metal diets alone.

A child’s blood Pb assay is often the first realization that exposure to environmental Pb has occurred. A critical gap is an investigative protocol that preempts harmful childhood Pb exposure. Mapping soil Pb and blood Pb evokes a novel approach. New Orleans was split into high (≥100 mg/kg) and low (<100 mg/kg) soil Pb census tracts (CT). Four soil sample locations, busy streets, residential streets, house sides, and open spaces (away from streets and houses), represent each CT. Soil and blood Pb concentrations within the high and low Pb census tracts were analyzed by multi-response permutation procedures (MRPP) and p-Values were <0.05. Pre-Katrina children’s blood Pb ≥ 5 µg/dL in high and low Pb CTs decreased to 29.6% and 7.5%, respectively. In high Pb CTs, median soil Pb for busy streets, residential streets, house sides, and open space sample locations were 367, 313, 1228, and 103 mg/kg, respectively; in the low Pb CTs median soil Pb for busy streets, residential streets, house sides, and open spaces were 64, 46, 32, and 28 mg/kg, respectively. The best predictor of children’s blood Pb is residential street-side samples systematically collected throughout residential New Orleans. Soils in high Pb CTs lack a margin of safety. Low Pb CTs were safer by factors ranging from 3 to 38 depending on soil sample location. Patterns of lead from decades of Pb deposition were not worsened by post-Katrina renovations. Contrarily major improvements are materializing in selected communities. Low Pb soils are available at the city outskirts to remedy Pb contamination. All large cities probably present similar characteristics as New Orleans. Soil Pb maps are a diagnostic tool that assist with comprehending and promoting proactive childhood Pb exposure prevention at the community scale. Funding support by U.S. HUD (Grant # LALT0002-11) to Tulane University.

2231 Vulnerability of Frontal Cortex to Chronic Manganese Exposure in Welders

Z. Long1, 2, C. Yeh1, 2, X. Li3, S. Snyder1, E. Zauber4, Y. Jiang3 and U. Dydak1.

1School of Health Sciences, Purdue Univ., West Lafayette, IN, 2Dept. of Radiology and Imaging Sciences, Indiana Univ. School of Medicine, West Lafayette, IN, 3Guangzhou Medical Univ., Nanning, China and 4Dept. of Neurology, Indiana Univ. School of Medicine, Indianapolis, IN.

Historically the basal ganglia were thought to be the main target of manganese (Mn) neurotoxicity. Recent evidences show significant effects of Mn exposure on the frontal cortex. The aim of this study is to test the vulnerability of the frontal cortex in Mn-exposed welders.

29 welders (14 from China and 15 from the U.S.) and 33 age- and gender-matched controls (23 from China, 10 from the U.S.) were recruited. Each subject underwent the same magnetic resonance imaging and spectroscopy exams. MR spectra were acquired from the frontal cortex, thalamus, motor cortex, and striatum in the U.S. cohort, while from the frontal cortex, thalamus, hippocampus and posterior cingulate cortex (PCC) in the Chinese cohort. Brain metabolites were quantified including myo-inositol (mI), glutamate (Glu), creatine (Cr). A series of high resolution inversion recovery images and multi-echo gradient echo images were acquired to calculate T1 and T2* values, which quantitatively measure brain Mn and Fe levels, respectively. Metabolic changes, T1 and T2* values of the same brain regions were compared between welders and controls within each cohort.

Both welder groups showed significantly reduced T1 values in many brain regions including the frontal cortex, and significantly reduced T2* values only in the frontal cortex. Chinese welders showed significant changes in Glu, Cr and macromolecules in the frontal cortex, mI in the thalamus and PCC, no changes in the hippocampus, while U.S. welders also showed more changes in the frontal cortex, without any changes in the other regions.

Overall, the frontal cortex of both welder groups showed more metabolic changes and Fe deposition assessed by reduced T2* values, indicating the frontal cortex may be particularly vulnerable to Mn exposure in welding fumes (Supported by NIH/NIEHS #R01 ES052059, National Science Foundation of China Grant #8107320).

2232 Measuring Community Lead (Pb) Toxicity: Filling the Prevention Gap to Advance from Reactive to Proactive Medicine

1Pharmacology, Tulane University School of Medicine, New Orleans, LA, 2Lead Lab, Inc, New Orleans, LA and 3Colorado State University, Fort Collins, CO.

The effect of Seasonal variation on the concentration of seven metals: cadmium (Cd), lead (Pb), iron (Fe), manganese (Mn), zinc (Zn) and copper (Cu) was evaluated in water, two species of most consumed fishes ( Tilapia nilotica & Clarias lazera), an aquatic plant ( Ceratophyllum demersum L), and soil sediments in Wadi Al Raiyan lakes, El-Fayoum, Egypt. Samples were collected in summer and winter 2010-2011. Metals concentrations were measured by Atomic Absorption Spectrophotometry.

2233 Correlation of Blood Cr (III) and Adverse Health Effects: Application of PBPK Modeling to Determine Nontoxic Blood Concentrations

Chromium (Cr) is a trace metal essential to human health and exposure typically occurs via the diet on a daily basis. Some groups of individuals, such as those consuming Cr(III) supplements or patients with Cr-containing implants, may have elevated blood Cr(III) concentrations. Although blood Cr(III) concentrations are thought to be an accurate metric of exposure, little is known about the relationship between these concentrations and possible adverse health risks. This study evaluated the various effects reported in animal and human epidemiological studies of Cr(III) exposure in an effort to correlate them with blood Cr(III) concentrations. The target endpoints identified in this analysis included the hematological, hepatic, and renal systems. Animal and human physiological based pharmacokinetic (PBPK) models were used to estimate steady state blood Cr(III) concentrations from a variety of dosing regimens. Our results suggest that blood Cr(III) concentrations as high as 480–580 µg/L are not associated with any responses. For each of the three health endpoints considered in this analysis (hematological, hepatic, and renal) no adverse effects were observed below 3,700 µg/L. Some hematological responses were observed at 3,700 µg/L, and adverse effects clearly occurred at 7,500 µg/L. These findings can be used to assess potential health risks to individuals with elevated blood Cr(III) concentrations.

2234 The Effect of Seasonal Variation on the Concentration of Metals in Water, Fish, Aquatic Plant, and Soil Sediment in El-Fayoum, Egypt

K. A. Abdou1, A. A. Sharkawy2, M. M. Mahmood1 and E. O. Hamed3.

The effect of Seasonal variation on the concentration of seven metals: cadmium (Cd), lead (Pb), iron (Fe), manganese (Mn), zinc (Zn) and copper (Cu) was evaluated in water, two species of most consumed fishes ( Tilapia nilotica & Clarias lazera), an aquatic plant ( Ceratophyllum demersum L), and soil sediments in Wadi Al Raiyan lakes, El-Fayoum, Egypt. Samples were collected in summer and winter 2010-2011. Metals concentrations were measured by Atomic Absorption Spectrophotometry.
Manganese (Mn) is a naturally occurring element, essential in trace amounts for living organisms, but is potentially toxic in high concentrations. Certain occupations including mining, welding and steel manufacturing can expose workers to chronically high levels of airborne Mn, leading to a clinical condition known as Manganism, which has Parkinson-like symptoms. Recent studies report excess dietary Mn can impair immune and reproductive functions in birds. Previously we showed Mn is present in some commercially available fertilizers. We hypothesized plants grown in soils high in Mn or supplemented with fertilizers containing Mn will accumulate Mn from the soil and that use of fertilizers with high concentrations of Mn will increase the accumulations, possibly creating a situation where animals and people ingesting the fruits and vegetables might be subjected to elevated Mn levels. This work was supported by grants 0516041071 of NYSDOE and 0622197 of the DUE Program of NSF.

Hundreds of pollutants are discharged into the environment every day. Of these, heavy metals are regarded as serious pollutants of the aquatic environment because of their environmental persistence and tendency to be concentrated in aquatic organisms. Abandoned mines are an important global concern and continue to pose potential threats to human health including environmental damage. There is not any specific regulation for mining wastes in Turkey and this situation puts the mining wastes into the dangerous category. Therefore, this study focuses on the potential causes of autoimmune disease (AD) as a follow-up to information generated from the total DINEH sample (N=1,304). Statistical modeling and geospatial data of abandoned U wastes and participants’ homes indicate an association between EU exposures and self-reported AD. To investigate immune system responses, we determined lymphocyte subpopulations and measured serum cytokines using flow cytometry. Whole blood samples were used to identify T cells (CD3+), T helper (CD4+), T cytotoxic (CD8+), B cells (CD19+), natural killer (NK) cells, and HLA-DR+ activated immune cells. Pro- and anti-inflammatory cytokines, as well as antimicrobial and specific autoantibodies, were measured in serum using enzyme-linked immunosorbent assays (ELISA). Regression modeling indicates that DINEH participants who reported increased EU exposure had increased proportion of activated T cells and decreased proportion of B cells and other antigen-presenting cells. Such cellular changes can lead to lower production of protective antibodies against invading pathogens. Alterations in cytokine production indicated an inflammatory response. These findings indicate altered immune response among the participants related to EU exposure.

Hundreds of workers with values more than 400 μg l−1 were invited on our clinic for mobilization treatment. We found important to monitor the exposed group regularly. We recommend to establish a regular medical control of exposure level.
Evaluation (BASE) database has been used extensively for comparative background values for indoor air in commercial buildings for risk assessments and soil vapor intrusion assessments. EPA’s BASE study sampled 100 buildings with a total of 298 sample sets. For this comparative study we collected indoor air samples from 37 sites and compared these data to the background values found in the BASE study. We collected a total of 794 indoor air sample sets that were analyzed for volatile organic compounds using EPA Method TO-14A and TO-15. The BASE study used a combination of two sample collection methods: 6 liter SUMMA canisters and multi-tube sorbents. This study utilized only SUMMA canisters and all samples were sent to a contract laboratory for analysis. The BASE method reporting limits ranged from 0.2 to 7.0 µg/m3. Our data set was then compared to the minimum, maximum, means, and the 25th, 50th, 75th, 90th, 95th and 99th percentile values in the BASE data set. Our results show that although similar to the background dataset there were enough differences to conclude that the "background" dataset is limited and should be expanded to include additional data. This additional data is readily available through State programs that have been collecting indoor air samples through a variety of programs including soil vapor intrusion assessments. This expanded dataset would be more reflective of actual background; allowing further evaluation of the data sets for more accurate risk assessment of the human population that it is being applied to.

When ocean water contaminants threaten the shoreline, risk to public health from contaminant exposure during recreational beach use must be evaluated and managed. This study was designed upon the assumption that users, including both skin surface area exposed and duration of contact. Currently, there are almost no data of this type available. The objective of this project is to determine the extent of water contact by the public during recreational beach use and how contact is influenced by weather and water conditions. Permanently mounted, high resolution video cameras are used to capture subjects' behavior on a public beach in Florida following an IRB approved protocol. Because the study involves passive observation of individuals in public, consent of subjects is not required. Video files are evaluated by an analyst post-hoc (i.e., not in real time). Potential subjects are restricted to those who spend their entire time on the beach within the field of view of the cameras so that the full extent of water contact during the day can be measured. Subjects are classified by gender and approximate age (adult, child, toddler) based upon appearance and are assigned a subject number. From the group of potential subjects identified for each study day, a subset is randomly selected for quantitative analysis. For each subject, the approximate extent and time of immersion are determined in time steps from the video files. The skin surface area exposed is assumed based upon age/gender classification and median body weight and surface area data from NHANES. An exposure time and average skin surface area in contact with water for the day is calculated for each subject. Ambient air and water temperatures are also recorded and will be used in a later phase of the study to develop a predictive model of water exposure on the beach as a function of weather conditions. Information derived from this study will be of value in risk assessment for estimating exposure to water borne contaminants on public beaches.

Exposure to the polynuclear diphenyl ethers flame retardants (PBDEs) causes concern for carcinogenicity, neurotoxicity, reproductive toxicity, and thyroid toxicity. Hydroxylated PBDE metabolites (HO-PBDEs) are of increasing toxicological interest because of their greater biological activity compared to parent compounds. Little is known about the extent and patterns of HO-PBDEs during pregnancy, especially in populations susceptible to heritable neurodevelopmental disorders. In this study, ExpoCast predicted emissions of 74 chemicals found in 32 flooring materials included a range of natural and synthetic floor coverings, upholstery, and articles of clothing. Depending on their physicalchemical properties, they may bioaccumulate in the indoor environment at higher magnitudes than in the outdoor environment, which is correlated with high indoor exposure rates. Halogenated flame retardants, such as polybrominated diphenyl ethers, are semi-volatile organic compounds (SVOCs) that are potentially harmful to humans. In this study, ExpoCast predicted emissions of 74 chemicals found in 32 flooring materials for which gas phase concentrations were measured by Wilke et al. (2004).1 Flooring materials include a range of natural and synthetic floor coverings, installations, and adhesives. Emissions calculations principally depend on the gas phase concentration of the SVOC in the material as well as the surface area of that source. A linear regression yielded R² and p values of approximately 0.3 and 2.0E-12, respectively, with logP and vapor pressure being the most significant predictors for gas-phase concentration followed by their presence in adhesives and resilient flooring. These results potentially allow for the forecasting of gas-phase concentrations of chemicals for which their analytical data in flooring materials are lacking. Data generated from high throughputs exposure methods are then combined with high-throughput chemical screening data from ToxCast projects to order to statistically assess risk in a time and cost effective manner. As a result, comprehensive risk assessment of indoor use chemicals may be achieved. This abstract does not necessarily reflect EPA policy.

Synthetic polynuclear diphenyl ethers (PBDEs) have been widely used as flame retardants in many consumer products including electronic devices. The most important routes of human exposure appear to be from contaminated food and contact with dust found in households and workplaces. Structurally related derivatives of PBDEs are the hydroxylated (OH-PBDEs) and methoxylated forms (MeO-PBDEs). Experimental evidence suggests the OH-PBDEs pose greater health risks than other forms of PBDEs. Certain OH-PBDEs and MeO-PBDEs are also marine natural products and it is unclear although likely, that marine fish and shellfish, which bioaccumulate these compounds serve as a vector for human exposures. In this study, we are measuring approximately 120 different PBDE, OH-PBDEs and MeO-PBDEs in household/workplace dust and blood plasma samples provided by human volunteers living in the Puget Sound region of Washington State and working in either the commercial fishing or recycling industries. The commercial fishing occupation is largely an outdoor activity that promotes above average seafood consumption while electronic recycling may expose workers to dust with higher than average levels of PBDEs. Thus, comparison of PBDE levels in samples associated with these occupations may provide insight on the relative importance of dust vs. food as a source of PBDEs. Initial results suggest the pattern of PBDE distribution in volunteers that consume low amounts of seafood are more comparable relative to those from volunteers consuming higher than average amounts of seafood. For example, 97% of OH-PBDEs were detected in volunteers consuming low amounts of seafood. Also, comparison of results from volunteers of white-European, African-American and Hispanic ethnicity suggested ethnicity was not an important variable in determining PBDE congener content of plasma relative to occupation and other lifestyle attributes. Supported by NIOSH Grant 1R21OH010259-01A1.

Risk due to chemical exposure is a function of chemical hazard and exposure. Proximate sources of exposure due to the presence of a chemical in consumer products are identified as key drivers of exposure and are not well quantified. The ExpoCast project is developing a model that forecasts indoor exposure to chemical additives in textiles. Flame retardant chemicals are found in flooring, upholstery, and articles of clothing. Depending on their physicochemical properties, they may bioaccumulate in the indoor environment at higher magnitudes than in the outdoor environment, which is correlated with high indoor exposure rates. Halogenated flame retardants, such as polybrominated diphenyl ethers, are semi-volatile organic compounds (SVOCs) that are potentially harmful to humans. In this study, ExpoCast predicted emissions of 74 chemicals found in 32 flooring materials for which gas phase concentrations were measured by Wilke et al. (2004).1 Flooring materials include a range of natural and synthetic floor coverings, installations, and adhesives. Emissions calculations principally depend on the gas phase concentration of the SVOC in the material as well as the surface area of that source. A linear regression yielded R² and p values of approximately 0.3 and 2.0E-12, respectively, with logP and vapor pressure being the most significant predictors for gas-phase concentration followed by their presence in adhesives and resilient flooring. These results potentially allow for the forecasting of gas-phase concentrations of chemicals for which their analytical data in flooring materials are lacking. Data generated from high throughputs exposure methods are then combined with high-throughput chemical screening data from ToxCast projects to order to statistically assess risk in a time and cost effective manner. As a result, comprehensive risk assessment of indoor use chemicals may be achieved. This abstract does not necessarily reflect EPA policy.
Bisphenol A (BPA) is an organic compound with a weak estrogenic property, the health effects of BPA remain inconclusive but it is agreed that it has low acute toxicity. Because of the ubiquitous presence of BPA in our daily lives, there is concern about its ability to leach from products into consumables creating adverse health effects. Such scenarios led “BPA free” products. We have characterized the presence of BPA in various plastic products: baby bottles, water and food containers; investigated the effects of temperature, and degree of use on BPA leachates. Various plastic baby bottles, water/sports bottles, and food containers were filled with water, boiled to 90, 95, or 100oc for 36, 48, 60 times/hours, sample collected along with 0.5gm from different plastics were extracted and analyzed along with standard using HPLC-Uv-Vis at 225-310 nm; with a mobile phase (acetonitrile: water (70:30 v/v)) and mass confirmed with MALDI-TOF for BPA and metabolites. HPLC: BPA elutes with a mean retention time (RT) of 7.35 +/- 0.05 min and quantification showed differential leaching of BPA from different plastic containers depending on the temperature and extent of use. Microswab water in plastic containers showed temperature and time-dependent concentration of BPA leachates. Analysis of different containers showed presence of BPA in all samples except from Ziploc Smart Snap. MALDI-TOF analysis of sample extracts confirmed presence of BPA and other derivatives. Most of the plastic containers tested leached BPA from baby bottle, water bottles and food containers even those labeled “BPA free” except Gumdrop baby bottle and Ziploc Smart Snap. Concern remains of how free and safe are plastic containers labeled “BPA free”? Though, BPA has low estrogenic activity and not considered a major threat to human health, but manufacturers of consumer products need to live up to their product standard and avoid the guessing game. However, more research is required to identify conditions that lead to BPA leach from products and the long term toxic effects of BPA.
Introduction: Inorganic arsenic (iAs) exposure is potential occupational hazard in copper mining and smelting. After absorption, As undergoes successive reductions and methylations metabolism. As excretion profile was related with environmental arsenic levels, individual arsenicism risk, sex, age, nutritional status and body weight. The current investigation was carried out to evaluate As exposure and the urine metabolite profiles of workers with different jobs in a copper mining and processing plant in China. Methods: A total of 170 male workers in 5 different departments (administrative employees (Group 1), copper ore miners (Group 2), copper ore grinding and milling (Group 3), electrolytic procession (Group 4) and copper smelters (Group 5)) of a copper mining and processing plant were randomly recruited. Subject age, job history, alcohol and smoking habit, dietary habits, et al. were collected. Blood pressure, height and weight were measured and body mass index (BMI) was calculated. Spot urine samples were collected and determined for iAs, MMA, DMA, and trimethylated arsenic (TMA) by atomic absorption spectrophotometer with an arsenic speciation pretreatment system. Results: The highest urinary levels of iAs, MMA, DMA and TMA were found in the Group 5. There was a statistically higher excretion of urinary As in the Group 4 and 5 compared to Group 1, 2 and 3 (p<0.05). In Group 4 and 5, 77.8% and 93.3% of workers had total urinary As values higher than 50μg/g Cr, and significantly higher than that of Group 1, 2 and 3. There was a statistically higher excretion of urinary DMA in the workers of BMI>25 and intake seafood in recent 3 days. The odds of subjects with urinary As exceeded 50μg/g Cr were positively and significantly associated with different production type (OR=1.907; CI=1.387-2.621; p=0.000) and BMI (OR=1.504; CI=1.009-2.242; p=0.045). Conclusion: The workers in copper production plant presented significantly elevated levels of iAs, MMA, DMA and TAs, especially for smelters and workers of electrolytic process.

In New Mexico (NM), arsenic in groundwater has been measured as high as 600 μg/L. Arsenic in drinking water is a potential public health concern in areas of NM where concentrations in groundwater exceed the Environmental Protection Agency maximum contaminant level of 10 μg/L. Approximately 90% of NM’s drinking water supply comes from groundwater. A biomarker of arsenic exposure could estimate the contribution of arsenic from drinking water. The analysis evaluated how well urinary arsenic concentration is associated with arsenic concentration in drinking water among NM biomonitoring project participants.

Data were utilized from three NM Department of Health projects conducted from 2004 through 2012, which included volunteer participants residing in 76 communities. For this analysis, only adults who provided samples of their drinking water, a spot urine sample and completed an exposure assessment survey were included (N=1009). Total arsenic concentrations from drinking water and urine samples were analyzed. Sample collections and analytical methods applied were similar among the biomonitoring projects, therefore, it was concluded that the results could be pooled for analysis. A multiple regression model was developed to evaluate the effect of drinking water arsenic concentration on urinary arsenic level, with adjustment for variables such as age, sex, dietary supplement use, tobacco use, fish/seafood consumption, and daily water consumption.

After adjusting for relevant covariates, for each 1 μg/L increase of total arsenic in drinking water, there was a 2.7% increase in creatinine-corrected total urinary arsenic concentration.

Urinary arsenic concentration can serve as a biomarker of exposure to arsenic in drinking water; however, other factors also contribute to urinary arsenic levels. Education about the importance of arsenic testing and methods of reducing arsenic in drinking water, especially for those on private wells, can positively affect health behavior of communities at risk for excessive exposure to arsenic.

Arsenic (As) can exist in the environment in several different forms, and each form has unique chemical characteristics that influence its toxicity. Within the last decade or so, the increased focus on speciated As (both the inorganic and organic forms) and its potential toxicity has resulted in a large body of literature on speciated As in different food types. We evaluated the state of knowledge of As speciation in food and calculated the average levels of several species of As measured in food. Because inorganic arsenic (iAs) is considered the most toxicologically important form of As, we focused our analysis on papers presenting information on total inAs and speciated inAs (inAs3+ or inAs5+). Other As species (e.g., monomethylarsonic acid [MMA], dimethylarsinic acid [DMA]) were also evaluated when presented with inAs information. Publications were drawn from the peer-reviewed literature and reports by authoritative health agencies. We compiled a large database of measurements, including over 6,000 unique inAs data points. Our analysis demonstrated that inAs in foods can vary widely by type and even by sample, with mean inAs concentrations ranging from undetectable (in milk) to 8,100 μg/kg (in seaweed/algae). After seaweed, the highest mean inAs concentrations were found in rice-based products such as flour and bran, followed by rice and rice cereals. We also found a high percentage of non-measurable As in many food types. We believe this is one of the first analyses to combine data from the available literature on speciated arsenic to calculate summary statistics for exposed and non-exposed individuals, and thus provide a more complete profile of the community exposure to arsenic.
We are exposed to thousands of chemicals over our lifetimes. A major challenge to risk assessors is to understand how and when chemical exposures occur, and which "exposure pathways" contribute the most. An informatics-driven approach to assigning "product-use" categories to product "ingredients" will help prioritize which chemicals will be given more scrutiny for a target population (life-stage, gender, ethnicity), identifying (a) human activities that result in increased chemical exposure while (b) reducing the dimensionality of hazard assessment to a tangible subset for risk characterization. How chemicals are used is directly related to their potential exposure routes, and in the sense of near-field source apportionment, to the identification of chemical-specific use-to-receptor exposure pathways. We have developed the Chemical/Products Categories Database (CPCat) to explore these pathways. CPCat is a relational database comprised of chemical "use category" information, including both consumer- and industrial-process-based uses for chemicals, using mined and curated data from 14 major sources from multiple countries, including data from regulatory bodies, manufacturers and retailers. CPCat contains information on 42k unique chemicals mapped to a set of >700 use categories. We provide an example of how CPCat can be used to link life-stage to use-pattern to products and their ingredients for children's exposure. CPCat can be used to identify chemicals that children would potentially be exposed to, and the major activity/source of such exposures; a database query of the "child" or "baby" keywords results in the identification of 1,300 chemicals, of which the majority are associated with the "child toy" CPCat category. This information can then be used to rank plausible exposures of chemicals which may be investigated for potential biological activity. The entire database and a set of tools will be made publicly available. The views expressed in this abstract are those of the authors and do not reflect the views or policies of the U.S. EPA.
black carbon content. Aging of radiolabelled benz(a)pyrene (BaP) on the soils was conducted for eight weekly cycles in which soils were wetted and dried. Eight- and 24-hr absorption experiments were then conducted in vitro using heat-separated human cadaver epithelids to assess the flux of BaP from each soil and to investigate the effect of soil characteristics and BaP concentrations on flux. Experiments were also conducted with BaP delivered in solvent to permit comparison to absorption from a soil matrix. Uptake (as assessed by radiolabel recovered from swabbed skin) of solvent-deposited BaP was more rapid than penetration to receptor fluid, reflecting lag time in skin. Uptake and penetration from aged soils at nominal initial concentrations of 5 and 10 ppm BaP were correspondingly lower, reflecting reduced thermodynamic activity in soil. This research is particularly relevant in light of EPA’s draft toxicity profile for BaP, which introduces a Dermal Cancer Slope Factor for use in risk assessment of BaP exposures, including exposures from soil.

2234x Hematotoxicity and Genotoxicity in Children Exposed to Benzene in a Petrochemical Area in México

P. Nadia1, R. Diana2, H. Alejandra1, E. D. Izrael2 and M. Brenda1, 1Instituto de Ciencias de la Salud, Universidad Autónoma del Estado de Hidalgo, Pachuca, Hidalgo, México and 2Universidad de Guanajuato, Guanajuato, Mexico. Sponsor: M. Gonsebaut.

Background Children living in Tula, Hidalgo, México, are exposed to pollutants from petrochemical and chemical industries located in the area. The Secretaría de Medio Ambiente y Recursos Naturales (SEMARNA) reports emissions to environment of some toxic compounds. Benzene emission has been reported to the environment and it is well known that is a hematotoxic and genotoxic compound. Objective The aim of this study was to evaluate the genotoxicity and hematological effects in children environmentally exposed to benzene. Methods Samples of urine, blood and buccal epithelium were obtained from 26 children (6–8 years old). Exposure to benzene was assessed by determination of an urine metabolite: trans, trans-mucic acid (t,t-MA). Micronucleous frequency (MNf) was evaluated in buccal epithelial cells and hematological parameters were determined.

Results: Exposure assessment indicates that the 35% of children have levels above de Biological Exposure Index (500 ng/gCreatinine). The mean of the t,t-MA urinary levels was 460 ng/gCreatinine; this value is above of levels reported in previous studies in children from Italy, Thailand and México. In the hematological status assessment, 100% of children have some hematic parameter abnormal. The 78% have hemoglobin levels above normal values for the age group; 42% has altered lymphocytes (10% lymphopenia, 19% granulocytes alterations, 22% monocytes). The preliminary results (n = 8) the mean of MNf was 12.7/1000; this value is three times higher than those reported in other studies in children. No statistic significant correlation between benzene exposure and hematological parameters was found.

