Deadline for Proposals
for SOT 2015
Annual Meeting
Sessions: April 30, 2014

Session Types

**Continuing Education**—Emphasis on quality presentations of generally accepted, established knowledge in toxicology
*Note: CE courses will be held on Sunday.*

**Symposia**—Cutting-edge science; new areas, concepts, or data

**Workshops**—State-of-the-art knowledge in toxicology

**Roundtables**—Controversial subjects

**Continuing Medical Education**—Emphasis on state-of-the-art knowledge to assist medical doctors, health professionals, and researchers in life-long learning for providing high-quality health care
*Note: Any session type may be considered for CME.*

**Historical Highlights**—Review of a historical body of science that has impacted toxicology

**Informational Sessions**—Scientific planning or membership development

**Education-Career Development Sessions**—Sessions that provide the tools and resources to toxicologists that will enhance their professional and scientific development

**Regional Interest**—Central topics of relevance that describe public health and/or ecological problems of a particular region

---

**Why Submit a Proposal?**

1. To present new developments in toxicology.
2. To provide attendees with an opportunity to learn about state-of-the-art technology and how it applies to toxicological research.
3. To provide attendees with an opportunity to learn about the emerging fields and how they apply to toxicology.

---

Submit your proposal online at www.toxicology.org
Preface

This issue is devoted to the abstracts of the presentations for the Continuing Education courses and scientific sessions of the 53rd Annual Meeting of the Society of Toxicology, held at the Phoenix Convention Center, March 23–27, 2014.

An alphabetical Author Index, cross referencing the corresponding abstract number(s), begins on page 627.

The issue also contains a Keyword Index (by subject or chemical) of all the presentations, beginning on page 655.

The abstracts are reproduced as accepted by the Scientific Program Committee of the Society of Toxicology and appear in numerical sequence.

NOTE: Abstract numbers including a lower-case letter were programmed during second submission phase.

Scientific Session Types:

| EC | Education-Career Development Sessions |
| HH | Historical Highlights Session         |
| IS | Informational Sessions                |
| PL | Platform Sessions                     |
| PS | Poster Sessions                       |
| RI | Regional Interest Session             |
| R  | Roundtable Sessions                   |
| S  | Symposium Sessions                    |
| W  | Workshop Sessions                     |

The 2014 SOT Mobile Event App and Event Website

Use the enhanced planning and networking tools to access the latest meeting information, connect with fellow attendees, build your own schedule, view presentation details, abstracts, and ePosters, request meetings with attendees and exhibitors, and navigate ToxExpo with an interactive floor plan. In addition to these networking and meeting planning tools, use the mobile event app and website to access a complete Phoenix city guide including hotels, restaurants, attractions, nightlife, and shopping. One-on-one technology training and support is available during the meeting; visit the @SOT Center—Internet Access and App Training located outside the ToxExpo on the Lower Level or the SOT Pavilion in ToxExpo.

Copies of The Toxicologist are available at $50 each plus $5 postage and handling (US funds) from:

Society of Toxicology
1821 Michael Faraday Drive, Suite 300 • Reston, VA 20190

---

This abstract book has been produced electronically by ScholarOne, Inc. Every effort has been made to faithfully reproduce the abstracts as submitted. The author(s) of each abstract appearing in this publication is/are solely responsible for the content thereof; the publication of an article shall not constitute or be deemed to constitute any representation by the Society of Toxicology or its boards that the data presented therein are correct or are sufficient to support the conclusions reached or that the experiment design or methodology is adequate. Because of the rapid advances in the medical sciences, we recommend that independent verification of diagnoses and drug dosage be made.
1 Combination Products: Toxicology and Regulatory Challenges

J. N. Cammack1, C. Ghosh1 and T. Nguyen2, 1AstraZeneca Biologics, Gaithersburg, MD and 2US FDA, Silver Spring, MD.

Therapeutic and diagnostic products that combine drugs, devices, and/or biological elements are termed and regulated by US FDA as combination products. Technological advances continue to merge product types and blur the historical lines of separation among traditional drugs, biologics, and medical devices. Concomitantly. FDA’s medical product centers, the Center for Biologics Evaluation and Research (CBER), the Center for Drug Evaluation and Research (CDER), and the Center for Devices and Radiological Health (CDRH), are employing ever-evolving collaborative efforts to address the regulatory complexities of combination products. Because combination products involve components that would normally be developed and regulated under different types of processes and policies (and frequently submitted to different FDA Centers), these products raise challenging development, regulatory, and review management questions. Differences in these pathways for each combination product type can impact the processes for all aspects of product development and management (especially preclinical testing), but also clinical investigation, marketing applications, manufacturing and quality control, adverse event reporting, promotion and advertising, and post-approval modifications. Trends and strategies for addressing the impact of overlapping technologies and evolving regulatory processes in developing a successful preclinical evaluation program will be highlighted. A regulatory overview of definitions and combination product examples, as well as a high-level review of FDA’s final rule (effective July 22, 2013), will be included. A primary focus of the course is discussion of approaches in optimizing a pre-clinical program for a hypothetical drug-device combination product (e.g., a monoclonal antibody packaged in a pre-filled syringe). Additionally, regulatory overview of the preclinical evaluation program will be provided. Future trends in combination product therapies will also be highlighted.

2 Computational and Experimental Aspects of microRNAs in Toxicology

S. C. Tilton1, K. Wang1, J. Popribia2, R. J. Brennan3 and K. Thompson3.

MicroRNAs (miRNAs) are small noncoding RNAs that function as post-transcriptional regulators of gene expression. miRNAs are increasingly recognized for their importance in regulating mechanisms of disease and exposure, including those associated with nervous system development, cardiac function, metabolism and cancer. miRNAs and their transcriptional targets are highly conserved across species. They are also stable in plasma and urine as biomarkers of tissue-specific damage or response. Furthermore, miRNAs are unique in that not only can they be experimentally measured along with their inhibitory effects on transcripts and protein levels, but their post-transcriptional regulation can also be computationally predicted based on sequence specificity and conservation across species. Given the overall importance of miRNAs in toxicology, it is necessary to understand both computational and experimental aspects of miRNAs for accurate miRNA quantification and discovery of the functional consequences of their disruption by chemical or drug exposure. The goal of the course is to provide toxicologists with a better understanding of miRNA biology (biogenesis, sequence, structure, function, and species similarities), the experimental and computational resources available for identification and target prediction and how these resources can be leveraged to identify mechanisms and biomarkers of toxicity.

3 Current Trends in Genetic Toxicology Testing

B. Gollapudi1, S. Dertinger2, R. H. Heflich3 and M. J. LeBaron4, 1Exponent, Midland, MI, 2Litron Laboratories, Rochester, NY, 3US FDA-NCTR, Jefferson, AR and 4The Dow Chemical Company, Midland, MI.

The scientific discipline of genetic toxicology has played an important role in the safety assessment of existing and new chemicals during the past four decades. This field has undergone significant changes during this time, not only in its regulatory applications, but also in the tools and technologies employed to identify adverse events. While the emphasis during the early years was on protecting germ cells and future generations from the deleterious effects of mutagenic agents, the focus shifted in later years towards identifying carcinogenic chemicals through the use of short-term assays. Furthermore, genetic toxicology tended to operate as a standalone discipline, generating qualitative data and placing little importance on dose-response analysis or integration with other toxicology measurements. The field is now in the midst of a sea change. Regulatory requirements across the globe are being harmonized, with emphasis on “3 Rs”. Recent changes to ICH and OECD testing guidelines promote the integration of genetic toxicology endpoints (e.g., Comet, micronucleus, and gene mutation) into repeat-dose general toxicology studies. This integrated approach benefits the interpretation of genotoxic findings by placing them in context with other toxicology data, including pharmacokinetics and pharmacodynamics. Regulatory initiatives such as REACH stress the importance of germ cell effects as part of a comprehensive assessment of genotoxicity. Guidelines for the study of mutations in germ cells of transgenic animals (OECD 488) have recently been finalized. Rapid advances in molecular biology are facilitating the integration of genomic biomarkers into standard toxicology studies to identify various classes of genotoxic agents (DNA reactive and DNA nonreactive). Genetic toxicology is moving from a qualitative science to the quantitative assessment of dose-responses including the identification of point-of-departure (PoD) metrics to extrapolate effects to realistic human exposure levels. The course is designed to provide a comprehensive overview of recent changes and newly established practices in the field with emphasis on their application in safety assessments.

4 Elucidating Adverse Outcome Pathways (AOPs) for Developmental Toxicity

T. B. Knudsen1, G. Daston2, D. L. Villenevuel3, N. Kleinstreuer4 and A. Terskhel.1, 1US EPA, Research Triangle Park, NC, 2Procter & Gamble Company, Mason, OH, 3US EPA, Duluth, MN, 4NHES, Research Triangle Park, NC and 5Sanford-Burnham Medical Research Institute, La Jolla, CA.

An Adverse Outcome Pathway (AOP) is a theoretical construct that integrates the biological plausibility and weight of evidence supporting a linkage between a Molecular Initiating Event (MIE) to adverse response at the individual or population level. Conceptually, an AOP spans multiple levels of biological organization and organizes the stepwise propagation of chemical disruption from MIE to toxicological outcome via a series of key events. Qualitatively, the concept of an AOP is basic to establishing plausible hypotheses and weight of evidence for chemical mode of action. This has practical use in the integration of high-dimensional data with knowledge of a complex biological system and focusing research planning on critical data needs identified as gaps in the AOP, thereby enhancing current risk assessment practices. Alternatively, development of more quantitative AOP constructs requires a framework to delineate causal relationships across a temporal series of events, and will support more realistic quantitative risk assessment. As AOPs are initially governed by signaling networks and metabolic processes, SNPs in key genes relevant to the AOP could point toward susceptible populations. The course will delve into the science of AOP elucidation from a system biology perspective, focusing on developmental processes and toxicities for early life stage susceptibilities. The presenters will each focus on making extensive use of current knowledge, informatics and data-mining tools to advance predictive toxicology.

5 Inhalation Studies: Challenges and Complexities

The successful execution of animal inhalation studies (e.g., acute, subchronic, and chronic) present many challenges and complexities not encountered with other routes of exposure. Five inhalation study challenges will be addressed: 1) Comparison of methods of exposure and potential impact on inhalation studies; 2) Using various test materials, generating simple atmospheres (e.g., exposures to gases, nanoparticles, bioaerosols, micron-sized aerosols) and mixtures (e.g., semi-volatile compounds and particles, tobacco smoke); 3) Selection of the appropriate animal species (e.g., species specific dosimetry); 4) Incorporating standardized and novel toxicological endpoints; 5) Deciding which regulatory guidance document or specifications (e.g., US EPA, US FDA, OECD and NTP) to follow. The diversity of presenters’ backgrounds (government, contract research organization, industry, and academic), and depth of experience, will provide a broad and rich resource for the participants.
6 Methodologies in Human Health Risk Assessment

J. T. Sullivan1, B. Mee2, H. A. Barton3 and J. C. Lipscomb1
1US EPA, Cincinnati, OH, 2University of Ottawa, Ottawa, ON, Canada and 3Pfizer Inc., Groton, CT.

This course provides an overview of more advanced aspects of chemical risk assessment, following up from a successful CE course on basic principles offered at the Annual Meeting in 2013. This new course will focus on methodologies, which incorporate increased use of biological and chemical specific data as a basis to provide more accurate risk assessment. In addition, it will address evolving areas such as problem formulation as a basis to better target toxicity testing and tailor assessments to the needs of risk management. The course will feature presentations and discussions focusing on the value of mode of action analysis for characterization of hazard, the fundamental tenets of physiologically based pharmacokinetic (PBPK) model development and implementation, use of benchmark dose (BMD) models to identify points of departure, and use of chemical specific adjustment factors to address inter- and intraspecies uncertainty and variability. The principles and key components of these methodologies will be illustrated with applied case examples from the regulatory risk assessment arena.

7 Nonclinical Animal Models Enabling Biopharmaceutical Advances in Translational Medicine

T. M. Monticello1, R. Dixit2, S. Morgan3, N. Ganner4, V. K. Kadambi2 and J. T. Sullivan1
1Amgen Inc., Thousand Oaks, CA, 2MedImmune, Gaithersburg, MD, 3Abbott, Abbott Park, IL, 4Ellegaard Göttingen Minipigs A/S, Dalmose, Denmark and 5Millennium, Cambridge, MA.

A fundamental theme in drug discovery and nonclinical development is the utilization of appropriate animal models that are predictive for efficacy or adverse events in humans administered a novel biopharmaceutical. The accurate prediction of human adverse effects using nonclinical animal toxicology studies remains a major goal in drug development and relies on appropriate animal models. Essential attributes for an appropriate animal model include similar target distribution, target pharmacology, systemic pharmacokinetics, metabolism, and distribution to those of humans. Utilization of the most appropriate animal model aligns with the 2011 US FDA Strategic Plan to advance regulatory science and modernize toxicology in order to enhance product safety and develop better models of human adverse responses. The Preclinical Safety Leadership Group (PSLG) of the International Consortium for Innovation and Quality in Pharmaceutical Development (IQ) is creating a contemporary industry-wide database to determine accuracy with which the interpretation of nonclinical safety assessments in animal models correctly predicts human risk. The course will present considerations for the selection of an appropriate animal model for nonclinical safety, the use of animal models of disease in safety testing, emerging use of the minipig in safety testing, data from an industry-wide nonclinical to clinical translational database, and the use of animal safety data in the design and conduct of clinical trials. Output from the course will help identify advances and remaining gaps in the utilization of animal models in biopharmaceutical development.

8 Nanotoxicology: Past Achievements, Future Challenges, and Potential Solutions

S. M. Hussain1, D. B. Warheit2, L. K. Bravdo-Snolli3, C. Grubinski1, K. K. Comfort4 and C. Gera5
1US Air Force, Wright-Patterson AFB, OH, 2DrPept Hashold Laboratories, Newark, DE, 3University of Dayton, Dayton, OH and 4CDC-NIOSH, Cincinnati, OH.

Nanomaterials (NM) possess tremendous promise to advance consumer, military, and medical applications due to their unique physicochemical properties, such as enhanced surface area, tunable size, modifiable surface chemistry, and particulate reactivity. However, these same properties have made NMs a potential health hazard, thus giving rise to the field of nanotoxicology (NT), which has become a prominent player in toxicological advancement and research over the past decade. Initial NT studies were limited by a lack of both available materials and characterization tools. Through advances in material science, enhanced capabilities have been developed that allow for the synthesis of distinctive NMs and the ability to accurately evaluate their characteristics. Taking advantage of these developments, NT has made remarkable progress in evaluating the hazards of NMs and correlating specific properties, such as size, shape, coating, and composition, to observe cytotoxicity. However, even with these numerous advances, there are still a number of constraints plaguing the field of NT. One principal area of concern is the development of procedures that account for new NT facets; including NM behavior in a physiological environment, varied aggregate structure, role of ionic dissolution, and realistic modes of exposure. Another limitation is the need for new and more powerful characterization tools. Recently, the question of dosimetry has become a forefront topic and whether a universal, conceptual standard should be adopted, such as mass, surface area, or particle number. Arriving at a consensus on this issue is critical for the establishment of NM exposure limits and risk assessment metrics, which are significantly lacking. To accomplish accurate risk assessment and regulatory evaluations, NT will have to develop a means to improve the correlation of in vitro data to in vivo predictions, via enhanced cell models, relevant dosages (low vs. high), and realistic exposure scenarios. This CE course will evaluate where NT stands, by highlighting key research successes, identifying challenges facing the field today, and exploring solutions to overcome current limitations.

9 Epidemiology for Toxicologists: What the Numbers Really Mean

N. B. Beck1, M. Goodman2, S. Efron3, L. E. Goodman4 and J. Bus5
1American Chemistry Council, Washington, DC, 2Emory University, Atlanta, GA, 3George Washington University School of Public Health, Fairfax, VA, 4Harvard School of Public Health and GraduiMed, Cambridge, MA.

21st Century risk assessment relies on data from multiple lines of evidence. High quality human epidemiology data are generally preferred for regulatory decision-making, but the body of evidence often includes animal toxicity, in vitro, in silico, animal dosimetry, and human exposure data. The quality of individual epidemiology studies can be highly variable and dependent on study design as well as other critical factors that sometimes cannot be controlled for. For risk assessors to fully understand the implications of epidemiology evidence, they must understand how the overall integration of toxicity and mechanistic data with human epidemiology findings facilitates science-informed decision-making. A sufficient understanding of the epidemiology data is a necessary starting point at the regulatory decision-making process, to appropriately integrate all the available information. The course is geared towards the toxicologist who is trying to determine how to appropriately evaluate, use, and integrate epidemiology data in a weight-of-evidence evaluation or risk assessment. An overview of the field will be given, prior to providing a focus on different epidemiology study designs and their strengths and weaknesses. Attendees will also gain an understanding of exposure assessment and biomonitoring, and how this information is used and evaluated in epidemiology studies. Additional learning objectives of the course: How to determine when an association may be supportive of a causal relationship and what confidence intervals mean; how to use trend information; how to evaluate and understand adjustments that are made for potential confounding factors; and how to evaluate several epidemiology studies on the same topic, particularly in light of available toxicity and mechanistic data. Finally, attendees will learn to integrate all types of data streams with a real example. Attendees will leave the course with a stronger understanding of how to interpret and use epidemiology data in their weight-of-evidence analyses and risk assessments, and how epidemiology can help inform regulatory decision-making.

10 Innovations in Methodologies for Inhalation Exposure and Interpretations of In Vivo Toxicity

J. Pauluhn1, J. D. McDonald2, B. T. Chen3, T. E. Kleindienst4 and M. A. Higuchi5
1US EPA, Research Triangle Park, NC, 2Bayer HealthCare, Wuppertal, Germany, 3Love lace Respiratory Research Institute, Albuquerqu e, NM and 5NIOSH, Morgantown, WV.

The respiratory system presents most diverse structural and cellular heterogeneity suited to handle complicated aspects of air liquid interface such as the direct exposure of the delicate cellular and capillary surfaces to the atmosphere and the encounter of lung epithelial cells to complex mixtures of particles and gases. Not only the respiratory depositions of inhaled substances vary regionally but also the regional responses generated by the respiratory tract. Recently the field of inhalation technology and respiratory toxicology has seen revolutionary growth because of the emergence of the use of nanomaterials and renewable energy sources creating new environmental challenges. Moreover, the paradigm shift of toxicology testing to high throughput screening has led to the development of novel inhalational approaches for cells. Scientists will cover the recent advances in inhalation methodologies for various types of emerging inhalants and focus on generation of atmospheres for in vitro and in vivo toxicity assessment. These aerosols will include gas and particulate emissions from vehicles using old and new energy sources, forest fires, coal combustion, manufactured nanomaterials and mixtures formed from atmospheric aging. The dynamic of physicochemical composition of such mixed aerosols will be discussed to allow for identification of causative constituents and lung site-specific injuries. Structural differences in the respiratory tract of rodents and mammals, including humans, impacting dosimetry will be discussed. Respiratory system heterogeneity between humans and animals, and their differential neurohumoral mechanisms will be discussed to aid in interpretation of inhalational hazard for.
humans. This course will be useful for those involved in air pollution toxicology, nanotoxicology, novel drug delivery systems, pulmonary toxicology, and risk assessment.