2234y Refined Exposure Assessment for Three Active Ingredients of Humidifier Disinfectants

J. Lee1, J. Kwon2 and C. Kim1, 1Institute of Environmental Protection and Safety, NeoEnBiz Co., Bucheon, Republic of Korea and 2Division of Environmental Science and Ecological Engineering, Seoul, Republic of Korea. Sponsor: J. Chun.

Exposure assessment for three major active ingredients used for humidifier disinfectants, polyhexamethylene guanidine (PHMG), oligo(2-(2-ethoxy)ethoxyethyl guanidinium chloride (PGH), and 5-chloro-2-methylisothiazol-3-(2H)-one/2-methylisothiazol-3-(2H)-one (CMIT/MIT) mixture, were conducted in a bedroom for good occupational hygiene, and for active health monitoring, the respiratory and skin exposure were assessed. The objective of this study was to evaluate disinfectant exposure from selected products with simulated laboratory use. An environmental chamber was used to simulate laboratory application of the products. Bulk samples of various products were tested before and after use. Industrial hygiene personal and area air samples were collected during all testing following NIOSH 7400/7402 methodologies. Phase contrast microscopy (PCM) and transmission electron microscopy (TEM) were used for sample analyses. Collection of personal and area air samples varied between 4 and 6 hours. Analysis of personal air samples using PCM, showed airborne fiber concentrations as high as 0.058 f/ml during use of tongs fitted with asbestos sleeves. Further analysis using TEM showed the highest asbestos level of 0.0036 f/ml. Manipulation of transit boxes resulted in personal TWA asbestos levels as high as 0.02 f/ml. Analysis of area air samples during heating of gauze pads using PCM showed airborne fibers concentrations ranging from less than 0.007 to 0.009 f/ml. When analyzed using TEM, asbestos levels ranged from 0.001 to 0.002 f/ml. Personal samples were in similar ranges. Some asbestos was lost from gauze pads during use. Asbestos-containing gauze pads produce de minimis levels of asbestos when heated. Testing of various asbestos containing materials used in research laboratories indicate low potential for asbestos fiber exposures.

2235 Asbestos Content of Heavy Equipment Brake-Wear Debris and Associated Airborne Exposures during Brake Work

M. Gresep1, E. Donovan1, R. Ward1, A. Madf1 and B. L. Finley1, 1Cardno ChemRisk, San Francisco, CA, 2Cardno ChemRisk, Aliso Viejo, CA and 3Cardno ChemRisk, Brooklyn, NY.

Asbestos-containing brake linings were commonly used in heavy construction equipment until the 1980s. However, asbestos exposures and potential health risks associated with brake repair on heavy equipment have not been comprehensively evaluated. The present study determined whether individuals working with heavy equipment brake components, or bystanders to such work, were exposed to chrysotile asbestos above exposure limits dependent upon chrysotile content of equipment brake wear debris (BWD) and type of machinery. Publicly available published and unpublished studies examining BWD asbestos content in various heavy equipment were identified. Variables potentially contributing to BWD and airborne asbestos concentrations included common brake job practices, infrequent
manipulative activities, cleaning methods, and brake component dimensionality. Tasks included combinations of changing brakes, inspection of brake pads, glazing brakes with sandpaper, and cleaning with solvent or compressed air. The degree to which airborne asbestos concentrations correlated to BWD composition and physical characteristics, the type of heavy machinery, and the brake work activities was determined. Most, but not all, BWD samples contained less than one percent chrysotile by weight. For air samples, phase contrast microscopy results for personal, bystander or area samples did not exceed 0.622 total fibers based on short-term, task-based sampling. 8-hr time weighted average concentrations did not exceed 0.045 asbestos fibers after adjusting for asbestos content using transmission electron microscopy. These results are consistent with those observed for smaller vehicles, including automobiles. This suggests that individuals working with these materials would not have been exposed to asbestos above contemporary or current exposure limits, regardless of BWD chrysotile content. It is unlikely that the dimension of brake components influences the degree to which mechanics working with such products were historically exposed to asbestos.

**2236 Determination of Air Conc. and Exposure to Spores from Microbe-Based Cleaning Products: Influence of Human Activity and Vacuuming**

N. W. Berg$^4$, J. Sediq$^5$, R. Testman$^5$, K. Acedo$^6$ and T. G. Omitz$^7$

$^4$Novozymes A/S, Bagsvaerd, Denmark, $^5$Novozymes Biologicals, Inc., Salem, VA, $^6$Golden Pacific Laboratories, Fresno, CA and $^7$Science Strategies, LLC, Charlottesville, VA.

Microbe-based carpet cleaning products contain non-pathogenic, highly specialized microbes that produce appropriate enzymes in the presence of soils ceasing production when the stains or soils have been removed. These products are used in homes and institutions and potential for human exposure from residues in the air and on treated surfaces exists. The purpose of this study was to determine the air conc. of viable bacterial spores after use of two microbe-based carpet cleaning products based on a blend of Bacillus spores: a whole room consumer-use product and a spot treatment product using a trigger sprayer. The influence of choreographed human activities on airborne spore levels was investigated. Studies were conducted in a simulated residential exposure room carpeted with plush nylon carpet and equipped with impingers to collect airborne spores. Airborne spore levels were elevated after application of either product but quickly returned to values similar to the 95th percentile or less of field measurements of airborne spores in indoor settings. Vacuuming and passage of time continued to cause a decrease in airborne levels. The trigger sprayer for spot application produced levels of airborne spores slightly above the provisional threshold limit (TLV) of 1x10^4 CFU/m^3, established for airborne microbes in occupational settings. The spores are, however, mainly carried in non-inhalable water-based particles. So although airborne spore counts in the spot application exceeded the TLV, trigger sprayer products typically produce non-inspirable particles that, despite their presence, actually pose minimal potential for pulmonary exposure.

Based on the data from these exposure studies, and a critical evaluation of the published literature, it is concluded that carpet cleaning products containing a mix of Bacillus spores can be regarded as safe for the users.

**2237 A Continuing Legacy of Chlordane and Dieldrin—A Case Example of Pesticides in Well Water in Stamford, Connecticut**

S. M. Rusnak$^1$ and A. Fountain$^2$.

$^1$Novozymes A/S, Bagsvaerd, Denmark, $^2$Novozymes Biologicals, Inc., Salem, VA.

The Connecticut Department of Public Health (CT DPH), the Connecticut Department of Energy and Environmental Protection (CT DEEP), and the city of Stamford have been involved over the past four years with a number of contaminated private wells in Stamford. Banned pesticides, dieldrin and chlordane, were discovered in several private wells at levels exceeding Connecticut’s state drinking water guidelines. The source of the contamination was originally thought to be a nearby landfill, but it is now believed to be from either home pesticide treatment for termites or agricultural use several decades ago. The well contamination issue was originally thought to be limited to a small area of Stamford, but now it is known to be more widespread. To better understand the scope of the pesticide contamination in Stamford, the Stamford Health Department launched a small random sampling program and a subsidized city testing program. There are almost 2000 wells that have been tested to date where approximately 15% of wells tested have either dieldrin and/or chlordane present with 6% exceeding state drinking water guidelines. The maximum concentrations of chlordane and dieldrin in wells are 7.4 and 1.3 parts per billion (ppb), respectively, and 25 and 43 times the state drinking water guidelines. Using these maximum levels for chlordane and dieldrin, the lifetime cancer risk from drinking the contaminated water is up to 5 excess cancer cases out of a population of 10,000. The city of Stamford, with assistance from CT DEEP and CTDPH, took a proactive approach and placed many of these homes on whole house filters and later to municipal water. CT DEEP, CTDPH, and the city of Stamford have taken a number of actions to deal with the private well contamination and inform the community. The testing of contamination in Stamford raises broader questions about the past practice of treating home foundations for termite control using chlordane and dieldrin and the nature and scope of potential impacts to groundwater quality in Connecticut and possibly other states.

**2238 Surface Water Risk Assessment of Pesticides in Ethiopia**

Scenarios for future use in the pesticide registration procedure in Ethiopia have been devised for 3 separate Ethiopian locations, which are considered to be protective for 99% of Ethiopia. The scenarios estimate concentrations in surface water resulting from agricultural use of pesticides for a small stream and for 2 types of small ponds (Adriaanse et al., 2013). Preliminary results from scenario calculations will be presented.

On the basis of volume of use, application rate in Ethiopia and acute human toxicity the 7 pesticides considered to be of most risk to humans were selected, assuming exposure as a result of the consumption of surface water. Estimates of exposure concentrations in surface water were established using modelling software also applied in the EU registration procedure (PRZM and TOXSWA). Calculations generated the 99-percentile maximum concentration for use in human risk assessment and the 90-percentile maximum concentration for use in ecotoxicological risk assessment. Input variables included physicochemical properties, and data such as crop calendars, irrigation information, meteorological information and detailed application data which were specifically tailored to the Ethiopian situation. The results indicate that for all the pesticides investigated the acute human risk resulting from the consumption of surface water is low to negligible, whereas agricultural use of Chlorothalonil and Endosulfan may result in medium to high risk to aquatic species.

Key words: Risk assessment, pesticides, models simulation, aquatic ecosystem, Ethiopia

**2239 Human Health Risk Assessment of Metals in Fish in Ghana**

D. Dokie and J. M. Gohlie.

Environmental Health Sciences, Univ of Alabama at Birmingham (UAB), Birmingham, AL.

Fish advisories have been established by many nations to protect the public from potentially harmful health effects linked to eating contaminated fish. Advisories are based on estimations of cancer and non-cancer health risks associated with concentrations of contaminating chemicals found in fish, and the average levels of consumption of fish in the population. Fish is an important source of nutrition in Ghana; however, little is known about potential health effects associated with eating fish in Ghana. The overall aim was to estimate the extent of contamination of the fishery resource so as to inform guidelines on fish consumption. We gathered information on levels of metals in fish in Ghana from scientific publications identified using the PubMed database. We estimated human health risk by calculating a hazard quotient based on the reported levels of mercury in fish and compared risk across different fish species and water bodies in Ghana. Mercury was the only metal in which there was sufficient data to estimate human health risk from eating fish caught in Ghana. The mean for all the recorded values for mercury concentrations in fish was 0.10 mg/kg wet weight. This concentration is associated with a hazard quotient of greater than 1, meaning that adverse health effects are possible. Generally, lower concentrations of mercury were found in fish from the lakes sampled while higher concentrations were detected in fish from rivers, particularly in gold mining areas of Ghana. Our results indicate mercury found in fish may be causing health effects, such as impaired neurological development. It is important for the government and relevant agencies in Ghana to consider a mechanism to effectively monitor pollution, issue fish consumption advisories when warranted, and determine and remediate the source of contamination, which likely includes mercury emissions from artisanal mining based on the heightened levels found in fish from rivers in the gold-mining region.
The lead (Pb) content consumer products has become an increasing concern over the past several years. In 2007, the Campaign for Safe Cosmetics published the test results of 33 lipstick samples and found that 61% contained lead, with a maximum Pb concentration of 0.65 ppm. In 2010 the US FDA tested 400 lipstick samples and found a median Pb concentration of 0.9 ppm and a maximum Pb concentration of 7.19 ppm. To assess the safety of these lipsticks in instances where children might intentionally or incidentally ingest lipstick products, we used the US EPA’s Integrated Exposure Uptake Biokinetic (IEUBK) Model for Lead in Children to determine the blood Pb concentrations of children (aged 0-7) ingesting varying amounts of lipstick of different Pb concentrations. Modeled blood Pb concentrations were then compared to the estimated blood Pb concentration for the US Consumer Product Safety Commission’s (CPSC) guideline of 15 ug Pb/day (orally) and to the Centers for Disease Control (CDC) and US EPA actionable blood Pb levels (BLL) of 5 ug/dL and 10 ug/dL, respectively. The maximum estimated geometric mean blood Pb level resulting from the ingestion of the CPSC guideline was 3.8 ug/dL, assuming inclusion of background sources in the guidance value. The amount of the highest concentrated lipstick (7.19 ppm) required to yield a blood Pb concentration in the range generated by the CPSC guidance value and the US EPA BLL (3.8 – 10 ug/dL) was 0.25 – 4.94 g lipstick/day; this is equivalent to ingestion of around 1/50th to 2/5th of a 3.0 oz tube of lipstick/week, assuming concomitant background exposure. The amount of lipstick with the FDA median concentration of 0.9 ppm that would need to be ingested to reach this blood Pb concentration range was 2.0 – 39.4 g lipstick/day, or around 1/5th to three 3.0 oz tubes of lipstick/week. Our results suggest that the safety of these products and cosmetics should be assessed not only by the presence and amounts of hazardous contents, but also through an assessment of estimated exposures and comparison to health based standards.

Mercury is a naturally-occurring volatile contaminant of natural gas; concentrations range from <0.01 to 2000 μg/m³ worldwide depending on the geologic deposit. Hydraulic fracturing has revolutionized the scale of natural gas extraction, with certain shale deposits supporting thousands of active wells. At production platforms, large volumes of natural gas are flared (burned) to remove unwanted elements; in the process mercury may be released to ambient air. Mercury is a well-recognized toxin that can affect the nervous, immune, and other systems. We used a range of published natural gas mercury levels, well completion flared volumes, and a screening level dispersion model (SCREENS) to model mercury concentrations in ambient air near a model gas well. We speculated total mercury emissions into elemental and mercuric forms and considered soil deposition and mercury methylation. Potential health effects from inhalation, ingestion, and dermal exposure to different mercury species were evaluated by using USEPA exposure parameters and standard toxicity reference levels. Our results indicate that maximum annual average airborne concentrations of mercury occur approximately 1000 meters from the well. Based on modeled concentrations, mercury emitted from flaring during the completion phase of a single well does not pose chronic health concerns (health index [HI] <1). There are many uncertainties inherent in this screening-level assessment, including modeling emissions from single well, inclusion of only a single category of flare source, the mercury concentration of natural gas, the use of a screening air dispersion model, and mercury speciation and deposition. While preliminary, given the complexity of active high-density natural gas well fields with diverse mercury content, a refined risk assessment should be performed to ensure that health risk impacts are appropriately characterized.

New toxicological information has prompted USEPA to consider acute in utero toxicity at low levels of TCE in the air. Further, data reported from studies of vapor intrusion suggest both high variability in indoor levels, and little correlation with parameters such as temperature and pressure differentials, shallow soil vapor concentrations, precipitation, and soil characteristics. If acute effects from inhalation of TCE do occur, they may occur on few days per year, and these days cannot be reliably predicted. This dilemma presents challenges when assessing risks from acute exposure to TCE in air. Key questions include: how often will extreme concentrations occur; what extremes might be expected; how likely are these extremes to occur during the window for heart development; what data are needed to support risk assessment that addresses these issues; how should the results of the analysis be interpreted? These issues were considered where one unit of a building is used as a church. The unit is adjacent to a source of TCE contamination and overlies a “plume” of TCE vapors. Indoor air concentrations in this unit have varied somewhat over time, but have often been within an order of magnitude of the lowest air concentration of TCE being considered as a threshold for teratogenic effects (2 μg/m³). A one-dimensional stochastic analysis, using data from residential situations to estimate frequency and magnitude of TCE excursions, occupancy information appropriate for church use, a target of indoor air concentration of 2 μg/m³, and a window early in pregnancy for developmental effects on the heart, suggest low probability of pregnant women being present at times when TCE concentrations could be toxic. A “worst case” might suggest a few percent of days in a year; a “best case” might suggest a few percent of days over two or three years. Unless understanding of vapor intrusion improves substantially, risk managers may have to decide where along a continuum of days per unit time where risks become acceptable. The situation appears similar to that of lead, where an acceptable target is based on achieving target blood lead levels in percentage of children.
fied in raw biogas from these sources, including numerous straight and branched alkanes, alkenes, aldehydes, esters, alkyl benzenes, thiols, sulfides, organometallics, and many regulated toxic volatile organics. We collated risk-estimating criteria (i.e., toxicity values) for the biogas constituents from databases published by OEHHA, the U.S. EPA, and two other federal agencies. In some cases, we grouped chemicals whose toxicological properties were judged to be similar, and developed a single toxicity value for each group. Approximately 50 constituents lacked either individual or group risk criteria and could thus not be quantitatively assessed (e.g., several benzene derivatives and alkyl sulfides). We obtained air concentration estimates from CARB and evaluated cancer and non-cancer risks using standard assessment methods developed by OEHHA. Twelve biogas constituents were determined to be of health concern to consumers or workers based on screening thresholds for carcinogens (1 or 30-per-million additional risk, respectively) and non-carcinogens (a hazard quotient > 0.01 or 0.3, respectively). The contaminants were: Alkyl Thiols, Antimony, Arsenic, Copper, p-Dichlorobenzene, Ethylbenzene, Hydrogen Sulfide, Lead, Methanesulfonic Acid, Nitroso-di-n-Propylamine, Toluene, and Vinyl Chloride. As a result of the assessment, biomethane producers will be required to test for these chemicals to ensure that they are adequately removed from raw biogas during processing. OEHHA will update the risk assessment as new information becomes available.

Octamethylocyclotetrasiloxane (D4) and Decamethylocyclopentasiloxane (D5), two low molecular weight cyclic siloxanes, are used globally as intermediates in the production of several widely-used industrial and consumer products. Their global use requires consideration of consumer use information and risk assessment requirements from various sources and authoritative bodies. A global “harmonized” risk assessment was conducted to meet requirements for substance-specific risk assessments conducted by regulatory agencies such as the US EPA’s Integrated Risk Information System (IRIS) and Health Canada, various independent scientific committees of the European Commission, as well as provide guidance for chemical safety assessments under the REACH Regulation in Europe, and other relevant authoritative bodies. This risk assessment incorporates global exposure information combined with a Monte Carlo analyses to determine the most significant routes of exposure, utilization of a multi-species, multi-route physiologically-based pharmacokinetic (PBPK) model to estimate internal dose metrics, benchmark modeling to determine a point of departure (POD), and a Margin of Safety (MOS) evaluation to compare the estimates of intake with the POD. Because of the unusual pharmacokinetic behaviors of D4 and D5, including high lipophilicity, high volatility with low blood-to-air-partition coefficients, and extensive metabolic clearance that regulate tissue dose after exposure, the use of a PBPK model was essential to provide a comprehensive model that reflects these processes. The characterization of the potential for adverse effects after exposure to D4 and D5 using a MOS approach based on an internal dose metric removes the subjective application of uncertainty factors that may be applied across various regulatory agencies and allows examination of the differences between internal dose metrics associated with exposure and those associated with adverse effects.

Groundwater in agricultural regions often exceeds the nitrate Maximum Contaminant Level (MCL) of 10 mg/L as nitrogen (~45 mg/L as NO3) and reducing NO3 below the MCL can be costly. The MCL is based on a link to infant methemoglobinemia from studies circa 1950. While later research questions this relationship, the MCL is the legal limit. A risk assessment was completed to support the safety of groundwater NO3 levels above the MCL for use in distillation of plant oils for dietary supplement uses by children (age ≤3) and adults. The method considers the acceptable daily intake (ADI) for NO3 (mg/kg/d), body weight of consumer (BW, kg), fraction of total daily exposure from supplement use (allocation factor (AF), %), the daily supplement dose (g/d), volume of water (mL) needed to produce 1 g of oil (distillate ratio (DR), mL/g), and partitioning to the oil phase (partitioning factor (PF), %). Values used in this assessment: ADI=3.7 mg/kg/d (as NO3) from JECFA (since supplement is not for infants); BW=10 kg; AF=assumed 20%; Dose=4 g/d; DR=30 mL/g; PF=100% (worst case) or 0.0041% (reasonable case based on log Kow of ~4.39). The NO3 concentration in groundwater resulting in an exposure equal to 20% of the ADI from consumption of the supplement and assuming a worst case scenario of all NO3 from water ending up in the oil (PF=100%) was calculated to be 62 mg/L based on the following equation: $\text{Con}}_{\text{sup}} (\text{mg/L}) = \text{ADI (mg/kg/d)} \times \text{BW (kg) \times AF (\%)} \times 1000 \text{mL/L} / (\text{Dose (g/d) \times DR (mL/g) \times PF (\%)})$. However, as NO3 is a highly water soluble compound, the realistic PF value of 0.0041% (based on the log Kow of NO3) should be used in estimating the amount of NO3 that would partition to the oil. Using this PF value, the groundwater concentration of NO3 that would equal 20% of the ADI from use of the supplement is 1,594,065 mg NO3/L. This concentration could result in a severe health risk. Thus, as essentially zero NO3 in groundwater would likely partition to the oil, otherwise potable groundwater containing NO3 levels above the MCL may still be safe for oil distillation.

There has been and continues to be concern in the airline industry about pilot and flight attendant exposure to TOCP, a well-known neurotoxin. Oil used in jet engines may contain 1-3% tricresyl phosphate of which 0.1-1% is TOCP. The workplace 8 hour time weighted average OSHA Permissible Exposure Limit (PEL), NIOSH Recommended Exposure Limit (REL), and ACGIH Threshold Limit Value for TOCP are all 0.1 mg/cubic meter. Investigations of in-plane air contamination by aircraft turbine engine oil via engine bleed air supply systems have reported no levels of TOCP below limits of detection (LOD, 0.000009-0.0001059 mg/cubic meter) in the cockpit or cabins of sampled aircraft. Since there is no inhalation toxicity factor for TOCP, we performed a risk assessment comparing the acceptable daily intake based on an oral exposure with exposure at the LOD and PEL. Our assessment indicates that pilots and flight attendants are not exposed to sufficient TOCP to cause any adverse health effects. Our assessment is consistent with recent publications reporting that there are no detectable biomarkers of exposure to TOCP in flight crews.

2248 Exposure to Vitamin A (Retinol and Retinyl Esters) from Cosmetics Increases the Proportion of the Population That Exceeds the Upper Intake Level R. B. Hetland1, B. Granum1, J. E. Paulsen1, V. Thranie1, J. L. Lyche1, C. Luznow-Holm2, T. O. Fjordland1, I. L. Lillegaard1 and I. Steffensen1. 1Norwegian Scientific Committee for Food Safety, Oslo, Norway and 2External Expert, Oslo, Norway.

Vitamin A, a group of compounds including retinol (ROL) and retinyl esters, is required in numerous physiological functions. ROL and retinyl esters are widely used in cosmetics such as anti-wrinkle creams and moisturisers due to their positive effects in the skin. The Norwegian Scientific Committee for Food Safety (VKM, 2012) performed a risk assessment of ROL and retinyl esters in cosmetics based on the tolerable upper intake level (UL) of 3,000 μg ROL equivalents (RE)/day (SCF, 2002) and the lower guidance level (GL) of 1,500 μg RE/day for individuals at risk of osteoporosis and bone fracture (EFSF, 2008). Oral intake of vitamin A was estimated based on national food consumption surveys. Systemic exposure dose from cosmetics (with 0.05 and 0.3% RE) was estimated based on The Scientific Committee for Consumer Safety’s Notes of Guidance for the Testing of Cosmetic Ingredients (2010) and a study by Yourick et al. (2008). Intake of vitamin A is high in parts of the Norwegian population; the most important source is diet. Use of food supplements contributes significantly and increases the proportion of the population exceeding the UL. The contribution from cosmetics to the total intake of ROL and retinyl esters is most prominent for 13-year-olds (23% of UL) and adults (29% of UL). Excess exposure to vitamin A is of concern for individuals at risk of osteoporosis and bone fracture (e.g. post-menopausal women). About 10% of adult women in Norway exceed the GL of 1,500 μg RE/day by intake from food and food supplements alone. The additional contribution of retinol and retinyl esters from cosmetics increases this proportion to ca. 75% which means a significant increase in number of individuals at risk of osteoporosis and bone fracture. Acknowledgement. The assessment was performed by the VKM Panel on Food Additives, Flavoursings, Processing Aids, Materials in Contact with Food and Cosmetics.
2249 Assessment of Potential Health Risks on the Basis of the Character and Degree of Chemical Pollution of the Environment

Health risks to the population living in the protective action zone of the Maradykovsky Chemical Weapons Storage and Destruction Facility (CWSDF), Kirov Region, Russia, were assessed. The risk assessment process included four steps (hazard identification, dose–response evaluation, exposure assessment, and risk characterization) and involved ranking possible carcinogenic and non-carcinogenic hazards from exposure to pollutants emitted by the CWSDF, preliminary ranking potential carcinogens on the basis of the total annual emission and the weighing coefficient of carcinogenic activity, and emission dispersion modeling. Ranking the atmospheric pollutants of the CWSDF allowed identification of priority pollutants to be monitored, which included 1-13 non-carcinogens (sulfur dioxide, fuel-oil ash from power stations, nitrogen dioxide, PM 10, C12-C19 alkanes, nitrogen oxide, sodium sulfate, potassium sulfate, sodium carbonate, sodium dichromate, manganese and its compounds, and carbon monoxide); specific pollutants: RVX, 2-(diethylamino)ethyl isobutyl sulfide (DS), isobutyl methylphosphonic acid (IMP), and monoehanolamine; and carcinogens: soil, benz[a] pyrene, and gasoline.

The respiratory system, central nervous system, vision organs, and digestive tract were found to be the target organs for chronic inhalation exposure to the priority pollutants. The potential health risks were calculated using the average annual concentrations of the priority pollutants in the CWSDF emissions in the chosen reference points. The noncarcinogenic risks for specific priority pollutants were as follows: IMPA 0.000001–0.000086; DS 6.3E-008–2.2E-005; RVX 9.9E-007–2.4E-005. The carcinogenic risks varied in the ranges 1.5E-007–1.4E-007 for benz[a]pyrene and 5.9E-10–0.5E-09 for carbon (soot). The chronic non-carcinogenic and carcinogenic risk parameters were at acceptable levels for all reference points.

The work was supported in part by the International Science and Technology Center (project no. 3697).

2250 In Vivo Bioactivity in ToxCast Assays for Fruit and Vegetable Extracts

B. A. Wetmore1, E. Berg2, M. A. Polokoff2, R. S. Thomas3 and M. E. Andersen4. 1The Hamner Institutes for Health Sciences, Research Triangle Park, NC; 2Bioseek, a Division of Diacore Inc., South San Francisco, CA and 3NERL, US EPA, Duluth, MN.

The ToxCast and Tox21 programs have generated in vitro screening data for over 1000 chemicals to aid in hazard identification and setting chemical testing priorities. These data, together with high-throughput pharmacokinetic data, are used to infer possible toxic responses and external concentrations required to elicit these effects. There is only limited experience in evaluating dose-response for natural products in these assays. In this study, juices were extracted from 30 organically grown fruits and vegetables. These juices were screened in concentration-response format across multiple cell types using the BioMap platform to assess similarities of pathway responses of the extracts with those of database compounds. Bioactivities noted with unpeeled potato juice were immunomodulatory and tissue remodeling activities across endothelial, peripheral blood mononuclear and fibroblast cells. This pattern of response was similar to quercetin, a plant-derived flavonoid. Broccoli juice initiated anti-proliferative effects on endothelial, fibroblast and smooth muscle cells with significant similarity to mitomycin C (374 ng/mL; Pearson, r=0.806) and the fungicide mancozeb (40 μM; Pearson, r=0.776). To relate in vitro concentrations to administered dose, the filtered juice yield per g item was used with the plasma volume of a 70kg adult to approximate % juice present in systemic circulation after eating. This value was used as a surrogate for target tissue concentration. The activity described for broccoli was elicited at 0.5%, the amount of juice anticipated in the circulation following consumption of 2 cups of broccoli. Importantly, the bioactivities noted do not necessarily lead to adverse effects. These data provide context for assessing the in vivo relevance of in vitro concentration-response and bioactivity data generated in ToxCast and similar screening programs. This abstract does not necessarily reflect EPA policy.

2250a Merging ExpoCast™ with ToxCast™: Incorporating High-Throughput Exposure Predictions with Dosimetry-Adjusted In Vitro Bioactivity to Inform Toxicity Testing Strategies

Our previous work incorporating dosimetry and exposure with high-throughput screening (HTS) enhanced the utility of HTS data by translating in vitro bioactivity concentrations to external exposures required to achieve these levels internally. These oral equivalents were compared against exposure estimates to provide a margin of exposure (MOE). ToxCast Phase I chemicals are primarily food use pesticides for which regulatory estimates are available. As ToxCast efforts transition to chemicals lacking exposure information, exposure prediction tools become increasingly important. In this study, in vitro hepatic clearance and plasma protein binding were measured to estimate dosimetry-adjusted oral equivalents for Phase II chemicals. Chemical exposures were predicted from HT field mass balance models coupled with a predictor for near-field human exposure. Joint regression on all factors provided a calibrated consensus exposure prediction and a measure of variance conveying the uncertainty of the predictions. These values were compared against the calculated oral equivalents to assess the potential that actual exposures might elicit bioactivity. Exposure predictions across the lower and upper 95th confidence interval typically spanned eight orders of magnitude. Comparison of the minimum oral equivalent to the upper bound exposure prediction indicated that 49 and 95 of the 178 chemicals had MOEs < 1 and < 100, respectively. Application of these HT tools provides a first order approximation of MOEs to aid in prioritization of testing. Efforts are underway to reduce the uncertainty in the exposure predictions and increase the utility of this approach. This abstract does not necessarily reflect EPA policy.

2250b Development of Reverse Toxicokinetic Models to Correlate In Vitro and In Vivo Estrogen Receptor Activity

X. Chang1, N. Kleinstreuer1, P. Cegert1, J. T. Hamlin1, B. Jones1, L. Rinckel1 and W. Casey1. 1ills, Inc., Research Triangle Park, NC and 2DHHS/NIEHS/NTP/NICEATM, Research Triangle Park, NC.

Through the use of Tox21 high-throughput screening (HTS) program, efforts are underway to use quantitative high throughput in vitro assays to assess chemical effects across multiple cellular pathways, including the estrogen receptor (ER) pathway. HTS assays provide an efficient way of identifying potential biological targets for chemicals. However, the nominal in vitro assay concentrations may not accurately reflect the potential in vivo effects of these chemicals due to the differences in bioavailability and clearance. A set of pharmacokinetic models was developed to correlate in vitro concentrations with potential in vivo effects for Tox21 chemicals with potential to interact with the ER. These models estimate the daily oral doses in laboratory animals and humans for Tox21 ER active chemicals that would result in a steady-state in vivo blood concentration equivalent to the in vitro AC50 (concentration at 50% maximum activity) values identified using HTS assays that specifically target the ER pathway. These models were built using published experimental data and quantitative structure–activity relationship predictions for hepatic metabolic clearance and unbound plasma protein fraction for tested chemicals. The models were also adapted to incorporate infant physiology to include this most vulnerable human population. Using daily oral doses estimated from the model, Tox21 ER active chemicals were ranked, with chemicals having the lowest effective dose in these models being considered the most likely to interact with the ER, and further, as agonists or antagonists. The estimated oral dose for a subset of chemicals was also compared to the in vivo dose range reported to elicit ER-related effects. This project was funded in whole or in part with Federal funds from the NIEHS, NIH Under Contract No. N01-ES-35504.

2250c Estimation of Methylmercury Intake Doses in the South Korea Population Using a PBPK Model

S. Lee1, Y. Tan2, J. Sobus2, M. Phillips3 and S. Kim1. 1School of Public Health, Seoul National University, Seoul, Republic of Korea, 2NERL, US EPA, RTP, NC and 3NERL, US EPA, Duluth, MN.

Recently, South Korea has measured total mercury (Hg) in blood as part of Korean National Environmental Health Survey (koNEHS) in 6311 subjects representing Korean general population. About 25 % of the biomarker measurements were above the German HBM1 (biomonitoring guidance value) of 5 μg Hg/L and...
about 1% was above the HBMD of 15 μg Hg/L. Among the various mercury-containing compounds, methylmercury (MeHg) is the most toxic because of its ability to be readily absorbed and to accumulate in the body. It has been linked to developmental deficits in children and increased risk of cardiovascular disease in adults. USEPA has a guidance value for MeHg exposure, but it is reported as a daily intake dose, requiring an exposure reconstruction step in order to compare the measured biomarker concentrations with average intake. Thus, the current study used these biomarker data to further investigate the potential of this population being exposed to MeHg at or above the U.S. Reference Dose (RfD) of 0.1 μg MeHg/day. First, total blood Hg concentrations were converted to MeHg using a randomly selected MeHg/Hg ratio from a previously reported distribution measured among South Korean. Next, these estimated blood MeHg concentrations were used to reconstruct MeHg intake amounts using a published physiologically based pharmacokinetic (PBPK) model for MeHg. Monte Carlo analysis was conducted to account for variability in physiology and pharmacokinetics in estimating the distribution of MeHg intake. The resulting mean amount was 2.88 μg/day, which is comparable to the estimate from the South Korean environmental monitoring report in 2011 based on MeHg residues in fish (2.8 μg/day). The estimated mean dose was 0.045 μg/kg/day, which was approximately half of the RfD, and above 10% of the estimated doses were higher than the RfD. Additional analysis will be conducted to examine what variables are associated with those biomarker measurements that are higher than the other guidance values.

Protecting Astronaut Health at First Entry into Vehicles  
Visiting the International Space Station: Insights from Whole-Module Offgas Testing  

NASA has accumulated considerable experience in offgas testing of whole modules prior to their docking with the International Space Station (ISS). Since 1998, the Space Toxicology Office has performed offgas testing of the Lab module, both MPL modules, US Airlock, Node 1, Node 2, Node 3, ATV1, HTV1, and three commercial vehicles. The goal of these tests is twofold: first, to protect the crew from adverse health effects of accumulated volatile pollutants when they first enter the module on orbit, and secondly, to determine the additional pollutant load that the ISS and its systems must handle. In order to predict the amount of accumulated pollutants, the module is sealed for at least 1/5th the worst-case time interval that could occur between the last clean air purge and final hatch closure on the ground and the crew’s first entry on orbit. This time range can come from a few days to a few months. Typically, triplicate samples are taken at pre-planned times throughout the test. Samples are then analyzed by gas chromatography and mass spectrometry, and the rate of accumulation of pollutants is then extrapolated over time. The analytical values are indexed against 7-day spacecraft maximum allowable concentrations (SMACs) to provide a prediction of the total toxicity value (T-value) at the time of first entry. This T-value and the toxicological effects of specific pollutants that contribute most to the overall toxicity are then used to guide first entry operations. Finally, results are compared to first entry samples collected on orbit to determine the predictive ability of the ground-based offgas test.

Public Health Concerns Surrounding Fine Particulate Matter Generated from Hydraulic Fracturing  
A. LeBeau and A. Pawlik, CRA, Dallas, TX.

To evaluate the potential impact of fine particulates on public health in communities relatively close to hydraulic fracturing (i.e., fracking) activities, a preliminary evaluation of available particulate matter (PM2.5) data from three air monitoring stations in the Dallas, TX area was conducted. Annual air quality monitoring data for 2013 was obtained from the Texas Commission of Environmental Quality (TCEQ) web site. Air quality monitoring stations in Texas Region 4 sampled and monitored ambient air and meteorological conditions to generate the hourly averages that were used for this data analysis. The monitoring stations selected for this evaluation were: CS6 at Denton Airport South; C52 near Midlothian, TX; and C1044 near Haltom City, TX. The stations were selected due to the fact that they recorded PM2.5 and wind direction data that were needed to evaluate any potential impacts from fracking activities. These locations were also identified due to their relative distance from the potential influence of the Dallas/Fort Worth metro area. Geometric means of annual PM2.5 concentrations were determined for each location, for both PM2.5 appearing to originate from heavy fracturing activity, and for PM2.5 appearing to originate from a direction relatively free of fracturing activity. Wind direction was used to estimate the origin of the PM2.5. At all three locations, the annual PM2.5 concentration from the direction of fracturing was significantly elevated in comparison to the PM2.5 concentration facing away from the heaviest fracturing activity in the area (i.e., CS6: Toward Fracking (TF) PM2.5=7.6 μg/m3 vs. Away from Fracking (AF) PM2.5=6.2 μg/m3, p<0.001; C52: TF PM2.5=9.0 μg/m3 vs. AF PM2.5=5.8 μg/m3, p<0.001; C1044: TF PM2.5=7.6 μg/m3 vs. AF PM2.5=6.3 μg/m3, p<0.001). No direction-specific concentrations were above the primary EPA annual PM2.5 air quality standard of 12 μg/m3. These preliminary data indicate that mean PM2.5 levels from the direction of fracking are significantly higher than those from the direction that is relatively free of nearby fracking activities; however, the levels are not above the annual EPA standard.

Cancer Risk of PAHs in Particulate Matter from Biofuel Combustion  

The risk of cancer attributable to PAH exposure has been assessed, in the light of increased use of biomass for space heating associated to the financial crisis over the last couple of winters. Ambient air PMs was sampled in several urban sites, and analysed chemically for PAHs and levoglucosan, used here as the most specific tracer of biomass combustion. Internal exposure to PAHs was estimated taking into account the deposition of the respective PM fractions across the human respiratory tract (HRT). Deposition at different regions of the HRT was carried out using the Multiple-Path Particle Dosimetry (MPPD) model. MPPD calculates the deposition and clearance of mono- and poly-disperse aerosols in the respiratory tract of rats and human adults and children (deposition only) for particles ranging from ultratine (0.01 microns) to coarse (20 microns) sizes. Potential cancer risk due to exposure to the mixture of PAHs in urban ambient air was calculated according to the toxicity equivalence factor (TEF) approach using as basis the benzo[a]pyrene (Ba[a]P) cancer potency. The Ba[a]P-TEQ (Toxicity Equivalent Quotient) (carcinogenic equivalent, in ng/m3) was calculated by multiplying the concentrations of each compound in the PAH mixture with the respective TEF for cancer potency relative to Ba[a]P. To estimate cancer risk the TEQ of the respective fraction of particulate matter deposited across HRT daily, was multiplied to a dose-response function, derived from the [Ba[a]P] Inhalation Unit Risk (the latter is equal to 0.88E-6 (ng/m3)-1). Significant variation in risk was observed among different age groups, much larger than variation due to geospatial attributes. The risk for children is four times higher than for adults. Only limited difference was found between traffic and urban background sites in the winter (mean cancer risk for both is close to 10-6). The carcinogenic potency of PM emitted from biofuel combustion (main PM source of the urban background pollution) was slightly higher compared to the potency of traffic-originated PM when using conventional fuel types.

Data Source Summary Documents (DSSDs) Derived for Updated Drinking Water Standards and Health Advisories (DWSHA) Tables  

The DWSHA tables, sponsored by the U.S. Environmental Protection Agency’s (EPA’s) Office of Water (OW), summarize the drinking water regulations and Health Advisory (HA) values as well as the reference dose (RfD) and cancer risk values for drinking water contaminants. The tables provide Maximum Contaminant Level Goals (MCLGs), Maximum Contaminant Levels (MCLs), and HAs. HAs in the tables are guidance values based on non-cancer health effects for different durations of exposure (one-day, ten-day, and lifetime) or a specific probability of cancer (10-4 – 10-6 cancer risks). HAs are recommendations for unregulated drinking water contaminants to protect public health as needed. Based on EPA policy, all DWSHA Tables published after 2012 will calculate lifetime HAs for all contaminants with RfDs, regardless of their carcinogenicity status. This will allow risk assessment managers to compare the noncancer and cancer values and determine which level provides a more meaningful scenario-specific risk reduction.

A systematic review of the DWSHA table was initiated in 2012 to ensure that the benchmark values are consistent with the most current EPA assessments and all contaminants with RfDs have lifetime HAs. A total of 75 RfD and oral slope factor updates were identified that needed to be confirmed. The associated DWEL, Lifetime HA, or Cancer Risk values are being recalculated accordingly. Additionally, 29 contaminants without lifetime HAs will be reviewed. These changes are summarized in Data Source Summary Documents (DSSDs), along with principal study information and uses and occurrence, and hypertexted to the DWSHA Tables. Quality assurance/control is an ongoing process to review.
Toluene and Dibutyl Phthalate in Nail Lacquers: A Proposition 65 Exposure Assessment

L. Keenan, L. Kopelovich and N. Jacobs.
Cardno ChemRisk, San Francisco, CA.

Toluene and Dibutyl Phthalate (DBP) can be found in many consumer products, including nail lacquers. In 2012, the California Environmental Protection Agency (Cal EPA) evaluated 25 nail products and found that 64% of lacquer polishes contained toluene and 28% contained DBP. Concentrations of toluene and DBP ranged from 42 to 190,000 ppm and 14,000 to 88,000 ppm, respectively. Exposure to these chemicals is regulated by the California Safe Drinking Water and Toxic Enforcement Act of 1986 (commonly referred to as Prop 65). The purpose of this study was to estimate consumer exposure to toluene and DBP from nail lacquers via dermal and inhalation exposure routes. Using the results collected by the Cal EPA, a Prop 65 exposure assessment was performed based on minimum, median, and maximum toluene and DBP concentrations in nail lacquer. Inhalation exposure was estimated using standard conservative exposure assessment equations, and dermal exposure was calculated using SkinPerm Quantitative Structural Activity Relationship methodology. The Maximum Allowable Dose Level (MADL) of toluene is 7000 µg/day and assumes that 50% of the inhaled toluene is absorbed. To compare the total absorbed toluene concentration from nail polish application to the MADL, we combined the estimated dermal exposure with 50% of the calculated inhalation exposure. Our estimated absorbed toluene dose for a consumer ranged from 39.5 to 1.8 x 10^5 µg/day. Overall, most concentrations of toluene reported by the Cal EPA resulted in exposures that fell below the Proposition 65 MADL; however, higher toluene concentrations resulted in exposure values that exceeded the MADL. Given the negligible volatilization rate of DBP, only dermal exposure was evaluated. Consumer DBP exposure ranged from 3.4 x 10^3 to 4.2 x 10^3 µg/day. All estimated DBP exposures were above the MADL of 87.5 µg/day.

A Tiered Safety Assessment Approach for Evaluating Chemicals in Consumer Products and Applications for Asthma Risk Management

Toxicology Excellence for Risk Assessment, Cincinnati, OH, 2University of Cincinnati, Cincinnati, OH and 3Jayjock & Associates, Langhorne, PA.

Asthma is a complex syndrome with potentially severe consequences. The number of affected individuals is growing, although the reason for the increase is uncertain. Substantial evidence that exposure to some chemicals is linked to asthmatic responses increases the need for effective management of potential chemical exposures. A safety assessment approach tailored to the screening of asthma risks from consumer product ingredients was developed for use as a risk management tool. Several key features of the approach advance the use and integration of assessment resources often used for asthma investigations. First, a quantitative health benchmark for asthma or related endpoints (irritation and sensitization) is provided that extends the assessment beyond qualitative hazard classification methods. Second, a parallel structure includes methods for dose-response assessment of asthma endpoints and for scenario specific exposure estimation. The two parallel tracks are integrated in a risk characterization step. Third, a tiered assessment structure is provided to accommodate different amounts of data for both dose-response assessment (i.e., use of existing benchmarks, hazard banding, or the threshold of toxicological concern) and exposure estimation (i.e., use of empirical data, model estimates, or exposure categories). Tools building from traditional methods and resources have been adapted to address specific issues pertinent to asthma toxicity (e.g., mode-of-action and dose-response features) and the nature of consumer cleaning product use scenarios (e.g., product use patterns and exposure durations). A case study for acetic acid was used in various sentinel products and residential cleaning scenarios, was developed to refine and verify relationships among tiered approaches within the safety assessment methodology with the goal that each lower data tier in the approach provides a similar or greater margin of safety for a given scenario.

Use of Text-Mining and Machine Learning to Prioritize the Results of a Complex Literature Search

Sciome LLC, RTP, NC, 2OHAT, National Toxicology Program, NIEHS, RTP, NC, 3Office of Scientific Information Management, NIEHS, RTP, NC and 4SSS, Durham, NC.

As part of the effort to conduct various meta-analysis studies, literature reviews and technical reports, toxicologists routinely conduct complex searches of the scientific literature. These searches can yield thousands or tens of thousands of candidate documents. Human curation of this large literature set is resource intensive. To that end, we have developed and implemented, in collaboration with NIEHS, tools and procedures that can assist researchers in prioritizing, filtering and organizing these large literature search results. To demonstrate the effectiveness of this approach, we tested our software using a set of 48,638 articles identified by researchers as potentially relevant in a review of the transgenerational inheritance of health effects. Given only the title and abstract information available from PubMed, human curators applied complex inclusion and exclusion criteria to identify the relevant subset from these candidates. This time-consuming baseline approach identified 765 “included” documents. 47,873 “excluded” documents. Compared to the manual process, the system we have developed makes this baseline approach more efficient by (1) Prioritizing the results such that relevant documents are more likely to appear near the top of the ranked results list, and (2) Organizing/clustering search results according to major themes and topics in a manner that makes it more manageable to navigate the resulting literature. For example, using a randomly selected “seed” consisting of only 50 included and 50 excluded documents, our system ranked the remaining unlabeled documents such that 56% and 93% of the included documents occurred in the top 10th and 50th percentiles, respectively. Furthermore, the system conveniently organizes the document set for interactive browsing using MeSH terms and other user-defined categories. Together, these facilities will allow researchers to identify relevant literature more efficiently, and to spend more time on the analysis and interpretation of the resulting documents.

HAWC (Health Assessment Workspace Collaborative): A Modular Web-Based Interface to Facilitate Development of Human Health Assessments of Chemicals

A. Shapiro and I. Rusyn.
Env. Sci. and Engin., Univ. North Carolina at Chapel Hill, Chapel Hill, NC.

Regulatory agencies conduct assessments of the potential for chemicals to pose a threat to human health. Such assessments typically consist of a critical review of available studies to identify adverse health effects to characterize exposure-response relationships. In addition to the systematic review of pertinent studies and the
an analyses of available data, opportunities for public input and multiple levels of scientific review are also critical steps to engage stakeholders who may be affected. The overall framework for how assessments are performed and what information should be evaluated is well established, yet the format and the process for how assessments are conducted remain to be a notable and persistent challenge. In this project, we aimed at addressing these challenges by creating a modular, web-based content-management system to synthesize multiple data sources into overall human health assessments of chemicals. We created an online tool, HAWC (Health Assessment Workspace Collaborative, https://hawcproject.org/) which integrates and documents the overall workflow from literature search and review, to data extraction, evidence synthesis through visualization tools, dose-response analysis, uncertainty characterization, and customized reports. Crucial benefits of such a system include improved integrity of the data and analysis results, greater transparency, standardization of data presentation, and increased consistency. By utilizing a web-based workspace, assessment team members can collaborate on the same project rather than share files and track edits. Utilizing HAWC as a web-based portal for reviewers and stakeholders, all interested parties have dynamic access to completed and ongoing assessments. Overall, this project creates a clear summary of the results of the assessment, and a source for primary data and/or tabulated study summaries and visual aids that constitute the scientific justification for its conclusions.

2251 Toxic Effects of Secondhand Smoke-Revealing Mechanism by Systems Biology Approach
1Cambridge Cell Networks Ltd, Cambridge, United Kingdom and 2Cell Networks, University of Heidelberg, Heidelberg, Germany.

The aim of this study was to investigate mechanism that enables tobacco smoke components to induce cardiovascular system toxicity. Secondhand smoke (or ETC) contains around 90 known toxic compounds emitted from tobacco combustion. We focused on 8 compounds labeled as harmful and potentially harmful constituents (HPHCs) by FDA and present mainly in the side-stream smoke with side-stream to mainstream smoke ratio of two. We created a computational model of biological pathways describing cellular processes activated by these compounds by manually annotating and processing molecular information from the literature from the public domain (PubMed articles and FDA reports) and made the data computable. We generated a comprehensive database of known side effects and protein targets of these 8 compounds. By applying bioinformatics analysis tools to this data we have identified several adverse effects regarding heart diseases, reproductive and developmental toxicity. For each of these adverse effects we generated the hypothesis of mechanism of action that is supported by current knowledge.

2252 Profiling Environmental Chemicals That Induce the Antioxidant Response Pathway Using Cell-Based Assays and Cheminformatics Tools
M. T. Kim, A. Sedykh, J. Zhang, R. Huang, M. Xia, and H. Zhu.
1Chemistry, Rutgers, The State University of New Jersey, Camden, NJ, 2Center for Computational and Integrative Biology, Rutgers, The State University of New Jersey, Camden, NJ, 3Multiplex Inc., Blackwood, NJ, and 4Center for Advancing Translational Sciences, Division of Health and Human Services, Rockville, MD.

Oxidative stress causes cell damage which can lead to a variety of neurodegenerative diseases. Exogenous compounds that induce oxidative stress cause cell damage which triggers the transcription of antioxidative genes located in the antioxidant response element (ARE) signaling pathway. This process is essential for alleviating cell injury, but the mechanisms that lead to cytotoxicity and further animal toxicity are still unclear. Previously, a cell-based ARE beta-lactamase reporter gene assay was used to screen 14,086 compounds in the National Toxicology Program (NTP) library in a Quantitative High Throughput Screening (qHTS) format. Then, compounds that induced the ARE pathway were identified. In this study, we first used various Quantitative Structure-Activity Relationship (QSAR) approaches to develop predictive ARE models. The resulting models were used to virtually screen other compounds of interest (e.g. Tox21 chemical library). Next, we used our in-house automatic profiling tools to gather and analyze available animal toxicity data for each of the compounds in both the NTP-14086 and the extended chemical library. The in vitro and in vivo relationship established by this step could be used to develop predictive models for complicated animal toxicity endpoints (e.g. those of neurotoxicity). The final alternative computational toxicity predictors could be used to prioritize potentially toxic compounds that cause oxidative stress and induce the ARE pathway.

2253 Improving the Development of Adverse Outcome Pathways: Lessons Learned from the AhR Rodent Liver Tumor and AhR Avian Teratogenicity/Embryolethality AOPs
1American Chemistry Council, Washington, DC, 2Tel Simon LLC, Winston, GA, 3Dupont Haskell Global Centers, Newark, DE, 4Environment Canada, Ottawa, ON, Canada and 5The Dow Chemical Company, Midland, MI.

An adverse outcome pathway (AOP) represents the sequence & causal linkages between initial molecular events, key events and an adverse outcome. As part of the OECD AOP Programme, we separately developed an Aryl Hydrocarbon Receptor (AhR) AOP for rat liver tumor promotion (RLTP) & an AhR AOP for avian deformities/lethality & then collaborated to enter these in the AOP Wiki (beta). Differing levels of polymorphism-dependent AhR activation provides strong evidence identifying AhR activation during critical periods of avian development as the molecular initiating event (MIE) for avian teratogenicity/embryolethality. While AhR binding is the initial molecular event, there is strong evidence that sustained AhR activation for a significant portion of the lifespan is the MIE causally related to RLTP. In developing & adapting these for the AOP Wiki, we arrived at a recommendations applicable to other AOPs; these are 1) recognizing that while receptor binding & acute changes in gene transcription may be the IMEs, they do not always predict the MIE & the Wiki should be revised accordingly; 2) expanding the AOP Wiki structure beyond key events to include a) associative events (biomarkers that are not themselves necessary for the adverse outcome but are reliable indicators for key events) & b) modulating factors (e.g., aspects of homeostasis or other factors that may alter the occurrence &/or dose-response of the MIE or subsequent key events); 3) the need for a robust & transparent framework to document scientific confidence for use of the AOP & assays that measure responses related to each specific key event for predictive toxicology; & 4) the need to discuss explicitly application of the AOP for each different regulatory purpose: priority setting; chemical categorization; integrated approaches to testing & assessment (IATA); and screening level hazard/risk assessment.

2254 Data Mining Approach to Formulate Alerting Chemotypes for Liver Steatosis/Steatohepatitis/Fibrosis
1Altamira LLC, Columbus, OH, 2Liverpool John Moores University, Liverpool, United Kingdom, 3European Commission - Joint Research Centre, Institute for Health & Consumer Protection, Ispra, Italy and 4Bulgarian Academy of Science, Institute of Biophysics and Biomedical Engineering, Sofia, Bulgaria.

COSMOS oRepeatToxDB, oral repeat-dose toxicity database, is designed with an ontology describing toxicological effects at each dose level using controlled vocabulary, thus enabling mechanistic data mining. Observations are also coupled to organism-level sites and more specific effects at lower levels are formulated within hierarchical framework: organs/segments/tissues→cells/organelles. The majority of biological/chemical processes occur at the cell/organelle level, and so interactions between chemicals and proteins/gene are investigated in order to associate chemical structures with phenotypic effects resulting from related toxicity mechanisms. Furthermore, common structural fragments are extracted and refined into mechanistic chemotypes representing underlying molecular initiating events. We present a data mining view for liver steatosis, steatohepatitis and fibrosis. Over 20% of cosmetics-related chemicals in this database were associated with lipid deposition, fatty changes, cytoplasmic vacuolization, cellular infiltration and inflammation in various hepatocytes, ultimately leading to fibrosis. Combined phenotypic effects and morphological changes at various sites were mapped onto chemical compounds. Applying the ToxPrint chemotypes to these compounds, the set of alerting chemotypes for liver steatosis/steatohepatitis/fibrosis was identified. They include alcohols, diols, glycol ethers, aminophenols, tertiary amines, aromatic amines, polychlorinated short alkanes, halogenated amines, and Michael acceptors. Identification of these alerting chemotypes can be considered as the initial step in developing the categories used in safety/risk assessment. This approach also provides a way to investigate molecular pathways relevant to toxicological mechanisms. Supported by EU FP7 COSMOS Project.
Nephroticity and functional impairment in the kidney caused by drugs, have increased in recent years and become one of the major stumbling blocks in new drug candidates' safety. Currently, there are predominantly pre-clinical animal tests and in vitro models for assessing drug induced kidney injury (DIKI). The aim of this study is to develop, accelerate and ratify a unique computational model as a strategy in predicting drug induced organ injury, including DIKI. We manually annotated publicly available data (more than 10,000 articles) and proprietary company datasets (several thousand gene expression observations) related to nephrotoxicity, to build a complex molecular network of genes, proteins and chemicals within the knowledge base. We focused on known DIKI associated drugs, together with their metabolites, signaling molecules, nuclear hormone receptors and all known affected proteins for each relation within the knowledge base, with the ultimate goal in predicting possible kidney injury of a drug. We tested our system with the current standards of renal function, as blood urea nitrogen and serum creatinine, which were confirmed as proof of the concept for the DIKI. In addition, our model also confirmed recently discovered beta-2-microglobulin as molecule that could be used for detecting kidney injury.