11 Nonclinical Pediatric Drug Development: Considerations, Study Designs, and Strategies

Although nonclinical and clinical testing needs for drugs for pediatric populations have been discussed for more than 40 years, there is no default approach to evaluating safety in this age group. Over the last decade there has been a heightened awareness of the differences between the pediatric and adult patient, and these differences are being addressed by the pharmaceutical and healthcare industries, as well as the governmental and regulatory bodies that sanction the development and testing of drugs for children. As regulatory demands evolve for nonclinical safety assessments in juvenile animals, industry leaders are developing innovative ways to meet the regulatory expectations and to overcome the challenges associated with pediatric drug development. Many practical issues regarding nonclinical testing in immature animals have been surmounted, using novel and/or adapted approaches. There are considerations related to the differences in regional guidelines (US FDA, EU, and Japan), therefore development of appropriate information for submission to worldwide agencies is critical. History and experience provide the best scientific arguments as to why juvenile animals can be useful. There are numerous examples of drugs that have identified findings in various species, including information regarding kinetic and toxicity differences that highlight considerations regarding nonclinical testing models. Additionally, there are unique challenges associated with nonclinical juvenile toxicity testing for biopharmaceuticals, including selection of appropriate animal models, immunogenicity, dose selection (toxicity vs. pharmacology), and relevant endpoints. Developing a juvenile animal program requires an appreciation of the complexity of the nonclinical strategies to enable pediatric trials and an overview of the historical perspective and the current approaches to evaluating safety during this unique period of life.

12 Stem Cells in Toxicology

Stem cells are revolutionizing toxicological research and remain an area with tremendous potential. Recently, research on stem cells has generated tremendous public and professional interest. However, some areas of toxicological research have lagged behind in the integration of stem cells as a concept in toxicant-induced disease etiology. We will describe the utility and suitability of the assorted types of stem cell models (i.e. embryonic, fetal, progenitor, induced pluripotent, immortalized stem cell lines, etc.) for various research purposes, including disease modeling, drug discovery and toxicity testing in order to describe the potential applications of stem cells in toxicological research. This important overview of stem cells will highlight their nomenclature, properties, and their roles in the genesis of various diseases.

13 Translational Biomarkers in the Assessment of Health and Disease
V. S. Vaidya, M. Moses, D. L. Mendrick, J. Aubrecht and C. Leptak, Harvard Medical School, Boston, MA; US FDA-NCTR, Jefferson, AR; Pfizer Inc., Groton, CT; Children’s Hospital Boston, Boston, MA and US FDA, Silver Spring, MD.

Biomarkers serve as quantitative measures of chemical exposures and biologically effective doses, early warning signals of biologic effect, predict outcome in a patient with disease, and identify who will respond to an intervention and whether the intervention is working. The current era of scientific discovery has brought seemingly limitless opportunities for improvements in medical care. Translational biomarkers that can be measured in blood or urine in both experimental animals and man are of particular interest. Given the importance to the clinical, pharmaceutical, and regulatory communities motivated by more specific and timely diagnoses, early intervention and safer therapies, clinically useful biomarkers have evolved over time, reflecting the scientific and technologic progress made over the centuries. An increasing number of clinically relevant tests and procedures are available to estimate organ injury and guide treatment. The use of molecular signals in the assessment of health and disease is not new; however, the concept of what constitutes a useful biomarker has evolved considerably in the past two to three decades given the advanced enabling technologies, deeper molecular understanding of disease, and the advent of a regulatory framework for biomarker qualification. Our panel experts will highlight the potential of these biomarkers over a wide variety of applications spanning preclinical-clinical-safety in liver and kidney, to disease monitoring in cancer. The panel will also demonstrate the application of translational biomarkers in clinical trial design. Coordinated efforts at biomarker discovery and validation as well as technologies for biomarker measurement will help ensure that the ultimate goal of safer drugs, a cleaner environment, and improved patient outcomes are realized.

14 Air Pollution and Cardiovascular Effects: Mechanisms and Role of Lipid Peroxidation
D. J. Conklin, Cardiovascular Medicine, University of Louisville, Louisville, KY.

The mechanisms by which air pollution, including particulate matter (PM2.5) and volatile gases, affect human cardiovascular health are incompletely known. Yet many animal studies performed to probe these mechanisms have observed changes in the levels of lipids and/or lipid peroxidation products regardless of the specific form of air pollution, e.g., diesel engine exhaust, concentrated ambient particulate matter, or volatile gases, used in the exposure that associates with severity of injury. These studies suggest a potential common pathway of injury that is dependent on oxidative stress and an increased production of lipid mediators. The role of lipids and lipid peroxidation as final common mediators of air pollution-induced injury in the cardiovascular system is the focus of this symposium. Speakers will address how exposures to diverse types of air pollutants, including complex mixtures, traffic emissions, volatile acrolein, and concentrated ambient particulate matter, result in alterations in circulating lipid levels, lipids structure and function, and lipid peroxidation indicators in target organs including lungs, blood, and the vasculature. Collectively, these presentations will shed light on the specific role of lipid and lipid peroxidation in air pollution-induced cardiovascular injury.

15 Air Pollution, Lipid Oxidation, and Cardiovascular Effects in Humans and Animals Models
A. Bhattacharya, Cardiovascular Medicine, University of Louisville, Louisville, KY. Sponsor: D. Conklin.

Epidemiological studies indicate that ambient air pollution enhances the incidence and progression of cardiovascular disease and increases the risk of cardiovascular mortality primarily by promoting acute coronary syndromes and ischemic heart disease. Exposure to air pollutants associates with systemic lipid peroxidation, which has been shown to be an important marker and pathogenic mediator of atherosclerosis, acute plaque rupture and myocardial infarction. This symposium will address the relationship between air pollutants and lipid peroxidation that often accompanies exposures resulting in altered tissue and blood lipids. Moreover, this symposium will address the question whether and how these changes contribute to subsequent cardiovascular dysfunction and potentially increase the risk of cardiovascular disease.

16 Vascular Lipid Peroxidation Induced by Complex Emissions Indicates Gas-Particle Interactions in Driving Systemic Toxicity
M. Campana, Pharmaceutical Sciences, University of New Mexico, Albuquerque, NM.

Air pollution is associated with adverse cardiovascular events in epidemiological studies. Several recent studies have indicated a role for oxidative changes to phospholipids following inhalation of various pollutants, which leads to altered biological activity of those modified lipids. To better understand the important causal components of the ambient pollution mixture, we have investigated the relative lipid peroxidation induced in the murine aortic wall by diverse exposure conditions involving fresh emissions of gasoline and/or diesel engines, resuspended road dust, and secondary particulates of sulfate or nitrate composition. We noted that emissions containing mixtures of particulate and gas phase components typically induced greater vascular lipid peroxidation than did individual components. Moreover, our data suggest that gases may deposit on particulates, thereby driving toxicity in a surface area-dependent manner. Further studies highlight a role for modified lipids and metabolites in the circulation after exposures, in human and rodent studies, that may drive the accumulation of vascular lipid peroxides.
Effects of Acrolein or Concentrated Ambient Particulate Matter Exposure on Plasma Lipids and Vascular Targets

D. J. Conklin, Cardiovascular Medicine, University of Louisville, Louisville, KY.

Acute exposure to the inhaled carbonyl, acrolein, or to fine (concentrated) ambient particulate matter (CAP) leads to alterations in plasma lipids, oxidized lipids, circulating progenitor cells and vascular insulin resistance but how these divergent endpoints are related to each other is not clear. Because vascular dysfunction and vascular insulin resistance are two early events associated with metabolic syndrome and the progression to diabetes (and in order to interrogate mechanistic relationships between disparate endpoints), we studied whether changes induced in lipids and the vasculature were shared across different pollutant exposures (gas or CAP) and to similar degrees dependent on exposure level to reveal potential common mechanisms of action.

Vehicle Emissions-Exposure Results in Increased Cerebrovascular Lipid Peroxidation Associated with Altered Blood Brain Barrier Permeability

A. K. Lund, Biological Sciences, University of North Texas, Arlington, TX.

Traffic-generated air pollution-exposure has recently been associated with adverse effects in the central nervous system (CNS) including neuroinflammation and neurodegeneration. While alterations in the blood brain barrier (BBB) have been implicated as a potential mechanism of air pollution-induced CNS pathologies, there is currently little known about the pathways involved. Lipid peroxidation and oxidative stress are known to regulate air pollution-mediated effects in the systemic vasculature resulting in progression of vascular disease states; therefore, we investigated their role in altered signaling, transport, and permeability in the cerebral vasculature after inhalation exposure to vehicle emissions. We observed significant increases in lipid peroxidation in the cerebral vasculature of mice, resulting from exposure to vehicle emissions, which was associated with increased BBB permeability. Additionally, we measured increased matrix metalloproteinase-9 activity and decreased tight junction expression in the cerebral vessels from exposed animals. Further studies using plasma from exposed vs. control mice in an in vitro BBB co-culture model suggest that a circulating "reactive factor" may mediate the observed alterations in BBB permeability and transport. Collectively, these data suggest that lipid peroxidation may mediate alterations in signaling and structural proteins responsible for maintaining BBB integrity.

Air Pollution, Lipid Peroxidation, and Alterations in HDL Functionality

J. Araujo, Medicine, University of California Los Angeles, Los Angeles, CA. Sponsor: D. Conklin.

Exposure to ambient particulate matter (PM) lead to enhanced atherosclerosis in experimental animal models. Particle size and composition play a role in the extent of how atherosclerosis is promoted. We have reported that inhalation of concentrated fine and ultrafine ambient particles led to alteration of plasma HDL anti-inflammatory capacity in ApoE null mice that correlated with their ability to enhance atherosclerotic lesion formation. In addition, we have also shown that exposures to diesel exhausts result in alteration of HDL anti-oxidant capacity. This presentation will focus on our studies that have evaluated whether HDL functional changes, induced by air pollutants, are related to effects on lipid peroxidation in the lungs, circulating blood and systemic tissues.

Carbon Nanotube Exposure Assessment: An Evaluation of Workplace Exposures in the US

M. Dahm1, M. Schubauer-Berigan2 and A. Erdely2. 1CDC-NIOSH, Cincinnati, OH and 2CDC-NIOSH, Morgantown, WV.

Just as there has been much advancement in the field of toxicology over the past decade relative to health outcomes from carbon nanotube (CNT) exposures, similar strides are being made in the field of exposure assessment. Recent developments in sampling methodologies have led to more accurate estimates for worker exposure levels as compared to preliminary studies, which may have overestimated exposures. As part of an ongoing NIOSH exposure assessment and epidemiologic study, worker exposure to CNT has been examined by sampling 14 different workstations across the US over a three year period. Personal breathing zone exposure levels were measured using a chemical specific marker for the mass concentration of elemental carbon (EC) at both the inhalable and respirable size fractions. The sampling methodologies are in accordance with the NIOSH Current Intelligence Bulletin on CNTs and carbon nanofibers which set a mass based Recommended Exposure Limit at 1 μg/m^3 of EC at the respirable size fraction. Overall, personal workplace exposures at the respirable size fraction to EC ranged from 0.02 – 1.47 μg/m^3 with an 8 hr time weighted geometric mean of 0.16 μg/m^3. Inhalable personal breathing zone exposures ranged from 0.003 – 22.40 μg/m^3 with a geometric mean of 0.38 μg/m^3. Concurrent personal breathing zone samples were also collected and analyzed by electron microscopy using methods similar to the asbestos counting convention. CNT structure agglomerate sizes averaged > 4 μm while few single CNT fibers were found. This study also focused on how exposure level and type change within the various industries in which CNTs are being applied (composites, electronics, production), between types of materials (multi-walled vs. single-walled), and under varying work conditions. The detailed information from these exposure assessment findings bring awareness to industries with higher experimental studies to human relevance difficult. Initial findings from epidemiological studies of workers handling engineered nanomaterials, recent advancements in detailed facility exposure assessment, pertinent in vivo toxicology studies with dosimetry-based human health implications, regulatory aspects, and risk assessment based on results from animal inhalation studies will be included. The outcome of this session is to provide the most recent human exposure assessment and epidemiological findings and to gather perspective on in vivo toxicology studies involving risk estimates and potential carcinogenicity. This data should have direct influence on the course of newly designed studies and add perspective on previous studies of CNT-induced toxicity.
exposure potentials and provide valuable data on job specific tasks where exposures are likely to occur. In addition, the findings from this study can provide valuable insight for designing and interpreting in vivo exposures.

23 Relationship between In Vivo Carcinogenicity and Human Risk to Carbon Nanotubes

L. M. Sargent1, D. W. Portet1, L. Starks2, A. F. Hubbs1, M. L. Kashon1, D. T. Lowry2, L. A. Battel11, B. T. Chen1, D. G. Frazer1, V. Castranova1 and S. H. Reynolds1. 1CDC-NIOSH, Morgantown, WV and 2Integrated Laboratory Systems, Inc., Morrisville, NC.

In vitro genotoxicity investigations have shown that high aspect ratio carbon nanotubes induce cell cycle disruption and errors in chromosome number. A subsequent in vivo multiwalled carbon nanotube (MWCNT) whole body inhalation exposure study further demonstrated that MWCNTs promoted the growth of DNA damaged (initiated) lung cells to form lung adenomas and adenocarcinomas. Twenty-three percent of the filtered air controls, 27% of the MWCNT-exposed, and 52% of the methylethylbenzene (MCA) followed by air-exposed mice, had a mean of 1.3, 1.3 and 1.4 lung tumors per mouse, respectively. By contrast, 91% of the mice exposed to MCA followed by inhaled MWCNTs (MCA/MWCNT) had an average of 3.24 tumors per mouse. A total of 61 adenocarcinomas and 2 metastatic ad- enocarcinomas were observed in 55 MCA/MWCNT-treated mice. Furthermore, MWCNT inhalation increased the incidence of sexual tumors consistent with the diagnosis of sarcomatous mesothelioma from 2% in the MCA-exposed mice to 9% in the MCA/MWCNT, a 4.5 fold increase. These data demonstrate that inhaled MWCNTs are strong promoters of pulmonary adenomas and adenocarcinomas in B6C3F1 mice. The presence of metastatic disease in 15% of the MCA/MWCNT-exposed mice compared to 1.6% in the MCA-exposed group suggests that carbon nanotubes also induce cancer progression. The mouse MWCNT lung burden in this study approximated feasible human occupational exposures at the NIOSH Recommended Exposure Limit (REL). Given that recent measurements of carbon nanotubes in the workplace indicate levels of nanotubes that can be higher than the NIOSH REL, adverse outcomes in occupationally exposed humans is a possibility. The presentation will include a discussion of the mechanism of MWCNT-induced tumor promotion and progression as well as work in progress to examine the dose response of MWCNT-induced tumor promotion.

24 Review of CNT Health and Environmental Risks under TSCA, and Areas Where More Data Are Needed

P. Savar. US EPA, Washington, DC.

EPA, under the Toxic Substances Control Act, reviews numerous types of nano- materials prior to their entry into the market, including a substantial number of carbon-based materials. For each one a risk assessment and a risk management plan are developed that address human and environmental risks, including occupational risks. Approaches for addressing the risks of CNTs will be discussed, based on available hazard and exposure data available. More information is needed that would allow predictive determinations of hazards and exposures. Predictive frameworks could be based on hazard and exposure categories, streamlined testing strategies, and/or control banding. Additional data are needed to underpin such frameworks.

25 Evaluation of Human Risks on Animal Models

J. Pauluhn. Bayer Pharma AG, Wuppertal, Germany.

Current inhalation testing approaches are designed to evaluate and assess systemic and portal-of-entry related toxicities of soluble and bioavailable chemical substances. Insoluble chemical substances may cause toxicity by two major mechanisms: The first depends on the site and acute dose of initial deposition and the cause of localized toxicity may depend mainly on physical factors, such as solubil- ity, particle surface activity including size, and shape. The second depends more on its durability and total dose accumulated with exposure time with time. It seems that the accumulated particle volume of inhaled low-density nanostructures delay clearance with associated faster manifestation of lung overload and toxicity. Each mechanism can dose-dependently destabilize the pulmonary barrier function, giving the structure access to the systemic circulation, depending on the degree of local inflammation. Toxicologists need to disentangle which of these etiopathologies is causing the critical toxic response under exposure conditions relevant to humans. Multiple chemical-, particle-, and experimental design-specific factors may affect the outcome of experimental studies with multi-walled Carbon Nanotubes (CNT). This adds another dimension of complexity as nanostructured particle morphologies change with their degree of agglomeration and purpose-driven modified surface characteristics. All may affect their compartmentalized retention within the lung and associated localized toxicity. Humans exposed chronically to CNTs may accumulate these structures over time and the mere exhaustion of the existing, physiological capacity of the lung may cause lung toxicity. Experimental models that most closely resemble these model-specific constraints may generate findings difficult to extrapolate to any real-life scenario of humans. This paper addresses how CNT-specific human risks can be evaluated and assessed in controlled experimental models and how kinetic modeling can be used to estimate safe Occupational Exposure Levels with a minimum number of animals.

26 Computational Approaches to Predict Repeat-Dose Toxicity: Lessons Learned from Cosmetic Ingredients

M. T. Cronin1 and C. Yang2. Liverpool John Moores University, Liverpool, United Kingdom and 1Altamira LLC, Columbus, OH.

Assessing the toxicity of cosmetic ingredients presents numerous challenges, the solution of which will contribute to the general understanding of chemically-in-duced toxicity. The goal is to predict the effects to humans of long-term repeated low-dose exposure to chemicals used in cosmetics. For risk assessment, the results of in vivo assays are often distilled in terms of NOAELs and LOAELs. However, alternatives are required for cases where animal test data are lacking or cannot be obtained due to cost, time, or legislation. The past decade has seen an im- mense growth in attempts to predict toxicity computationally, but even with these advances traditional approaches (e.g., quantitative structure-activity relationships (QSARs)) are limited due to the lack of understanding of xenobiotic targets and small molecular interactions associated with observed phenotypic effects. QSAR is also not appropriate for making reliable estimates of NOAELs; thus, a new paradigm is being sought. Despite these drawbacks, the key premise is that struc- ture-based computational analysis of a chemical of interest and close structural analogues for which experimental data are available will lead to improved predictivity due to greater association with mechanisms of toxicity. Exposure is often dermal, but inhalation or oral routes are also possible. Penetration and metabolism within the dermis, possibly followed by target organ toxicity, must all be considered and accounted for when necessary. The combined factors of relatively low-dose, dermal ADME properties and toxicity to specific organs are amongst the greatest chal- lenges facing computational toxicology for the prediction of the effects of exposure to cosmetics. This session will address these issues and review the current state of the art of computational modeling at the organ level to support risk assessment as it is being developed in a unique European Union Project called COSMOS. The funding of the COSMOS Project is from the European Commission and Cosmetics Europe.

27 Databases, Tools, and TTC Approach Applied to Chemicals in Cosmetics Products

C. Yang1, M. Ambrosio2, K. Arvidson3, M. T. Cronin4, E. Fioravanzo5, K. Muldoon-Jacob5, D. Keller6, J. Rathman1, A. N. Richardson7, L. Terlloth7, I. Tsakolska5, V. Vitcheva5, and A. P. Worth7. 1Altamira LLC, Columbus, OH, 2ILSI Europe, Brussels, Belgium, 3CFSAN, US FDA, College Park, MD, 4Liverpool John Moores University, Liverpool, United Kingdom, 5In Vitro, Italy, 6Henkel AG & Co. KGaA, Dusseldorf, Germany, 7Molecular Networks, Erlangen, Germany, 8BAS, Sofia, Bulgaria and 9EC JRC, Ispra, Italy.

The COSMOS consortium developed new databases and tools central to its mission of assisting in the ultimate replacement of animal testing of cosmetic products. COSMOS Database includes a new Cosmetics Inventory of more than 19,000 substances reported by EU CosIng and the US Personal Care Products Council. The chemical in-use functions include antioxidants, hair dyes/colorants, emol- lients, emulsifiers/surfactants, perfumes, preservatives, skin/hair conditioners, and UV absorbers/filters. A new toxicity database enriched with oral repeat dose studies for cosmetics ingredients was developed by compiling data from public sources in- cluding US FDA, EPA, EU SCCS, ECHA, and literature. A new non-cancer TTC database for cosmetics-related chemicals has been compiled by augmenting the COSMOS DB with relevant Munro data. The resulting TTC database contains over 500 chemical structures with reported NOAEL. The inclusion and selection criteria of the NOAEL decisions were established. ILSI Europe experts reviewed toxicity data for the high impact portion of the database, the lowest 10th percentile plus compounds for which there is a large variation across different sources. The chemical space of the new TTC database was compared with other TTC databases to demonstrate the coverage suitable for the assessment of cosmetics. A decision tree workflow incorporating structural and usage exposure categories specific to cosmetics to address the oral-to-dermal extrapolation of repeat dose toxicity data was also devised. Thus this talk addresses overall COSMOS efforts on the TTC.
approach to chemicals used in cosmetics products, building from the databases to implementation of tools. Abstract does not reflect US FDA or EC JRC policies. Authors acknowledge ILSI Experts.