Adverse outcome pathways (AOPs) describe the mechanistic link between a molecular initiating event (MIE) and an adverse toxicity outcome (AO). Anti-viral drugs, a class of compounds categorized as one of the most toxic in the FDA CIDER urinary tract toxicity dataset, were investigated to identify the mechanisms leading to renal toxicity. The FDA CIDER urinary tract toxicity dataset is based on the post-marketing adverse events of 1600 chemicals. Dataset clustering based on 70% sub-structure similarity provided five clusters covering purine and pyrimidine nucleosides, their corresponding phosphate nucleotide analogues, and other structurally related compounds. These classes were then investigated for the mechanistic pathways which lead to nephrotoxicity and the preparation of structural alerts for toxicity prediction. Four structural toxicity alerts were successfully implemented. These were based on publicly available in vivo reports of nephrotoxic events in man and other mammals, and data from relevant mechanistic in vitro assays. The collated data was also used to generate plausible mechanisms to describe the nephrotoxicity of anti-viral drugs in man and other mammals. We report the construction of AOPs to describe the mechanisms of the in vivo nephrotoxicity of anti-viral drugs. Structurally related nucleoside and nucleotide drugs lead to histologically and biochemically proven structural and functional alterations of both proximal tubular and glomerular cells. Proximal tubulopathies such as Fanconi syndrome and acute tubular necrosis, and glomerulopathies such as minimal change nephropathy and focal segmental glomerulosclerosis have been reported. Mitochondrial toxicity has been implicated in these highly metabolically active renal cells as one potential MIE, which is likely to be related to the clinical mode of action of these compounds in vivo. Furthermore, these compounds can act as potent inhibitors of mitochondrial polymerase gamma, which leads to mitochondrial toxicity.

We analysed rodent fetal dysmorphogenesis data (2141 chemicals) within the FDA CDER reproductive toxicity non-proprietary dataset. These data were investigated to identify pathways leading to teratogenic outcomes. Androgen receptor binding, estrogen receptor binding, 5alpha-reductase inhibition and aromatase inhibition were amongst the identified modes of action. Further literature work was undertaken to identify plausible supporting data, pathways and mechanisms. It was found that disruption of these pathways by xenobiotics and the subsequent mis-regulation of hormones can lead to teratogenic effects in developing sex organs and cause specific syndromes of defects in offspring. In rodent studies the most sensitive period of treatment is late organogenesis. Compounds may interact with various parts of these pathways rather than just at one point. Different receptor binding sites have a high degree of similarity and substrates may act as both agonists and antagonists depending on the conditions present. The sex which is predominantly affected can depend on the target and the type of binding. 5alpha-reductase inhibitors predominantly affect male offspring whereas the effects of estrogen receptor antagonism can predominantly be seen in female offspring. Investigations for compounds inhibiting the aromatase enzyme highlight data and knowledge gaps in the literature.

We report the construction of AOPs for in vivo teratogenicity, where the molecular initiating events are receptor based. The AOP framework helps to view how subtle differences in perturbation of the pathways can affect the final outcome.

Silent Spring Institute, Newton, MA.

Breast cancer is the most common cause of death of middle-aged American women and few preventable risk factors have been identified. Identifying breast carcinogens could lead to risk reduction, but this has not been a focus of toxicological research. High throughput screening initiatives such as ToxCast and Tox21 hold great promise for filling in data gaps on chemical hazards. We investigated the coverage of current ToxCast and Tox21 assays with respect to breast cancer-relevant pathways such as endocrine and cancer hallmark endpoints identified previously by an expert panel, comparing the two to identify gaps. We systematically searched ToxCast and Tox21 assay descriptions for keywords reflecting endocrine, cancer hallmark, and related pathways. We also searched for assays conducted in breast cells or with proteins isolated from breast cells. We verified our results with members of the ToxCast team. ToxCast and Tox21 contain several assays intended to evaluate chemicals' effects on estrogen signaling pathways and cancer hallmark pathways, both categories of pathways believed to be important in breast cancer etiology. However, other im-
portant pathways and endpoints, including Her2, ER-β, and expression of breast cancer-relevant genes, are less well represented, whether because they were not prioritized, or because of difficulties in developing suitable high throughput assays. ToxCast and Tox21 currently include assays measuring ER, PR, AR, and aromatase, as well as cell growth kinetics, cell cycle perturbations, steroidogenesis, and apoptosis, in breast cells or proteins isolated from breast cells. Measurement of gene expression, growth signals, metabolism, and other endpoints in breast cells might provide additional important information about breast cancer risk. This disease-focused approach can be extended to other health effects, such as neurotoxicity or asthma, in order to suggest additional assays for high throughput screening projects.

2260 High-Content Screening of Rodent Mammary Gland Carcinogens in Two Breast Cell Lines
J. M. Ackerman1, C. Vulpe1, A. Tagmount1 and R. Rudel2. 1University of California, Berkeley, CA and 2Silent Spring Institute, Newton, MA.

Breast cancer is the most common cause of death of middle-aged American women and few preventable risk factors have been identified. Identifying breast carcinogens could lead to risk reduction, but this has not been a focus of toxicological research. High throughput testing methods, such as those being developed in US EPA ToxCast and NTP Tox21 programs, have the potential to identify carcinogens more quickly and cheaply than traditional rodent bioassays; the predictive power of these methods is still being evaluated. We used high content screening to measure the responses of two human mammary epithelial cell types, MCF7 (derived from a tumor) and MCF10A (derived from normal cells), to 24 and 72 hour exposures to a set of 111 chemicals relevant to breast cancer. Endpoints included measurements of DNA damage repair (p53, pH2AX), mitochondrial health, and cytoskeletal integrity (tubulin), among others, but no endocrine-related pathways. Because few human breast carcinogens have been identified, we tested 74 rodent mammary carcinogens (MCs), 19 ‘non-carcinogens’ that did not induce any tumors in NTP bioassays, and 18 chemicals that disrupt mammary gland development in rodents. Comparing the two time points, assays run with 72 hours of exposure were more sensitive than those measured after 24 hours of exposure in either cell line, with more chemicals showing activity and more of the active chemicals showing activity at lower doses. Comparing the two cell lines, most assays were more sensitive in MCF10A than in MCF7 after 24 hours, and more sensitive in MCF7 than in MCF10A after 72 hours. Chemicals previously demonstrated to be genotoxic without metabolic activation in the Ames assay did not show more activity than Ames-negative chemicals in the two assays reflecting DNA damage repair (p53 and pH2AX). Additional research is required to relate high content screening endpoints to standard toxicity tests such as genotoxicity batteries and Ames, and to understand the importance of cell line and exposure conditions.

2261 Re-Evaluation and Expansion of the US FDA/CDER Rodent Carcinogenicity Database for Structure-Based Analysis

A high-quality database of well-characterized toxicities linked to chemical structures is crucial to the development of structure-activity relationships. In order to have available the most accurate experimental data possible for structure-activity relationship development and read-across purposes, we re-analyzed the results of laboratory testing of the 1683 chemicals in the FDA/CDER rodent carcinogenicity database using contemporary standards, with a focus on extracting additional data fields and employing a more structured format for data archiving than in previous efforts. Test protocols were re-evaluated by OECD TE 451 and ICH S1B standards, including the selection of test animals, dosage, dosing duration and study duration, clinical examinations and histopathology evaluations. For pharmaceticals, statistical significance in pair-wise comparison to concurrent controls (Fisher’s Exact Test or an equivalent statistical analysis) was defined for rare tumors as \( p \leq 0.025 \) and common tumors as \( p \leq 0.005 \). For other chemicals, significance was defined for rare tumors as \( p \leq 0.05 \) and common tumors as \( p \leq 0.01 \). A numerical activity scale algorithm was designed to consistently quantify and stratify the results of the rodent carcinogenicity studies to enable more sophisticated computer analyses of structure-based trends. Among all reviewed chemicals, 190 are rodent carcinogens which cause tumors in male and female rats and mice, 364 are non-carcinogens. 98 out of the 190 carcinogens target the same organs across species and gender. The number of chemicals that are tumorigenic to male rats, female rats, male mice and female mice is 519, 482, 447, and 459, respectively. The most common tumor sites are the liver and lung. All organ-specific carcinogenicity data, supporting citations, and their respective chemical structures will be made available to the FDA/CDER community as a structurally searchable data repository, facilitating complex structure- and text-based queries, and supporting the development of quantitative structure-activity relationships.

2262 Establishing Best Practice for the Application of a Novel Statistical-Based Model to Evaluate Potential Mutagenic Impurities under ICH M7
C. Barber1, T. Hanser1, N. L. Krulhak2 and L. Stavitskaya2. 1Research, Lhasa Limited, Leeds, United Kingdom and 2US Food and Drug Administration, Silver Spring, MD. Sponsor: C. Marchant.

Under the emerging International Conference on Harmonisation (ICH) M7 guideline, a safety assessment of a pharmaceutical impurity may, in some instances, be performed using in silico-based methods without the need for in vitro testing. Such assessments should consist of a statistical-based method (QSAR) and an expert rule-based method (SAR), both of which should be consistent with OECD guidelines for the regulatory use of (Q)SARs. These models need to be appropriately applied to ensure accurate and trustworthy predictions are generated. Furthermore, model predictions should be transparent and scientifically explicable to support the expert assessment recommended under the guideline.

In this work, we present best practice for the application of a new statistical-based QSAR software, Sarah Nexus, for the assessment of the genotoxic potential of pharmaceutical impurities. Sarah Nexus utilizes a novel machine-learning approach based upon self-organizing hierarchical networks, and was used to construct a statistical model based upon Salmonella mutagenicity data. The methodology allows for the tuning of model performance to balance sensitivity against specificity, as well as overall accuracy against coverage. To establish best practice, optimal model application settings were assessed using two independently-derived external validation sets containing 513 (19% positive) and 809 (42% positive) compounds. The same optimal settings of 10% sensitivity (defines the relative impact of positive signals) and 10% equivocal (the threshold under which the signal is not strong enough for the model to make a call) were identified for both cases, resulting in balanced accuracy of 74 and 77%, sensitivity of 64 and 68%, and specificity of 86 and 85%, respectively, for the two validation sets. While coverage is reduced to 81 and 86% under these conditions, this is considered an acceptable trade-off in favor of overall improved accuracy and, in particular, improved sensitivity.

2263 Genotoxic Risk Assessment of Impurities in Drug Substances

CPMP/SWP/S199/02 (2006) guidelines for Europe and FDA draft guidance (2008) for US are the current main reference documents for dealing with genotoxic and carcinogenic impurities in drug substances. An international effort for addressing different approaches and sometimes inconsistencies or gaps in the multiple guidances or papers published from different international bodies (ICH, EMA, PhRMA, FDA) is ongoing by the International Harmonization Conference (ICH), which M7 guideline is currently in step 2.

In this poster focus is given to the genotoxic impurity issue, describing the internal (Aptakis) Genotoxic Risk Assessment (GRA) process and presenting an overview of the results obtained from GRAs performed in the past three years. A perspective and process change once M7 guideline is released is also presented/discussed. GRA is an integrated, multidisciplinary process, involving essentially chemists, analysts and toxicologists, with the aim to evaluate the potential presence of genotoxic (DNA reactive, mutagenic) impurities in drug substance. The chemical route is first evaluated for potentially mutagenic compounds as defined by the “Genotoxic Impurities of High Concern” list of functional groups. Intermediates, reagents, major by-products (including reaction of reagents with solvents) and degradants are considered. Chemical structure rising concern are submitted to Derek Nexus (Lhasa Limited) for identification of structural features alerting for mutagenicity and carcinogenicity; those with confirmed alerting structure are submitted to the Ames test. Genotoxins should be removed or controlled at TTC (Threshold of Toxicological Concern) level. The group has evaluated in the past three years 20 synthetic routes (133 chemical stages), for an overall amount of approx 800 chemical structures assessed, of which 97 structures were recommended to DEREK screen. For most of these structures a control strategy was developed and only 59 were actually submitted to the analysis in silico. From these, 16 were confirmed to have mutagenicity and/or carcinogenicity concern. Ames test resulted positive for 3 structures.
It has long been axiomatic that predictive toxicology models built on data available in the public domain can encounter problems when attempting to predict proprietary data, e.g. from a drug development program. Conversely, model performance against public data is often used to support the selection of models for specific applications and such analyses are often published. One outcome of some recent model development work has been to produce metrics that can be used to experimentally test the axiom and assess the validity of basing conclusions on public data. A large data set, based primarily on public data, was used to identify improvements to an expert knowledge base for (Ames test) mutagenicity. These improvements were implemented as new or modified structural alerts, and were incorporated into successive knowledge base iterations. The performance of each iterative build was evaluated against a large public data set (Benchmark) and a proprietary data set (Vitic Intermediates).

Our analysis showed that the addition (or modification) of structural alerts consistently improved the detection of mutagens within the Benchmark data set. However, this improvement was not mirrored against the Vitic Intermediates data set.

It can be concluded that performance against public data should be weighted accordingly when considering the use of models within a given chemical space. This experimentally supports the original axiom, at least in part, and suggests that building a model comprising only of public datasets (however large) may not be sufficient to allow accurate predictions within proprietary chemical space. However, further analyses would be required to verify the robustness of this conclusion (e.g. other pharmaceutical data sets) and also to read-across these results into other domains (e.g. agrochemicals or personal care products). Future work will focus on this, as data become available.

**Development of an In Silico Profiler for Mitochondrial Toxicity**

M. D. Nelms1, M. T. Cronin1, A. N. Richarz1, C. Yang2 and S. J. Enoch1.

1School of Pharmacy and Chemistry, Liverpool John Moores University, Liverpool, United Kingdom and 2Altamira LLC, Columbus, OH.

Disruption of normal mitochondrial functioning can result in cell death and is implicated within a variety of diseases. There are a number of mechanisms by which normal functioning can be impaired these include, but are not limited to, uncoupling of oxidative phosphorylation, inhibition of the electron transport chain and membrane permeability induction. Mitochondrial toxicity has been identified as a source of chronic toxicity in a number of drugs leading to their withdrawal from the market. Thus, the ability to identify chemicals potentially capable of this type of toxicity would be of benefit in the risk assessment process. Despite this, few in silico methods have been developed capable of making such predictions. Therefore, the purpose of this study was to develop an in silico profiler consisting of a series of structural alerts related to the mechanisms involved in mitochondrial toxicity. Data for 288 compounds identified as being either toxic or non-toxic to mitochondria were extracted from the literature. Structural similarity was undertaken to group the data, producing fourteen categories, from which nine structural alerts were identified, covering nine chemical classes and five mechanisms of mitochondrial toxicity. The nine chemical classes covered include thiadiazolidinediones, anthracyclines and cholic acid derivatives. The identified mechanisms were uncoupling of oxidative phosphorylation, inhibition of the electron transport chain, induction of membrane permeability transition, alternative electron acceptance and initiation of the death receptor pathway. These structural alerts were supported by mechanistic information from the literature allowing the chemistry of the Molecular Initiating Event to be defined. In addition, a new structure knowledge representation method, chemotype, is also used to extract mechanistic alerts from the dataset. The alerting chemotypes can also be deployed in KNIME node or on ChemOtyper (free software from FDA). Supported by the EU FP7 COSMOS Project.
In silico prediction of off-target pharmacology and adverse effects for small molecule drugs has been hampered by small and/or poorly representative training sets, and subsequently low predictivity. Here we present the results of an evaluation of the Similarity Ensemble Approach (SEA) to large scale prediction of off-target pharmacology. SEA calculates whether a molecule will bind to a target based on the chemical features it shares with known ligands, using a statistical model to control for random similarity. An independent test of over 200 proprietary compounds was evaluated for off-target interactions in comparison to actual ligand binding or enzyme inhibition data across approximately 150 targets. Using a training set based on publically available data (CheMBL14), the prediction accuracy was poor and close to random (AUC of 0.53), however a second independent test set of over 850 well known drugs and chemicals had improved prediction accuracy (AUC of 0.79). As a result it was hypothesized that good prediction accuracy could be obtained if the training and test set compounds were structurally similar. To that end, we generated a training set based on a large comprehensive collection of internal drug-target interaction data and subsequently evaluated the algorithm using a 3-fold cross-validation approach. Using various affinity thresholds and compound fingerprinting methods, we consistently achieved high global prediction accuracy (AUC > 0.9). Sensitivity and specificity for individual off-targets could be optimized with altered thresholds to limit the number of false positives and still achieve a useful level of sensitivity. These results highlight the possibility of providing advanced knowledge of hundreds of off-targets based on structural information alone. It is anticipated such methods will be useful to guide selectivity screening strategies during lead optimization and provide novel insights to off-target toxicities not otherwise known.

**2270 Molecular Dynamic Simulation Studies of Bisphenol A and Its Analogs with Estrogen Related Receptor-Gamma and Human Androgen Receptor**

R. M. Uppu1, 2, 1Dept of Biology, Chemistry and Environmental Toxicology, Southern University and A & M College, Baton Rouge, LA and 2Biology Sciences, Louisiana State University, Baton Rouge, LA.

Bisphenol A (BPA) and several of its analogs are high volume chemicals used mainly in the manufacturing of polycarbonate plastics. It has long been recognized that BPA and its analogs behave as xenoestrogens, and can cause reproductive disorders. We have recently determined the free energies of binding of BPA and its chlorinated and nitrated products to the estrogen-related receptor-gamma (ERRγ) and compared the binding energies observed with the natural ligand, estradiol. These studies hold promise for characterizing binding pockets and changes in free energy of binding for biologically-relevant bisphenols and their environmentally-generated derivatives. The present study focuses on extending the molecular docking calculations/simulations to various BPA analogs based on binding to not only ERRγ but also to human androgen receptor (hAR) by performing Free Energy Perturbation (FEP) using NAMD software. The absolute binding free energies of the ligand complexes are computed by running annihilations forward and backward with explicit solvent. Restraining potentials were removed during the simulations to observe changes in conformational and translational energies of the ligand and receptor upon binding. The whole system was minimized and equilibrated before running the said annihilations to remove steric hindrance(s) between atoms. The net binding free energies of BPA and its analogs thus calculated are analyzed and compared with those of experimental values which revealed strong binding affinity of compounds towards the receptors when compared to the natural ligand. The results from this study are promising as they can be used to characterize binding pockets and changes in free energy of binding of BPA and helps in identifying the most significant molecular targets for xenoestrogens in general and BPA in particular [Support from NSF (HRD1043316) and the US DoEd (PO31B040030) is acknowledged; corresponding author’s email: rao_uppu@sbur.edu].

**2271 Amoxillin- and Pefloxacin-Induced Ionoregulatory Disruptions in Rat Tissues**

S. O. Restini1, 2, D. Ojo1, E. A. Balogun1, O. Talabi3 and O. Ademuyiwa1, 1Department of Biochemistry, Federal University of Agriculture, Abeokuta, Abeokuta, Ogun, Nigeria, 2Department of Microbiology, Federal University of Agriculture, Abeokuta, Abeokuta, Ogun, Nigeria, 3Health Centre, Federal University of Agriculture, Abeokuta, Abeokuta, Ogun, Nigeria and 4Department of Biological Sciences, Covenant University, Ota, Ogun, Nigeria.

Antibiotics are among the commonly prescribed and abused drugs in medicine. Their use is often associated with a variety of side/toxic effects. In order to investigate whether amoxillin and pefloxacin perturb electrolyte homeostasis, rats were treated with therapeutic doses of each antibiotic for 5 and 10 days respectively. Twenty four hours and 5 days after antibiotic withdrawal, blood and other tissues (liver, kidney, brain, heart and spleen) were removed from the animals analysed for their electrolyte contents and activities of Na+-K+- and Ca2+-Mg2+-ATPases. Molecular docking of the antibiotics against rat’s alpha-3 subunit of Na+-K+-ATPase (NCBI accession number: gi6978547) and Ca2+-ATPase (NCBI accession number: gi6758008) was also performed. After 5 days of pefloxacin administration, the activity of Ca2+-Mg2+-ATPase in erythrocyte ghost, liver, kidney, brain and heart dropped to 75%, 71%, 91%, 92% and 42% of the control respectively. Na+-K+-ATPase activity was reduced to 48% and 59% of the control in the kidney and brain respectively. There was however a reversal in the activities of renal and cardiac Na+-K+-ATPase as well as splenic and cardiac Ca2+-Mg2+-ATPase 5 days after the withdrawal of amoxicillin treatment. These culminated in hyponatremia, hypokalemia, hypocalemia and hyponagemesia. By day 15 however, there was a resolution of the ionoregulatory disruption. In silico docking revealed that three hydrogen bonds are formed between amoxillin and Glu818, Tyr1012, Arg930 and Arg827 of Na+-K+-ATPase. Pefloxacin however forms only one hydrogen bond with Arg930 of the enzyme. Only Glu875 and Pro828 of Ca2+-ATPase form hydrogen bond with amoxillin and pefloxacin respectively. The findings of this study further refuel the pattern and mechanisms of ionoregulatory disruptions by these antibiotics.

**2272 Enhanced Alternatives Analysis: Automated Evaluation of Chemical Hazard Attributes to Identify Preferred Substitutes**

P. I. Beatrice, J. P. Rinkevich and J. Orchard-Hays. SciVera, LLC, Charlottesville, VA.

Many companies, especially downstream users of chemicals, are moving toward improved chemicals management by establishing programs to better understand the chemicals in their products. In addition to collecting specific chemical ingredient information, companies are tasked with identifying chemicals of concern and prioritizing where to take action. One aspect of this process is to utilize Restricted Substance/Authoritative Lists (RSLs). A more robust approach focuses on understanding the underlying hazard data in the scientific literature to identify critical endpoints.

Benefits of an enhanced process for evaluating chemicals in products beyond basic RSL review includes predicting which chemicals are likely to be added to RSLs in the future and reducing cost of chemical substitution via proactive efforts. Our research made use of the SciVera Lens attributes-based chemical hazard assessment database and several accompanying automated analytical tools to identify the gap between chemicals on key RSLs and chemicals with reported high hazard (based on GHS criteria). The results are based on analysis of the set of over 135,000 chemicals in the SciVera Lens and European Chemical Agency (ECHA) databases and a group of over 40 common RSLs.

The analysis focused on the Developmental-Reproductive (D-R) endpoint due to the fact that several RSLs identify this endpoint as the rationale for listing. The results indicate that more than 30 percent of chemicals with reported scientific data for high D-R hazards were not on any RSL and greater than 50 percent when assessed against specific D-R lists.

This analysis confirms that a hazard attributes-based assessment, when combined with the efficiency and consistency of automated techniques, provides for a more robust and predictive approach for alternatives assessment, allowing users to identify chemicals of potential concern prior to inclusion on an RSL, thereby reducing the potential for regrettable substitutions.
We present an in silico workflow for evaluating chemical toxicity instigated upon dermal contact. The first step identifies compounds that will not be absorbed and removes these from further consideration. Compounds that are absorbed and cause skin irritation are identified next, while absorbed non-irritating compounds are passed on to the next module for evaluation of skin sensitization potential. Probable metabolites are added to the workflow along with the parent molecules. Skin sensitization potential is predicted by modeling mouse local lymph node assay (LLNA) data, with values ranging from non-sensitizing to weak, moderate, strong, or extreme. Covalent modification of proteins by sensitizers by well-known reaction mechanisms represents the molecular initiating event for the induction. ToxPrint chemotypes, structural fragments encoded with physicochemical properties and electronic system information, are used to categorize chemicals into MIE classes. Skin metabolic rules, coded in chemotypes, were also used to predict bioavailability and reactivity. Results from multimodal ordinal classification QSAR models for each MIE class are combined using a rigorous weight-of-evidence approach that explicitly quantifies the uncertainty associated with each prediction. Our approach has been externally validated using skin irritation and sensitization results from literature studies. The workflow effectively separates irritants from non-irritants. Approximately 70% of sensitizers are predicted in the correct category and better than 90% are predicted within one category or their reported experimental value. Further, all sensitizers are associated with chemotype alerts, illustrating the power of this approach in overcoming limitations of classical structural alerts. The workflow comprehensively addresses chemical toxicity via dermal contacts.

**2273a Computational Molecular Modeling for the Assessment of Nanoparticle Toxicity: Interactions with Biomolecules**

N. Yanamala1, V. E. Kagan2 and A. A. Shvedova3, 4. 1Held/PPRB, CDC/NIOSH, Morgantown, WV, 2Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA and 3Department Physiology and Pharmacology, West Virginia University, Morgantown, WV.

Over the past two decades, nanotechnology has emerged as a key player in various disciplines of science and technology. A detailed understanding of the molecular details of interactions between nanoparticles (NP) and biomolecules is crucial for obtaining adequate information on mechanisms of action of nanomaterials and their possible toxicological outcomes. There has been a recent surge in the application of in silico based methods and approaches to address interactions of NPs with biomolecules providing insights into their mechanisms. To do this, we used structure-based computational modeling as a tool to predict the molecular interactions between carbon nanotubes and graphene with the carboxyl moieties on carbon nanotubes and graphene – positioning them in close proximity to the catalytic site of the enzyme – are essential for the effective catalysis and safe degradation of these materials in vivo. The current draft of the International Conference on Harmonisation (ICH) M7 guideline describes the use of (quantitative) structure-activity relationship (Q) SAR) models during drug safety evaluation. The guideline, however, does not specify the use of any particular model, but instead recommends that the models meet the general definition of statistical or rule-based methodologies, and allow the identification of structural alerts. In this study, we evaluated the performance of Toxtree, a freely-available, open source SAR model and two newly-released commercial (Q)SAR programs, Sarah Nexus and Leadscope Expert Alert System, as potential candidates for qualifying pharmaceutical impurities. To effectively assess the performance of Toxtree, an in-house Salmonella mutagenicity database of 3979 compounds (43% positive) and a highly-curved version of the Hansen dataset of 3734 compounds (58% positive) were used. Performance statistics for the two datasets ranged from 79% to 85% sensitivity and 85% to 73% negative predictivity, respectively. The performance of the statistical-based system, Sarah Nexus, was assessed using the in-house Salmonella dataset after removal of compounds that overlapped with the training set. The resulting dataset comprised 809 chemicals (42% positive), and yielded sensitivity and negative predictivity of 68% and 79%, respectively. The rule-based Leadscope Expert Alert System was evaluated using the curated Hansen dataset of 3734 chemicals (58% positive) and yielded performance of 85% sensitivity and 78% negative predictivity. These performance statistics compare favorably with those of the three most widely-used commercial model systems tested with the same data sets, indicating their suitability for the qualification of pharmaceutical impurities under ICH M7.

**2273d Metabolism Simulation and Toxicity Prediction in the Evaluation of Food Ingredients/Contaminant Safety**

L. Terlho1, K. Arvidson2, K. Muldoon-Jacobs2, P. Volarath3, A. Tarkhov1, T. Magdziarz1, J. Rathman3, 4, D. Hristozov4 and C. Yang1, 4. 1Molecular Networks GmbH, Erlangen, Germany, 2Center for Food Safety and Applied Nutrition, Office of Food Additive Safety, U.S. Food and Drug Administration, College Park, MD, 3Chemical and Biomolecular Engineering, The Ohio State University, Columbus, OH and 4Altamira LLC, Columbus, OH.

During the safety assessment of food additives and their impurities, metabolic knowledge becomes critical when in vivo data are unavailable for the specific compound. Inclusion of metabolism information into the in silico workflow is therefore a pre-requisite for the US FDA’s Chemical Evaluation and Risk Estimation System (CERES). The chemical space of food additives was profiled using public ToxPrint and metabolic (human liver and S9-fraction) chemotypes. Chemotypes are structural fragments encoded with physicochemical properties, and are considered as alerts when associated with a specific endpoint. The metabolic potential was predicted by applying a diverse set of over 100 phase I as well as more than 20 phase II conjugation reactions of human liver metabolic chemotypes. As an example, the effect of S9 metabolic chemotypes on Ames mutagenicity was analysed against the food additives. Although nearly 20% of the compounds were perceived as genotoxic carcinogens by chemotype alerts, only 4% of such compounds were actually predicted to be mutagenic under CERES mechanistic QSAR paradigm. Nearly 50% of the food additives predicted to be mutagenic were matched with chemotype alerts for genotoxic carcinogens. When repeating the analysis after removing the compounds that may be detoxified by S9, the reliability of the genotoxic alerts is increased almost 3 times. This study demonstrates the value of the use of metabolic rules in conjunction with known chemotype alerts to reduce the false positive rate of structural rules. Implementation of the metabolic rulebase in CERES is also presented. The research was funded by EU FP7 and Cosmetics Europe. (Grant no 266835).
Establishing relationships between gene expression and phenotypic endpoints is important to discover mechanisms of action of a toxic compound. In this study, pattern recognition methods for the identification of genes whose expression time-courses are associated with phenotypic endpoints are compared. Pattern recognition methods have been shown to be very effective in answering many biological questions, because biological entities belonging to the same cluster are assumed to be functionally related (1,2). To compare pattern recognition methods for identification of gene-phenotypic endpoint relationships from time-courses, four representative methods were chosen: k-means clustering (1), short time series expression miner (STEM)(3), linear mixed model (LMM) mixtures (4) and dynamic time warping (DTW4omics)(5). The four methods were applied on two published data sets on a human liver carcinoma cell line (HeP2): the response to benzo(a)pyrene (6) and menadione (7). Both data sets consist of time-series of both gene expression and phenotypic endpoints.

Lists of genes associated with an endpoint were identified and the overlap among the four methods determined. Gene Ontology (GO) and pathway analysis were applied on the gene lists. Gene, pathway and GO lists show low overlap among the methods and each method provides biologically relevant information (large overlap with the literature). Additionally, relationships not occurring in the literature represent new hypotheses. Testing these hypotheses experimentally can lead to the discovery of new mechanisms of action for a toxic compound.

Currently mandated testing for potential estrogenic activity will involve thousands of chemicals, cost millions of dollars, and take decades to complete using current validated tests. High-throughput screening and computational toxicology tools may streamline this process by the quick and cost-effective identification of endocrine-active chemicals (EACs). Access to a comprehensive database of high-quality in vivo EAC toxicity data is critical for the validation of in silico models and in vitro assays. The database can be used to prioritize chemicals for screening. Validation of HTS assays using the database will enable replacement of current validated in vitro screening assays with validated HTS assays. The results of these tests will better inform and target in vivo screening assays. To create such a database, we reviewed the current scientific literature, identified high-quality in vivo endocrine disruption testing data, and compiled the data into a single database. Initial review focused on the estrogenic effects of 52 reference chemicals selected by the EPA and NTP. Studies including data for these 52 chemicals on a number of different estrogenic endpoints (i.e., uterotrophic, pubertal, multigenerational, etc.) were identified. Data from the studies were extracted and compiled using a standardized ontology. An R script was developed to evaluate the quality of the data according to modified Klimisch criteria in an efficient and standardized manner. Data that were classified as reliable were added to the database, which is available on the NTP website (http://ntp2.niehs.nih.gov/go/40658). This database constitutes a critical resource for validating in vitro and in silico models of estrogenic activity. This project was funded in whole or in part with Federal funds from the NIEHS, NIH under Contract No. N01-ES-35504.

Quantitative high-throughput screening (qHTS) assays from Phase II of the Tox21 collaboration provide concentration-response profiles for thousands of chemicals. It is necessary to be able to rank chemicals using data generated from such large-scale screening experiments in order to efficiently prioritize environmental agents for possible endocrine disruption effects. Rankings are typically based on parameter estimates derived from fits to a pre-specified model, such as the logistic Hill Equation model. In particular, chemicals are often ranked using AC50 parameter estimates from the Hill Equation model, where an AC50 value represents the concentration exhibiting 50% of maximal induction along a sigmoidal curve. However, rankings based on this metric can be unreliable due to large errors associated with the parameter estimates when response data does not adequately fit the assumed model structure. Here, we describe an alternative approach for ranking chemicals in qHTS experiments based on weighted entropy scores (WES). WES provides a measure of average activity level that can be calculated from the observed response values and the underlying assay detection limits. We use WES to rank chemicals based on 15-point concentration-response data obtained from Tox21 Phase II BGI ER-Luc estrogen receptor agonist and antagonist assays. A total of 276 substances in agonist mode, and 134 chemicals in antagonist mode, produced consistently high WES scores across all three experimental runs (WES ≥ 2 bits). Only 38 compounds in agonist mode, and 32 compounds in antagonist mode, were ranked in the top 1,000 compounds by WES and AC50. No significant correlation was observed when comparing ranks based on WES and AC50 for the 11,776 tested substances in agonist mode or antagonist mode.

FDA drug labels represent the consensus and combined experience of regulators, drug sponsors and manufacturers, and scientific experts with information about product indications, target populations, and adverse drug reactions (ADRs). The amount of information captured in drug labels has grown rapidly, and the total number has likewise increased with around 400 to 500 new or updated drug labels being added weekly from the SPL (Structured Product Labeling) group in the FDA. This rapid pace of change, along with the breadth and depth of information contained in drug labels, highlights the need for a powerful search tool. FDALabel (http://www.fda.gov/ScienceResearch/BioinformaticsTools/ucm289739.htm) is a freely available, web-based, comprehensive drug label database with powerful full-text query capabilities. The database contains the full set of approximately 50,000 FDA-approved drug labels downloaded weekly from the National Library of Medicine’s DailyMed archive (http://dailymed.nlm.nih.gov/). The simple search options in FDALabel include full-text search as well as searches within only the product or generic name. The advanced search enables query text based on any combination of specific sections, dosage forms, document types, market categories, market date and other information. We have selected study cases in this poster, including a pharmacogenomics biomarker study and also an ADR study which utilizes MedDRA standard terminologies. FDALabel provides researchers, regulators, drug developers, and physicians an effective and efficient means of accessing the rich amount of information contained in FDA drug labels. It also opens the possibility for new uses of drug labels in supporting the FDA’s goals of advancing translational and regulatory sciences, e.g., by identifying trends in ADRs or by identifying ADRs that are associated with increased risks to public health.

High-throughput screening (HTS) and high-content screening (HCS) assays have changed the pace of chemical data collection for gene-protein, cellular, whole-embryo, and pathway-based responses. However, without the necessary assay metadata, it becomes a challenge to communicate what kind of data an assay reports. Integrative semantic resources such as the BioAssay Ontology (BAO) were developed to facilitate the annotation of assay parameters. We have used BAO with expansions to its vocabulary to produce the ToxCast Assay Annotation, a metadata resource to aid in the communication and use of EPA’s ToxCast HTS and HCS assays. The ToxCast Assay Annotation describes 942 analyzed readouts (assay endpoints), which have complete Phase I and II disruption testing data (about 1000 chemicals). The annotation includes over 40 descriptor-classes (e.g., assay design type, detection technology type, and key assay reagent), which have been organized to aid in communication and analysis. In addition to BAO, various ontology sources such as the GPCR ontology and NCIt thesaurus were incorporated for an abstract view of the target annotations. Where applicable, the conceptual difference between the technological target (e.g., mRNA, chemical, or protein) and the intended target (e.g., transcription factor activity, enzyme activity, or signaling pathway activity, respectively) are separately annotated. This annotation allows for a clear and concise reference for interpreting the ToxCast data, allows for identification of comparable ToxCast assay endpoints, and offers the potential to link with other HTS data repositories. This abstract does not necessarily reflect Agency policy.
models on those test chemicals from publicly available toxicology databases and resources including OpenTox, ToxBank, Comparative Toxigenomics Database, TG-GATES, SEURAT, PubChem, and Tox21 databases for risk assessment and management decision-making supported by the remediation tool for contaminated sites and identified data gaps and limitations in applications. Disclaimer: “This poster abstract is based on a report to be finalized under contract to HC, Contaminated Sites Division; however, the abstract, the report and the poster does not necessarily reflect the opinion of HC nor is it HC guidance.”

**2273n Web Application Supporting Chemical Safety Decisions**

M. T. Martin, North Carolina, Chapel Hill, NC and 3ICF International, Durham, NC.

I. Shah, R. S. Thomas, and W. Setzer.

**MVC architecture** that allows separation of backend support and frontend dis- sources of data into customized information displays. iCSS is built using both (iCSS) Application. iCSS is a web-based dashboard that synthesizes multiple data, the USEPA has developed the Interactive Chemical Safety for Sustainability datapoints for thousands of chemicals. To allow for easier public access to this abstract does not necessarily reflect U.S. EPA policy.

serve as a portal for ToxCast data access for risk managers and the public. This larger chemical subsets down to finely focused chemical-wise views. The iCSS will plays streamlines the toxicity assessment process and allows users to zoom from scores are carried over into a prioritization process where the chemicals are ranked attention. Users can adjust global score criteria or apply expert knowledge to mod- ify prioritization, and all decisions saved for sharing or later consideration. The scores are carried over into a prioritization process where the chemicals are ranked in a weight-of-evidence scheme to identify candidates for focused assessment. The aggregation of relevant data and use of web applications to generate custom displays streamlines the toxicity assessment process and allows users to zoom from larger chemical subsets down to finely focused chemical-wise views. The iCSS will serve as a portal for ToxCast data access for risk managers and the public. This abstract does not necessarily reflect U.S. EPA policy.

**2273q Screening Environmental Chemicals in Metabolically Competent Human-Derived Hepatocytes**

J. Jack, 1 J. Franzosa, 2 P. G. Kotlany, 1 J. Bonzo, 2 P. Hurban, 2 S. Siferd, 3 S. Ferguson, 3 J. Liu, 4 S. D. Hester, 1 A. Lake, 3 X. Houck, 1 and J. F. Wambaugh, 1

1US EPA, Research Triangle Park, NC, 2North Carolina State University, Raleigh, NC, 3Life Technologies, Frederick, MD, 4Expression Analysis, Research Triangle Park, NC, and NTP, NIEHS, Research Triangle Park, NC.

ToxCast™ is the U.S. EPA’s screening program comprising hundreds of relatively inexpensive and high-throughput assays to compare thousands of chemicals toreference toxicants and evaluate potential bioactivity. A new suite of assays aimed at investigating gene specific perturbations elicited by environmental chemical exposure in metabolically-competent, human-derived HepaRG cell line was designed and optimized. Briefly, cells were treated with individual chemicals in an eight-point concentration-response format in duplicate for 48 hours in a 96-well plate format. Total RNA was collected for gene expression profiling via real-time quantitative polymerase chain reaction (qRT-PCR). We evaluated the expression of a diverse set of 93 genes representative of various biological processes and disease states including: cell proliferation, survival, and death; nuclear receptor (NR) mediated metabolism and transport; oxidative stress; steatosis and fibrosis. Many of the genes are known to be transcriptionally regulated by key NRs, including CAR, PXR, PPARα, and HNF4α. Additionally, we evaluated reference plates with dilutions from high concentrations (e.g. 1 mM) of known toxiancients phenobarbital (PB), alloxin B1, omeprazole (OMP), fenofibric acid, and chenodeoxycholic acid (CDCA). These results demonstrated that the HepaRG cells elicited classically reported expression responses for CAR/PXR and FXR activation upon exposure to PB, OMP and CDCA, respectively. Evaluating thousands of chemicals in this assay provides unique insight into endogenous gene signaling net-works intrinsic to key hepatocellular processes and disease states in humans. This abstract does not necessarily reflect U.S. federal government policy.

**2273r Prioritization of the Tox21 10K Library for Xenobiotic Metabolism and Toxicity Studies Using In Silico Metabolism Models**

S. Ferguson, 1 N. Kleinstreuer 2, M. Lawless 3, and R. R. Tice 4

1DHHS/NIH, National Center for Computational Toxicology, US EPA, Research Triangle Park, NC.

One of the challenges within the U.S. Tox21 high throughput screening program is the lack of in vitro approaches incorporating xenobiotic metabolism. To help address this issue, in silico methods (ADMET-Predictor) have been employed to

**2273o Estimation of Octanol/Water Partition Coefficient and Aqueous Solubility of Environmental Chemicals Using Molecular Fingerprints and Machine Learning Methods**

Q. Zang, K. Mansouri and B. Judson, National Center for Computational Toxicology, US EPA, Research Triangle Park, NC.

Octanol/water partition coefficient (logP) and aqueous solubility (logS) are two im-portant parameters in pharmacology and toxicology studies, and experimental mea-surements are usually time-consuming and expensive. In the present research, novel methods are presented for the estimation of both logP and logS of environmentally interesting chemicals solely based upon simple binary molecular fingerprints on a single data set which consists of 993 training samples and 251 test samples. A group of quantitative structure-property relationship (QSPR) models were developed using four approaches with different complexity: multiple linear regression (MLR), random forest (RF) regression, partial least squares regression (PLSR), and support vector regression (SVR). Genetic algorithms (GA) and RF method were employed to select the most information-rich subset of descriptors for obtaining reliable and robust regression models with high prediction performance. It was found that MLR, PLSR and SVM exhibited satisfactory predictive results with low prediction errors and substantially outperformed RF. MLR coupled with GA for descriptor selection was clearly superior to all other approaches and achieved cor-relation coefficients of 0.936 and 0.927 between the calculated and experimental data on the validation set for logP and logS, respectively. The inclusion of logP and molecular weights (MW) as two descriptors into logS models significantly improved the prediction accuracy, especially for RF modeling. The present study demonstrates that molecular fingerprints are very useful descriptors, GA is a very efficient feature selection tool and the selected descriptors can effectively model the two properties, and simple methods such as MLR give better results than more complicated methods. These models can be used for rapidly and accurately predict-ing logP and logS of environmental chemicals. This abstract does not necessarily reflect U.S. EPA policy.

**2273s Pharmacokinetic Triage for Environmental Chemicals**

J. F. Wambaugh, 1 C. Strope, 1 C. Nicolas, 1 R. Judson, 1 M. Goldsmith, 2 H. A. El-Massry, 1 B. A. Wermelien, 1 J. P. Shula, 1 A. Tropscha, 2 S. Bosgra, 1 A. Shah, 1 S. Thomas, 2 and W. Neter. 1

1DHHS/NIH, National Institute of Environmental Health Sciences, RTP, NC, 2Indiana University, Bloomington, IN, 3University of North Carolina, Chapel Hill, NC, and 4Utrecht University, Utrecht, Netherlands.

Pharmacokinetic (PK) models aid in determining whether chemical exposures pro-duce potentially hazardous tissue concentrations. For bioactivity identified in vitro (e.g. ToxCast™) – hazardous or not – PK models can forecast exposure thresholds, below which no significant bioactivity is expected. Successful methods have been developed for pharmaceutical compounds to determine PK from limited in vitro measurements and chemical structure-derived property predictions. These high throughut (HT) PK methods: provide a more rapid and less resource-intensive alternative to traditional PK model development. Unfortunately, predictions from HTPK approaches have demonstrated mixed success for environmental chemicals when compared to predictions made by PK models developed with extensive in vitro data. Here we tested assumptions of previous HT PK approaches using a sim-ply physiologically-based PK (PBPK) model and in vitro data for 232 chemicals in human and 39 chemicals in rat. We then analyzed the discrepancy between the predictions of HTPK and in vitro literature PK data for 44, mostly pharmaceutical, chemicals to characterize those properties that correlate with poor predictive ability (e.g., in vitro HTPK data, physico-chemical descriptors, chemical structure, and predicted transporter affinities). We propose a framework for PK triage in stages: First, in vitro measurements and in silico predictions determine whether the simpl-est HTPK approaches are likely to be sufficient. Second, identify and collect any additional, targeted in vitro data that is needed. Third, identify those chemicals most likely to require traditional, in vitro PK methods. This methodology allows prioritization of PK resources and characterizes the confidence in HTPK model predictions for potentially thousands of environmental chemicals that currently have no PK data. This abstract does not necessarily reflect EPA policy.
identify and prioritize chemicals likely to undergo xenobiotic metabolism transforms (human) for studies in assays using metabolically-competent cells (e.g., primary hepatocytes, HepaRG). Three general criteria were used for prioritization: 1) chemicals predicted as substrates for human metabolism enzymes, 2) chemicals predicted to undergo extensive metabolism, and 3) chemicals predicted to generate metabolites with structural alerts for toxicity endpoints. Over the 18 xenobiotic metabolism enzymes (P450s and UGTs) predicted, true positive prediction rates of 85.7% (CYP1A2), 90.4% (CYP2C9), 76.6% (CYP2C19), 93.3% (CYP2D6), and 93.5% (CYP3A4) were observed for established substrates of 5 major xenobiotic metabolism pathways (quantitative models). Applying ADMET Predictor to 8,193 unique chemicals in the 10k library, 47,320 hits were predicted. Intrinsic clearance predictions were generated for each chemical and these data were combined using the ToxPi application to rank chemicals based on extent of metabolism weighted to relative expression levels in human liver. Using MedChem Studio, 168,805 unique metabolites were predicted. These structures were analyzed in various toxicity prediction models (e.g., estrogenic/androgenic activity, mutagenicity) to rank molecules based on anticipated toxicity. Rankings (Tox Risk) revealed various structures including 49 with nitroso groups (e.g. N-Nitrosopiperazine) out of the top 100 (96 predicted metabolites). 2,152 unique molecules made up the top 94% was reached with a non-error rate of 89% in fitting and 80% with 5-fold cross-validation. The U.S. EPA and Tox21 partners screened 1,877 chemicals, including pesticides; food, cosmetics and personal care ingredients; pharmaceuticals; and industrial chemicals. Testing used 782 in vitro assays across 7 technologies and biological formats (cell-free, cell lines and primary cells, multiple tissues). Assays were run in concentration-response (0.01 to 100 μM) with replicates and controls. We report several key findings. First, in 91% of the genes assayed for which we have reference chemicals (defined as a chemical with a known molecular target, >75 out of 313 genes total), a reference chemical is in the top quartile of potency. Second, 41% of chemicals show a “burst” of non-specific activity related to cell stress / cytotoxicity. On average, once ~5% of assays are activated by a chemical, there is a linear increase in the number of cytotoxic/cell-stress-related hits relative to hits in other assays (R2=0.84). This indicates a potential for non-specific assay activity. In a set of 40 chemicals with both ToxCast and in vitro pharmacokinetic data, the burst concentration corresponds roughly to concentrations predicted to be seen in vivo at the maximum tolerated dose (MTD) in rat 2 year chronic cancer studies (78% of MTDs were in the burst region). Cholinesterase inhibitors were a prominent exception, with MTDs all below the burst range, since the MTD is driven by cholinesterase activity rather than systemic effects. Finally, chemicals were ranked by relative potency and target specificity to provide a quantitative metric to prioritize chemicals for further study. About ~1% of chemical-gen combinations show potent and specific activity (~3 hits per chemical on average). This abstract does not necessarily reflect U.S. EPA policy.

**2273s In Vitro Screening of 1877 Industrial and Consumer Chemicals, Pesticides, and Pharmaceuticals in up to 782 Assays: ToxCast Phase I and II**

**2273t Using ToxCast Nuclear Receptor Activity to Predict Liver Toxicity**

J. Liu1, J. B. Iudson1, M. T. Martin1, and J. Shah1. 1National Center for Computational Toxicology (NCCCT), US EPA, Durham, NC and 2University of Arkansas at Little Rock/University of Arkansas for Medical Sciences, Little Rock, AR.

Nuclear receptors (NR) are molecular initiating events in pathways to rodent liver cancer. 260 out of 309 ToxCast Phase I chemicals induced liver lesions in rat according to guideline testing studies from ToxRefDB. We used supervised machine learning to systematically investigate the accuracy of 621 ToxCast Phase I high-throughput screening (HTS) assays for classifying 260 chemicals into 10 types of adverse chronic hepatic histopathological outcomes. Predictive models using a variety of classification algorithms (LDA, Naive Bayes, SVM) yielded a cross-validation balanced accuracy of 68.7% (±8.9%) for proliferative effects; 58% (±2.3%) for chronic hyperplasia and 63.2% (±3.8%) for hypertrophy. Univariate analysis of 621 HTS assays based on statistical correlation with corresponding in vivo endpoints revealed distinct associations between NR assays and liver endpoints categories. Next, all 91 NR assays out of 621 HTS assays were selected, including: retinoic X receptor-like (RXRβ/β); peroxisome proliferator-activated receptor-like (PPARα/γ/δ); constitutive androstane receptor (CAR; NR1H3); pregnane X receptor (PXR; NR1I2); liver X receptor (LXR; FXR; NR1H4); steroid receptor-like (SR; ERβ/α; ERα); RARα; RAR-related orphan receptor (RORα/β/γ); NR1F; thyroid hormone receptor (TRHα/β); vitamin D receptor (VDR; NR1I1). Using these 91 NR assays for supervised machine learning produced in classification accuracy to 73% (± 0.0%) for proliferative effects; 85% (±5.9%) for chronic hyperplasia and 65.2% (±4.2%) for hypertrophy. This work documents the accuracy of nuclear receptor activity for predicting non-genotoxic rodent hepatocarcinogens, and, more broadly, it highlights the relevance of using molecular initiating events for prioritizing environmental chemicals. This abstract does not represent EPA policy.

**2273v Predicting Toxic and Therapeutic Mechanisms of the ToxCast Chemical Library by Phenotypic Screening**

K. Houck1, N. Kleinstreuer1, J. Yang2, E. Berg3, T. B. Knudsen1, A. M. Richard1, M. T. Martin1, D. Reif2, B. Iudson1 and M. A. Polokoff2.

1National Center for Computational Toxicology, US EPA, Research Triangle Park, NC, 2ILS/NICEATM, NIEHS, RTP, NC, 3BioSeek/DiscoverRx, S. San Francisco, CA and 4NCSU, Raleigh, NC.

Several thousand chemicals were tested in 700 toxicity-related in-vitro HTS biosays through the EPA’s ToxCast and Tox21 projects. This chemical set only covers a portion of the chemical space of interest for environmental exposure, leading to a need to fill data gaps with alternative methods. A cost effective and reliable approach to fulfill this task is to build Quantitative Structure-Activity Relationships (QSARs). In this work, a subset of 1800 ToxCast chemicals was used to build QSAR models for multiple ToxCast assays to predict activity of chemicals in a larger environmental database of ~30K structures. The initial molecular targets for this project were a set of 18 G-Protein Coupled Receptor (GPCR) assays. These assays are part of the aminergic category which was among the most active within the biochemical assays. The QSAR predictions were based on two levels; the first was a classification into active/non-active chemicals; then regression models were built to predict the AC50 potency values of the biosays for the active chemicals. Different software packages were used to calculate constitutional, topological and fingerprinted molecular descriptors based on two-dimensional structures. Then several classification and regression model-fitting methods including PLS-DA, SVM, MLR, PLS and KNN were tested. The overall approach also included variable selection techniques such as Genetic Algorithms that were applied in order to select the most predictive molecular descriptors for each assay. The models were evaluated using n-fold cross-validation and forward validation on a held-out subset of the initial data. Finally, the applicability domains of the models were defined. Using PLS-DA for the human histamine H1 GPCR assay, a classification accuracy of 94% was reached with an error rate of 8% in fitting and 10% with 5-fold cross-validation with only 2 latent variables. This work shows the promise of using in vitro data to develop structure-based models for use in predicting target activity across the diverse space of environmental chemicals. This abstract does not necessarily reflect U.S. EPA policy.

**2274 In Silico Study of ToxCast GPCR Assays by Quantitative Structure-Activity Relationships (QSARs) Modeling**

K. Manouri, N. S. Sipes and B. Iudson. EPA, Research Triangle Park, NC.

SOT 2014 Annual Meeting 611
agos and mTOR inhibitors, all chemical classes with susceptibility to venous thrombosis. Further, structure-based analysis demonstrated associations between chemical categories and mechanism class predictions. Our results yielded an extensive list of potential toxicological targets and biological pathways that we are incorporating into a chemical prioritization strategy for chemicals of concern to the Agency. This work does not necessarily reflect official Agency policy.

**2273w Predictive Models for Mechanism-of-Action Classification of Chemicals Using Phenotypic Data**

Introduction. There is increasing interest in applying in vitro methods to characterize the potential toxicity of drugs and chemicals. Methods that would allow automatic classification of in vitro activity profiles into mechanism classes could be helpful in prioritizing novel agents. Methods. We have developed primary human cell-based assay panels in which chemical effects on the expression of protein biomarkers are measured. Eighty-eight selective, well-characterized tool compounds representing 28 distinct mechanism classes relevant to key biological and toxicity mechanisms were profiled in a standardized panel of 8 assay systems that had been previously used for testing >1000 chemicals and materials for the Environmental Protection Agency’s ToxCast program (Houck, 2009). The resulting dataset of 83 endpoint measurements was then used to build predictive models for each of the 28 mechanism classes using machine learning. A support vector machine (SVM) approach gave the best performance, and so was applied to build a series of two-class SVM models for each mechanism class. Results. These models were then applied to evaluate several libraries and collections of bioactive materials including diversity and kinase focused libraries, biologics and natural products. Compounds from all collections types were highly active in phenotypic assays (hit rates of 7-60%) at 1-5 μM. Analysis of a kinase-focused library and a set of environmental bio-actives revealed 48-57% of actives could be classified into one of the 28 tested mechanism classes. The most common mechanisms were mitochondrial inhibitors (14-27%) and proteasome inhibitors (4-10%). Proteasome inhibitors and AMP elevators were more frequent in the environmental bioactive collection. Conclusions. These results suggest that compounds with potentially undesirable mechanisms are surprisingly common in most compound collections including libraries used for high throughput screening. This method may be useful for library characterization, determining compound mechanisms of action, and chemical prioritization.

**2273x Read-Across Driven by Molecular Initiating Events: Comparison of In Silico Profiling with Experimental Results for Reactivity**

1School of Pharmacy and Chemistry, Liverpool John Moores University, Liverpool, United Kingdom, 2College of Veterinary Medicine, The University of Tennessee, Knoxville, TN and 3Alatimalle LLC, Columbus, OH.

Grouping or category formation allows the filling of data gaps by read-across to predict toxicity. Ideally it should be based on mechanistic similarities. Adverse Outcome Pathways (AOPs) link the chemistry of the Molecular Initiating Event (MIE) to effects and thus provide a mechanistic framework for the category formation. Covalent binding to biological proteins is an important MIE for toxicological endpoints including skin and respiratory sensitization, liver toxicity and elevated acute toxicity. A profiler (a collection of 108 structural alerts based on organic reaction mechanisms) has been developed to group compounds according to their protein binding capability. However, the alerting potential has not been evaluated in terms of the applicability domain and ability to create robust categories. Therefore, the ability of the alerts to profile 27 sulfur-containing industrial chemicals from a range of chemical classes (mercaptans, sulfides, disulfides, sulfoxides, sulfones, sulfoxides, sulfoxides; saturated and unsaturated) was investigated. To achieve this aim, in silico predictions were compared with experimental results. Compounds were considered to be protein binders when reactive towards glutathione in chemico and demonstrating excess toxicity in the Tetrahymena pyriformis assay. The prediction of protein binding for thiols, disulfides, saturated sulfoxides and sulfates (via S2 reaction), unsaturated sulfoxides, sulfones and sulfonates (via Michael addition) was verified experimentally with distinct excess toxicity for Michael addition. The in silico profiler was able to predict reactivity and differentiate reaction mechanisms related to reaction potency; this was associated with the degree of saturation of the compounds. The knowledge from this analysis was coded into a new set of chemotypes to better group compounds to perform read-across. Supported by the EU FP7 COSMOS Project and ECHA.