## 28 Role of Bioavailability in Risk Assessment of Cosmetic Ingredients: Kinetics, Permeation, and Metabolism

When assessing the impact of cosmetics ingredients on human health risk assessment, the chemical’s toxicity is influenced by the degree to which it is absorbed into the body (i.e. its bioavailability). When developing Threshold of Toxicological Concern (TTC) categories for chemicals used in cosmetics products the comparison of exposure from the oral and dermal routes is mandatory as existing TTC approaches for an assessment of repeated dose toxicity are based on the oral route of administration. This presentation demonstrates the role of the prediction of permeability from the dermal and the oral routes and their role in toxicity prediction. This includes the use of relevant QSARs (e.g. the Ports and Guy equation for skin permeability) and more recent models. These models have been evaluated using two new databases: a database of skin permeability values (over 2,000 entries for more than 350 compounds) and a database of PAMPA permeability values. Prediction of skin metabolism is also considered in the context of identifying chemotypes (i.e. the sets of enzymes or enzyme pathways) that may be activated or detoxified more significantly than from the oral route. This scheme is based on a “tiered approach” for chemicals’ bioavailability which identifies four general scenarios according to the degree of oral and dermal absorption with each being subsequently considered for differences in metabolism.

## 29 Adverse Outcome Pathways (AOPs) for Target Organ Effects: The Role of Structural Alerts and Chemotypes for Lipotoxicity to Group Compounds and Apply Read-Across

AOPs provide a framework to organise information at the mechanistic and pathway level, providing evidence that a molecular initiating event (MIE) is linked, through a pathway, to an (adverse) effect. This allows for a direct linkage of chemistry to adverse effects. Capturing the chemistry related to organ level mechanisms of action has provided the capability to profile, and hence group, compounds together. Over 100 structural alerts, which form the basis of chemotypes, have been developed for liver toxicity. These alerts are for effects such as reactive hepatotoxicity, phospholipidosis and other liver toxicities. They were developed from grouping of known liver toxicants and are supported by mechanistic information within the AOP framework. The alerts, in the form of chemotypes, have been developed to extend the traditional structural approach by incorporating not only structural information but also physico-chemical properties. They show great potential for group grouping chemicals together to perform read-across predictions for complex endpoints. The alerts are freely available as a stand-alone toxicity profiler or as part of KNIME Workflows. KNIME is a flexible computational workflow technology that allows the user and developer to build flexible, adaptable and transparent models for toxicity prediction. Together with AOP-based profilers for other organs and adverse effects they create computational approaches to predict systemic toxicity and assist in risk assessment.

## 30 Applying Databases and Tools from COSMOS to the Scientific Needs of US FDA’s CERES Project

K. Arvidson1, A. McCarthy2, D. Hristozov3, C. Yang4 and M. T. Cronin5.

The Chemical Evaluation and Risk Estimation System (CERES) project aims to establish a single, unified data repository that compiles available information on a food substance, including: chemical structures and properties, regulatory records, summarized toxicity data, and other biological screening assays for the Office of Food Additive Safety’s (OFAS) pre- and post-market safety evaluations. In cases where no information is available for a particular substance, CERES provides tools to identify potential safety concerns by applying mode of action-driven QSAR prediction models as well as to identify and analyze data on structural and biological analogs. Such, CERES was designed with a robust foundation for handling chemical and toxicity data as well as knowledge derived from these data. In order to expand the diversity of CERES’ chemical space and incorporate additional high-quality toxicity data from oral repeated dose studies, CERES is exchanging knowledge with the COSMOS DB project. Although OFAS does not regulate cosmetics ingredients, the chemical space within OFAS has significant overlap with many cosmetic ingredients, including colorants, flavors, antimicrobials, anti-oxidants, emulsifiers and surfactants. Thus, scientifically, the setting of study inclusion criteria for the COSMOS TTC DB and data and tools developed by COSMOS are relevant to the CERES project. The chemical space of the COSMOS DB and CERES has been profiled using appropriate chemotypes. Chemotypes representing both the COSMOS DB and CERES are correlated with various phenotypic effects in the oral repeated-dose toxicity studies available within COSMOS and CERES. Results from both the COSMOS DB and TTC databases are used in this analysis. This analysis is able to identify gaps in the chemical domain of the databases so that we may better understand the applicability domain of the systems as well as identify where additional biological data are needed. Abstract does not reflect US FDA policy.

## 31 US EPA’s ToxCast, Tox21, and COSMOS Projects: Cheminformatics Approaches to Creating Data Linkages and Synergies

A. M. Richard1, C. Yang2, J. Rathman3, R. Bienstock4, M. T. Martin5, L. Truong1, M. T. Cronin1, A. Tarkhov5 and C. Schwab5.

The ToxCast and Tox21 projects are generating high-throughput screening (HTS) data for thousands of structurally diverse chemicals, spanning multiple use categories and chemical functionalities, and probing a wide diversity of biological targets, pathways and mechanisms related to toxicity. The ToxCast and Tox21 chemical libraries include substances of environmental, agrochemical, and industrial relevance, including drugs, food contact substances and cosmetics. While there are a number of common chemicals within the ToxCast, Tox21 and the COSMOS databases, there are even greater overlaps in “chemotype” space in these libraries. Chemotypes are fundamental units of chemical structure (structural features and associated atom/bond properties) that have been distilled from existing knowledge of metabolic transformations and structure-based mechanisms of toxicity. Using the concept of chemotypes as a holistic guiding principle, cheminformatics approaches were applied to highlight overlapping areas of chemical space in the ToxCast, Tox21 and COSMOS inventories, to focus mechanistic investigations, and to establish data linkages and synergies across the different project data landscapes. In particular, we illustrate how ToxCast Phase II HTS assays that are significantly linked to chemotypes enriched within the chemical space of the COSMOS RepeatDose toxicity database provide a conduit for leveraging ToxCast data across Tox21 and COSMOS. Similarly, chemotype analysis of the COSMOS RepeatDose toxicity data has been projected back onto the ToxCast and COSMOS inventories to both focus (mechanistically) and broaden (chemically) investigations to cover a wider range of environmentally relevant chemicals beyond cosmetics. Abstract does not represent EPA policy.
32  **Induced Human Pluripotent Stem Cells and Their Differentiated Progeny Cells: Implementation in Toxicity Testing**

Over the past two decades stem cell technology has progressed from isolating murine and nonhuman primate embryonic stem cells (ESCs) to reprogramming fully differentiated human samples into induced pluripotent stem cells (iPSCs). Concurrent advances have been made in the differentiation of stem cells into progeny tissue cells and the ability of those cells to increasingly recapitulate native behavior. Together, these advances have driven the translation of this technology from small-scale basic biological investigations into large-scale use within the pharmaceutical industry and potential clinical applications. This symposium will focus on several examples of iPSC-derived tissue cell use in understanding and translating preclinical cardiototoxicity to the clinic; hepatocyte function, toxicity, and idiosyncratic drug-induced liver injury; and developmental neuronal toxicity. Particular emphasis will be placed on practical implementations in toxicity testing as well as the ever-expanding functional incorporation of samples from clinic populations.

33  **Engineering the Microscale Environment around iPSC-Derived Human Hepatocytes In Vitro**

Engineered in vitro models of the human liver have proven utility in assessing liver metabolism and toxicity in preclinical drug development. Isolated primary human hepatocytes (PHHs) are ideal for constructing such models, but there is a shortage of donor livers, and PHH quality can vary widely. Induced pluripotent stem cells (iPSCs) derived from somatic cells can address the limitations of PHHs and have future potential for personalized drug screening and therapy; however, current methods yield more fetal-like hepatocytes that display only a fraction (<10%) PHH functions. We utilized microfabrication to investigate the effects of controlled homotypic and heterotypic cell interactions and extracellular matrix (ECM) cues on long-term iPSC-HH liver functions in vitro. We found that 3T3-J2 murine embryonic fibroblasts, previously shown to positively affect PHH functions, also induced liver functions (albumin secretion, urea synthesis, CYP3A4 activity) in iPSC-HHs when micropatterned onto collagencoated domains. Further, the addition of a Matrigel overlay enhanced both albumin production and CYP3A4 activity. We also assessed the utility of the iMPCC model for assessing drug toxicity and showed that prototypical liver toxins (i.e. diclofenac, acetaminophen) caused dose-dependent down-regulation of liver functions, while non-toxins (i.e. aspirin, propranolol) had little to no effects. Our current focus is on expanding these studies to include growth factors as well as more systematic presentations of ECM mixtures towards designing differentiation protocols that will be useful for the field at large while exploring the role of liver-derived stromal cells on iPSC-HH differentiation in vitro.

34  **iPSC-Derived Liver Cultures to Study Mechanisms Underlying Idiosyncratic Hepatotoxicity**

P. B. Watkins1, 2. The Hamner Institutes For Health Sciences, Research Triangle Park, NC, and Institute for Drug Safety Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC.

There are no accepted animal models of idiosyncratic drug-induced liver injury (IDILI); indeed, the vast majority of humans are not good models for IDILI since they are not susceptible to it. Because it is generally not possible to obtain liver biopsies for research purposes from patients who have experienced DILI, induced pluripotent stem cell (iPSC) technology is an alternative approach to develop liver culture systems capable of testing the components of the prevailing causal hypothesis. We have demonstrated that iPSC derived hepatocytes (iPSC-HHs) can be used to study mechanisms underlying IDILI due to other drugs implicated in the DILIN registry.
40 Inherited Effects of Low Levels of Methylmercury in Neural Stem Cells

Epidemiological studies have shown that chronic prenatal exposure to low levels of methylmercury (MeHg) can cause long-term neuropsychiatric alterations even in subjects who did not present signs of toxicity at birth. The mechanisms underlying the long-lasting consequences of MeHg exposure in early life are still unclear. The present study was designed to investigate short-term direct and long-term inherited effects of low levels of MeHg using primary cultures of rat embryonic neural stem cells (NSCs). We found that exposure to MeHg at nM concentrations decreased NSC proliferation and altered the expression of cell cycle regulators, such as p16 and p21, senescence-associated markers, including Bmi1 and Hmga1, and genes encoding mitochondrial respiratory chain proteins. MeHg induced a decrease in global DNA methylation, which pointed to the occurrence of epigenetic modifications. Interestingly, all changes occurring in NSCs directly exposed to MeHg (parent cells) were also present in their daughter cells kept in MeHg-free culture conditions. Data from adult mice exposed to low doses of MeHg in the perinatal period showed that the exposed mice, in addition to long-lasting behavioral alterations, exhibited a decreased proliferation of the neural stem/progenitor cells in the subgranular zone of the hippocampus, as well as long-lasting epigenetic modifications. The programming effects induced by MeHg in NSCs provide an explanation for the long-term consequences of developmental exposure to low levels of MeHg, which can predispose to neurodevelopmental disorders and/or neurodegeneration.
The Human Microbiome Project, a NIH initiative to understand the complexity, constitution, and diversity of microbes living on and in the human body, was recently completed in 2012. The term “Super-Organism” was coined to describe humans as a result of characterization of the breadth and diversity of microbes that live on the external surface as well as in the blood, tissues, and cells of the human body. What role do commensal organisms play in health and disease? What role do pathogenic microbes play in health and disease? For decades, a major emphasis in the field of immunotoxicology has been to understand the impact of environmental/occupational/therapeutic exposures on host defense against invading and opportunistic pathogens. Mounting evidence suggests that equal effort should be provided to understanding the relationship between the human microbiome and how alterations thereof can have profound implications for the development of complex immune and inflammatory diseases. Individuality of the microbiome contributes to immune-diversity, "metagenetic" diversity, and interindividual differences in susceptibility to many complex diseases, including allergic disease, autoimmune diseases, cancer, and others. Evidence suggests that development of an individual’s microbiome begins before birth, and the nature of this colonization can influence susceptibility to disease later in life. In addition, homeostasis of the microbiome is under continual attack due to exposures encountered in daily life. Recent research shows that exposure to toxic chemicals can shift the dominant characteristics of the microbiome, thereby providing a strong contribution to disease susceptibility. Therefore, it is important to consider this research in the context of human health risk assessment. The purpose of this symposium is to provide evidence of beneficial and detrimental contributions of the microbiome to the development of immune and inflammatory diseases and provide insight into how microbiome research integrates into human health risk assessment.

"The Completed Self" model for formation of the human-microbial superorganism in early life posits that: 1) symbiotic self completion is a critical step in the developmental programming of later-life health vs. disease, 2) the immune definition of self includes our internal microbial ecosystem, and 3) commensal-driven host metabolism and immune maturation are critical factors in subsequent tissue homeostasis. A consideration of humans as beyond-mammalian could shift our prevailing view of toxicity, health hazards, and preventive measures as well as the tools we employ for effective safety assessment. Prenatal, postnatal and even transgenerational epigenetic factors have the capacity to either support or interfere with the establishment of the microbiome and/or immune-microbiome interactions. Lack of self completion appears to be an important route to metabolic disorders, immune dysfunction, misregulated inflammation, tissue pathologies and chronic disease. Environmental risk factors (e.g., environmental chemicals, drugs, diet, physical and lifestyle factors) during development are considered in light of the goals of self completion in the child and a fully-developed immune system to support the newly-formed human-microbial symbiont.

It is recognized that the complex collection of microbes in our gut, the microbiome, plays a critical role in our health and well-being. It influences our responses, e.g., immunological, and reacts to environmental exposures, such as from food, drugs, and environmental contaminants. Regulatory agencies are putting a great deal of effort into understanding the sequence of mechanistic events that lead to disease. However, they haven’t generally incorporated the importance of the microbiome to a great extent and how it can provide insight into human health risk assessment. We will likely need to rethink some of the risk assessments to take into account the contribution of the microbiome. Research will greatly help assessments by addressing the lack of understanding of how xenobiotic exposures can affect the composition and function of the microbiome as well as how the microbiome can affect bioavailability of contaminants and susceptibility to pathogens. Also, the interplay between chemical exposures and pathogens with commensal gut flora and with each other need to be examined as potential risk factors. While the microbiome raises the complexity of the research in disease etiology, it will help human health risk assessors to rethink how chemicals and pathogens interact with exposed people.
emerging research from a number of laboratories demonstrates that maternal expo-
sure to environmental chemicals during the perinatal period alters the expression and function of metabolic and transport proteins in progeny later in life. Up- or down-regulation of key hepatic metabolic processes, including cytochrome (Cyp) P450 and carboxylesterase (Ces) enzymes, as well as secretory transporters, may have a significant impact on the pharmacological and toxicological responses to xenobiotics during puberty and adulthood and, additionally, impact systemic hemo-

nence levels. The purpose of this workshop is to bring together experts in the field of toxicoology to highlight the regulatory mechanisms underlying the developmental programming of hepatic metabolism and transport, and to discuss the potential impact of early exposure to xenobiotics on the ability of the liver to metabolize and excrete chemicals later in life. Experimental design and cutting-edge technologies will also be discussed. The workshop contains presentations and a roundtable dis-

cussion that will address four questions: What is the role of nuclear receptors and transcription factors in the ontogenic regulation of hepatic metabolism? What epigenetic mechanisms are involved in the hepatic programming of drug processes in newborns? Therefore, characterization of the gene expression profiles of drug processing genes and their regulatory mechanisms during liver maturation is needed for im-

proving drug therapy in pediatric patients. Mouse is frequently used as an experi-

mental model to determine how developmental expression of drug processing enzymes and epigenetic modifiers in mouse liver during development. Liver samples from male C57BL/6J mice were collected at 12 different ages from prenatal to adulthood (n=3 per age) for RNA-Seq. Several distinct ontogenic patterns were identified among the drug processing genes, which reflect a functional transition of liver from a hematopoietic organ in prenatal stage to a metabolic organ in postnatal stages during maturation. A correlation of the gene expression patterns among the Phase-I/II enzymes, transporters, and nuclear receptors was recognized, which provides a valuable foundation for mechanistic studies in the future. This study was supported by the National Institute for Environmental Health Science [RO1ES-019487] (to Xiao-bo Zhong, Curtis D. Klaassen, and Hong Lu); the National Institute of General Medical Sciences [R01GM-087376] (to Xiao-bo Zhong); the National Institute for Environmental Health Science [RO1ES-009669] (to Curtis D. Klaassen).

50 Xenobiotic Receptor CAR and Epigenetic Misprogramming

W. Huang, Beckman Research Institute, City of Hope National Medical Center, Duarte, CA. Sponsor: L. Alesunes.

Constitutive androstane receptor (CAR; NR1I3) is a central regulator of drug.

xenobiotic and endobiotic metabolism. CAR also regulates other metabolism, such as glucose and lipid metabolism. Interestingly, a transient activation of CAR during animal development induces epigenetic changes, which results in epigenetic mem-

ory and permanent changes of liver drug metabolism and detoxification. CAR activation by neonatal exposure to its ligand, 1,4-bis[(2-(3,5-dichloropyridylo)] benzene (TCPOBOP), persistently induces the expression of CAR target genes Cyp2B10 and Cyp2C37 throughout the life course. These mice also show a per-

manently reduced sensitivity to zoxazolamine treatment. The induced expression of CAR target genes in hepatocytes isolated from these mice is more sensitive to low concentrations of CAR agonist TCPOBOP in vitro. There are significant changes of histone modifications at the gene promoters of Cyp2B10 as analyzed by chromatin immunoprecipitation assays. These results demonstrate that epigenetic misprogramming mediated by CAR may result in a long-term epigenetic memory and permanent effect on the health of subjects.

51 Pharmacokinetic and Pharmacodynamic Consequences of Long-Term Increases in Carboxylesterase Expression following Developmental Pesticide Exposure

J. Richardson1,2, 1Department of Environmental and Occupational Medicine, Rutgers Robert Wood Johnson Medical School, Piscataway, NJ and 2Environmental and Occupational Health Sciences Institute, Rutgers, The State University of New Jersey, Piscataway, NJ.

Carboxylesterases (Ces) play important roles in mediating the metabolism of thera-

peutic drugs and environmental chemicals. As such, developmental exposures that cause changes in Ces expression and activity have the potential to exert significant influence on the metabolism of drugs and chemicals. We have identified that de-

velopmental pyrethroid exposure causes persistent increases in Ces mRNA expres-

sion, protein levels and activity that appear to be mediated through the constitut-

ive androstane receptor. These increases have functional consequences, decreased peak plasma and brain levels of methylphenidate, a drug commonly used to treat ADHD, are observed after oral dosing. These decreased levels of methylphenidate also result in decreased efficacy of methylphenidate in raising brain neurotransmitter levels. Data will also be presented regarding potential mechanisms responsible for persistent Ces up-regulation, including alterations in DNA methylation and histone modifications. Supported by NIEHS RO1ES015991, T32ES007149, and P30ES050520.

52 Developmental Bisphenol A Exposure Alters Hepatic Phase II Metabolism and Transport via Histone Deacetylase

A. L. Slitt, Department of Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.

Developmental exposure to Bisphenol A (BPA), a component of plastics manufactur-

ing, is associated with adverse effects in rodents through epigenetic mechanisms. Multiple mechanisms and etiologies for BPA effects have been examined, with few examining BPA effects on hepatic metabolism and excretion, despite its importance in maintaining metabolic and endocrine balance for the body. We hypothesized that maternal BPA exposure could affect liver metabolism and disposition in re-

sulting progeny. Virgin females (C57BL/6, a/a) were fed one of the following diets containing corn oil, BPA, BPA in combination with genistein, or ethynyl estradiol (EE) through gestation and lactation. Exposure ceased at weaning and livers were collected from male progeny at 135 days of age or older. Developmental BPA and EE exposure decreased UDP-glucuronosyl transferase (Ugt) and Multidrug Resistance-Associated Protein 2 (MRP2/ABCC2) expression and function, which was associated with significant alteration in nuclear receptor expression and bind-

ing. Developmental BPA and EE exposure decreased BPA glucuronidation and hepatic dibromosulfotetraethane (DBSP) clearance. Lastly, down regulation of mouse MRP2/ABCC2 expression was associated with increased Histone Deacetylase 2 (HDAC2) and decreased acetylated Histone 3 recruitment to function oxidant response elements for the Nr2 transcription factor in the mouse MRP2/ 

ABCC2 promoter. These observations were not observed in progeny from dams that were fed diet containing BPA and genistein. Together, these data illustrate that BPA exposure early in life can reprogram liver function, which is associated with altered Nr2 receptor binding and histone recruitment.

53 New Concerns and New Science Addressing Environmental Asbestos Exposures

D. J. Carlin1 and R. N. Hines2, 1NIEHS, Research Triangle Park, NC and 2USEPA, Research Triangle Park, NC.

Although extensive research has been conducted on asbestos health effects for spe-
cific fiber types, there are still many unresolved issues and controversies, particularly related to environmental asbestos exposures. Further, the health effects of mixtures of elongate mineral fibers have not previously been studied in detail. Approximately 120,000 asbestos-related deaths occur in the US and worldwide every year, and it has been well known for the past 30–40 years that occupational exposure to asbestos causes mesothelioma, asbestosis, and lung cancer. Moreover, environmen-
tal asbestos exposures have led to a declared public health emergency in Libby, Montana, an area known to have a higher incidence of asbestos-related diseases than the rest of the US. Other areas, such as El Dorado Hills, California, and Nooksack and Sumas, Washington, are also currently being evaluated for abes-
tos-contaminated soils and potential exposure to populations living in these areas. Although occupational asbestos exposures have been limited, there is increased concern related to exposures to environmental asbestos. For both environmental and occupational exposures, there are a number of critical issues, including: (1) How can complex mixtures of different forms of asbestos and nonasbestos contam-

inants be evaluated?; (2) What are the cellular and systemic mechanisms resulting
in fibrosis and/or tumor development; (3) What is the relative toxicity of different forms of asbestos?; (4) What is the proper dose-metric to consider (e.g., mass, fiber number, or surface area of fibers) when interpreting asbestos toxicity?; (5) What are the effects of asbestos exposure on susceptible populations (e.g., children and adolescents)?; and (6) How do we implement toxicological findings into risk assessment and clean-up efforts? This workshop has been designed to present the latest epidemiological and basic research findings in an attempt to address some of these questions, and to highlight the efforts of all stakeholders in determining the role of asbestos in various disease endpoints.

**54 Human Health and Environmental Exposure to Libby Amphibole Asbestos**

T. Larson, ATSDR, Atlanta, GA Sponsor: D. Carlin.

The public health situation in Libby, Montana has afforded a body of new research on the impacts of asbestos exposure on human health. While the focus of much of the preexisting asbestos literature has been on occupational cohorts comprising mostly men, the spectrum of exposures in Libby includes low levels among residents without occupational exposure. Consequently, ATSDR and EPA have funded a program of community-based epidemiologic research in Libby. Research topics include pulmonary disease progression using computed tomography, pulmonary health of child residents of Libby who subsequently moved away, and study of the relationship between residential exposure, system autoimmunity, and asbestos-related pulmonary disease. In addition to this in-process research program, several papers have been published examining health outcomes in sensitive subpopulations, health effects not classically associated with asbestos exposure, and health outcomes in residents. Self-reported pulmonary symptoms have been associated with frequency of handling vermiculite in Libby residents who were minors when the Libby vermiculite mine was operational and pleural plaque has been detected on the chest radiographs of Libby children. Residents of Libby who reported frequent contact with vermiculite also demonstrated elevated risk for systemic lupus erythematosus, scleroderma, or rheumatoid arthritis. Also among residents, radiographic pleural plaque was associated with restrictive spirometry.

**55 Autoimmune Responses following Asbestos Exposure**

J. C. Pfau, Idaho State University, Pocatello, ID.

Immune dysfunction is well established as part of the response following asbestos exposures, ranging from the inflammatory component of fibrotic disease to increased autoantibody production. However, epidemiological data clearly linking asbestos exposure to autoimmune disease is lacking, with only one study showing an increased risk of systemic autoimmune diseases in an amphibole exposed population. Because that study population was Libby, MT, where both occupational and environmental exposures occurred, hypotheses regarding the autoimmune component focus on differences either in exposure levels or exposure type—environmental versus occupational and/or chrysotile versus amphibole. Recent work is beginning to tease apart these issues using both human cohort comparisons and mouse models, revealing that the immune dysfunction following fiber exposure is highly complex and fiber specific. While amphibole asbestos clearly affects autoantibody production in both mice and humans, the human health outcomes do not seem to fit into current diagnostic criteria for specific rheumatic disease, but may dramatically impact pulmonary outcomes for environmental amphibole exposures. A key objective for research, therefore, is to identify specific immune changes that may be predictive of severity or progression of disease.

**56 Determinants of Toxicity of Environmental Asbestos Fibers**

S. H. Gavett, US EPA, Research Triangle Park, NC.

Recent EPA-led studies have addressed the comparative toxicity and pathological mechanisms of environmental asbestos samples from Libby, Montana and other communities in the United States. Longer amphibole fibers induce a 4-10 fold greater induction of pro-inflammatory mediators COX-2 and HO-1 than Libby fibers in human airway epithelial cells, as well as a number of other genes involved in cellular stress and toxicity. Similarly, equal mass doses of longer amphibole fibers administered intratracheally to F344 rats cause greater pathological effects than Libby fibers, from 1 to 2 years post-exposure. However, both intratracheal and inhalation studies show comparable effects of Libby fibers and shorter UICC amphibole fibers. Dosimetry modeling and potency analysis studies are using these data to predict effects in humans. Libby fibers induce an acute phase response and systemic increases in selected markers of inflammation, and induce components of the NALP-3 inflammasome in the lung, while surface complexed iron inhibits these responses. Libby fibers alter genes involved in inflammation, immune regulation, and cell-cycle control, and also induce autoimmune responses in a rat model. Comparative toxicity studies showed that chrysotile fibers from Sumas Mountain, Washington caused greater lung interstitial fibrosis than Libby fibers, which were significantly smaller in diameter than tremolite fibers from El Dorado, California and act as “cleavage fragments” from Ontario, Canada. These data are improving the scientific basis for the risk assessment of asbestos-contaminated communities, defining key determinants of internal dose, and providing critical insight on additional key health or pathologic endpoints.

**57 Role of Inflammasomes in Malignant Mesotheliomas**

A. Shukla, University of Vermont, Burlington, VT Sponsor: D. Carlin.

Asbestos fibers cause a number of respiratory diseases including pleural fibrosis and malignant mesothelioma (MM), however, the mechanisms initiating these diseases are not well understood. We are the first to demonstrate that asbestos-induced MM development involves activation of the NOD like receptor protein 3 (NLRP3) inflammasome, caspase-1 activation and mature IL-1β release from human mesothelial cells (HMC). This priming and activation of NLRP3 in HMC by asbestos does not require exogenous TNFα or lipopolysaccharide to initiate the response. In addition, using an IL-1 receptor antagonist, Anakinra, we document that there exists an autocrine feedback loop for activation of the inflammasome and production of cytokines perpetuating inflammation in mesothelial cells. Other studies in human MM tumors and MM cells have shown significantly decreased levels of NLRP3 and caspase-1, in contrast to normal mesothelial cells, which may in part be responsible for increased drug resistance observed in these tumors. Based on our findings, the use of chemotherapeutic drugs including Bcl-2 inhibitors in combination with an IL-1 receptor antagonist could be projected as better treatment strategies for MMs. The data generated by our research will help in understanding the mechanistic(s) by which asbestos can cause MM and eventually may lead to development of beneficial therapeutic strategies for asbestos-associated diseases.

**58 Challenges and Recommendations for Future Asbestos Research**

A. Miller, NIEHS, Bethesda, MD.

In an effort to address a host of new challenges associated with environmental asbestos exposures the NIEHS, USEPA, ATSDR, NIOSH, and academic institutions have closely collaborated over the past several years. Multidisciplinary research teams comprised of epidemiologists, toxicologists, mineralogists, clinicians, and statisticians have worked through array of complex issues elucidated by the Libby, Montana site, as well as other sites around the United States containing hazardous mineral fibers. Such issues include exposures to non-work populations including children, development of more robust sampling and analytical approaches to better characterize environmental exposures, and new epidemiologic and medical studies to understand resultant health effects including autoimmune and inflammatory health endpoints. Utilizing collaborative research platforms, Interagency Working Groups, and workshops such as an NIEHS-sponsored Mechanisms of Asbestos Action Workshop that occurred in December 2009 (Chapel Hill, NC) experts from these organizations have identified data gaps and mechanistic, epidemiologic, and exposure assessment research needs. Recent collaborative research efforts also include investigations of exposures and risks among communities in North Dakota and Turkey exposed to erionite, an unregulated but very hazardous mineral fiber. Recently, the NIEHS National Toxicology Program has been designing projects (e.g. 2 year bioassays) to better assess the toxicity of Libby amphibole material in conjunction with a comprehensive program to study naturally occurring asbestos and related mineral fibers. These studies will consist of collecting toxicity data, complete detailed physical and chemical characterizations, dose-response characterization for the fibers, and the influence of mineralogy and morphology on toxicity. It is anticipated that these collective efforts will lead to an improved understanding of fiber induced illnesses and new risk assessment strategies to help protect impacted communities.
Predicting Children’s Internal Exposure to Pyrethroids Using a Physiologically-Based Pharmacokinetic Model with Age-Appropriate In Vitro Metabolism Data

H. J. Clewell1, H. Wu1, B. G. Lake1, T. G. Osimire1, N. Assaf1 and M. Yoon1.
1The Hamner Institutes for Health Sciences, RTP, NC, 2LFR Molecular Sciences, Surrey, United Kingdom, 3Facility Management, Science Strategies, LLC, Charlottesville, VA and 4Valent BioSciences, Libertyville, IL.

Due to species differences in physiological and biochemical maturation as well as differences in major metabolic pathways, predicting early age sensitivity to a chemical exposure based on animal data requires caution. In our previous modeling with deltamethrin (DLM), while lower metabolic clearance of DLM resulted in increased sensitivity in neonatal rats, no age related sensitivity was predicted for humans. In this study, the DLM model was tested as a general platform to predict age-dependent pharmacokinetic sensitivity to other pyrethroids using compound specific kinetic parameters for trans-permethrin (TPM). In addition to maturation physiology, developmental changes in pyrethroid hydrolysis by carboxylesterases (CESs), the major metabolic pathway for both DLM and TPM in humans, were incorporated in the model. Age-appropriate hydrolysis estimates were obtained based on adult data measured in hepatic microsomes and cytosol, and ontogeny of CESs. No substantial age-differences in brain exposure to pyrethroids were predicted for TPM at a constant daily exposure (0.1 mg/kg/d) as shown by less than a 2-fold difference in average daily brain AUCs across ages. This study demonstrates that taking into consideration species-specific enzyme ontogeny and the resulting age-dependent changes in metabolic clearance of a given pyrethroid is critical in estimating early age sensitivity. The difference between environmentally relevant exposure levels and dose levels used in animal toxicity studies also needs to be considered. This modeling platform can serve as a tool to properly evaluate children’s sensitivity to pyrethroids when combined with age-appropriate metabolism data and environmentally relevant exposure estimates for children (supported by the Council for Advancement of Pyrethroid Human Risk Assessment, LLC [CAPHRA]).

Using a Two-Dimension Monte Carlo Model to Develop Chemical Specific Adjustment Factors (CSAFs) for Chlorpyrifos and Chlorpyrifos Oxon

P. S. Price1, T. S. Poet1, M. I. Bartels1 and D. R. Iuberg2.
1Toxicology & Environmental Research & Consulting, Dow Chemical Company, Midland, MI, 2Dow AgroSciences, Indianapolis, IN and 3Summit Toxicology, Richland, WA.

The traditional values of 10 for inter- and intra-individual uncertainty factors have been recognized as resulting in overly conservative health-based standards for most chemicals (Baird et al. 1996; Gayler and Kedell, 2000). This paper presents chemical specific adjustment factors (CSAFs) for setting the acute oral Population Adjusted Doses (aPADs) for chlorpyrifos and chlorpyrifos oxon consistent with recent WHO and USEPA guidance. The CSAFs are developed using data generated by a Biologically Based Dose Response Model (BBDR). The BBDR is based on a PBPK/PD model (Smith et al. 2013) that simulates the inhibition of red blood cell acetylcholinesterase (RBC AChE). This model is placed in the framework of a two-dimensional Monte Carlo model of uncertainty and variation in the response. RBC AChE is the critical effect used by USEPA in setting the aPADs for chlorpyrifos. Using the predicted average response in humans and the 99th percentile of variation in sensitivity, the inter- and intra-individual CSAFs for chlorpyrifos were 1.3 and 2.7, respectively. The corresponding values for chlorpyrifos oxon are 0.9 and 2.4. The relatively small CSAFs (as compared to traditional values) for the compounds are due to the use of RBC AChE as the critical effect. RBC AChE is the main target for chlorpyrifos in the human body that occurs early in the compounds’ adverse outcome pathways (AOPs). The slightly larger values for chlorpyrifos CSAFs are due to the additional activation step (conversion of chlorpyrifos to oxon) in the chlorpyrifos AOP. Variation in activation increases the intra- and inter-species differences in response for chlorpyrifos and thus the CSAF values. The use of the BBDR and its use in setting CSAFs can be applied to other chemicals where chemical reactions are events, or markers of events, that occur early in a chemical’s AOP.

Predicting Inhalation Toxicity of Bifenthrin Using a Pharmacokinetic Rationale

Z. Liu, A. Chandrasekaran and D. W. Gammon.
FMC Corporation, Ewing, NJ.

Numerous studies with the pyrethroid bifenthrin have demonstrated relatively low acute inhalation toxicity in rats. However, due to increased toxicity following inhalation exposure for some pyrethroids, such as flumethrin and cyfluthrin, there was hesitation to assign an inhalation BMDL for bifenthrin. The objective of this work was to use a pharmacokinetic (PK) basis for setting an inhalation BMDL for bifenthrin. To obtain internal exposure data and disposition characteristics, two PK studies were conducted in rats. These studies used far fewer rats than a Guideline 28-day or acute inhalation neurotoxicity study. In the first study, bifenthrin concentrations were measured in brain and plasma following inhalation exposure (3.1 mg/kg) or inhalation exposure (0.018 mg/L for 4 hours, equivalent to the same delivered oral dose), relative to time. The maximum concentrations (Cmax) and area under the concentration curves (AUCs) in both plasma and brain were slightly lower following inhalation than those after oral dosing. These new PK data for oral exposure were comparable to previous literature data. After intravenous administration to rats (1 mg/kg) in the second study, bifenthrin elimination was relatively rapid with a plasma half-life of 13.4 hours, i.e. limited tendency to bio-accumulate. Since bifenthrin peak neurotoxicity is proportional to Cmax in brain and/or plasma, an inhalation BMDL of 3.5 mg/kg/day was calculated based on the oral BMDL of 3.1 mg/kg/day and a ratio of 1.14 (brain oral Cmax/plasma concentration Cmax). These PK data demonstrate that there is an acceptable margin of safety even for the worst case worker exposure scenario, having an inhalation MDE=946 using the inhalation BMDL (3.5 mg/kg/day). Furthermore, the PK properties shown here for bifenthrin after multiple exposure routes, enable a complete picture of internal exposure levels to emerge for this pyrethroid, having predictive value for risk assessment without conducting additional animal toxicity studies.

Reframing of an Acute Inhalation Reference Concentration for 1,3-Dichloropropene

A. Maier1, A. Parker2, L. T. Haber3 and S. C. Gehlen4.
1University of Cincinnati, Cincinnati, OH, 2Toxicology Excellence for Risk Assessment, Cincinnati, OH and 3Dow AgroSciences, LLC, Indianapolis, IN.

The acute inhalation reference concentration (aRIC) is an important component of fugitive health risk assessment. For the soil fugitive 1,3-dichloropropane (1,3-D) there have been two aRIC values derived which differ significantly. We conducted a critical analysis of the basis for the differences between these values and provide an updated aRIC incorporating additional data. Key elements of the aRIC derivation process include point of departure (POD) selection, dosimetric adjustments, and uncertainty factor use. For POD selection, the acute studies have insufficient information to characterize the dose-response for the pertinent effects. Well conducted repeat-exposure studies are available, but comparison of dose and temporal concordance patterns indicated that these studies were inappropriate in terms of temporal relevance for the aRIC. For the updated assessment a LOAEL of 357 ppm, based on decreased body weight and clinical signs, was selected as the POD from a 4-hour inhalation study in albino Wistar rats. The two assessments also differ in terms of dosimetry methods used to estimate a human equivalent concentration (HEC). One based the HEC on partition coefficient ratios, while the other used respiratory rates for this conversion. The choice of methods depends on toxicokinetic behavior following acute exposure and on whether the critical effect is related to systemic or portal of entry toxicity. Additional analysis of the rate at which steady-state toxicokinetics would be reached for 1,3-D suggested that the approach based on partition coefficients ratios is most appropriate. Thus, the LOAEL of 357 ppm was adjusted for exposure duration (4 h/24 h) and a factor of 1 was applied to reflect species differences in steady-state blood concentrations, resulting in an HEC value of 60 ppm. An updated aRIC of 0.6 ppm was derived by applying a composite uncertainty factor of 100 to this POD. Overall, the analysis highlights the importance of a systematic analysis of each step in the aRIC derivation process.
Toxicokinetic (TK) data can provide valuable information for human health risk assessment. The following describes the advantages of integrated TK (no additional animal usage) to the process of risk assessment, using halauxifen-methyl, a new herbicide, as a case-study to show integrated TK allows:

Hazard Identification: Available TK data, including target tissue concentrations, provided insight as to why acid- and methyl-forms of halauxifen had different primary target organs, kidney and liver, respectively. Halauxifen-methyl is rapidly hydrolyzed in liver to the primary metabolite, halauxifen-acid, such that post-hepatic systemic exposure is exclusively to the acid. However, unlike the acid, its methyl ester was subsequently shown to selectively activate the hepatic AhR, and be responsible for its hepatotoxicity.

Dose-Response Assessment: Halauxifen-methyl has a rapid half-life of elimination (<6 hrs in rats); metabolism data in primary hepatocytes were used and AhR activation as measured by Cyp1a1 transcript levels was assessed. Subsequent primary hepatocyte studies in rats, mice and humans, using rat TK-based target tissue concentrations, provided data on AhR activation across species at relevant concentrations.

Exposure Assessment: PBPK models for rats and humans predicted similar systemic exposures, primarily to halauxifen-acid. Dietary exposures at the NOAEL of 10 mg/kg/day from the rat 90-day study were modeled. Similar results were obtained at relevant human exposure levels (i.e., proposed chronic RfD).

Risk Characterisation: In vitro, cross-species comparative hydrolysis data and integrated TK analyses supported quantitative non-human relevance of the halauxifen-methyl AhR-mediated hepatotoxicity in rodents by establishing: 1) a clear threshold for rat liver effects, 2) that systemic exposure is to acid, and 3) a chronic RfD significantly higher than any potential human exposure.

Mode of action (MOA) provides a central framework for assessing human relevance of adverse health outcomes observed in nonclinical safety studies. The goal of this study was to characterize MOA profiles for known rodent liver tumorogens identified from a database of pesticides assessed by the U.S. Environmental Protection Agency (EPA) Office of Pesticide Programs. Among 464 compounds, with mouse and rat carcinogenicity study data, liver tumor effects were observed for 23% of compounds (108/464; 95/464 for mouse and 32/464 for rat). Of these, 74% (80/108) were classified by the EPA as possible (43%) or probable/likely (31%) human carcinogens. Twenty-one compounds had a MOA proposed by the registrant for liver tumor outcomes used in quantitative risk assessment.