**2273y ToxBank Integrated Data Analysis of SEURAT-1 Reference Compounds**

B. Hardi1, G. J. Myatt2, P. Kohonen3 and R. C. Graefstrom1.

1Douglas Connect GmbH, Zeiningen, Switzerland, 2Leadscope, Columbus, OH and 3Karolinska Institute, Stockholm, Sweden.

The SEURAT-1 (Safety Evaluation Ultimately Replacing Animal Testing-1) research cluster is comprised of seven EU FP7 Health projects and is co-financed by Cosmetics Europe. The SEURAT-1 strategy is to adopt a mode-of-action framework to describe repeated dose toxicity to derive predictions of in vivo toxicity responses. ToxBank is the cross-cluster infrastructure project which provides a web-accessible shared repository of research data and protocols. Experiments generate dose response data over multiple timepoints using different omics platforms including transcriptomics, proteomics, metabolomics, and epigenetics over different cell lines and a common set of reference compounds (details available at wiki.toxbank.net). Data is also generated from functional assays and bioreactors and supplemented with in silico approaches. This complex and heterogeneous data is consolidated and harmonized through the ToxBank data warehouse in order to perform an integrated data analysis. We describe for 14 reference compounds the meta-analysis of multiple types of time-dependent dose response omics and functional data combined with in vitro and in vivo background knowledge including consideration of modeling variations in biokinetic responses. Open TG-GATEs human in vitro liver data of the reference compounds includes reactive compounds (e.g., acetaminophen, CCH4), mitochondrial disruptors (e.g., Rotenone), promiscuous binders (e.g., valproic acid, amiodarone), nuclear hormone receptor ligands (e.g., tamoxifen, WY14643), selective binders (e.g. fluoxetine and cardioxotins (e.g., Doxorubicin, Nifedipine). Adverse events of interest that are represented include cytotoxicity, fibrosis, steatosis, cholesterol and phospholipidosis. Overall we obtained 31,717 differential expression results with 14 compounds from the 45 comparisons, with Doxorubicin providing over 5000 results. Pathway enrichment analysis of Doxorubicin identified a number of key pathways including mismatch repair after 24 hours treatment and TNF-signaling at high doses after 24 hours.
Profiling (especially weak, which tend to be less reproducible), which then can be phosphate flame retardants. Many of the known chemical-target interactions demonstrate the in vitro activity profiling results using 49 brominated or organo-
the actual number of active compounds noticeably drops (by as much as 7%). We applying the signal processing protocol, signal reproducibility greatly improves (by
weak signals, which may serve as early indicators for toxicity, is also challenging. To
data for in vitro activity profiling is challenging due to presence of non-reproduc-
and NCATS, is currently screening a 10K (~8,300 unique) compound library
The finalized results have been uploaded into the ToxCast Dashboard for data
integration and analysis, as well as to serve as the primary portal for publication and
data release. This work does not necessarily reflect Agency policy.

Tox21, a federal inter-agency collaboration involving NIEHS/NTP, EPA, FDA,
capabilities, and outlier detection/masking, concentration activity estimates using dose-response
modeling, and identifying & filtering confounded activity calls based on other
assays. To increase curve-fitting and hit-calling accuracy, the ToxCast workflow incorporates a data-scan feature in the early stage of processing to identify noise and response variation. Moreover, the ToxCast workflow standardizes the analysis of highly-heterogeneous chemical assay data sets by accepting heterogeneous data formats, allowing for rapid processing with a convenient interface enabling easier access and interpretation of data at all levels for repeatable and transparent analyses. The finalized results have been uploaded into the ToxCast Dashboard for data integration and analysis, as well as to serve as the primary portal for publication and data release. This work does not necessarily reflect Agency policy.

Drug-induced liver injury (DILI) remains the primary cause of drug failures during clinical development and post-marketing. It is estimated that up to 40% of poten-
tially hepatotoxic compounds in humans go undetected in preclinical studies that utilize conventional biomarkers. Serum alanine aminotransferase (ALT) activity is a widely used clinical biomarker to assess the risk of liver injury during drug development and approvals by regulatory agencies. Since ALT increases may be transient, thus less clinically relevant, the development of alternative biomarker strategies capable of differentiating transient ALT increases from those that progress to severe DILI is essential. Several biomarkers identified by evidence from peer-reviewed literature and datasets at various institutions are being evaluated as potential DILI biomarkers by individual scientists and international research consortia such as Innovative Medicines Initiative and Critical Path Institute’s Predictive Safety Testing Consortium. In this symposium we will discuss gaps and opportunities for clinical evaluation of DILI biomarkers and their application in DILI biomarkers strategies. Special attention will be given to the evaluation of protein- and miRNA-based biomarkers for detection of DILI in the clinic including their potential to facilitate the understanding of underlying toxic mechanisms. Furthermore, we will introduce the application of NextGen Sequencing in DILI biomarker research in human subjects.

Drug-induced liver injury is a serious complication in drug therapy that is a pri-
mary cause of drug failure during clinical development. Commonly used biomark-
ers, particularly the serum transaminases (ALT, AST) and bilirubin (TBil) are used as useful indicators of hepatocellular of cholestatic liver injury. Because ALT is a very sensitive biomarkers of DILI, the differentiation of ALT increases that sponta-
neously resolve from the ones that signal serious liver injury is very difficult. On the
other hand, increases of TBil levels that are considered a hallmark of severe DILI
occur only after significant damage has already occurred. Therefore the develop-
ment of new biomarker strategies capable of assessing the risk of clinically relevant liver injury in early stages is essential. Because prospective clinical studies evaluating performance of biomarkers of DILI are ethically not feasible, biomarker research of DILI in human subjects requires new approaches. Here we will focus on current status, gaps and opportunities in the development and evaluation of new clinical DILI biomarker strategies including the utilization of samples from subjects with variety of liver impairments via retrospective study design as well as validation and qualification process including the impact of international collaborative efforts.
Hepatotoxicity remains a major challenge in drug development. Although alanine aminotransferase (ALT) remains the gold standard biomarker of liver injury, alternative biomarker strategies to better predict the potential for severe drug-induced liver injury (DILI) are essential. Here, we evaluated the utility of glutamate dehydrogenase (GLDH), purine nucleoside phosphorylase (PNP), malate dehydrogenase (MDH), and paraxonase 1 (PON1) as indicators of liver injury in cohorts of human subjects, including healthy subjects across age and gender, subjects with a variety of liver impairments, and several cases of acetaminophen poisoning. GLDH and MDH had a strong correlation with elevated ALT levels and possessed a high predictive power for liver injury, as determined by ROC analysis. In contrast, PON1 and PNP did not detect liver injury in our study. Finally, evaluation of patients with acetaminophen-induced liver injury provided evidence that both GLDH and MDH might have utility as biomarkers of DILI in humans. This study is the first to evaluate GLDH, MDH, PON1, and PNP in a large number of human subjects and, and it provides an impetus for prospective clinical studies to fully evaluate the diagnostic value of GLDH and MDH for detection of liver injury.

**Mechanistic Biomarkers of Mitochondrial Dysfunction during Drug-Induced Liver Injury in Humans**

H. Jaeschke. Dept. of Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.

Extensive progress has been made during the last decade in the understanding of mechanisms of drug-induced liver injury (DILI), especially acetaminophen (APAP) hepatotoxicity, in experimental animals. Binding of reactive metabolites to cellular, in particular mitochondrial proteins, mitochondrial dysfunction and oxidant stress, MAP kinase activation, nuclear DNA fragmentation and mitophagy are critical events. Mitochondria clearly emerged as the converging point of various signaling pathways leading to cell death. Despite the progress in animals, the understanding of DILI mechanisms in humans is limited. The presentation will focus on a mechanistic serum biomarker approach to study mechanisms of cell injury, especially mitochondrial dysfunction, in human APAP overdose patients and in mice. Biomarkers that are being used in patients after validation in experimental animals (APAP, furasamide toxicity), include the mitochondrial matrix enzyme GLDH, mitochondrial DNA, nuclear DNA fragments (generated by endonuclease G from mitochondria), and various acylcarnitines. These studies have demonstrated the successful use and some caveats of mechanistic biomarkers in humans suggesting that mitochondrial damage and nuclear DNA fragmentation are critical components of liver injury mechanisms in patients. In addition, the use of these biomarkers as predictors for acute liver failure will be discussed.

**Novel Liver Biomarkers Provide Insight into Benign Drug-Induced ALT Elevations in the Clinic**

A. H. Hareill. University of Arkansas for Medical Sciences, Little Rock, AR

Aminotransferase elevations can be an important indicator of overt liver injury in the clinic; however, there are several drugs in clinical use that cause benign alanine aminotransferase (ALT) elevations yet have no injury risk. Novel biomarkers are currently in development to more accurately discern acute drug-induced liver injury potential and we hypothesized that these newer biomarkers would not be elevated in the context of benign drug-induced ALT elevations. To test this hypothesis, ALT, glutamate dehydrogenase (GLDH), sorbitol dehydrogenase (SDH), high mobility group box 1 protein (HMGB1), cytokerin 18, and miRNA(miR)-122 were assessed in the serum of healthy volunteers enrolled in two separate clinical studies of hepatitis or cholestatics administration. Elevations in all of the novel biomarkers were found to be coincident with ALT in both clinical studies. We conclude that the novel biomarkers may have less utility to be predictive of overt hepatotoxicity that previously assumed. Yet, it is clear that the pattern of biomarker elevations provide important insights into the mechanisms underlying the low-level liver injury that occurs following exposure to hepatic (i.e. necrosis with secondary activation of an innate immune response) and cholestatics (i.e. necroapoptosis).

**Evaluation of Emerging Biomarkers of DILI in Human Populations**

S. J. Schomaker. Department of Drug Safety Evaluation, Pfizer Inc., Groton, CT.

MicroRNAs are stable and reliably detectable in blood. Recently, levels of circulating microRNAs such as miR122 and miR192 have been shown to respond to treatment with hepatotoxicants. Since microRNAs are either organ specific and/or associated with molecular pathways, microRNA-based biomarkers provide exciting opportunities. Deep sequencing technologies for microRNAs (smallRNA-seq) provide the most unbiased assessment of the many microRNA variants that can exist. In this study, we have compared profiles of circulating microRNA in human subjects with accidental acetaminophen (APAP) overdose with matched controlled subjects. We have identified over 30 microRNA species with time dependent response to APAP overdose. The set included known microRNAs such as mir122 and mir192 as well as novel, so far unknown, microRNAs whose levels drastically increased upon the hepatotoxic exposure. We have confirmed the identified microRNAs by independent RT-PCR methods, and evaluated their levels in other subjects with liver impairments.

**Does Evolution Matter in Toxicity Testing? Rethinking Cross-Species Extrapolation in Hazard Characterization**

Training in evolutionary thinking can help biomedical researchers, clinicians, and toxicologists ask useful questions that they might not otherwise pose. Emerging high-throughput technologies, predictive toxicology, and bioinformatics, as well as alternative toxicity models such as bacteria, yeast, C. elegans, zebrafish, and stem cells, provide new information across the phylogenetic tree at a molecular scale to support human health risk assessments. These novel approaches also create an opportunity to consider what role evolution plays in toxicity testing, particularly in cross-species toxicity extrapolation of pollutants and manufactured chemicals. This symposium aims to generate discussion on evolution and three specific aspects of toxicity testing: (1) how can the phylogeny of species-xenobiotics interaction influence the design and interpretation of high-throughput screens with microbes and alternative animal models; (2) how can the molecular evolution of naturally-occurring toxins and species interaction in the natural world inform the hazard characterization of pollutants and manufactured chemicals; and (3) how can comparative physiology in both vertebrates and invertebrates influence the development of adverse outcome pathways for human health risk assessments.

**Application of NextGen Sequencing for Discovery of Novel miR-Based Candidate Biomarkers of DILI in Human Subjects**

MicroRNAs are stable and reliably detectable in blood. Recently, levels of circulating microRNAs such as miR122 and miR192 have been shown to respond to treatment with hepatotoxicants. Since microRNAs are either organ specific and/or associated with molecular pathways, microRNA-based biomarkers provide exciting opportunities. Deep sequencing technologies for microRNAs (smallRNA-seq) provide the most unbiased assessment of the many microRNA variants that can exist. In this study, we have compared profiles of circulating microRNA in human subjects with accidental acetaminophen (APAP) overdose with matched controlled subjects. We have identified over 30 microRNA species with time dependent response to APAP overdose. The set included known microRNAs such as mir122 and mir192 as well as novel, so far unknown, microRNAs whose levels drastically increased upon the hepatotoxic exposure. We have confirmed the identified microRNAs by independent RT-PCR methods, and evaluated their levels in other subjects with liver impairments.

**Evolutionary Approaches in Cross-Species Toxicity Extrapolation: A Naturalist’s Perspective**

A basic tenet of evolutionary biology is that species adapt to changes in its environment, including chemical exposures, over extended time and multiple generations. The mechanism of natural selection allows their progeny to eventually survive and reproduce in the changed environment (i.e. evolutionary fitness). While the choice of test animal species in laboratory toxicity testing is often based on the conservatism of biology with humans, a better understanding in molecular evolution and comparative toxicology of naturally-occurring toxins can also inform the hazard characterization of pollutants and manufactured chemicals. This presentation will introduce the principal concepts of evolutionary biology that are applicable in toxicological sciences, including site directed mutagenesis, phylogenetic inference, purifying selection, and plant-herbivore coevolution. Specific examples of living poisonous and venomous species will be given, including toxicological cocktails (e.g. venoms or suites of alkaloids acting in concert) as well as proteinaceous toxins (e.g. enzymes or physiological pathway inhibitors). Their relevance to hazard characterization of environmental toxicants will be discussed.
Both the evolution of species and the clonal selection of cells into tumors require a balance between genomic stability and diversification. DNA repair is essential for preserving DNA sequence information, and many DNA repair processes have been conserved across species. During evolution from microbes to mammals, key repair activities were not only conserved, but they were also leveraged to address selective pressures specific to mammals, such as antibody diversification. The role of base excision repair (BER) in these contexts will be presented. To learn more about BER in humans, we recently developed a novel high-throughput DNA repair platforms for assessing DNA repair capacity in primary human cells. The "CometChip" leverages photolithography to enable hundreds of samples to be assessed for their DNA damage levels in parallel, enabling studies of inter-individual variation in DNA repair. Here we show that BER is highly variable in cells from ethnically diverse individuals. In addition to BER, we are also very interested in repair that is facilitated by homologous recombination (HR). Ironically, the BER pathway, while critical for removing damaged bases, also creates single strand breaks as repair intermediates. HR is required to tolerate the presence of these DNA repair intermediates. Here we describe the development of novel fluorescence based animal models in which rare cells that have undergone HR can be detected within intact tissues. A fundamental discovery resulting from this model is that BER in mammals puts pressure on HR under normal physiological conditions, raising the possibility that one DNA repair pathway creates selective pressure for another.

Small fish models such as the zebrafish are commonly used in toxicity and pharmacological testing, particularly to screen for early life stage effects, as well as in mechanistic studies. It is important to consider the evolutionary relationship between these fish models and humans, as fish have undergone at least one genome duplication event, and for many mammalian transcription factors fish often have duplicate copies (co-orthologs). Here, we will present the comparative evolutionary relationship of two families of genes encoding transcriptionally relevant transcription factors—the aryl hydrocarbon receptor (Ahr) and nfe2-related (Nrf) gene families—and their associated signaling pathways. We will compare the Ahr and Nrf genes in two small fish models, the killifish (Fundulus heteroclitus) and zebrafish (Danio rerio), with those in humans and rodents, focusing on multiple fish Ahr (Ahr1a, Ahr1b, Ahr2a, Ahr2b) and Nrf2 (Nrf2a, Nrf2b) genes. We will discuss the implications of transcription factor multiplicity for biomedical and environmental toxicology, including both the challenges and the opportunities provided by differences in gene number and function among fish and mammals. [NIH grants F32ES017585, R01ES016366, and R01ES006272]

This symposium will highlight advances in our understanding of the complex causal relationships between early-life environmental manganese (Mn) exposure and lasting neurobehavioral impairment, gained through the coordinated integration of epidemiological and animal model studies. Behavior and cognitive function are among the most important public health outcomes, since the potential loss of neurological functioning early in life due to toxic exposures may result in diminished academic and economic productivity that can persist over the life span. Motor abnormalities are likewise relevant in relation to neurodegenerative disorders, leading to Parkinsonian disturbances in the aged. Multidisciplinary investigations that synthesize advances in developmental testing, animal toxicology, exposure assessment, statistical modeling, and epidemiology are necessary to gain insights into the impacts of early-life Mn exposure—impacts that have direct implications for public health. This symposium will address this research need through presentation of coordinated human and animal research that focuses on comparable neurophenotypes across species and age ranges, and that incorporates novel exposure-assessment tools, such as Mn levels in shed deciduous teeth, to assess the impacts of early-life and lifelong Mn exposure over distinct developmental windows/life stages.

This presentation will highlight a critical issue in the neurotoxicology of manganese (Mn) - the translation of animal results to humans. Because human randomized trials of Mn exposure cannot be conducted for Mn or any potentially neurotoxic agent, translation of animal study neurotoxicology research to humans must involve epidemiologic observational studies. Animal/human studies planned in tandem could also better elucidate mechanisms of action in the CNS. Human and animal studies seldom measure the same functional domains or address exposures at the same life stages, at least not in a coordinated fashion. Although there are several caveats when extrapolating results from animals to humans, one caveat, the use of different neurophenotypes, can be overcome given the development of computerized tests of animal/human behavior, such as the virtual radial arm maze (VRAM), the delayed spatial alternation and temporal response differentiation test models for specific research questions. This presentation will discuss the comparative data content in CTD, provide examples of cross-species analysis capabilities for mechanistic studies and describe future curation and integration initiatives that will further expand the comparative analysis capacity of CTD.
(a fixed interval response), and the continuous performance test (CPT), among others. In preliminary analysis of Italian children performing the Virtual Radial Arm Maze Increased hair Mn was not associated with latency (2.8 sec 95%CI 1.3-6.7) but was associated with increased total distance traveled (0.6 95%CI 0.0-1.3) and increased working memory count ratio (1.68, 95% CI 1.09-2.01), suggesting worse performance overall on this task in Mn-exposed children. In the delayed spatial alternation task performed in a Mexico cohort of 2 year olds, blood Mn was inversely associated with total number of errors performed correctly (-0.84, 95% CI -1.5, -0.15). Potential links to animal studies with similar designs will be discussed.

2288 Neurodevelopmental Effects of Ambient Exposure to Manganese in Appalachian Children Residing near a Ferromanganese Refinery
E. Haynes. Department of Environmental Health, University of Cincinnati, Cincinnati, OH. Sponsor: D. Smith.

Airborne manganese (Mn) exposure can result in neurotoxicity in workers and adults exposed to high levels of Mn, yet there is limited data on its effects on children. Marietta, Ohio has the longest operating ferromanganese refinery in the United States. The goals of the research were to characterize environmental exposures to Mn and determine the effect of chronic exposure on neurobehavior in children. A total of 408 children ages 7-9 years were enrolled in the Marietta Community Actively Researching Exposure Study (CARES). Internal dose measures were determined for lead, Mn, and secondhand tobacco smoke exposure. Children with hair Mn concentrations greater 610 ng/g had a 3 point mean decrease in full scale IQ compared to children with hair Mn in the low and middle tertiles. In backward elimination regression modeling, in hair Mn was also statistically and inversely associated with full scale IQ (β = -1.38; p=0.008) after adjusting for parent IQ, parent education, and gender. Additionally, in blood Mn was also significantly associated with internalizing problems (p<0.03), but not ln hair Mn. Increases in hair and blood Mn and a decrease in time-weighted distance from the refinery were also significantly associated with poor postural instability. Presentation of these results will include discussion of SFS, an alternative source of Mn, and will be integrated similar epidemiological studies in Mexico and Italy, as well as the animal model studies presented in this symposium.

2289 Manganese Exposure across Different Life Stages Produces Comparable Deficits in Neuromotor Function and Olfactory Discrimination
R. Lucchini1,2. 1Department of Preventive Medicine, Icahn School of Medicine at Mount Sinai, New York, NY and 2Occupational Medicine, University of Brescia, Brescia, Italy.

Results from our cross-sectional epidemiological study on environmental metal exposure in children and elderly living in the vicinity of previously and currently active ferroalloy plant emissions in northern Italy will be presented, and integrated with other epidemiological studies in Mexico and Ohio, as well as the coordinated animal model studies presented in this symposium. Our studies in Italy have comprehensively assessed Mn exposure over the lifespan, as well as olfactory function (using the Sniffin’ Sticks test for odor identification) and motor function (using the Virtual Radial Arm Maze and the Ladder Rung Walking tests) among children and the elderly. To address this, we undertook detailed studies on rats exposed to controlled doses of Mn for different durations including early life exposure (low and high doses) and lifelong exposure (low and high doses). Results show that tooth-Mn levels accurately reflect both short- and long-term exposure and are also predictive of levels in other tissues including bone and brain. To validate this in humans, we undertook a prospective study comparing Mn levels in environmental and biological matrices with tooth-Mn levels measured using a laser ablation method that allowed us to develop a temporal map of Mn exposure over the prenatal and early postnatal periods. Results confirm that the tooth-Mn biomarker can be used to reliably reconstruct perinatal Mn exposure.

2290 Validation of Novel Exposure Biomarkers in Manganese-Exposed Rats and in a Cohort of Children at Risk of Environmental Manganese Exposure
M. Arora. Department of Preventive Medicine, Icahn School of Medicine at Mount Sinai, New York City, NY. Sponsor: D. Smith.

This presentation will integrate assessment and validation of novel Mn exposure biomarkers across the animal model and epidemiological studies presented in this symposium. Transfer of manganese (Mn) across the placenta is tightly regulated and maternal blood levels do not accurately reflect fetal exposure and furthermore, because of complex kinetics, blood Mn in children may not precisely measure postnatal exposure. Consequently, measuring Mn exposure during the prenatal and early childhood periods remains a major challenge in studies exploring health outcomes of early Mn exposure. To address this, we undertook detailed studies on rats exposed to controlled doses of Mn for different durations including early life exposure (low and high doses) and lifelong exposure (low and high doses). Results show that tooth-Mn levels accurately reflect both short- and long-term exposure and are also predictive of levels in other tissues including bone and brain. To validate this in humans, we undertook a prospective study comparing Mn levels in environmental and biological matrices with tooth-Mn levels measured using a laser ablation method that allowed us to develop a temporal map of Mn exposure over the prenatal and early postnatal periods. Results confirm that the tooth-Mn biomarker can be used to reliably reconstruct perinatal Mn exposure.

2291 Fine Neuromotor Deficits following Early and Lifelong Manganese Exposure, and the Efficacy of Oral Methylphenidate Treatment to Alleviate Motor Function Deficits
D. Smith. Microbiology and Environmental Toxicology, University of California Santa Cruz, Santa Cruz, CA.

Results from the epidemiological studies presented above indicate that environmental manganese (Mn) exposure produces lasting deficits in fine motor function in children and the elderly. To address this and establish exposure causality, we used a rodent model and the Montoya staircase and Ladder Rung Walking tests to determine whether developmental Mn exposure produces lasting deficits in sensorimotor performance in adulthood. Long-Evans male neonate rats were exposed daily to oral Mn from postnatal day 1-21 (early life only), or from PND 1 - throughout life. Results revealed that early life Mn exposure alone caused long-lasting impairments in fine motor control of reaching skills at the higher, but not lower Mn dose, lifelong Mn exposure led to widespread impairment in reaching and grasping/retrieval performance in adult rats, with the lower Mn dose group showing the greatest impairment, and lifelong Mn exposure produced similar (higher Mn group) or more severe (lower Mn group) impairments compared to their early life-only Mn exposed counterparts. Results of the Ladder Walking test, and the efficacy of oral methylphenidate treatment to alleviate lasting deficits will also be presented. These results substantiate the emerging clinical evidence in children reported above showing associations between environmental Mn exposure and deficits in fine sensorimotor function.

2292 Attentional Deficits in Early-Life and Lifelong Manganese-Exposed Rats and Their Reversal with Oral Methylphenidate Treatment
S. A. Beaudin. Microbiology and Environmental Toxicology, University of California Santa Cruz, Santa Cruz, CA.

As suggested by results from the epidemiological studies presented above and elsewhere, overexposure to manganese (Mn) in early life is associated with attention deficit with hyperactivity disorder in children, but the specific nature and causal relationship of these attentional deficits have yet to be demonstrated. To address this, we determined whether early life Mn exposed rats exhibited persistent deficits in visual attentional processes and impulsive behavior in adulthood, and if lifelong Mn exposure caused similar or more severe attention deficits than early life exposure alone. The Mn-exposed groups showed normal visual attention performance in vigilance tasks. However, the Mn-exposed groups displayed deficits in attentional accuracy when required to attend selectively to visual cues in the presence of olfactory distractors. Notably, impulse control was not measurably impaired in the Mn groups. The results substantiate the emerging epidemiological evidence and show that developmental Mn exposure can cause selective attentional deficits across a range of doses and exposure durations, including lasting susceptibility to greater distractibility in adulthood. The efficacy of oral methylphenidate to ameliorate the attention deficits will also be presented – these latter results will inform the mechanistic basis for these deficits as well as the potential efficacy of MPH for treating Mn-related attentional deficits in children.
Are Biofuels More or Less Toxic than Conventional Fuels and What Are the Implications for Human Exposure and Risk?

A. M. van Erp and M. C. Madden. Health Effects Institute, Boston, MA and US EPA, Research Triangle Park, NC.

During the past decade, the use of biofuels such as biodiesel and bioethanol has been steadily increasing as a viable alternative to the use of petroleum-based fuels. Although there are clear advantages in terms of energy security and climate change, there are several unknowns about the long-term effects of the use of biofuels on the environment and on human health. Because there are many different biofuels and biofuel blends that originate from different feedstocks, evaluating their effects on the environment and human health over their entire lifecycle becomes rather complex. Although there may be reductions in emissions of certain compounds, there may also be unintended consequences. For example, adding bioethanol to gasoline reduces emissions of benzene and other hydrocarbons, but increases the levels of toxic aldehydes in the engine exhaust, and also leads to increased evaporative emissions. While first-generation biofuels such as ethanol derived from corn are now widespread, next-generation fuels such as those produced by microorganisms are under development. The workshop will start with an overview of the types of biofuels that are currently available and recent results of comparative emissions-testing programs in the US. We will then present the latest results from several research programs to evaluate the emissions and comparative toxicity of biofuels, including in vitro testing for genotoxicity, in vivo evaluation of pulmonary and cardiovascular effects, and the toxicity of fatty acid methyl esters (FAME) that are found in biodiesel. In addition to new results regarding emissions testing, the workshop will discuss different approaches and harmonization of toxicity testing in vitro and in vivo. Finally, we will conclude with approaches to assess human exposure and health impacts. (This may not represent official US EPA policy.)