Of these, 16 MOAs were accepted by the EPA Cancer Assessment Review Committee. Molecular initiating events for these MOAs included constitutive androstane receptor (CAR) activation (10/16), peroxisome proliferator-activated receptor (PPARα) activation (4/16), and sustained hepatic cytotoxicity (2/16), followed by increased liver cell proliferation as measured by BrdU, Ki67, or PCNA labeling index (LI). A significant increase in proliferation was observed at ≥7 days for 13/14 compounds with accepted mitogenic (CAR- and PPARα-mediated) but not cytotoxic (0/2) MOAs, while short-term effects on proliferation LI were not provided (4/5) or were inconclusive (1/5). None of the compounds included decreased liver cell apoptosis as a key event. These findings highlight the central role of quantitative proliferation data in MOA evaluation and support current efforts to prioritize potent hepatotoxins based on early key biological effects.
To aid in completing the human health risk assessment (HHRA) for diesel exhaust (DE), inhalation dosimetry models (addressing deposition and clearance) were compared, with particular attention to applicability to DE particle (DEP) retention modeling. The literature was reviewed, and the six models of greatest relevance were identified. The model evaluation included: model compartments, clearance and deposition approach, species extrapolation approach, model assumptions and validation, usability and applicability to DEP. The model comparison highlighted model aspects that reflected state of the science/best practice, as well as issues that could decrease the reliability or validity of the results. For example, the Yu and Yoon (1992) model uses chemical-specific clearance information, including separate accounting for clearance of particles and of organics adsorbed to particles, but the human model has not been verified. Conversely, MPPD reflects the state of the science for deposition modeling, and the current version (2.2) includes alveolar clearance. We found that predicted or optimized deposition efficiencies were generally similar across the models; to a large degree, the observed differences reflected differences in the assumed ventilation rate, rather than inherent model differences. This observation is consistent with the finding by U.S. EPA (2002) that the alveolar deposition was very similar among the Yu and Yoon, ICRP, and MPPD (ver. 1.1) models. However, under conditions of continuous exposure, the net cumulative dose to the lung reflects the balance between delivery and clearance, and model differences in clearance appeared to be larger than for deposited dose. Based on these results, the MPPD model was deemed most appropriate for re-evaluation of the dosimetry and inclusion in a human health risk assessment of DE, to reflect the understanding of the science.

**68 Evaluation and Comparison of Inhalation Dosimetric Models for Applicability to Diesel Exhaust Particle (DEP)-Retention Modeling**

A. Willis1, L. T. Haber1, L. M. Sweener2 and C. J. Matz2. 1Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH and 2Air Health Effects Assessment Division, Ottawa, ON, Canada.

Model aspects that reflected state of the science/best practice, as well as issues that could decrease the reliability or validity of the results. For example, the Yu and Yoon (1992) model uses chemical-specific clearance information, including separate accounting for clearance of particles and of organics adsorbed to particles, but the human model has not been verified. Conversely, MPPD reflects the state of the science for deposition modeling, and the current version (2.2) includes alveolar clearance. We found that predicted or optimized deposition efficiencies were generally similar across the models; to a large degree, the observed differences reflected differences in the assumed ventilation rate, rather than inherent model differences. This observation is consistent with the finding by U.S. EPA (2002) that the alveolar deposition was very similar among the Yu and Yoon, ICRP, and MPPD (ver. 1.1) models. However, under conditions of continuous exposure, the net cumulative dose to the lung reflects the balance between delivery and clearance, and model differences in clearance appeared to be larger than for deposited dose. Based on these results, the MPPD model was deemed most appropriate for re-evaluation of the dosimetry and inclusion in a human health risk assessment of DE, to reflect the understanding of the science.

**69 Cross-Species Dosimetry for Upper Respiratory Tract Naphthalene Exposure with a Hybrid CFD-PBPK Model**

J. Campbell, M. E. Andersen and H. J. Clewell. The Hamner Institutes, Research Triangle Park, NC.

A hybrid CFD-PBPK model for naphthalene in the rat and human was developed to support cross-species dosimetry comparisons of naphthalene concentrations in the nasal respiratory and olfactory epithelium. The model reproduces time courses of naphthalene blood concentrations from intravenous and inhalation exposures in rats, and upper respiratory tract extraction data in both naïve rats and rats pretreated to inhibit nasal metabolism. Metabolic rates in the nasal tissue compartments were based on in vitro to in vivo extrapolation from published studies employing nasal tissue microsomes in rats and monkeys. The model was applied to estimate human equivalent inhalation concentrations (HECs) in dorsal olfactory and ventral respiratory tissues (i.e., nasal regions where tumors were observed in the NTP animal studies) corresponding to several endpoints for cancer and non-cancer effects of naphthalene in rats, as well as benchmark doses for genomic responses observed in rat studies conducted at The Hamner Institutes. Two approaches for cross-species extrapolation were compared: (1) equivalence based on tissue naphthalene concentration, and (2) equivalence based on amount metabolized per minute (normalized to tissue volume). At the NOAEL of 0.1 ppm (based on absence of hyperplasia in nasal tissue in a 90 day exposure study), the RGD based on naphthalene concentration was 0.2 for the dorsal olfactory; however, the ratio rises to 5.3 when based on the normalized amount metabolized due to the lower of expression of CYP2F2 isoforms in the nasal epithelium of primates and humans. HECs based on amount of naphthalene metabolized per minute could not be extrapolated to TWA concentrations above 0.54 ppm in the dorsal olfactory region or 0.018 ppm in the ventral respiratory region due to saturation of metabolic activity in the human nasal epithelium.

**70 A Regional Model of Lung Metabolism for Improving Species-Dependent Descriptions of 1,3-Butadiene and Its Metabolites**

1,3-Butadiene (BD), a volatile organic chemical used in synthetic rubber production and other industrial processes, is detectable at low levels in outdoor air and in tobacco smoke. Exposures to high concentrations of BD have been associated with cancer in humans and animals, although there are species differences in sensitivity. Following inhalation, respiratory tissues are a primary site of BD metabolism as well as targets for exsudate-induced damage and carcinogenicity. Pulmonary Type I epithelial cells, Type II epithelial cells and Clara Cells are metabolically active cells and thus potential targets of BD metabolite-induced toxicity. Metabolic capacities of these cells, their regional densities, and distributions vary throughout the respiratory tract as well as between species and cell types. Despite these differences in lung physiology/metabolic capacity, physiologically based pharmacokinetic (PBPK) models for BD to date have relied on metabolic parameters derived from whole-lung studies, and treat the lung as a homogenous organ. Here we present a novel regional model of lung metabolism for improving species dependent descriptions of BD metabolism for PBPK modeling. The overall structure of the model was also expanded by adding a kidney compartment and descriptions of higher order metabolism to allow consideration of available urinary and blood biomarker data in animals and humans to enable better model calibration between exposure and internal levels. Simulation results of inhalation exposures to BD indicate that incorporation of differential lung metabolism is important in describing species differences in pulmonary response and that these differences may have implications in cross-species extrapolation for risk assessment of BD.

**71 Development of an Inhalation PBPK Model for Benzo[a]pyrene in Rats and Humans**

Benzo[a]pyrene (BaP) is a by-product of incomplete combustion of fossil fuels and plant/wood products, including tobacco. Since human inhalation exposure to BaP is most commonly associated with particles, the bioavailability of inhaled BaP in humans is uncertain; however, PBPK models may assist in estimating internal dosimetry. The existing PBPK model of Crowell et al. (2011) for BaP in rats was extended to simulate inhalation exposures to BaP in rats and humans. An important step identified in modeling inhaled BaP was the impact of BaP-carrier particle dissociation on lung dosimetry. A kidney compartment was also added to allow preliminary reverse dosimetry using human urinary biomarker data to determine if carrier particle-specific BaP dissociation rates in the lung significantly impact long-term BaP dosimetry. Existing data for inhalation of BaP coated on various particle types suggested that lung clearance is bi--phasic. However, this behavior may be driven by rapid and slow particle desorption phases, the effect of mucociliary clearance, or a combination of these processes. Thus, parameter values for BaP-particle dissociation were estimated, tested in the extended inhalation model for rats, and optimized to the available rat data. Simulations of acute inhalation exposures suggest that diffusion-limited transfer of BaP from lung tissue to blood, ciliated clearance, swallowing of BaP particles, or all of these processes, may be critical for modeling lung dosimetry over time. Modeling of long-term human urinary biomarker data informed the relative significance of accounting for particle dissociation rates on chronic human dosimetry.

**72 Predicting Blood Lead Following Short-Term Exposures Using the All Ages Lead Model (AALM)**

Models currently used by EPA to predict blood lead concentration following exposure to lead (Pb) in environmental media are limited with respect to the exposure pathways and durations that can be simulated (e.g., the Integrated Exposure Uptake
The views expressed are those of the authors, and do not necessarily represent the choice of dose-metric has a significant impact on the evaluation of potential human for hexavalent chromium, and a variety of different internal dose-metrics may be between individuals. In addition, multiple PBPK models have been developed the GI lumen, and only total chromium can be analytically measured from a total of 109 based on completeness of information on cadmium levels in the current modeling approach to estimate the internal uptake of Cd and subsequent induction of metallothionein (MT) that retains Cd in the placenta. The simulated total Cd contents in the lung, blood, liver, placenta, uterus, and kidney in the dam on GD 17.5 were in good agreement with the observed values. The model predicted a rapid build-up of Cd in the placenta and uterus with daily inhalation exposure to CdO NPs compared to a relatively slower increase resulting from every other day exposure. Although the Cd levels were similar on GD 17.5, the AUC values in the placenta and uterus from the daily exposure were 1.4 and 1.8 fold higher, respectively, compared to those from every other day exposure indicating that the observed effects on fetal and neonatal development may be attributable to the difference in time profiles of Cd exposure in the placenta and uterus. The current modeling approach to estimate the internal exposure to CdO NPs in the placenta and the fetus can also be applied to other NPs (This work was supported by NIEHS Award #U19ES019525)

Hexavalent chromium (Cr(VI)) is an environmental and occupational contaminant, and is present in both soil and drinking water in the United States. In 2-year drinking water bioassays, the National Toxicology Program observed effects including carcinogenicity of the gastrointestinal (GI) tract in mice and oral cavity in rats. Physiologically-based pharmacokinetic (PBPK) models have been developed to estimate interspecies differences in toxicity and assess human health risk from oral exposure to Cr(VI). However, there are significant uncertainties and inter-individual variabilities to consider when modeling chromium in the gastrointestinal tract. Hexavalent chromium is rapidly reduced to trivalent chromium (Cr(III)) in the GI lumen, and only total chromium can be analytically measured in vivo. The reduction and absorption of hexavalent chromium will vary with intestinal pH, dietary intake, and gastric contents and physiology. These factors vary over time and between individuals. In addition, multiple PBPK models have been developed for hexavalent chromium, and a variety of different internal dose-metrics may be applied to link external exposure and toxic effects. Toxicity may be correlated to 1) concentration of Cr(VI) in the GI tract lumen; 2) absorption of Cr(VI) into specific GI tract tissue sites; 3) total absorption of Cr(VI) in the full GI tract. This work quantifies the impact of different modeling assumptions on the interpretation of toxicological data in rodents, and extrapolation to humans. It was found that the choice of dose-metric has a significant impact on the evaluation of potential human health effects from oral exposure to hexavalent chromium. The views expressed are those of the authors, and do not necessarily represent the views or policies of the U.S. EPA.

Hexavalent chromium (Cr(VI)) is an environmental and occupational contaminant, and is present in both soil and drinking water in the United States. Pharmacokinetic [IEUBK] model for Pb in children, and the Adult Lead Methodology (ALM)). In some cases, inputs into these models must necessarily approximate actual exposures, adding to uncertainty in model results and strategies to meet remediation goals. To improve estimates of Pb internal dosimetry following a wide range of exposure conditions and populations, EPA developed (and is testing) a PBPK model called the All Ages Lead Model (AALM). The AALM predicts blood and tissue Pb concentrations following Pb intake from contaminated air, drinking water, surface dust, food, or miscellaneous ingestion pathways. The AALM exposure module (an Excel™ interface) allows users to simulate multi-pathway exposures from 24 time constant or that vary in time increments as small as one day, and that occur at any age from birth to 90 years. Values for gastrointestinal absorption fractions for any age as well as values for relative bioavailability of Pb from all ingestion pathways are set by the user. The AALM model is implemented in acs[IEUBK] using either a Leggett et al. (AALM-LG) or O’Flaherty et al. (AALM-OF) based biokinetic submodel. The deposition and absorption parameter values (for either submodel) are those used in ICRP’s Human Respiratory Tract Model. Two case studies for short-term exposures (exposure 30 days) demonstrated the expanded capability of the AALM model: 1) exposures to construction workers, and 2) exposures to children following a home renovation. Additional AALM capabilities are listed, and next steps in the AALM model development and testing are discussed. [The views expressed are those of the authors, and do not necessarily reflect the views or policies of the U.S. EPA. Mention of any products does not constitute endorsement or recommendation for use.]

Hexavalent chromium is rapidly reduced to trivalent chromium (Cr(III)) in the GI lumen, and only total chromium can be analytically measured in vivo. Manganese to Include Rates of Cellular Uptake and Efflux

C. Peebles1, M. Yoong1, A. M. Keene2, M. Taylor1, H. J. Clewell1 and M. E. Anderson2. 1The Hamner Institutes for Health Sciences, Cary, NC. 2Afton Chemical Corporation, Richmond, VA and 3NiPERA, Research Triangle Park, NC.

Previously, we developed a series of physiologically based pharmacokinetic (PBPK) models for manganese (Mn) using the importance of Mn homeostasis and that this can be accounted for by a gender-specific uptake parameter.

Improved Toxicokinetic Model for Cadmium Using Urine, Blood, and Kidney Cortex Concentrations from Living Kidney Donors

M. N. Fransson1, L. Barregard2, G. Sallsten3, M. Akerstrom2 and G. Johanson1. 1Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden and 2Department of Occupational and Environmental Medicine, Sahlgrenska University Hospital, University of Gothenburg, Gothenburg, Sweden.

Several toxicokinetic models have been developed to describe the relation between external exposure, tissue levels and urinary excretion of cadmium. The aim of the present work was to analyse and validate one of the most common models (K&N, Kjellström & Nordberg, Environ Res, 1978) by using new data on cadmium concentrations in kidney cortex, blood and urine (Barregard et al., Environ Res, 2010). Measured data from 30 living kidney donors (14 males, 16 females) were selected from a total of 109 based on completeness of information on cadmium levels in urine, whole blood, plasma and kidney cortex, and donor status as never smokers. Markov Chain Monte Carlo simulations and flat priors were used to estimate posterior parameter distributions for the three most sensitive of the independent parameters in the model, including the systemic uptake (not to be confused with oral intake). Two additional parameters accounting for the covariate effects of gender and serum ferritin on uptake were also tested. For the gender effect, the uptake was 48% (posterior median) higher in women. For gender and serum ferritin combined, the uptake was 44% (posterior median) higher in women and 20% higher in individuals who had a serum ferritin level <30 µg/L. However, the uncertainty in the effect of serum ferritin included the null value, indicating that the parameter may not be significant. In conclusion, the K&N model described the new data well; however these new data suggest that the uptake is higher in females than in males and that this can be accounted for by a gender-specific uptake parameter.

Clinical and Pharmacological Studies for the Evaluation of Potential Human Health Effects of Cadmium Exposure in Pregnant Mice

Y. Zhao1, M. Yoong1, L.L. Blumenthal, T. Zeikoff1, T. Fenwiek1 and H. J. Clewell2. 1The Hamner Institutes for Health Sciences, Research Triangle Park, NC,2New York University School of Medicine, Tuxedo, NY and 3RTI International, Research Triangle Park, NC.

Fetal and neonatal periods may represent vulnerable life stages for exposure to nanoparticles (NP). In this study, we used a physiologically based pharmacokinetic (PBPK) model to simulate Cd disposition in pregnant mice from two different inhalation exposures to CdO NPs: every other day inhalation at 100 µg CdO/m3 and daily inhalation at 230 µg/m3 between gestation day (GD) 4.5 and 16.5. Although there was no difference in Cd levels in the maternal placenta or uterus between the two exposures, developmental effects were observed only with daily inhalation of 230 µg CdO NPs/m3. The respiratory tract deposition of inhaled CdO NPs was simulated using the Multiple-Path Particle Dosimetry model and was linked to the PBPK model. The saturable accumulation of CdO in the placenta was based on the reported involvement of active transporters such as DMT-1 and ZIP14 for uptake of Cd and subsequent induction of metallothionein (MT) that retains Cd in the placenta. The simulated total Cd contents in the lung, blood, liver, placenta, uterus, and kidney in the dam on GD 17.5 were in good agreement with the observed values. The model predicted a rapid build-up of Cd in the placenta and uterus with daily inhalation exposure to CdO NPs compared to a relatively slower increase resulting from every other day exposure. Although the Cd levels were similar on GD 17.5, the AUC values in the placenta and uterus from the daily exposure were 1.4 and 1.8 fold higher, respectively, compared to those from every other day exposure indicating that the observed effects on fetal and neonatal development and growth may be attributable to the difference in time profiles of Cd exposure in the placenta and uterus. The current modeling approach to estimate the internal exposure to CdO NPs in the placenta and the fetus can also be applied to other NPs (This work was supported by NIEHS Award #U19ES019525).
Cobalt (Co) supplements are available for sale, and concerns about metals released in patients with Co-containing hip implants have been raised. However, simultaneously collected whole blood, serum, urine, excretion and serum protein binding data have not been available to evaluate Co biokinetic models. Blood and urine data from ten healthy volunteers who ingested ~1.0 mg Co/day of a Co supplement for three months were used to refine previously published Co-biokinetic models. The model was modified to account for three key experimental observations: 1) an increase in serum protein bound Co from 9% during dosing to 99% after dosing; 2) a linear decrease in Co renal cell concentration post-dosing period, and 3) Co renal clearance consistent with estimated glomerular filtration rates. New model compartments included: 1) albumin bound Co in intravascular fluid (serum), 2) albumin bound Co in extravascular fluid exchanging with intravascular albumin, and 3) a series of compartments representing red blood cell ages between 1 and 120 days. Renal excretion was estimated by glomerular filtration rates and free Co2+ concentration. Agreement between the modeled and measured urine, serum, and whole blood concentrations were observed (r=0.8) with oral absorption rates between 10% and 65%, a RBC Co transfer coefficient equal to 10% of the rate suggested in vitro studies, and albumin binding rate constants adjusted to reflect the measured fraction of large molecular serum protein bound Co before and after dosing. Distribution of Co to systemic tissues over three months of dosing was approximately 1/10th of the amount suggested by historical single-dose radiological tracer studies, and the increase in albumin-bound Co after dosing is consistent with exchange of albumin-bound Co from extravascular fluid to intravascular fluid after source elimination. Our revised model provides useful insights on human Co kinetics, and should be helpful in the evaluation of elevated blood Co concentrations in MoM hip implant patients.

Predicting human pharmacokinetics for acid liver transporter substrates is needed due to the increasing frequency of novel acid substrates in drug discovery and development. Initially, a previously developed prediction method using sandwich cultured human hepatocytes (SCHH) and human liver microsomes (HLM) was applied to telmisartan. The human data show experimental and pharmacogenomic variability; the predictions were moderately successful using empirically determined in vitro to in vivo extrapolation scaling factors. Several improvements for the modeling were considered, Partition coefficients (Kp) were estimated from positron emission tomography (PET) data for tissues other than liver considered to have limited transporter activity. These Kp values were largely within the 3-fold error associated with Kp prediction methods, but improved the plasma profile predictions. Telmisartan is largely metabolized to a glucuronide conjugate, so a minimal model for the glucuronide was incorporated to predict PET data for the liver. Parameters were estimated from HLM, with cofactor added, and SCHH in which parent and glucuronide distribution in cells and media was measured. The longer times (>2.5 h) for the plasma telmisartan profiles were substantially underpredicted suggesting that enterohepatic recirculation played an important role. An empirical recirculation description was added incorporating meal induced gall bladder emptying, biliary efflux transport of the glucuronide, and instantaneous cleavage to parent in the gut. This provided reasonable simulation of the plasma profile. Overall, this modeling demonstrated that while prediction of liver transporter activity is necessary for transporter substrates, simulation of additional pharmacokinetic processes can be essential including better estimates of partition coefficients and enterohepatic recirculation.
Chlorpyrifos (CPF), an organophosphorus pesticide (OP), is metabolized by CYPs to the detoxified metabolite trichloro-2-pyridinol (TCPy), or to the active metabolite, chlorpyrifos-oxon (CPF-O), which is a potent esterase inhibitor. For CPF, urinary TCPy concentrations are a reliable biomarker of CPF exposure while RBC acetylcholinesterase (AChE) and plasma butyrylcholinesterase (BuChE) are biomarkers of effect. A PBPK/PD model was developed to predict exposure to CPF, dermal absorption, distribution, metabolism, elimination and adverse health effects in Egyptian agricultural workers based on urinary TCPy, blood AChE and BuChE data collected in the field over a period of 33 consecutive days. Regression analysis of 24 hr urinary TCPy values was used to establish an array of 33 daily linear transfer coefficients of CPF to clothing and skin of 35 workers (14 backpack applicators, 9 technicians and 12 engineers). The array based model predicted skin exposure (dose) for the workers, ranging from 0.07 to 9.05 mg/kg/day, dermal absorption (1.88% of skin dose), daily wash-off (95.5% of dose), evaporation (2.14% of dose), and total overall recovery (99.6% of dermal dose). Model simulations estimate CPF and CPF-O blood levels as high as 124800 and 1275 pmol/L, respectively, with model Ki values for blood AChE and BuChE varying between 1.03 x 10−4 and 1.03 x 10−3 pmol-1hr-1 for applicators and between 1.03 x 10−4 and 6.0 x 10−3 for technicians and engineers. PBPK/PD modeling is generally consistent with human biomarker data, however, there is some variability between model estimates and observed ChE inhibition, suggesting that there may be genetic susceptibility components that can alter an individual's sensitivity to CPF. (US EPA STAR, grant R-83068301 and NIEHS grants ES016308, ES022163).

Chlorpyrifos (CPF) is an important pesticide used to control crop insects. Biological effects occur following metabolic activation to chlorpyrifos oxon, and these effects are monitored using RBC cholinesterase inhibition. Non-occupational exposures to CPF will occur primarily through residues on foods, with occupational exposure also from dermal contact or low-level inhalation exposures to the non-volatile CPF. A physiologically based pharmacokinetic/pharmacodynamic (PBPK/PD) model has been developed that describes the relationship between oral, dermal, and inhalation doses of chlorpyrifos and key associated events in the pathway for cholinergic effects. Pharmacokinetic data is available for controlled human exposures via the oral and dermal routes and from multiple oral or inhalation studies in rats. The multi-route model was developed in these two species to validate all modeled scenarios in a parallel design. Since bioactivation is key to CPF effects, small amount of metabolism in tissues potentially have a great affect on PK and PD. Metabolism was therefore added in diaphragm, brain, lung, and skin, based on published data. For most tissues, metabolism that represented 2% of the measured hepatic metabolism resulted in fits to available cholinesterase inhibition and dosimetry. Due to the lipophilic nature of CPF most of the inhaled dose will either be delivered via superficial nasal deposition into the stomach or associated with the metabolically active pulmonary tissue, thus metabolism in the lung is comparable to liver. The resultant model fits to human and rat multi-route data, and shows that CPF Cmax will be higher through non-oral routes when cholinesterase inhibition in non-portal of entry tissues will be less following exposure via these non-oral routes. This resulting model will be highly useful in risk assessments for CPF from one or more routes of exposure.

A Physiologically-Based Pharmacokinetic and Pharmacodynamic (PBPK/PD) Model of Daily Chlorpyrifos Exposure in Egyptian Agricultural Workers

A General PBPK Model for IV-Injected Nanoparticles

U. Carlander and G. Johanson, IMM, Unit of Work Environmental Toxicology, Karolinska Institutet, Stockholm, Sweden.

In order to link NP exposure to toxicity, information about absorption, distribution, degradation and excretion (ADME) is essential. Experience from pharmaceuticals and industrial chemicals shows that the ADME can successfully be simulated, described and predicted by physiologically based pharmacokinetic (PBPK) modeling. The few PBPK models for NPs published to date have been developed and evaluated for a single type of NP. The aim of this study was to develop a general NP-PBPK model for intravenously injected NPs in rats. The model was based on a recently developed PBPK model for pegylated polyacrylamide (PAApeg) NPs (Dinghuang et al., submitted manuscript), which in turn was developed using detailed experimental data (time courses of NP mass in different tissues) after single intravenous administration (Wenger et al., Toxicol. Appl. Pharmacol. 2011). In addition to PAApeg, we retrieved intravenous rat data for nonpegylated PAA, gold and polyethylene maleate NPs (Lescure et al., Pharm. Res. 1994; Wang et al., Anal. Bioanal. Chem. 2010). NP-dependent parameters were adjusted by best fit to each data set, whereas NP-independent physiological and anatomical parameters were kept constant. The general model was able to adequately describe the ADME behavior of all four NP types. The fitted parameters that varied most were the clearance to urine and feces, the biodistribution permeability coefficients and the uptake rate and capacity of phagocytic cells. Additional data on NP properties such as corona formation and physiological parameters, such as number of phagocytic cells in different tissues and their capacity and turnover, are required to further improve the model. The study was supported by the Swedish Research Council for Health, Working Life and Welfare (Forte).

A PBPK Model of Hypobaric and Hyperbaric Toluene Exposure

C. Hack1, T. R. Covington1, P. J. Robinson1, P. Shivanov1, D. A. Mahle2 and J. M. Geath2,1 (HFP, AFR, Wright-Patterson AFB, OH and RHDJ, APRF, Wright-Patterson AFB, OH).

Modern high-performance jets achieve extreme altitudes and operate in hypobaric pressure environments. Conversely, divers operate at hyperbaric depths. Inhalation exposure to toluene in these extreme pressure environments may result in altered kinetics, and therefore, altered response and exposure safety guidelines. Such pressure-dependent differences in kinetics have been observed for some compounds, while absent for others. To test whether toluene kinetics are sensitive to pressure, we developed a physiologically-based pharmacokinetic (PBPK) model as a tool for examining potential physiological contributors to such differences. Our approach was to compare model predictions to hypobaric and hyperbaric toluene kinetics data in Sprague-Dawley (SD) rats, and then adjust model parameters and/or processes to fit the data, thereby identifying potential effectors of observed differences. The model was based on a typical Ramsey-Andersen model of isopropanol, with tissue compartments for the brain, liver, fat, skin, and lumped rapidly perfused and slowly perfused tissues. Toluene parameters were obtained from literature sources. The model was verified for normal pressure through comparison with previously published data and models in the literature, and produced good agreement with the data. For hyper/hypobaric simulations, the model was first adjusted with explicit implementation of the ideal gas law for conversion of ppm to mass at different pressures. Male and female SD rats were exposed to toluene via inhalation, and the data were compared with model predictions. Initial model predictions underestimated the experimental data. However, the model predicted decreased toluene in tissues with decreasing pressure, which was consistent with the experimental data. Predictions of published hyperbaric exposures slightly overestimated those data by about 30%. Future work will focus on comparison of predictions with additional hypobaric and hyperbaric, and examination of other potential physiological contributors to pressure-dependent kinetic differences.

Understanding the Differences in the Toxicity of Tolcapone and Entacapone: A Comparative Study Using the Virtual Liver Platform—HeptoX

The effect of two catechol-O-methyltransferase (COMT) inhibitors, entacapone and tolcapone are compared using our toxicity prediction platform, a combination of an in silico model of liver metabolism with a set of in vitro biochemical measure-ments. Although both tolcapone and entacapone show similar on-target inhibitory potencies (Ki for COMT~10 nM), their off-target effects in the liver and their pharmacokinetic and pharmacodynamic properties are different. We measured the dose- and time-dependent impact of both drugs on key liver metabolic pathways using a HepG2 cell system. HepG2 cells were treated for different time periods up to 72 hours, and we estimated both the direct action of the drug on enzyme activity as well as compensatory mechanisms that are invoked with time in response to the drug treatment. This information is used to simulate a virtual clinical trial for both the drugs using their respective pharmacokinetic data as input. Tolcapone with a three fold higher Cmax than entacapone as well as higher plasma half-life (2.9 vs 0.9 hrs) has a far greater impact on the off-targets leading to more toxicity compared to entacapone. In this study we show a relationship between drug-exposure and the toxic impact of these two drugs on different off-targets, and derive an explanation as to why tolcapone is more hepatotoxic than entacapone. Our simulations indicate the onset of tolcapone induced toxicity starts in after 6 weeks of treatment and predicts that over a period of 3 months, tolcapone induces mitochondrial damage, inhibits transport of ATP across the mitochondrial membrane and leads to a lowering of cytosolic ATP and eventual necrotic damage.

The Association between Prenatal Exposure to Perfluoroalkyl Substances (PFAS) and Reduced Birth Weight: Is Glomerular Filtration Rate the Underlying Cause?

M. Verney1,2, A. Loccisano3, M. Yoon1, H. Wu1, R. McDougall4, M. Maisonier1, R. Marcus1, R. Kishi5, C. Miyashita6, M. Chen7, W. Hsieh7, M. E. Anderson3, H. J. Clewell3 and M. P. Longnecker4. 1Harvard Medical School, Boston, MA, 2Karolinska Institutet, Stockholm, Sweden, 3The Hamner Institutes for Health Sciences, Research Triangle Park, NC, 4Argis Technologies, Hamden, CT, 5Emory University, Atlanta, GA, 6University of Sendai, Sendai, Japan, 7National Taiwan University College of Medicine, Taipei, Taiwan and 8National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Prenatal exposure to PFAS has been associated with lower birth weight in epidemiologic studies. Because glomerular filtration rate (GFR) during pregnancy is associated with PFAS excretion and birth weight, the observed association between PFAS levels and reduced birth weight could be driven by GFR. We used an existing physiologically-based pharmacokinetic (PBPK) model of human pregnancy to simulate PFAS in maternal and cord blood and to subsequently assess how much of the PFAS-birth weight association observed in epidemiologic studies might be attributable to GFR. We modified the model to reflect the association of birth weight with GFR. Data from 100,000 Monte Carlo simulations was analyzed using linear regression to evaluate the association between simulated PFAS levels and birth weight. Based on the simulations, we estimated reductions of 2.61 g and 6.23 g in birth weight for each 1 ng/ml increase in cord PFOS and PFOA, respectively. Each 1 ng/ml increase in simulated maternal blood PFOS and PFOA levels at delivery was associated with reductions of 1.84 g and 6.99 g in birth weight. In comparison, a meta-analysis of published epidemiologic studies suggested that each 1 ng/ml increase in prenatal PFOS and PFOA levels is associated with 5.00 g and 14.72 g reductions in birth weight. Our results revealed that a substantial portion of the reported association between prenatal PFAS and birth weight might be attributable to GFR. This study shows that PBPK models can be used to assess how much of an epidemiologic association can be explained on the basis of pharmacokinetics.

PBPK Modeling of Human PFOA Exposure Predicts Measured Serum Concentrations from Consumption of Contaminated Drinking Water

R. R. Worley1,2, D. A. Fowler1, C. Webb1 and L. Fisher1,2. 1Division of Community Health Investigations, Centers for Disease Control/Agency for Toxic Substances and Disease Registry, Atlanta, GA, 2Interdisciplinary Toxicology Program, University of Georgia, Athens, GA and 3National Center for Toxicological Research, Food and Drug Administration, Jefferson, AR.

Human exposure to perfluorooctanoic acid (PFOA) is common and widespread - PFOA is regularly found in human blood samples as reported by the National Health and Nutrition Examination Survey (NHANES). A physiologically-based pharmacokinetic (PBPK) model was developed that predicts the behavior of PFOA in humans and computational research is underway to evaluate human biomonitoring data collected in a community with known exposures to PFOA as a result of contaminated drinking water. Exposure scenarios that may approximate those occurring in the community are simulated and the resulting PFOA-serum concentrations are compared to those measured in the field study. The water supply for this community was known to be contaminated with PFOA for at least 12 years and the contaminants were simulated and the resulting PFOA-serum concentrations are compared to those measured in the field study. The water supply for this community was known to be contaminated with PFOA for at least 12 years and the contaminants were simulated in humans and computational research is underway to evaluate human biomonitoring data. The few PBPK models for NPs published to date have been developed and evaluated for a single type of NP. The aim of this study was to develop a general NP-PBPK model for intravenously injected NPs in rats. The model was based on a recently developed PBPK model for pegylated polyacrylamide (PAApeg) NPs (Dinghuang et al., submitted manuscript), which in turn was developed using detailed experimental data (time courses of NP mass in different tissues) after single intravenous administration (Wenger et al., Toxicol. Appl. Pharmacol. 2011). In addition to PAApeg, we retrieved intravenous rat data for nonpegylated PAA, gold and polyethylene maleate NPs (Lescure et al., Pharm. Res. 1994; Wang et al., Anal. Bioanal. Predictions of published hyperbaric exposures slightly overestimated those data by about 30%. Future work will focus on comparison of predictions with additional hypobaric and hyperbaric, and examination of other potential physiological contributors to pressure-dependent kinetic differences.
either 0.4 ppb (EPA’s Provisional Health Advisory Level) or 2.2 ppb (a concentration measured in a private well in the community and considered to be at the high end of plausible drinking water concentrations from private wells). A simple description of PFOA elimination kinetics using a urinary clearance coefficient of 4.0 x 10^-5 L/min/ml was used to simulate serum PFOA concentrations for the predicted dose-response relationship applied to in vivo measurements and then fitted with available rodent pharmacokinetic data. Blood and tissues estimations were consistent for all congeners using the same model structure. Each congener had small changes for a few model parameters (exchange rates between blood lipoproteins, liver tissues and fatty tissues). The model simulations suggest a more rapid uptake in blood lipoproteins compared to the reported PBDE kinetics due to growth dilution and an additional excetration route associated with menstruation may underlie the reported relationship between serum PBDE levels and age at menarche. The model structure was extended using adipose tissues divided into blood lipoproteins, fatty tissues, and depot tissues to 94 A Multiscale Mechanistic Model of TCDD-Induced Toxicity for Assessing Expected Dose-Responses for Adverse Outcome Pathways in Liver

S. Bhattacharya, P. D. McMullen, S. Pendse and M. E. Andersen, Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

Ongoing efforts to describe and apply adverse outcome pathways (AOPs) for risk assessment require linkage of early molecular interactions to phenotypic responses. New advances in multiscale “virtual tissue” models provide a quantitative framework to link together: (a) tissue disposition of a chemical; (b) molecular initiating events such as receptor binding; (c) explicit models of intraacellular and organism level AOPs; and (iv) phenotypic endpoints like cell proliferation. Here we describe our development of a virtual tissue model of the rodent liver lobule for activation of the aryl hydrocarbon receptor (AhR) toxicity pathway in hepatocytes exposed to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). This case study shows the process of data integration and multiscale model development for mechanistic dose-response prediction and application of the AOP framework to risk assessment. First, a modified cluster aggregation algorithm provided a two-dimensional computational representation of the rodent liver lobule. This multiscale lobular model was linked to the ComputCell3D modeling environment that incorporated a network representation of intra-hepatocyte activation of the AhR signaling pathway. A PBPK description of TCDD uptake in the liver through hepatic sinusoids estimated differential cellular dosimetry as an input to the spatial model. Zonal heterogeneity in TCDD-induced cytochrome induction arises from for descriptions of spatial gradients in basal AhR expression across the lobule. Simultaneously, a combination of published gene expression and chromatin immunoprecipitation data served to refine a detailed transcriptional network of the AhR pathway with differential sensitivity ascribed for different liver regions. Overall, the multiscale model accurately simulated the observed dose-responses for various endpoints. Virtual tissue models promise more quantitative linkage to AOPs than possible through simple narrative descriptions of these processes.

92 Evaluation of the Observed Association between the Early-Age Exposure to Polybrominated Diphenyl Ethers (PBDEs) and Altered Age at Menarche on the Basis of Kinetics

M. Yoon1, H. Wu1, M. Luo1, M. P. Longnecker2 and H. J. Clewell1, 1The Hamner Institutes for Health Sciences, RTP, NC; and 2National Institutes of Environmental Health Sciences, RTP, NC.

Epidemiological associations between blood PBDEs and earlier menarche in the general population have raised concerns for possible reproductive health effects. However, rapidly changing physiology during puberty that can affect the kinetics of a chemical may underlie the observed associations. To assess the role of pharmacokinetic variability during puberty on the reported PBDE epidemiologic study results, we used a Monte Carlo (MC) Physiologically-based Pharmacokinetic (PBPK) model. A PBPK model was developed based on single pharmacokinetic structure that can predict tissue and blood concentrations for BDE 47, 99, 100, and 153 in rodents. The model structure was extended using adipose tissues divided into blood lipoproteins, fatty tissues, and depot tissues to 94 A Multiscale Mechanistic Model of TCDD-Induced Toxicity for Assessing Expected Dose-Responses for Adverse Outcome Pathways in Liver

S. Bhattacharya, P. D. McMullen, S. Pendse and M. E. Andersen, Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

Dosimetric Analysis of VITROCELL VC10® Smoke Exposure System with Photometer and Quartz Crystal Microbalance

Air liquid interface whole smoke exposure technologies such as the VITROCELL VC10® smoke exposure system (VC10) are applied to assess the effect of cigarette smoke on biological endpoints (e.g. cytotoxicity, mutagenicity and DNA modifications). Presently, dose response evaluations have been primarily determined on an airflow dilution basis following smoke generation under ISO or intense smoking regimes. Correlation of the biological response to dose is important for comparative analyses of products and data from other smoke exposure systems and may be facilitated by dosimetry tools such as photometers, quartz crystal microbalances (QCMs) and carbon monoxide monitors. The goals of this study were to 1) assess the consistency of particle detection via deposition or mass with QCMs and photometers, respectively, across all dilution bars and at airflows spanning the operating range of the VC10, 2) assess consistency of particle detection in multiple exposure modules and 3) correlate photometer readings at set airflows to deposited mass such that estimates of mass can be derived from the VC10 Photometer Monitor Software.

Consistency in particle deposition and mass was generally observed across all dilution bars and between modules at a range of airflows that spanned the operating range of the VC10. Consistency was also observed across all chamber positions within modules from 12 to 1L/min while some variability was observed at 0.5L/min. Linear correlations between particulate deposition and measured particulate mass were observed, and statistical and power curve analyses confirmed the accuracy of the predicted QCM data generated with the VC10 Photometer Monitor Software. Collectively, we report the capacity to assess deposited mass with reproducibility with QCMs and to accurately estimate mass based on area under the curve data from photometer readings. These data will be helpful in correlating biological responses to dose related exposures with the VC10.

Predicting Tissue:Plasma Partition Coefficients: Interindividual and Interspecies Variability

C. D. Ruark1, C. Hack1, P. J. Robinson1, D. A. Mahle2 and J. M. Gearhart1. 1HF, Molecular Bioffsets Branch, Bioffsets Division, 711 Human Performance Wing, Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH and 2Molecular Bioffsets Branch, Bioffsets Division, 711 Human Performance Wing, Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH.