Biofuel Usage, Composition, and Engine Emissions

This presentation will provide an overview of biofuels in the United States, with a focus on biodiesel and other biodistillate fuels. In recent years, the volume of biofuels has increased steadily due to a variety of legal and regulatory drivers for the promotion of biofuels. These drivers and their influence on current and predicted future volumes of different kinds of biofuels will be presented. Currently, there are many different biodistillate fuels in use or under development but it is difficult to predict what their effect will be in terms of future market shares. This presentation will provide an overview of the main kinds of biofuels, including the major categories of biodistillates, explaining their terminology, feedstocks, manufacturing processes, compositions, and properties. Fuel composition is inevitably linked to vehicle emissions and their potential air quality and public health impacts. Emissions standards for diesel engines and vehicles have become much more stringent over time. Compliance with these standards has been achieved by a combination of engine and fuel modification and utilization of emissions control systems. The incremental emissions impacts of biodiesel compared to conventional diesel fuel have been investigated extensively. There is widespread agreement that in most situations, biodiesel blends provide modest reductions in emissions of carbon monoxide (CO), total hydrocarbons (HC), and fine particulate matter (PM), but slight increases (or no change) in emissions of nitrogen oxides (NOx). The effects of other biodistillate fuels upon these so-called "criteria emissions" have not been studied as thoroughly, but are probably similar to the effects of biodiesel.

Emissions of non-criteria pollutants including mobile source air toxic (MSAT) emissions are also of concern, especially in terms of the use of bioethanol and the formation of aldehydes. However, much less information is available regarding the impacts of biodiesel, and other biodistillates, on MSAT emissions. This area will be discussed, other open issues will be identified, and recommendations for additional work will be presented.

In Vitro Toxicological Evaluations of Emissions from Heavy-Duty Vehicles Using Biofuel Blends

N. Kado and C. F. Vogel. Environmental Toxicology and Center for Health and the Environment, University of California Davis, Davis, CA.

The evaluation of the potential health effects from exposure to emissions from motor vehicles presents numerous challenges because these emissions are complex mixtures of gases, vary with fuel and engine type, and the emissions may be altered due to evolving control strategies and technologies. One approach toward evaluating these complex particle and vapor-phase mixtures is to use screening tools, such as directed chemical analyses and in vitro biological analyses. An example of this approach is the detailed emissions study of biodiesel, renewable diesel, and ultra-low sulfur diesel fuels, which was conducted as part of a multi-investigator and multi-institutional study on regulated emissions as well as unregulated toxic emissions. Samples from heavy-duty trucks following standard test cycles on a chassis dynamometer were evaluated chemically and in a screening effort using in vitro assays. These assays included mutagenicity tests and expressions of inflammatory and oxidative stress markers in human macrophage cells and lung epithelial cells. The trend for many of the tests/species compared to ultra-low sulfur diesel fuel was lower with increasing biofuel blends, but with some tests/species, results were highly dependent on biofuel blend. This presentation will provide a brief overview of some of the in vitro evaluations with focus on heavy-duty vehicle tests. (The abstract and opinions are of the authors and do not represent policy of the California Air Resources Board or the University of California)

Comparative Toxicity and Mutagenicity of Biodiesel Exhaust

Biodiesel (BD) is commercially made from the transesterification of plant and animal derived oils, and the composition of biodiesel exhaust (BE) depends on the type of fuel, the blend ratio and the engine and operating conditions. While numerous studies have characterized the health effects associated with petroleum diesel (PD) emissions following controlled animal and human exposures, information on pure and blended BD emissions are far more limited. We developed a test program to compare the mutagenicity and toxicity of 100% (B100) or a 20% mix (B20) of soy-based BD exhaust to emissions from conventional PD (B0). Exhaust was generated by a 3.2 L Yanmar engine driving a 3.8 kW Pramac generator with a constant load of 3 kW and diluted to target concentrations of 0, 50, 150, or 500 ppm/m3 as determined by TEOM. Average NO (ppm) at the 500 ppm/m3 level were 15.2 (B100), 12.7 (B20) and 14.8 (B0). Rats and mice were exposed independently for 4 hours per day for up to 6 weeks depending on the experimental protocol and model system. In general, B0 had the greatest pro-inflammatory effects in normal mice while both B0 and B100 potentiated plaque formation in Apo E mice. The B0 and B100 also caused changes in heart rate variability and systemic inflammatory responses in hypertensive rats. Organic extracts of B0 were the most mutagenic with respect to both the Ames Salmonella assay and the U.S. Environmental Protection Agency’s Ames test. This presentation will provide an overview of biofuels in the United States, with a focus on biodiesel and other biodistillate fuels. In recent years, the volume of biofuels has increased steadily due to a variety of legal and regulatory drivers for the promotion of biofuels. These drivers and their influence on current and predicted future volumes of different kinds of biofuels will be presented. Currently, there are many different biodistillate fuels in use or under development but it is difficult to predict what their effect will be in terms of future market shares. This presentation will provide an overview of the main kinds of biofuels, including the major categories of biodistillates, explaining their terminology, feedstocks, manufacturing processes, compositions, and properties. Fuel composition is inevitably linked to vehicle emissions and their potential air quality and public health impacts. Emissions standards for diesel engines and vehicles have become much more stringent over time. Compliance with these standards has been achieved by a combination of engine and fuel modification and utilization of emissions control systems. The incremental emissions impacts of biodiesel compared to conventional diesel fuel have been investigated extensively. There is widespread agreement that in most situations, biodiesel blends provide modest reductions in emissions of carbon monoxide (CO), total hydrocarbons (HC), and fine particulate matter (PM), but slight increases (or no change) in emissions of nitrogen oxides (NOx). The effects of other biodistillate fuels upon these so-called "criteria emissions" have not been studied as thoroughly, but are probably similar to the effects of biodiesel.

Emissions of non-criteria pollutants including mobile source air toxic (MSAT) emissions are also of concern, especially in terms of the use of bioethanol and the formation of aldehydes. However, much less information is available regarding the impacts of biodiesel, and other biodistillates, on MSAT emissions. This area will be discussed, other open issues will be identified, and recommendations for additional work will be presented.

Approaches to Comparative Biofuels Toxicity Testing and Recent Results from Europe

On a regular basis new combustion or after treatment technology is brought on the market to meet the new stricter standards or to reduce the costs to meet the current regulations. The use of new (bio)fuels and fuel additives is also increasing to reduce the emission of NOx and to be less dependent on natural petroleum. The current type approvals are mostly not sufficient to examine the effects for man and the environment. This implies that when harmfulness is examined for a specific biofuel, opposite outcomes could be reached by different institutes due to diverse measurement set up and risk assessment. This presentation will discuss the difficulties in testing toxicity of emissions associated with combustion of biofuels, given the large number of permutations of possible fuel and engine combinations. With regard to measuring/limiting air pollution exposure and its health impact caused by automotive emissions, and more specifically biofuel combustion, there are no common testing guidelines and standards on which to base policy. Clearly, it would be preferable to come to agreement on a harmonized approach for in vitro and in vivo testing, so that new fuels that come to market can be assessed relatively quickly and in standardized way. One of the main questions is what biological pathways and health outcomes should be covered in such "screening" evaluations. So far, mutagenicity and genotoxicity have been a major focus but other end points should be considered as well, given the increasing evidence of cardiovascular and other health effects associated with inhalation of combustion products. In addition, a standardization approach is needed for the generation of combustion aerosols and exposure conditions to really support comparative hazard screening. Examples of recent results from Europe including human exposure studies will be shown as illustrations.
2298 Human Health Impact Assessment of Biofuels

Transportation fuel use represents a key source of air pollutant exposure, particularly in urban areas where mobile source emissions and large populations overlap. Changes in fuel composition can substantially alter the complex mixture of combustion emissions. The increased use of biofuel blends over the past decade and development of policies to promote their uptake necessitate detailed evaluation of the associated health implications. Health Canada (HC) has developed a risk assessment framework to evaluate health impacts of non-conventional fuels and applied it to biofuels. The approach used is: 1) comparative (basecase vs. new fuel) in order to estimate the incremental health risks/benefits of biofuels; and 2) comprehensive, with a focus on principal pathways of risk. The recent HC biodiesel (BD) assessment includes a review of the relative toxicity of BD emissions compared to diesel emissions, and modeling of the impact of the use of BD blends (5% or 20% by volume in ultra low sulphur diesel) in on-road heavy duty vehicles on Canadian air emissions, air quality and resultant health impacts. Incremental health impacts are estimated based on concentration-response functions linking ambient air pollutants with increased risk of premature mortality, hospital admissions, emergency room visits and respiratory outcomes. It is estimated that BD blend use in Canada would reduce emissions of particulate matter, carbon monoxide, volatile organic compounds and polycyclic aromatic hydrocarbons, and increase emissions of nitrogen oxides. These effects are expected to attenuate by 2020 due to the incorporation of new technology vehicles in the fleet. Changes in air pollutant levels due to BD use are expected to be small (<1%), and the associated health impacts minimal. The health effects literature on the comparative toxicity of BD emissions was limited for most endpoints. It was concluded that compared to diesel exhaust, BD exhaust is unlikely to elicit greater respiratory toxicity and may be less mutagenic. Biofuel research to address risk assessment needs and a comparison with the US approach will be reviewed.

2299 Role of Circulating Factors in Mediating Systemic Toxicity of Inhaled Substances

L. Chen1 and M. Campen2. 1Environmental Medicine, New York University School of Medicine, Tuxedo Park, NY and 2Pharmaceutical Sciences, University of New Mexico, Albuquerque, NM.

Air pollution has been known to cause chronic and acute systemic health effects, including cardiovascular and possibly neurodegenerative diseases, but the pathway by which inhaled substances drive effects beyond the lung is unclear. The lung provides an effective barrier against most gaseous and particulate components of air pollution, and those that are taken up systemically are often in remarkably low concentrations. Moreover, several studies fail to see the same effects at relevant concentrations when particulates are delivered by gavage, intravenously, or in cell culture studies, implying that there is a lung-specific reaction that occurs to drive systemic effects. Recent studies have revealed that inhalation exposures to a variety of pollutants can lead to the generation of circulating bioactive factors that drive endothelial cell activation and may also be responsible for neuroinflammation. Circulatory changes include generation of adducted proteins, altered metabolites and lipids, and altered function of lipoproteins. The identity of the causal components(s) in the circulation remains unclear, but ongoing lipidomic and metabonomic research is providing important insights. This workshop will highlight a number of advances in this area related to exposures to particulate matter, metals, ozone, combustion mixtures, and nanomaterials.

2300 Influence of PM2.5 Exposure on the Receptor for Advanced Glycation End Products: Insight into an Emerging Risk for Diabetes

J. M. Vaughan1, B. Narayanan1, A. Schmidt2 and L. Chen1. 1Environmental Medicine, New York University, New York City, NY and 2Medicine, New York University, New York City, NY.

Diabetics are a particularly vulnerable population to the adverse cardiopulmonary effects of particulate air pollution (PM)- this is often attributed to enhanced inflammation and endothelial dysfunction. Recent reports have implicated activated receptors for advanced glycation end-products (RAGE) as an integral factor in the inflammatory processes in cardiovascular dysfunction and diabetes; nonetheless, it is unclear whether ambient air pollutants (PM) alone/or in combination with other endogenous factors may contribute to the activation of RAGE. In this study, we have determined that RAGE was significantly (P=0.0358) higher in serum samples of residents in Jinchang than that in Zhangye (452.6±29.1ng/ml). This change was due to higher levels of Ni, Cu, As, and Se in PM2.5 in Jinchang than that in Zhangye. We also found a dose dependent increase in cell proliferation and small increases in sRAGE activity when human vascular endothelial cells exposed to ambient PM. Immunofluorescence detection showed an elevated number of cells positive for membranous RAGE expression; accompanied with a two-fold increase in mRNA for RAGE and NF-κB. Furthermore, results also showed a >2 fold increase of ATP4 and NF-kB in cells treated with PM+BSA. We also measured the expression of other non-glycated ligands (S100, HMGBl). Using siRNA to silence RAGE in human endothelial cells and RAGE knock out mice, we have confirmed the plausible interaction between PM and RAGE and verified that RAGE is a potential inflammatory mediator of inhaled ambient PM.

2301 Carbon-Based Engineered Nanomaterial Exposure Alters Circulating Factors that Induce Endothelial Activation and Impairment of Nitric Oxide Synthesis

A. Eredi1 and M. Aragon2. 1CDR-NIOSH, Morgantown, WV and 2University of New Mexico, Albuquerque, NM.

Carbon-based engineered nanomaterials (ENM), including carbon nanotubes (CNT), graphene, and fullerenes, have profound utility in medicine, electronics, and composites. While the surface is just being scratched on the diverse applications, a growing workforce is subject to exposure by inhalation. In vitro studies identify pulmonary cytotoxicity, inflammation, and fibrosis as a result of carbon-based ENM exposure. In addition to the pulmonary response, effects related to cardiovascular dysfunction included vascular inflammation and oxidative stress, endothelial dysfunction, and increased atherosclerotic plaque formation. The mechanisms linking the initial pulmonary exposure to resultant cardiovascular dysfunction are under investigation. Given the apparent toxicity of certain ENM and the vast number of ENM including various permutations of each, controlled toxicology studies in humans are not practical. Therefore, a translational in vitro screening assay was developed for rodents to assess the potential cardiovascular toxicity of ENM. Specifically, this particular study explored the ability of circulating factors after pulmonary exposure to affect mechanisms related to vascular dysfunction. Serum collected from mice exposed to carbon black, multi-walled CNT, or varying types of graphene were incubated with murine primary endothelial cells. The serum from exposed mice increased endothelial cell surface expression of VCAM-1 and ICAM-1 as early as 4 hr post-exposure when compared to respective shams. In addition, the serum from exposed mice reduced ATP-stimulated endothelial cell nitric oxide production by 25%. These results complement end point cardiovascular effects and showed the presence of circulating factors contributing to vascular dysfunction following carbon-based ENM exposure. Furthermore, the methodological design allows for interpretation of systemic effects in an unbiased approach while providing a platform for comparative studies of differing ENM in a translational context.

2302 Endothelial Cell Pattern Recognition Receptors, CD36 and LOX-1, Contribute to Responses to Pollution-Induced Circulating Factors

M. Campen. Pharmaceutical Sciences, University of New Mexico, Albuquerque, NM.

Our laboratory initially discovered that the serum from human volunteers contains a bioactive component following controlled exposures to diesel or nitrogen dioxide that can activate inflammatory endothelial cell responses. While we have eliminated the possibility that common cytokines are the driving factor(s) in this response, the identity of the biochemical ligands that drive such responses remains unknown. However, we have considered the possibility that multiligand pattern recognition receptors (PRRs), as mediators of response to extracellular damage, could play a specific role in endothelial cell responses to pollution-induced circulating factors. Two specific receptors have been investigated: cluster of differentiation 36 (CD36) and the lecinth-like oxidized low density lipoprotein receptor-1 (LOX-1). These observations help explain systemic vascular inflammatory effects of diverse inhaled pollutants such as ozone and PM, along with complex mixtures from combustion sources. Ongoing translational work enables cumulative response patterns in controlled settings to improve assessment of relative toxicity of individual components and mixtures of pollutants.
We and others have shown that exposure to concentrated ambient particles and motor vehicle emissions induce lipid peroxidation in the lungs, circulating blood and systemic tissues such as the liver and the aorta. It is unclear however, whether effects induced in the lungs are required for the induction of systemic vascular effects. It is possible that circulating factors such as plasma lipoproteins could be altered and serve as mediators of the systemic toxicity of inhaled substances. This presentation will focus on our studies designed to evaluate the functional changes induced by air pollutants on plasma HDL lipoproteins, their relationship to lipid peroxidation in the lungs, circulating blood and systemic tissues and the activation of endogenous peroxidation pathways.

### Systemic Effects of Inhalation Exposure Mediated by ‘Omic Perturbation in Serum

**A. K. Ottens. Neuroscience, Virginia Commonwealth University, Richmond, VA. Sponsor: M. Campen.**

Recent studies suggest that inhalation exposure to ozone generates circulating factors in blood that can result in systemic health consequences, including activation of microglia and inflammatory responses in the brain; however, the nature and complexity of these products have remained a mystery. As ozone rapidly reacts in the lung surfactant, the generation of pulmonary-derived modified lipids, proteins, or small molecules may be a plausible outcome that leads to systemic effects. Through recent development of a label-free quantitative data-independent Omic platform, analysis of serum factors reveals a diverse and dose-dependent molecular perturbation with broad biochemical implications. Specific effects observed in coronary vascular and nervous systems will be discussed related to the compositional alterations in the serum.

### The Use of Dogs and Minipigs As an Alternative to the Nonhuman Primate in Nonclinical Safety Assessment of Biopharmaceuticals

**J. A. Wieler1 and J. Bluemel1. 1MedImmune, Gaithersburg, MD and 2Amgen, Thousand Oaks, CA.**

Appropriate species selection is paramount for the nonclinical safety evaluation of biopharmaceuticals. Regulatory guidance requires the use of a pharmacological responder species, in particular for biopharmaceuticals. Most often the nonhuman primate (NHP) is considered as the only pharmacologically relevant species, and especially the cynomolgus monkey is frequently used for nonclinical safety studies. In recent years, ethical concerns, increased public scrutiny, and issues of availability and transportation of NHPs have put considerable pressure on researchers worldwide to improve study designs and to intensify the search for alternative species. Besides recent activities to improve study designs to reduce the number of animals used, there is a sense of urgency to intensify the search for alternative species and consider nontraditional approaches beyond the use of “standard” toxicology species. Species like the dog and minipig are meanwhile widely used in toxicity studies for chemical-derived pharmaceuticals but rarely considered for nonclinical safety evaluation of biopharmaceuticals. The limited availability of scientific background data, e.g., pharmacogenomic or physiology comparisons, and limited regulatory experiences are considered as major obstacles for a wider use of dogs and minipigs for biopharmaceutical safety testing. A better understanding of factors like sequence homology, target/ligand expression, downstream signaling, effector functions, and antibody kinetics, as well as the availability of tools like species-specific background databases, in vitro assays, or reagents, would greatly facilitate the use of dogs and minipigs. Increased use of dogs and minipigs for nonclinical safety assessment of biopharmaceuticals would in turn increase the regulatory confidence and experience. The objective of this workshop is to review and discuss recent progression and challenges in the scientific characterization of dogs and minipigs and discuss their utility and limitations for regulatory safety testing of biopharmaceuticals.

### The Immune System and Immune Function Testing in the Dog and Minipig

Reactivity with canine and minipig targets and to some extent the level of immunogenicity of human/humanized proteins in these species may be limitations to their use with regards to safety assessment of biopharmaceuticals. However, tools are available or can be developed to address immunology-related questions. The availability of appropriate knowledge and analytical tools regarding the immune system may be critical for proper nonclinical safety assessment of biopharmaceuticals in the dog and in the minipig from the following standpoints: demonstration of species relevance (on target specific binding, pharmacodynamics); conduct of immunotoxicology assessments (including immunophenotyping of subpopulations of lymphocytes and functional assessments [e.g., T cell-dependent antibody response [TDAR], cytotoxic T cell activity, NK function]; assessment of immunogenicity and documentation of immunogenicity-related toxicity. This presentation will provide a comparison of the human, dog, and minipig immune system (overall structural and functional organization, ontogeny, innate immunity, humoral and cell-mediated immunity). It will then provide an overview of the tools available to document and characterize immunotoxicology in the dog and minipig (with a focus on TDAR and immunophenotyping), as well as existing gaps. It will then discuss available methods for documentation of anti-drug antibodies, circulating or tissue immune complexes.

### The Dog and Minipig As Pharmacology Models to Evaluate Biopharmaceuticals

**N. Dybdal. Safety Assessment Pathology, Genentech, South San Francisco, CA.**

Whether being considered for use in general toxicology or pharmacology studies, the many features of the dog and minipig which make them attractive for consideration as a non-rodent toxicology species must never overshadow the need to first determine if their use is appropriate and justified biologically. First is the species specificity of the biopharmaceutical which must be characterized and relevance in dog and/or minipig must be established (e.g. is the protein appropriately cross-reactive with the target – receptor/ligand). The biological pathway of concern needs to be characterized and comparative activity and control of the pathway understood (e.g. downregulation, upregulation, effector function). Although the potential immunogenicity of the biopharmaceutical may present a challenge, duration of dosing, dose or schedule can often be managed to help avoid this issue. Immunogenicity of foreign proteins reflects a challenge to the feasibility of conducting studies in dogs and minipigs and should not be confused with an opportunity for use of these species as predictive models of immunogenicity in humans. This presentation will provide case examples of the use of dogs and minipigs as pharmacology models. In these examples the obstacles remaining will be balanced against the opportunities and growing feasibility of fully realizing the benefits of conducting pharmacology studies of biopharmaceuticals in these species.

### Animal Model Genomic Data Aids Species Selection in Pharmaceutical Discovery and Development

**J. J. Vamathévan. Computational Biology, GlaxoSmithKline, Stevenage, United Kingdom. Sponsor: J. Wieler.**

Improving drug attrition remains a challenge in pharmacological discovery and development. A major cause of early attrition is the demonstration of safety signals which can negate any therapeutic index previously established. Safety attrition needs to be put in context of clinical translation (i.e. human relevance) and is negatively impacted by differences between animal models and human. In order to minimize such an impact, an earlier assessment of pharmacological target homology across animal model species will enhance understanding of the context of animal safety signals and aid species selection during later regulatory toxicology studies. This talk will cover the genomes of the scrofa Göttingen minipig and the Canis familiaris beagle. Comparative analysis of these genomes with other key model organisms, namely mouse, rat, cynomolgus macaque, rhesus macaque, two related breeds (S. scrofa Duroc and C. familiaris boxer) and human reveal considerable variation in gene content. Key genes in toxicology and metabolism studies, such as the UGT2 family, CYP2D6, and SLC01A2, displayed unique duplication patterns. The use of simple phylogenetic tools allow for the comparisons of known human drug targets prior to starting safety studies. Example studies of such drug targets have revealed surprising variation such as species-specific positive selection, duplication and pseudogenized targets. These data will facilitate the more effective use of animals in biomedical research as well as enhance the understanding of the context of animal safety signals and aid species selection during later regulatory toxicology studies.
Animal welfare is enshrined in the Treaty of the EU. The revision of the Directive on animal protection in the EU was discussed intensely under the framework of the European Commission, because the use of animals, particularly the nonhuman primate (NHP), for testing purposes is a sensitive issue in Europe. The European Community funded a Specific Support Action (SSA) to evaluate the potential impact of toxicity testing in minipig as an alternative approach in regulatory toxicity testing, with the aim of contributing to replacement, refinement and reduction of animal testing. This SSA was named the RETHINK project. The use of NHP and minipig as animal models have been discussed in different forums and this presentation focuses on the minipig as an alternative and draws extensively on RETHINK. The EU launched the Directive 2010/63 indicating that the use of NHP in biomedical research is of the greatest concern to the general public. It is recognized that the use of live animals continues to be necessary to protect human health, but the use of NHP should be restricted to potentially life-threatening conditions in humans or in relation to cases of debilitating conditions. An important application of NHP is in the area of biotechnology-derived proteins. ICH S6(R1) guidance recommends the use of a relevant species, i.e., a species that does respond to the pharmacological action of the product. Because of the high specificity of biopharmaceuticals there is an important restriction in the choice of species. In most cases the cynomolgus monkey is the default species being chosen. Based on the EU-legal restrictions mentioned above the minipig might be considered as an important ‘alternative’ species. There are several opportunities and challenges in using minipig as the nonrodent species of choice.

- Application of minipigs in the testing strategy of dermally-applied products
- Limitations in reproductive and developmental toxicity testing of biopharmaceuticals
- Cardiovascular functioning in minipigs as a model for humans.

These topics will be discussed using case reports.
**RI 2314** Effects of *In Utero* and Early Postnatal Exposures to Metal-Containing Dusts

R. Lantz. Dept of Cellular and Molecular Medicine, University of Arizona, Tucson, AZ.

In the arid Southwest of the United States, dusts, especially downwind of legacy mine tailings and smelters, can contain high levels of metals, including arsenic. The levels of arsenic in these dusts can be an order of magnitude above ambient levels. In addition, because of high levels of arsenic in drinking water, simultaneous exposure to arsenic from water and from airborne particulate dust occurs. Exposure to airborne toxicants, that are downwind of toxic sources, can cause adverse health effects. Exposure of pregnant female mice to air pollutants has been shown to alter lung function and to enhance sensitization and airway reactivity in offspring. *In utero* and/or postnatal exposure to cigarette smoke, ambient urban air particles or metals leads to increased airway reactivity, decreased surface to volume ratios in the lung and altered lung function in the offspring. In this study, we examined the effects of inhalation of arsenic compounds during sensitive developmental time periods. Mice were exposed by inhalation to dusts containing various forms of arsenic that can be found in mine tailings or downwind of smelters, either during *in utero* development, after birth or both. Pulmonary function, structure and inflammation were analyzed to determine the effects of these exposures on the developing lung. The effect of combined inhalation and ingestion was also analyzed. Alterations in lung resistance, elastance and airway reactivity were seen. These changes correlated with alterations that occurred in the connective tissue around airways. The responses depended on the form of arsenic that was inhaled as well as the developmental time when the exposures occurred. Children living in an arid region of Mexico who would be expected to be exposed both through ingestion and inhalation of arsenic showed decrements in lung function. These data indicate that inhalation of dusts containing arsenic during sensitive developmental times may result in altered pulmonary function and structure later in life.

**PI 2316** Metabolic Pathways Related to Inflammation Are Disrupted by Arsenic in the Livers of Mice Fed a Western Diet

W. H. Watson1, X. Shi, X. Wei2, I. Koo2, R. H. Schmidt1, X. Yin2, S. Kim2, A. Vaughn3, C. McClain1, G. E. Arter2 and X. Zhang2. 1Department of Medicine,Geisel School of Medicine at Dartmouth, Hanover, NH. 2Chemistry, University of Louisville, Louisville, KY. 3Pharmacology & Toxicology, University of Louisville, Louisville, KY and 4Robby Rex VAMC, Louisville, KY.

Arsenic is a widely-distributed environmental component that is associated with a variety of cancer and non-cancer adverse health effects. Additional lifestyle factors, such as diet, contribute to the manifestation of disease. Recently, arsenic was found to increase inflammation and liver injury in a dietary model of fatty liver disease. The purpose of the present study was to investigate potential mechanisms of this diet-environment interaction via a high throughput metabolomics approach. GC×GC-TOF MS was used to identify metabolites that were significantly increased or decreased in the livers of mice fed a Western diet (a diet high in fat and cholesterol) and co-exposed to arsenic-contaminated drinking water. The results showed that there are distinct hepatic metabolomic profiles associated with eating a high fat diet, drinking arsenic-contaminated water, and the combination of the two. The high fat diet significantly altered nine metabolites, and the addition of arsenic resulted in further changes to three of these metabolites as well as introducing changes in six additional metabolites. The profiles of altered metabolites were consistent with perturbations in the metabolism of glutathione, short-chain fatty acids and medium-chain fatty acids. Of particular interest was the apparent block in the synthesis of glycine when arsenic was combined with a high fat diet. Glycine can inhibit inflammatory signaling by hepatic Kupffer cells in other model systems, and the decrease in glycine levels seen in our model may account for the observed increase in inflammatory cytokines and markers of Kupffer cell activation. These results point to potentially novel mechanisms by which arsenic can promote the progression of fatty liver disease.