A tissue composition based mechanistic model for the prediction of steady state tissue: plasma partition coefficients (Kt:p) of organic chemicals in mammalian species was used to assess interindividual and interspecies variability. The approach predicts Kt:p using available chemical properties (lipophility, binding to phospholipid membranes, and pK±K±), together with biological properties of the tissue itself (fraction of water, neutral lipids, neutral and acidic phospholipids, proteins and pH). Biological properties were identified from the biomedical literature for rat, pig, human, guinea pig, monkey, mouse, beagle dog and rabbit species. Property means and coefficients of variation were used in a Monte Carlo simulation to assess variability within and between species. The results show that interindividual and interspecies variability becomes more pronounced as LogPO:W increases and the difference is insignificant for compounds with LogPO:W<2.0. Interspecies variation is shown to be driven by differences in the acidic phospholipid composition. The Monte Carlo composition based mechanistic model can be used to predict Kt:p for organic chemicals across 8 different species and can be an important component in population physiologically based pharmacokinetic (PBPK) modeling, safety evaluation, chemical risk assessment and screening.

Integrating Biological Variability with QSARs in PBPK Models to Simulate Distributions of Internal Dose in Humans

K. Krishnan and T. Peyret, Université de Montreal, Montreal, QC, Canada.

Existing mechanistic algorithms use point estimates for blood and tissue composition to predict the blood-air and tissue-air partition coefficients (PCs) required for PBPK modeling. The objectives of this study were: i) to develop a framework to predict the probability of distributions of PCs and ii) to incorporate them, along with published information on the variability of cytochrome P450 CYP2E1 content and physiological parameters, within a human PBPK model to simulate the variability of toxicokinetics of inhaled VOCs. Previously published human and rat data on matrixicr PCs of toluene and acetone (in blood, fat, liver, and muscle tissueair PCs), along with data on oilair and waterair PCs were used in a Markov chain Monte Carlo (MCMC) approach to characterize the distributions of human blood and fat tissue composition parameters in the mechanistic algorithm for PCs (i.e., neutral lipid, water and protein contents). The posterior distributions resulting from the MCMC analysis were used along with physicochemical properties predicted with QSARs to compute distributions of chemical-specific tissueblood and tissuefat PCs. Monte Carlo simulations were then carried out with the PBPK model to predict the blood kinetics of VOCs (benzene (25 ppm, 2 h), styrene (80 ppm, 6 h) and trichloroethylene (100 ppm, 4 h)) following inhalation exposures. For these VOCs, the predictions of the PBPK model compared well with the available human volunteer data. Overall, this study demonstrated the feasibility of using PBPK models to simulate the combined impact of the variability of biological and chemical properties on the internal dose of chemicals. (Supported by Natural Sciences and Engineering Research Council of Canada)

PPB Models for Gasoline-Ethanol Biofuels in Adult and Pregnant Rats

As utilization of biofuels (BF) in the commercial marketplace has increased in recent years, so has the need for evaluation of exposure-related health effects, such as developmental neurotoxicity. This research describes the development of inhalation life-stage physiologically-based pharmacokinetic (PBPK) models for vapors of gasoline (E0) and two BF blends, E15 (15% EtOH) and E85 (85% EtOH). Time course blood hydrocarbon concentration (BHC) data were collected from non-pregnant female rats exposed to E0, E15, and E85, at total hydrocarbon concentrations (THC) of 3K, 6K, and 9Kppm (60h exposure, 4-6 time points per dose). Peak (end-of-exposure) BHC data were also collected from pregnant dams exposed to 9Kppm (6-36h, GD9, 16, 20) of E0 or E15. These datasets were used to evaluate and refine PBPK models for each mixture and to compare estimates of BHCs across BF types at comparable THC. PBPK models were constructed using a series of sub-models for prominent aromatic and aliphatic HCs representing ~45-66% of total vapor (depending on BF), while the remaining fractions were lumped. The overall modeling framework allowed for flexibility across blend compositions. The sub-models were parameterized with literature and structure-activity-based estimates; estimated physicochemical and metabolic parameters were used for the lumps. The models adequately simulated BHCs for most aromatic and aliphatic HCs across the various exposure scenarios. Specifically, HCs with robust calibration literature were usually well simulated, while clearance rates for the other aliphatics often did not adequately match model BHC predictions. Simulations for aromatics at high vapor concentrations were improved by including metabolic interactions; HCs at low concentrations were often better simulated without these interactions. The final models may be relevant for simulations of other blend ratios. Abstract does not reflect EPA policy.

Evaluation of Semi-Generic PBTK Modelling for Emergency Risk Assessment after Acute Inhalation Exposure to Volatile Hazardous Chemicals

J. Olie1, 2, C. C. Hunault1, J. Bessems3, H. L. Clewed4 and J. Meulenbelt5, 6. 1National Poison Information Center, University Medical Center Utrecht, Utrecht, Netherlands, 2University of Nijmegen, Nijmegen, Netherlands, 3ECJRC, Institute for Health and Consumer Protection, Iprra, Italy, 4The Hamner Institutes, Research Triangle Park, NC, 5RAS, Utrecht University, Utrecht, Netherlands and 6Department of Intensive Care Medicine, UMCG, Utrecht, Utrecht, Netherlands.

Rationale: Physiologically Based Toxicokinetic Models (PBTK) may facilitate emergency risk assessment after chemical incidents, but are rarely used due to their relative complexity and skill requirements. We aimed to evaluating a semi-generic PBTK model built in MS Excel for nine chemicals that are widely-used and often released in a chemical incident.

Methods: The semi-generic PBTK model was used to predict blood concentration-time curves using exposure scenarios from human volunteer studies (low exposure doses), case reports (medium to high exposure doses) and hypothetical exposures at EPA Group-3 Levels (high exposure doses). Semi-generic means the model uses built-in QSARs to set some parameter values. Predictions were compared to measured blood concentrations from volunteer studies or case reports as well as to...
blood concentrations predicted by chemical-specific models. The performances of the semi-generic model were evaluated on biological rationale, accuracy and shape of predicted concentration-time profiles, ease of use and range of application. Results: Our results indicate that the semi-generic PBTK model can be readily used to predict blood levels for 6 out of 9 parent chemicals (benzene, xylene, toluene, styrene, trichloroethylene and tetrachloroethylene), with the exception of methanol, 2-propanol and dichloromethane. The semi-generic model could not cope with the endogenous production of methanol and acetone (metabolite of 2-propanol). The model could not simulate the formation of HbCO, which is one of the toxic end-points of dichloromethane. Conclusion: For some hazardous chemicals, a semi-generic PBTK modelling approach can be just as accurate as a more chemical-specific PBTK modelling approach.

**96d** Interpreting NHANES Biomonitoring Data: Dioxins

P. Ruiz1, J. Simon1 and M. Murtaaz1, 1Computational Toxicology Lab, ATSDR/CDC, Atlanta, GA and 2Ted Simon LLC, Winston, GA.

Polychlorinated dibenzo-p-dioxins (PCDDs), polychlorinated dibenzofurans (PCDFs), mono-ortho and non-ortho polychlorinated biphenyls (dioxin-like PCBs) are identified as a family of organic compounds known as “dioxins”. Dioxins are persistent endocrine-disrupting chemicals that bioaccumulate following environmental exposure or dietary intake. Additional adverse health effects of dioxin exposure in humans include the development of serious diseases such as diabetes, cancer, deleterious effects such as an altered immunological response and changes in the expression of receptors and metabolic enzymes. As part of translational research to make computerized models accessible to health risk assessors we recorded the Concentration-and-Age-Dependent Model (CADM) for pharmacokinetics of dioxins in Berkeley Madonna simulation language. The recorded model was evaluated by comparing simulation results to published model simulations and to human data sets. Overall, there was good agreement between the estimated and measured values. Our recorded model allows the estimation of dioxin concentrations in breastfed infants. Also presented is an application of the recorded model to interpret biomonitoring data from the National Health and Nutritional Examination Survey (NHANES). The model simulated the NHANES-measured data very well from ages 6 to 60+ years. The model describes TCDD cumulative nature in humans and accommodates the observed variation in exposure/uptake over the course of a lifetime. Hence, this model may be useful as a screening tool that can provide information on interpreting biomonitoring data and risk assessment.

**96e** Physiologically-Based Pharmacokinetic (PBPK) Models Application to Screen Environmental Hazards Related to Adverse Outcome Pathways (AOPs)

PBPK models are useful in estimating exposure levels based on in vitro to in vivo extrapolation (IVIVE) calculations. Linkage of large sets of chemically screened vitro signature effects to in vivo adverse outcomes using IVIVE is central to the concepts of the National Academy of Sciences’ Toxicology in 21st century vision. Except for metabolic clearance, most parameters used to develop PBPK models are readily available in literature, or calculated using chemical structure activity relationships. Lack of computational methods to determine clearance inhibits the application of PBPK models to large sets of chemicals without conducting costly and time-consuming experiments. This problem, however, should not exclude the use of PBPK models to screen a large set of chemicals for possible environmental exposure levels that can lead to adverse outcome effects. This can be accomplished by developing “generic” PBPK models. Metabolic clearance capacity in the generic model is set to zero to estimate maximal exposure level (EXPmax) that will yield parent chemical tissue levels equivalent to in vitro levels identified for the signature effects along an identified adverse outcome pathway (AOP). EXPmax levels are then screened against environmental exposure levels (EXPenv). If EXPenv is less than EXPmax, then parent target tissue levels of the chemical under the environmental exposure situations will be less than toxicologically-effective in vitro levels (EC50s or LELs), indicating that the assumption of zero clearance is health hazard conservative. For chemicals where EXPenv is larger than EXPmax, metabolic clearance of these chemical may be a critical factor in determining their health risks. This abstract does not necessarily reflect EPA policy.

**96f** Evaluation of the Pharmacokinetics of Methylphenidate in Juvenile and Adult Humans and Nonhuman Primates Using a Physiological Model

X. Yang1, S. Morris1, J. M. Gearhart2, C. D. Ruark2, M. G. Pauls2, W. Slifker1, D. F. Matson1, N. C. Twaddle2, D. R. Doerge1, J. F. Young1 and J. Fisher1, 1U.S. Food and Drug Administration, National Center for Toxicological Research, Jefferson, AR, 2The Henry M. Jackson Foundation for the Military Medicine, Wright-Patterson Air Force Base, OH and 3Risk Sciences International, Ottawa, ON, Canada.

Methylphenidate (MPH) is a psychostimulant drug marketed for treatment of attention deficit hyperactivity disorder in children and adults. A physiologically-based pharmacokinetic (PBPK) model was developed to characterize the age- and species-dependent pharmacokinetics of MPH in juvenile and adult humans and rhesus monkeys. The model was first calibrated in adult humans for MPH enantiomers and then extrapolated to children and monkeys. The calibrated MPH PBPK model was then utilized to extrapolate to children the pharmacokinetic MPH serum profiles associated with toxicity observed in juvenile monkeys. MPH is extensively and rapidly metabolized in the liver and gastrointestinal tract, primarily by carboxylesterase 1, with minor contributions from oxidative enzymes. Juvenile monkeys and children appear to metabolize MPH more rapidly than adults, with more rapid metabolism in juvenile monkeys than in children. Juvenile monkeys chronically exposed to oral MPH doses of 2.5 and 12.5 mg/kg (twice per day) showed a temporary delay in puberty (Mattison et al. 2011). Pharmacokinetically equivalent MPH doses for a 15-year-old boy were estimated to be 0.3 and 0.1 mg/kg using Cmax and AUC dose metrics from juvenile monkeys given 2.5 mg/kg of MPH. Therapeutic MPH doses in children ranging from 0.3-0.8 mg/kg, given twice a day, produce MPH kinetic profiles similar to those in juvenile monkeys that experienced delays in puberty. This computational analysis suggests that continued pharmacovigilance is prudent.

**96g** Intra- and Interspecies Extrapolation of Dose during the Developmental Period Using PBPK Models

J. W. Fisher, D. R. Doerge, A. Lumen, A. Fu and X. Yang, Biochemical Toxicology, FDA/NICTR, Jefferson, AR.

PBPK models are increasingly used to extrapolate the pharmacokinetics of a chemical or drug within a species from adult to young (intraspecies extrapolation) and between species, young animals to children (interspecies extrapolation). We developed adult and neonatal monkey and adult human and newborn PBPK models for bisphenol A (BPA) and for methylphenidate (MPH, Ritalin), adult and juvenile monkey and adult human and children PBPK models. Both the BPA and the MPH models relied on intra- and interspecies extrapolation. PBPK models were constructed using pharmacokinetic studies in infant (PND 5 to 77) and adult monkeys and adult humans for BPA and for MPH, juvenile (4-5 years) and adult monkeys and children (boys, 6 to 15 years old) and adult humans. These PBPK models were constructed using literature on the physiology of young and adult monkeys and humans and body weight scaling of chemical- or drug-specific model parameters (intra- and interspecies extrapolation). The acceptance or recalibration of the scaled parameters was determined by comparing predicted serum time courses data with observed data. Scaling of hepatic metabolism (iv dosing of adult monkey and infant monkey) and systemic (urinary) clearance of BPA metabolites (oral dosing of adult monkey and adult human) was not adequate to describe the kinetics of BPA and its metabolites, thus these model parameters were recalibrated. Lack of data precluded the evaluation of the human infant. For MPH, scaling of hepatic metabolism (hydrolysis) was successful for the oral administration of MPH in the child, adult human and adult monkey, but not in the juvenile monkey. Systematic clearance of diarylpropionic acid, the metabolic fate of MPH could be described by scaling for the adult and juvenile monkey and the adult human and child. The successful use of adult scaled parameters in PBPK models to predict pharmacokinetics during the developmental period is a useful method to evaluate age dependencies for both intra- and interspecies extrapolation.

**96h** Assessing Biomonitoring of Bisphenol A in Infants and Pregnant Women Using a Lifestaging Physiologically-Based Pharmacokinetic Model

D. Lefebvre, C. Lang, M. Fisher, T. E. Arbuckle and A. Nong, Environmental Health Sciences and Research Bureau, Health Canada, Ottawa, ON, Canada.

Growing concerns about exposure to various contaminants in the environment has led to major efforts at gathering a database of chemicals measured in blood and/or urine. These biomonitoring surveys provide a wealth of information on the levels of chemicals or metabolites detected in the general population and only give an
indication on the possible dose exposure leading to these observed internal levels. A study led by Health Canada scientists, the Plastics and Personal-care Product use in Pregnancy (P4) is a great example of where urine levels of chemicals are being measured in pregnant woman-infant pairs. The objective of this work is to explore biomonitoring and exposure data of Bisphenol-A (BPA) in pregnant women and levels found in their infants using biological models. At various life stages from infancy to adulthood, physiologically-based pharmacokinetic (PBPK) models can be used to describe age-dependent changing biological processes that can affect the fate of a chemical in the body. A lifestyle PBPK model was developed to estimate the changing levels of BPA internally in women and infants. Datasets collected from human and animal studies were used to define these biological processes in the models. Parameters for human pregnancy kinetics, such as mother placental transfer to the foetus, cord blood distribution or neonatal metabolism of BPA, were extrapolated from published pregnancy studies in monkeys. Model simulations of adult women urine levels were compared against data from the P4 study to evaluate study species differences of the biological processes. The PBPK model was also simulated and examined against meconium levels from the P4 study during foetal stages. Model simulations of urine levels were generally consistent, within a two-fold difference, with the pregnancy data. As a tool to support risk assessments of chemicals, the current PBPK lifestyle model will help in the evaluation of exposure in pregnant women as measured in BPA biomonitoring which can affect body burdens in their infants.

Two pancreatic injury models were tested in male Wistar Han rats. (1) Caerulein: animals were dosed by IP injection on day 1 at 0, 15 or 50 μg/kg, x3, one hour apart; (2) CHB: animals were dosed by SQ injection on day 1 at 0, 50 or 150 mg/kg. Serum samples were collected at 1, 6, 24, and 48 hr post last dose. Fasted animal weights were recorded up to 72 hr. Pancreatic injury was observed in rats treated with Caerulein at 15 or 50 μg/kg and CHB at 150 mg/kg. Both mir-216a and mir-217 correlated with acinar cell injury in each rat model however mir-217 was more sensitive with a larger magnitude of response. While lipase and microRNAs correlated well in the Caerulein treated animals, microRNAs remained elevated longer than lipase. In conclusion, our data show that in rats, mir-216a & mir-217 are sensitive indicators of acute exocrine pancreatic toxicity that are equal to, or better than, amylase and lipase. Further validation of these microRNAs as exocrine pancreatic injury biomarkers in rats and other nonclinical species with other pancreatic toxicants is needed.

MicroRNAs (miRNAs) are small, single stranded, non-coding RNAs that function as post-transcriptional regulators. Upon binding, target mRNA transcripts undergo degradation or translational repression. Dysregulation of miRNAs has been implicated in the pathogenesis of many disease states. Extracellular miRNAs have been detected in the blood and body fluids of animal models and patients. These, circulating miRNAs (cmiRNAs) have high potential utility in preclinical toxicology as biomarkers of organ toxicity because they are minimally-invasive, stable in biofluids, and likely translatable to humans due to their high cross-species conservation. We hypothesized that a rat model of pancreatic injury would have circulating miRNA biomarkers of injury. Sprague-Dawley rats were treated with intraepineuronal injection of 0.05 mg/kg caerulein once per hour for three consecutive hours to induce pancreatitis. Microscopic examination of pancreatic slices along with increased lipase and amylase levels confirmed pancreatic injury. 742 miRNA were assayed in plasma by quantitative PCR analysis. There were 17 miRNA which showed greater than a 3-fold difference between treated and control rats. 4 of these miRNAs were increased in rats treated with caerulein when compared with vehicle treated controls. In particular, mir-375-3p was increased 32-fold in treated rats. mir-375 is a relatively well studied miRNA reported to be expressed in pancreatic islets and brain. It is documented to play a role in pancreatic cell development and has been reported as a biomarker of beta cell death and diabetes in mice. The large increase in circulating mir-375-3p and clear link with pancreatic biology suggests that mir-375-3p is a potential candidate biomarker for pancreatic injury. Confirmation and characterization of sensitivity and specificity is underway with a larger study size and other treatment conditions.

Characterization of Urinary microRNAs As Biomarkers of Acetaminophen Toxicity in Children

Acetaminophen (APAP) is the most common drug used for the treatment of pain and fever in children. While generally considered to be safe, APAP is also responsible for 14% of acute liver failure cases in children. Recently, several studies have reported human circulating microRNAs (miRNAs) as novel biomarkers of APAP hepatotoxicity. Elevations of urinary miRNAs have been detected in rats administered toxic doses of APAP. This study examined urinary miRNA as a potential biomarker of APAP toxicity in children. Real-time quantitative polymerase chain reaction (qRT-PCR) arrays were used to detect global expression of miRNAs from three pediatric subgroups: i) healthy children (n=10, ALT median 18, range 10-37 IU/L), ii) hospitalized children receiving therapeutic doses of APAP (n=10, ALT median 26, range 6-177 IU/L) and iii) children hospitalised for APAP overdose (n=5, ALT median 2314, range 25-9909 IU/L). Urinary miR-375 was significantly increased in children with APAP overdose, compared to control subjects and therapeutic exposure subjects (p=0.05). The elevation of urinary miR-375 was further confirmed by qRT-PCR single reaction. Urine levels of miR-375 correlated with serum APAP protein adducts, an indicator of the oxidative metabolism of APAP (r=0.61). In conclusion, this study suggests that urinary miR-375 could represent a non-invasive clinical biomarker of APAP toxicity in children. This study was funded in part by a grant (R01 DK75936 to LJP) from the National Institute of Diabetes, Digestive and Kidney Diseases.
MicroRNAs (miRNAs) are increasingly emerging as promising biomarkers of cardiovascular pathologies and therapeutic response. While cardiac troponins are used as clinical biomarkers of cardiac tissue injury, there is a lack of biomarkers of early events of cardiac cell damage. Using a newly developed chronic cardiotoxicity mouse model, expression profiling of 1179 unique miRNAs was performed to identify early predictive biomarkers of cardiac tissue damage. Male B6C3F1 mice were given a weekly dose of 3 mg/kg doxorubicin (DOX; an anti-cancer drug), or an equivalent volume of saline via tail vein for 2, 3, 4, 6, and 8 weeks, resulting in cumulative DOX doses of 6, 9, 12, 18, and 24 mg/kg, respectively. Mice were euthanized a week after the last dose. Plasma levels of cardiac troponin T indicated cardiac cell injury following exposures to 18 mg/kg DOX and higher, whereas microscopic examination of heart tissues revealed the presence of cardiac lesions at 24 mg/kg. Thirty-three heart miRNAs showed significant (FDR<0.1) perturbation in expression, with the expression of 1, 1, 2, 8, and 24 miRNAs being affected at cumulative doses of 6, 9, 12, 18, and 24 mg/kg DOX, respectively. miRNA-34a was the only miRNA that showed increased expression at all DOX doses and exhibited a significant dose response. Considering the pro-apoptotic effects of miR-34a during myocardial infarction and cardiac aging, up-regulation of miR-34a at 6 mg/kg cumulative DOX dose may indicate apoptosis as an early event in hearts of DOX-treated mice. Increased transcription of apoptotic genes in the heart further support this notion. These data suggest the utility of miRNAs as predictive biomarkers of early stages of cardiac cell injury that may serve as a potential tool in therapeutic risk assessment.