**RI 2315** Metals, the West, and Translational Science

J. L. Lewis. Community Environmental Health Program, University of New Mexico, Albuquerque, NM.

The western US has been heavily mined for a range of heavy metals, leaving the majority of the 500,000 abandoned mines in the US behind. Among these abandoned mines are also more than 10,400 abandoned uranium mine waste sites scattered throughout the west, with more than 1100 located on the Navajo Nation. Arsenic, both naturally occurring and as a co-contaminant in mine waste, also complicates exposures through its presence in unregulated water sources relied on by up to 30% of the populations in some of these regions. Evaluating the impact of these mixed-metal exposures in Western communities is further complicated by the fact that the sites often impact rural and tribal communities that have not been adequately represented in the research base from which toxicity has been evaluated. Evaluating the health impacts of the unique mixtures in the waste within the context of existing lifestyle and risk factors presents unique challenges, and an opportunity for developing novel approaches that integrate disciplines including population science, toxicology, and clinical care with physical sciences and novel statistical approaches to understand the complex interactions. We have been able to build on a diversity of strengths to develop an integrated transdisciplinary response to these issues and to begin not only characterizing the problems, but identifying interventions, informing clinical care, and informing policy to reduce the impact on our communities. In Navajo communities, we have found that while exposures in communities during the active phase of mining increased the risk for kidney disease, chronic lower dose exposures to legacy waste increase the likelihood of hypertension, autoimmune disease and immune dysfunction in adults. We are currently investigating the relationship between these exposures to mixed metals in legacy waste, reproduction, and development in Navajo children. These community-based approaches also represent efforts to integrate Western science with Native learning models and underscore the importance and impact of translational science in meeting the needs of improving community health.

**PI 2317** Organic Species of Arsenic Have Adverse Effects on *Pseudomonas aeruginosa*-Induced Immune Response

E. Notch, R. Barnaby, B. Coutermarch, V. Taylor, B. Jackson and B. Stanton. Geisel School of Medicine at Dartmouth, Hanover, NH.

Arsenic is the number one environmental contaminant of concern with regard to human health. Epidemiological studies have linked arsenic exposure with lung disease, including bacterial infections, and chronic obstructive pulmonary disease, which are associated with *Pseudomonas aeruginosa* (Pa) infection. Animal models have also shown that arsenic alters the immune response. Little is known about effects of low doses relevant to US population exposure or the contributions of organic arsenic to altered immune response. This study examined impacts of inorganic sodium arsenite (iAsIII) and two major metabolites, monomethylarsonous acid (MMAIII) and dimethylarsenic acid (DMAIII), on Pa induced cytokine secretion by primary human bronchial epithelial cells (HBEC). Exposure of HBEC to 1μg (10ppb) did not alter Pa induced cytokine secretion. In contrast, 5ppb DMA significantly decreased IL-8, IL-6, CXCL1 and CXCL2 secretion after Pa stimulation compared to cells exposed to Pa alone. Exposure to 5ppb MMA increased Pa induced IL-8, and CXCL2 secretion. These alterations in HBEC proinflammatory cytokine secretion can impact macrophage recruitment or amplification of chemotactic stimulus through reduced macrophage cytokine secretion. Differentiated THP-1 cells (macrophages), were exposed to purified CXCL1 and CXCL2 at concentrations based on HBEC secretion. Lower concentrations of CXCL1 and CXCL2, equivalent to those released by HBEC exposed to DMA and Pa, reduced THP-1 IL-8 and IL-1β secretion. Higher concentrations of CXCL1 and CXCL2, equivalent to those released by HBEC exposed to MMA and Pa, significantly increased THP-1 IL-1β secretion. This suggests that MMA will enhance inflammatory response potentially leading to lung damage and DMA will suppress inflammatory response resulting in increased pathogen burden. These results demonstrate that exposure to low levels of organic arsenic, that may occur from ingestion of rice and rice based products, have untoward effects on the respiratory immune response to Pa infection.
Arsenic Exposure and Cell-Mediated Immunity in Preschool Children in Rural Bangladesh

S. Ahmed1,2, Y. Wagatsuma3, M. Kippler4, R. Raqi1 and M. E. Vaheri1, 1Institute of Environmental Medicine (IEM), Karolinska Institutet, Stockholm, Sweden, 2International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh and 3University of Tsukuba, Tsukuba, Japan.

Prenatal arsenic exposure is associated with reduced infant’s thymic size and function and increased morbidity, indicating arsenic-related impaired immune maturation. In this follow-up study, we evaluated the persistence of arsenic-related impaired immunity by measuring the delayed type hypersensitivity response (DTH) in pre-school aged children, in relation to prenatal and concurrent arsenic exposure. Children born in a longitudinal mother-child cohort in rural Bangladesh were studied at 4 years of age (n=577). Exposure to arsenic was assessed by the concentrations of arsenic metabolites in maternal urine (U-As) collected in gestational week 8 (GW8), as well as in children’s concurrent urine. U-As was measured by HPLC online with ICP-MS. Children were given an intradermal injection of purified protein derivative (PPD), and the diameter (mm) of induration was measured after 48 hours. Plasma levels of 27 cytokines were analyzed by multiplex cytokine assay. Concurrent, but not prenatal, arsenic exposure was associated with increased risk of not responding to PPD (induration <5mm) injection. The odds ratio (OR) of not responding to PPD was 1.91, (95% confidence interval (CI): 1.18, 3.07) in children in the highest quartile of U-As (125-1228 μg/L) compared with lowest quartile (12-34 μg/L). The associations were stronger in underweight children and those in families with low socioeconomic status. Concurrent arsenic exposure was inversely associated with Th1 cytokines (IL-2 and TNF-α) (regression coefficient (95% CI): -0.38 (-0.69, -0.06); and -1.17 (-2.38, 0.05), respectively) and, thus, Th1/Th2 ratios (IL-2/IL-4 and IL-2/IL-10). In subsequent stratified analyses, these associations were more evident in underweight children and those in families with low socioeconomic status. In conclusion, arsenic exposure appeared to impair cell-mediated immunity in children by reducing the DTH, presumably linked to reduced Th1 cytokines.

Inhibition of Arsenic-Induced Unfolded Protein Response Prevents Endothelial Activation and Inhibits Atherosclerosis in APO E-Knockout Mice

Epidemiological and animal studies suggest that exposure to arsenic exacerbates atherosclerosis. However, the mechanisms by which arsenic exerts itsatherogenic effects are not known. We observed that exposure of endothelial cells to sodium arsenite for 4 days increased the expression of pro-inflammatory cytokine IL-8 by 5-fold and molecular chaperones of protein folding - GRP78 and HERP by 2-fold. Moreover, acute exposure of sodium arsenite (2-6 hours) to endothelial cells increased the surface expression of adhesion molecules ICAM-1, VCAM-1 and E-Selectin by 1.2-1.5-fold; leukocyte adhesion by 1.3-2.5-fold; leukocyte trans-endothelial migration by 2.5-4.0-fold; and expression of pro-inflammatory cytokines and chemokines by 27-150-fold. Acute exposure of endothelial cells to sodium arsenite also activated the IRE-1 and ATF-6 arms of unfolded protein response (UPR) and increased the expression of molecular chaperones. Knockdown of IRE-1 by siRNA and adenosine transfection with ATF-6 prevented sodium arsenite-induced endothelial activation. Similarly, phenyl butyric acid (PBA), a chemical chaperone of protein folding, prevented sodium arsenite-induced endothelial activation. Moreover, feeding PBA to apoE-null mice for 16 weeks inhibited sodium arsenite-induced UPR in atherosclerotic lesions; expression of adhesion molecules on endothelial cells lining the atherosclerotic lesions; lesional and systemic inflammation and prevented the arsenic-induced exacerbation of lesion formation in the aortic valve. Together, these data suggest that arsenic causes endothelial activation and exacerbation of atherosclerosis by triggering UPR and chemical chaperones of protein folding could prevent arsenic-induced exacerbation of atherogenesis and inflammation.

Characteristics of Activated Lymphocytes in Silicosis Differing in Th17 Phenotype from Systemic Scleroderma

Y. Nishimura1, S. Lee1, N. Kumagai-Takei1, H. Matsuzaki1, H. Hayashi2, W. Fujimoto2, Y. Morita3, M. Kusaka4 and T. Otsuki1. 1Hygiene, Kawasaki Medical School, Kurashiki, Japan, 2Dermatology, Kawasaki Medical School, Kurashiki, Japan, 3Rheumatology, Kawasaki Medical School, Kurashiki, Japan and 4Kusaka Hospital, Bizan, Japan.

Inhalation of silica causes lung pneumonia, silicosis, the patients with which occasionally suffer from autoimmune diseases including systemic scleroderma (SSc). We hypothesized an immunological effect of silica exposure, and examined immunologically patients with silicosis and SSc using flow cytometry, realtime PCR and cell culture techniques. Both the patients with silicosis and SSc showed increases in CTLA-4, CXCR3 and IL-1R1 on CD4+ T cells and CD25, FasL, CXCR3 and HLA-DR on CD8+ T cells. Additionally, silicosis showed increases in CD45RO on CD8+ T cells and FasL on NK cells, but SSc did not. Foxp3 mRNA level was high in CD4+ T cells of silicosis as well as SSc, but IL-1R1 mRNA was high only in SSc. Silicosis showed high TNF-α mRNA in stimulated CD4+ T cells,
whereas SSC showed high IL-17A mRNA. Both stimulated CD8+ T cells of silicosis and SSC showed high mRNA levels of granzyme B, IFN-γ and FasL, IP-10, MCP-1 and TNF-α levels in plasma were high in silicosis as well as SSC. These results indicate that silicosis and SSC patients have several similar characteristics of increases in regulated on activation, normal T cell expressed and secreted (RAGE) and inflammatory cytokine, and that Th17 function increases in CD4+ T cells of SSC patients. The similarities between silicosis and SSC suggest a potentially immune-activating effect of exposure to silica, leading to autoimmune diseases. The difference in characteristics observed in both the diseases might contribute to understanding pathogenesis of autoimmune diseases following exposure to silica.

### 2323 Transient Receptor Potential Cation Channel A1 (TRPA1) Mediates Decrements in Cardiac Mechanical Function and Dysrhythmia Caused by a Single Air Pollution Exposure in Mice

N. Kusnawicz1, R. McIntosh-Kautzinsky1, A. Ledbetter2, L. Walsh3, A. K. Farraj4 and M. S. Hazari1. 1University of North Carolina, Chapel Hill, NC and 2Environmental Public Health Division, USEPA, Research Triangle Park, NC.

Time-series studies indicate that the risk of cardiac events and arrhythmia increase significantly in the hours to days directly following exposure to air pollution. Previous studies have demonstrated that pharmacological inhibition of transient receptor potential cation A1 (TRPA1) attenuates diesel exhaust-induced cardiac arrhythmia. In this study, we sought to further confirm the role of TRPA1 in acute cardiovascular dysfunction due to air pollution exposure by utilizing a TRPA1 knockout mouse model. We hypothesized that acrolein and ozone (O3), both potent TRPA1 agonists, would cause decrements in cardiac function and electrical disturbances via TRPA1 mediated mechanisms. Conscious, unrestrained C57BL/6 (wt) and TRPA1 knockout (ko) mice were exposed to 3ppm acrolein for 3 hours or 0.3ppm O3 for 4 hours; separate groups were exposed to filtered air (FA). Electrocardiogram (ECG) was recorded continuously before, during and after exposure. 24 hours post-exposure, cardiac function was assessed using a Langendorff cardiac perfusion preparation. Acrolein exposed wt mice demonstrated a significant decrease in HR during exposure as well as an increased incidence of arrhythmia compared with FA controls. Acrolein also produced a significant increase in ventricular relaxation, whereas exposure to O3 produced a significant decrease in contractility and relaxation in wt mice. No effects were seen in acrolein or O3 exposed ko mice. These data indicate that TRPA1 mediates, at least in part, the development of acute cardiac function decrements and dysrhythmia following exposure to either of these two relatively ubiquitous pollutants. While both acrolein and O3 are TRPA1 agonists, they appear to cause divergent cardiac responses, which suggest the underlying mechanisms are more complex than mere sensory activation. (This abstract does not reflect EPA policy)

### 2324 Inhalation Exposures to Ozone Induce Insulin Resistance and Pulmonary Pathology in Type II Diabetes-Prene Mice

K. Allen, R. Lewandowski, J. G. Wagner and J. R. Harkema. Great Lakes Air Center for Integrated Environmental Research, Michigan State University, East Lansing, MI.

Introduction: Epidemiological studies suggest that diabetics may be more susceptible to the adverse health effects of air pollution. Mice chronically exposed to particulate air pollutants induce insulin resistance (IR), an early indicator of type II diabetes (T2D). In the present study we tested the hypothesis that episodic inhalation exposures to a common gaseous air pollutant, ozone (O3), will induce early onset of IR in mice genetically prone to develop T2D.

Methods: Male C57BL/6, KK, and KKAY mice were exposed to 0 ppm (filtered air; FA) or 0.5 ppm O3, 4h/day, for 13 weeks. Two hours after the last exposure, mice were subjected to insulin tolerance tests (ITT) and then sacrificed 4 hours postexposure. Mice received a single intraperitoneal injection of insulin and blood samples were collected at 0, 10, 20, 30, 60, 90, 120 and 130 minutes after injection. Bronchoalveolar lavage fluid (BALF) was analyzed for inflammatory cells, and lungs were processed for light microscopy.

Results: Normoglycemic, C57BL/6 mice exposed to FA or O3 had normal ITT. In these mice, O3 caused modest increases in the number of BALF inflammatory cells and minimal to mild pulmonary pathology. In contrast, O3 induced greater increases in BALF inflammatory cells in the hyperglycemic KK mice, along with more severe pulmonary pathology. Marked IR was present in O3-, but not FA-, exposed KK mice. Both FA- and O3-exposed, hyperglycemic KKAY mice developed IR. KKAY mice exposed to O3 had the greatest number of BALF inflammatory cells and the most severe pulmonary pathology of all the mice on study.

Conclusions: Episodic O3 exposures caused an early onset of IR in mice genetically prone to T2D. These hyperglycemic animals had greater O3-induced lung injury and inflammation compared to normoglycemic, insulin responsive mice. These results suggest that people at risk for T2D may be more susceptible to respiratory and metabolic health effects caused by elevated concentrations of ambient O3. Funded by USEPA RD83479701.

### 2325 Ozone-Induced Impairment of Systemic Metabolic Processes: Influence of Prior Ozone Exposure and Metformin Pretreatment on Aged Wistar Kyoto (WKY) Rats

Ozone (O3) exposure is associated with adverse cardiopulmonary health effects in humans and thought to produce metabolic impairment, such as insulin resistance. Recently, we showed that acute O3 exposure caused glucose intolerance and increased serum leptin and epinephrine in aged Brown Norway rats. We hypothesized that 1) subchronic pre-exposure to O3 at a young age would predispose rats to exacerbated metabolic effects of subsequent O3 exposure later in life and 2) metabolic effects of O3 would be different in aged rats pretreated with metformin to improve glucose uptake in tissue. WKY rats were exposed to O3 at 0 or 0.5 ppm 6h/day×2days/week x 13 weeks starting at 3 months of age. To study the effects of pre-exposure, the same rats were re-exposed to 0 or 1 ppm ozone acutely for 6h at 14 months of age. To examine if treatment to improve glucose uptake would reduce the effects of O3, another group of 18 month old WKY rats were treated with the anti-diabetic drug metformin in drinking water (3g/L) for 2 weeks prior to a 6h/day x 2 day acute exposure to 0 or 1ppm ozone. Glucose tolerance tests, serum, and Bronchoalveolar lavage fluid (BALF) analyses were done immediately after exposure in both studies. Marked age-related impairment of glucose tolerance was observed. Additionally, O3 exposure caused further impairment of glucose tolerance. O3 exposure resulted in acute lung injury/inflammation and increases in serum levels of leptin, insulin, cholesterol and triglycerides in aged WKY rats. Pre-exposure to O3 had no significant impact on any of these parameters. Treatment with metformin did not reduce O3-induced lung injury or glucose intolerance, but decreased serum leptin and insulin in all rats. Our results suggest that pre-exposure to O3 does not impact response to re-exposure at an older age. We believe that the metabolic effects of O3 are not mediated by impaired cellular glucose regulation. (Does not reflect US EPA policy).

### 2326 Serum Metabolomic Profiling and Liver Transcriptomic Analysis Provides Mechanistic Evidence of Ozone (O3)- Induced Systemic Metabolic Impairment

Recently, air pollution has been linked to insulin resistance and obesity but the mechanisms remain to be elucidated. We have recently shown that acute O3 exposure induces glucose intolerance, hyperglycemia and increases in leptin and epinephrine in rats. Here, we hypothesized that the metabolic effects of O3 are associated with global changes in liver fatty acid and amino acid metabolism and that global metabolomic and transcriptomic approaches will provide insight into the mechanisms by which O3 might contribute to increased insulin resistance and/or obesity. Male Wistar Kyoto (WKY) rats were exposed to air or 1 ppm O3, 6 hrs/day for 1 or 2 days and liver gene expression and serum metabolomic analysis were performed immediately after. Metabolomic analysis identified O3 effects on numerous small metabolite biomarkers. O3 increased blood glucose, long chain free fatty acids, cholesterol and decreased 1,5-anhydroglucitol (AG); biomarkers of insulin resistance. Metabolites of glycosylation were increased, however; intermediates of the TCA cycle and bile acids were decreased in the serum by O3. Branched chain amino acids were increased, suggesting muscle amino acid catabolism. Of particular interest, metabolites that are associated with gut microbiome (e.g. phe- nylacetylglycine) were also markedly affected by O3. Liver gene expression profile after O3 exposure correlated with the serum metabolite changes. For example, elevated serum fatty acids coincided with decreased expression of lipid biosynthetic genes, suggesting that the liver might have initiated homeostatic control for metabolic changes. In conclusion, our metabolomic and genomic analyses show that O3 induces acute systemic alterations reflective of changes in glucose, lipid, and amino acid metabolism which upon chronic exposure might contribute to insulin resistance and obesity. (Does not reflect EPA Policy).
Ccr2 is a chemokine receptor that mediates the migration of macrophages (MP) to sites of injury. In these studies we analyzed the role of Ccr2 in ozone-induced inflammatory cell trafficking to the lung. Treatment of C57Bl/6 mice with ozone (0.8 ppm, 3 h) resulted in increased bronchoalveolar lavage (BAL) protein after 24-48 h, indicative of alveolar epithelial injury. This was associated with a time-related increase in CD11b+ inflammatory cells in the lung. The majority of these cells expressed CD11c and F4/80 indicating that they are mature lung MP. Ly6C is expressed at high levels on proinflammatory MP. CD11b+F4/80+Ly6Chi proinflammatory MP increased in the lung after ozone, peaking at 24-48 h. CD11b+F4/80+Ly6C midinflammatory MP also increased in the lung, peaking 48-72 h after ozone. Loss of Ccr2 resulted in a decrease in ozone-induced accumulation of CD11b+ cells in the lung. This was correlated with decreases in CD11b+F4/80+Ly6Chi and CD11b+F4/80+Ly6C midipopulations. Whereas decreases in proinflammatory Ly6C midMP persisted for at least 72 h post ozone, decreases in antiinflammatory Ly6C midMP were transient, and by 72 h were near control levels. CD11b+F4/80+Ly6g+Ly6c+ myeloid-derived suppressor cells (MDSC), which display antiinflammatory activity and are known to migrate to sites of injury, were increased in the lung 48 h after ozone. Loss of Ccr2 resulted in a persistent increase in MDSC. Changes in lung MP and MDSC were linked to reduced toxicity of ozone, measured by BAL protein levels. The effects of loss of Ccr2 on splenic monocytes, which function as an extramedullary source of inflammatory cells were also analyzed. Ozone caused a decrease in CD11b+F4/80+Ly6Chi proinflammatory monocytes in the spleen; this response was attenuated in Ccr2−/− mice 24-72 h after ozone. These results demonstrate a key role of Ccr2 in ozone-induced inflammatory cell migration into the lung and toxicity. Moreover, it appears that the effects of Ccr2 are predominantly on proinflammatory MP.

2327 Ccr2 Regulates Inflammatory Cell Accumulation in the Lung and Tissue Injury following Ozone Exposure
A. M. Groves, M. Francis, M. Mandal, H. Choi, J. D. Laskin and D. L. Laskin, Rutgers University, Piscataway, NJ.

Introduction: Ozone (O3) is an oxidant air pollutant in photochemical smog. While nasal epithelial injury and remodelling have been reported in laboratory animals repeatedly exposed to O3, associated granulocytic rhinitis and pro-inflammatory cytokine expression have not been fully characterized. We investigated the temporal changes in granulocyte influx, cytokine gene expression, and epithelial remodelling in the nasal mucosa of mice episodically exposed to O3. Methods: Male mice were exposed to 0 or 0.5 ppm O3 for 1, 2, 4, 9, or 24 weeks (4h/day). Airway mucosa from nasal turbinates and lateral wall were analyzed for cytokine and epithelial gene expression. Nasal tissues were prepared for light microscopy and morphometry. Immunohistochemistry was used to identify neutrophils, eosinophils, and chitinase-like proteins (Ym1/Ym2). Epithelial mucous and goblet cell surfaces were histochemically detected. Results: 1-day-O3 exposure induced a neutrophilic influx with few eosinophils and concurrent epithelial necrosis. These responses were associated with overexpression of KC, MIP-2, IL-1β, IFNγ, IL-5, IL-6 and eotaxin genes. After repeated O3 exposures, neutrophils waned and eosinophils increased, along with epithelial regeneration and remodelling. 9-day-O3 mice had marked eosinophilic rhinitis with few neutrophils, mucous cell metaplasia and increased epithelial Ym1/Ym2 proteins. Concurrently there was overexpression of Gob5, Muc5AC, IL4, IL5, eotaxin and Ym2 genes. 24-day-O3 mice developed marked eosinophilic rhinitis, epithelial hyperplasia, mucous cell metaplasia, hyalinosis, and increased Ym1/Ym2 expression.

Conclusion: Repeated, episodic O3 exposures in mice induce Th2 cytokine overexpression, eosinophilic rhinitis, epithelial remodelling, and increased epithelial chitinase-like proteins. These results suggest an etiologic role of ambient ozone in the development of nonallergic eosinophilic rhinitis. Funded by USEPA R83479701.

Reference Concentration .................................................. 632j
Reference Dose .................................................. 777
Refusal Function ...................................................................................... 2012
Refinement .......................................................... 1226
Regional Divergence .......................................................... 1885
Regepahenf .......................................................... 1200a
Regulation ................................................................................................. 210
Regulation Groups .......................................................... 208k
Regulatory Acceptance .......................................................... 635
Regulatory and Safety Evaluation ................................................................. 1441, 1442, 1443, 1444, 1445, 1446
Regulatory Considerations ................................................................. 465
Regulatory Guidelines .......................................................... 456, 2250g
Regulatory Risk Assessment .............................................................. 631
Regulatory Safety Evaluation ................................................................. 2109, 2114
Regulatory Science .......................................................... 2110
Regulatory Testing ................................................................................. 2112
Regulatory Toxicity Testing ................................................................. 2306
Regulatory Toxicology .......................................................... 185, 639, 1415
Reintegrated Behavioral Sensitivity .......................................................... 369
Release ................................................................................................. 641
Remediation .......................................................... 1467d
Renal ...................................................................................................... 1543
Renal Biomarkers .......................................................... 1544
Renal Cell Carcinogenesis ................................................................. 253, 251
Renal Dysfunction .................................................................................. 2012
Renal Function ........................................................................................... 2049
Renal Proximal Tubule Cells ................................................................. 320
Renal Toxicity .......................................................... 649, 718, 1546
Renal Transport ....................................................................................... 2066
Renal Transporters .................................................................................. 2067
Renal Tumor .......................................................... 2196e, 2196g, 2196i
Renovirus ................................................................................................. 2037
Repair ................................................................................................. 1936
Repeal Dose .............................................................................................. 280
Repealed-Dose Toxicity ........................................................................ 164, 1625, 2192
Repealed-Dose Toxicity Study ................................................................. 164, 1601
Repealed-Dose Toxicology Studies ........................................................... 1992
Replication Stress ..................................................................................... 1293
Replication ............................................................................................... 26
Refill Fluid ................................................................................................. 1612
Repeat Dose ............................................................................................... 26
Referring Dose ............................................................................................ 777
Regulation of Safety Evaluation ................................................................. 1441
Renal Dysfunction ..................................................................................... 2045
Redox Biology .......................................................... 1102, 1795, 2039
Redox Status ............................................................................................. 1456
Redox Potential ........................................................................................... 591
Redox Cycling ............................................................................................. 1083
Red Blood Cells .......................................................................................... 1768
Reconstructed Vaginal Tissue ........................................................................... 467
Regulatory and Safety Evaluation ................................................................. 1441, 1442, 1443, 1444, 1445, 1446
Regulatory Risk Assessment ................................................................. 631
Regulatory Safety Evaluation ................................................................. 2109, 2114
Regulatory Science ................................................................................... 2110
Regulatory Testing .................................................................................... 2112
Regulatory Toxicity Testing ................................................................. 2306
Regulatory Toxicology .......................................................... 185, 639, 1415
Reintegrated Behavioral Sensitivity .......................................................... 369
Release ................................................................................................. 641
Remediation .......................................................... 1467d
Renal ...................................................................................................... 1543
Renal Biomarkers .......................................................... 1544
Renal Cell Carcinogenesis ................................................................. 253, 251
Renal Dysfunction .................................................................................. 2012
Renal Function ........................................................................................... 2049
Renal Proximal Tubule Cells ................................................................. 320
Renal Toxicity .......................................................... 649, 718, 1546
Renal Transport ....................................................................................... 2066
Renal Transporters .................................................................................. 2067
Renal Tumor .......................................................... 2196e, 2196g, 2196i
Renovirus ................................................................................................. 2037
Repair ................................................................................................. 1936
Repeal Dose .............................................................................................. 280
Repealed-Dose Toxicity ........................................................................ 164, 1605, 2192
Repealed-Dose Toxicity Study ................................................................. 164, 1601
Repealed-Dose Toxicology Studies ........................................................... 1992
Replication Stress ..................................................................................... 1293
Replication ............................................................................................... 26
Refill Fluid ................................................................................................. 1612
Repeat Dose ............................................................................................... 26
Referring Dose ............................................................................................ 777
Regulation of Safety Evaluation ................................................................. 1441
The Official Journal of the Society of Toxicology

Toxicological Sciences

- A top original research journal in Toxicology
- Ranked 8 out of 85 in this category
- Advance Access—quick online publication, weeks ahead of print
- Optional open access for authors