MicroRNAs (miRs) are single-stranded, non-coding RNAs that mediate post-translational inhibition or promote degradation of mRNA targets. miRNA profiles have been shown to be detectable in cell-free body fluids including serum and plasma samples. Moreover, circulating miRNAs have been proposed as attractive blood biomarkers of human diseases and toxicities because of their disease/toxicity-specific dysregulation and their relative stability compared with mRNAs. MicroRNAs (miRs) have the potential to be translatable biomarkers of target organ injury. An ideal miR biomarker would be specific with sequence homology across different species. Identification of such candidates requires generation of a miR tissue atlas and the identification of tissue-specific/enriched miRs with sequence homology across relevant nonclinical species and human. Tissues from 5 male Marshall Beagle dogs were acquired from Bioréclamation, LLC (Hicksville, NY). RNA from 20 individual tissues was analyzed by microRNA-SEQ using the Illumina platform. miR sequences were aligned to the canine genome. MiR counts were quantified, normalized, and analyzed for statistical significance (value < 0.005). Specific miRs indentified in pancreas (miR-216a, miR-216b, miR-802, miR-200), tests (miR-34a) and sciatic nerve (miR-432) have potential as new biomarkers for tissues which currently have limited or no validated biomarkers of injury. In a dog proof of concept study, plasma levels of two liver injury candidate miRs, miR-122 and miR-885, were demonstrated to be elevated following 7-days treatment with Compound X, and correlated with ALT and liver pathology. In collaboration with Eli Lilly and Co., via HESI Genomics Group, we are in the process of comparing rat and dog tissue atlases to pinpoint miRs with sequence homology and tissue specificity in both species. Preliminary results of the atlas comparison suggest good correlation between tissue specific miRs (miR-122, liver) and non-specific miRs (miR-192). Results of this comparison suggest that certain miRs have the potential to be translatable biomarkers of target organ injury.

MicroRNAs (miRs) are expressed in an organ specific manner and are easily detectable in serum or plasma. In contrast to protein biomarkers, many miR sequences are conserved across species and assays are readily available for quantification. This has elicited interest in miRs as sensitive, specific and species translatable biomarkers for organ toxicity. In fact, liver (miR-122), skeletal muscle (miR-133a) and brain (miR-124) have been shown to be increased in the serum of rats with the respective organ toxicity. Interpretation of serum miR changes with respect to organ toxicity necessitates an understanding of the tissue(s) of origin of each miR and its isomiR(s). In order to confirm existing miRs and discover novel miRs we process of comparing rat and dog tissue atlases to pinpoint miRs with sequence homology and its isomiR(s). In order to confirm existing miRs and discover novel miRs we have utilized Illumina deep sequencing to construct a rat miR body atlas which consists of ~20 tissues of toxicologic interest. The data has confirmed many of the known tissue enriched miRs and revealed novel tissue enriched miRs such as liver miR-802-5p, brain 125a-5p, pancreas 148a-3p, adrenal 351-3p and stomach 205-5p. Serum miR profiling in rat and dog with histopathologic evidence of caerulein induced pancreatic injury revealed that miRs-375 and 216a increased in the serum, suggesting they may be translatable biomarkers of pancreatic injury. Takeda Pharmaceuticals created a dog miR body atlas utilizing deep sequencing and, in conjunction with HESI (Health and Environmental Sciences Institute), we have compared the rat and dog atlases for conserved tissue enriched miRs. We believe the combined data sets will be a valuable miR biomarker resource for application in preclinical toxicology studies.
The use of IL2 is limited in the clinic because of its unmonitorable vascular toxicity. Here, we assessed tissue and circulating microRNAs as candidate biomarkers of vascular injury in male Wistar-Han rats administered IL2 for up to 5 days. Vascular changes consisted of endothelial hypertrophy/hyperplasia and/or medial vascular hyalinization and perivascular inflammation, most notably in the liver, kidneys, papimfornx and areas of injection, with perivascular mixed cell infiltrates. These changes were accompanied with increased expression of CD31 as assessed by immunohistochemistry, decreased expression of miR-126 as assessed by in situ hybridization, and increases in circulating miR-145 and miR-155. These changes and the histomorphologic findings were partially reversible after a 7 day recovery period. These observations identify increases in circulating miR-145, a marker of smooth muscle cells, prior to the onset of necrosis of the vascular wall, and support the further evaluation of miR-145 as a marker of acute vascular injury.

While no histological renal injury was evident on D7, significant urinary albumin elevations measured for DOX treated animals, compared to vehicle-treated controls, suggested ongoing glomerular injury at this time point. By D14, following a second drug injection given on D7, rats developed overt glomerular and tubular injury accompanied by further urinary elevation of albumin, along with urinary elevations in tubular injury markers lipocalin-2, kidney injury molecule-1, cystatin c, and β2-microglobulin, compared to vehicle-treated controls. Microarray profiling identified eight miRNA species significantly elevated in urine during time points at which albumin was significantly elevated and six of these species make attractive biomarker candidates based on proposed function. Additionally, three of these miRNAs show suggestive elevations in urine prior to observable changes in albumin concentrations, which may indicate that these miRNA biomarkers may be sensitive for the detection of glomerular injury.
Cardiac troponin I (cTnI) is an established biomarker of cardiotoxicity, but its utility is limited by its short half-life. The present study was conducted to identify potential circulating cardiotoxicity miRNA biomarkers as an alternative to cTnI using a rat isoproterenol myocardial-injury model. In an initial screen, 9 heart or heart/skeletal muscle specific miRNAs were identified out of 768 miRNAs across a panel of tissues from untreated male Sprague-Dawley rats. The same panel of miRNAs was assessed in the serum following cardiac injury. In a subsequent experiment, male Sprague-Dawley rats received a single subcutaneous injection of isoproterenol (0.05 mg/kg) or vehicle. All surviving rats were sacrificed 24 hours post-injection, and cardiotoxicity was confirmed by histopathology. Serum was collected just prior to sacrifice from treated and control rats for analysis of circulating miRNAs. Plasma samples were collected predose and 24 hrs post dose for cTnI measurements. Consistent with its short half-life, plasma cTnI levels at 24 hrs post dose were comparable to baseline despite histologic evidence of cardiac injury. Several miRNAs were only present in the serum from isoproterenol-treated rats relative to controls. However, of the 9 heart or heart/skeletal muscle-specific miRNAs identified in the tissue screen, only miR-208, a potential biomarker of cardiac toxicity was detected in the serum following isoproterenol treatment 24 hrs post-dose. To our knowledge, this represents the first report of tissue expression profiling to identify heart-specific miRNAs. Ongoing work is examining the serum half-life of miR-208 after cardiac injury following isoproterenol treatment.

Cardiotoxicity is one of the critical toxicities and it is important to appropriately detect cardiac toxicity early. However, there are few helpful biomarkers for cardiotoxicity. This study was conducted to obtain possible biomarkers for estimating cardiotoxicity. Isoproterenol (ISO, 5 mg/kg), an adrenergic β agonist which can induce cardiotoxicity, was intraperitoneally administered to male F344 rats at 7 weeks old (3 or 4 animals/group). The heart for the histopathological analysis and the plasma for the metabolomics analysis were obtained from the rats 2, 6, 24 and 48 hours after the administration. Metabolites were measured using an UPLC/QTOF-MS, and a principal component analysis (PCA) was used for screening of potential biomarkers. In the histopathological analysis, focal vascular degeneration and coagulation necrosis at 2 hours, sporadic coagulation necrosis at 6 hours, inflammatory cell infiltration and coagulation necrosis at 24 hours, and fibrotic changes along with the infiltration at 48 hours were observed in the ISO-treated groups. The most severe changes in histopathology were observed at 24 hours during the progress of the heart damage. In the metabolomics analysis, PCA indicated the clear differentiation of the control and ISO-treated groups at 2 and 6 hours, and 9 metabolites including arachidonic acid contributed to the differentiation. These metabolites in the ISO-treated groups were increased more than those in the corresponding control groups at 2 and 6 hours, and the metabolites in the ISO-treated groups were equivalent to the corresponding control groups at 24 and 48 hours. These results showed that the identified metabolites were increased along with the histopathological changes in the heart and these metabolites achieved the peak levels earlier than the histopathological changes. Additionally, the identified metabolites can be the possible biomarkers for ISO-induced cardiotoxicity.

Cardiovascular disease is one of the critical toxicities and it is important to appropriately detect cardiovascular disease early. However, there are few helpful biomarkers for cardiovascular toxicity. This study was conducted to obtain possible biomarkers for estimating cardiovascular toxicity. Isoproterenol (ISO, 5 mg/kg), an adrenergic β agonist which can induce cardiovascular toxicity, was intraperitoneally administered to male F344 rats at 7 weeks old (3 or 4 animals/group). The heart for the histopathological analysis and the plasma for the metabolomics analysis were obtained from the rats 2, 6, 24 and 48 hours after the administration. Metabolites were measured using an UPLC/QTOF-MS, and a principal component analysis (PCA) was used for screening of potential biomarkers. In the histopathological analysis, focal vascular degeneration and coagulation necrosis at 2 hours, sporadic coagulation necrosis at 6 hours, inflammatory cell infiltration and coagulation necrosis at 24 hours, and fibrotic changes along with the infiltration at 48 hours were observed in the ISO-treated groups. The most severe changes in histopathology were observed at 24 hours during the progress of the heart damage. In the metabolomics analysis, PCA indicated the clear differentiation of the control and ISO-treated groups at 2 and 6 hours, and 9 metabolites including arachidonic acid contributed to the differentiation. These metabolites in the ISO-treated groups were increased more than those in the corresponding control groups at 2 and 6 hours, and the metabolites in the ISO-treated groups were equivalent to the corresponding control groups at 24 and 48 hours. These results showed that the identified metabolites were increased along with the histopathological changes in the heart and these metabolites achieved the peak levels earlier than the histopathological changes. Additionally, the identified metabolites can be the possible biomarkers for ISO-induced cardiotoxicity.

Drug-induced vascular Injury (DIVI) is a preclinical toxicity usually characterized by hemorrhage, vascular endothelial and smooth muscle damage and inflammation. Preclinical DIVI findings cause delays or termination of drug candidates due to low safety margins, the absence of non-invasive biomarkers for monitoring vascular injury and the uncertain relevance to humans. Under the framework of the EU-funded IMI SAFE-T consortium, we are qualifying a set of translatable biomarkers associated with the onset of histopathologic damage in various vascular beds in humans. Patients with conditions involving inflammatory in-filrates, a-\vati-\jion and injury to the vascular endothelium and fibinoid necrosis of the media were included, along with age- and sex-matched healthy volunteers. Twenty soluble proteins were measured in serum samples collected in healthy subjects and in patients during the acute and the resolution phases of disease. The panel of markers included inflammatory factors as well as endothelial proteins: CRP, E-Selectin, GROα, IL-6, IL-8, IP-10, I-TAC, NGAL, MCP-1, MIG, MIP-1, P-Selectin, SAA, sICAM-1, sICAM-3, sVCAM-1, thrombomodulin, TIMP-1, TNFRSF1A and VEGF. Univariate analysis showed that no single marker measurement provided a sufficient predictive power with an area under ROC curve (AUROC) above 0.8. In contrast, a multivariate score based on a robust combination of healthy volunteers from patients with vascular injury, and further separated the latter group into those in the acute and quiescent stages of disease. Of the several machine learning approaches used to calculate the performance of combinations of markers, a naïve Bayes classifier based on 10 parameters (MIP-1, SAA, TNFRSF1A, TIMP-1, P-Selectin, sICAM-1, sICAM-3, thrombomodulin, age and sex) achieved the best diagnostic performance (AUROC = 0.88). Studies to further validate these biomarkers are currently on-going. The panel of biomarkers established in this study shows promise as a clinical monitoring tool for compounds that cause DIVI in preclinical studies.

L-type Fatty Acid Binding Protein (L-FABP), which is located in the cytoplasm of renal proximal tubular cells, responses to ischemia and oxidative stress and is excreted in urine. KDIGO (Kidney Disease Improving Global Outcomes) selected L-FABP as one of the major 5 biomarkers (L-FABP, cystatin C, NGAL, Interleukins, KIM-1) for detecting the acute kidney injury. The L-FABP ELISA kit has already been approved as a clinical diagnostic agent for renal injury in Japan and in experimental animals widely used in non-clinical toxicity studies. The purpose of this research was to evaluate L-FABP as a nephrotoxicity biomarker in experimental animals. We used Wistar rats and found that L-FABP was superior to traditional biomarkers such as BUN and serum creatinine in measuring kidney injury which partially recovered over 144 h after injury. LC/MS/MS studies of 24 h urine samples revealed increased urinary ATP5P protein in mice subjected to I/R-induced AKI and rats subjected to gycerol-induced AKI when mitochondrial function was decreased. Consistent with LC/MS/MS data, Western blotting of 24 h urine samples revealed increased ATP5P protein in mice subjected to a range of I/R times and degrees of kidney injury. Also, preliminary LC-MS/MS findings revealed that urinary ATP5P was increased in human subjects with post-cardiac bypass surgery-induced AKI increased when compared to controls. These studies provide evidence that ATP5P is a urinary marker of mitochondrial dysfunction and will permit better understanding of the timing and mechanisms of renal injury and the state of mitochondrial homeostasis during AKI.
both strains in urinary L-FABP excretion. Histological observation revealed that foamy eosinophilic globules slightly existed in proximal tubule on Day 4 and those urinary L-FABP excretion elevated on Day 1 in correspondent rats. These results suggest that the urinary L-FABP may be a very useful sensitive biomarker of nephrotoxicity not only in humans but also in experiment animals.

114 Preclinical Nephrotoxicity Biomarker Analysis Using Toxicoproteomics Approaches

L. Yu1, Z. Li2, Z. Cao3, Y. Gao3 and T. Chen3. 1Biomarkers and Alternative Models Branch, Division of Systems Biology, National Center for Toxicological Research, FDA, Jefferson, AR and 2Division of Genetic and Molecular Toxicology, National Center for Toxicological Research, FDA, Jefferson, AR.

Increased application of proteomics approaches to toxicological studies has led to the development of a new discipline that is being called "toxicoproteomics". Major research areas of toxicoproteomics include development of biomarkers of toxicity, identification of molecular targets of toxicants, and elucidation of toxicity mechanisms. To understand the molecular mechanisms of toxicity and identify kidney injury biomarkers, quantitative proteomic analyses were conducted on kidneys from aristolochic acid (AA)-treated rats. Animal treatment was conducted according to the protocol approved by the NCTR Institutional Animal Care and Use Committee. Big Blue rats were treated with 0.9% sodium chloride as the control or AA at 10 mg/kg body weight, five times/week, for 12 weeks. Kidneys were collected one day after the last treatment. Kidney tissues from the control and the AA-treated rats were processed for proteomic analysis using stable isotope labeling and two-dimensional liquid chromatography coupled online with tandem mass spectrometry (LC-MS/MS). More than 100 proteins changed their abundance as a result of AA treatment, which may be related to the toxicity and carcinogenicity of AA. Intriguingly, several FDA-qualified preclinical kidney injury biomarkers were identified in this study, and their abundance showed significant changes. A mass spectrometry-based multiplex kidney injury biomarker assay was developed for targeted quantitative measurement of the biomarker candidates discovered in this study, and many of the expression-changed proteins were confirmed. The combined open discovery and targeted proteomics approaches facilitated the identification of kidney injury biomarkers. Additional studies need to be performed in animals and humans to investigate their translational nature. The views presented do not necessarily reflect those of the U. S. Food and Drug Administration.

115 Detailing the Human Exposome: Mass Spectrometry-Based Chemical Profiling of Human Mitochondria

D. I. Walker1, 2, K. D. Pennell1 and D. P. Jones2. 1Civil and Environmental Eng, Tufts University, Medford, MA and 2Clinical Biomarkers Laboratory, Emory School of Medicine, Atlanta, GA.

While most studies have utilized easily accessible bio-fluids to monitor environmental agents and associated metabolic response, few have measured exogenous compounds within sub-cellular compartments. The purpose of this study was to profile the endogenous and exogenous mitochondrial metabolome of human organ tissue, with an emphasis on identifying the presence of environmental agents. Viable mitochondria were obtained from human adrenal glands (n=5) within 36 hours of removal using a differential centrifugation isolation procedure. Isolates adapted to identify OP insecticide adducts on both plasma BChE and RBC acyl-phosphate hydrolase (APH), two known biomarkers of OP exposure. Plasma, RBCs or dried blood spots (DBS) are used for our IMB-MS methods. The methods have been designed for adaptation to high-throughput protocols to facilitate their transfer to clinical laboratories. These methods will be validated using a cohort of Washington State agricultural workers with characterized OP exposures to chlorpyrifos or azinphos-methyl. The IMB-MS protocols purely BChE and APH from as low as 25 μL of plasma or RBCs, respectively, or from DBS. The use of DBS will facilitate sample collection, shipping, and archiving as well as the analysis of already archived samples. The IMB-MS protocols have significant advantages: they do not require a pre-exposure measurement, they can detect low levels of exposure, they can be automated, and they provide information on both the OP and percentage modification of the active site serines. Supported by NIH (P42ES04696, R01ES009883, ES09601/ EPA-R826886, P41GM103533); the PNASH Center (U50CH07544-10); and by financial support from the CDC (Atlanta, GA).

116 Proteomic Analysis of Dried Blood Spots for Biomonitoring Organophosphorus Exposures

J. Marsiliach Lopez1, 2, E. J. Haich3, R. J. Richter1, 2, M. J. MacCoss1, A. N. Hoofnagle4 and C. E. Furlong5, 6. 1Medicine (Division of Medical Genetics), University of Washington, Seattle, WA, 2Geome Sciences, University of Washington, Seattle, WA and 3Laboratory Medicine, University of Washington, Seattle, WA.

Organophosphorus (OP) compounds are involved in most of the occupational and environmental intoxications reported worldwide. They inhibit cholinesterases and other serine hydrolases, leading to neurological damage and serious health effects. The standard methods used for biomonitoring OP exposures are the Ellman assays, which measure the enzymatic activity of either red blood cell (RBC) acetylcholinesterase or plasma butyrylcholinesterase (BChE). Despite being fast and inexpensive, these assays suffer from several drawbacks. We have developed a rapid immunomagnetic bead (IMB) purification for biomarkers of OP exposure, followed by OP-adduct identification on active site serines by high-resolution mass spectrometry (MS). The IMB-MS methods have been adapted to identify OP insecticide adducts on both plasma BChE and RBC acyl-peptide hydrolase (APH), two known biomarkers of OP exposure. Plasma, RBCs or dried blood spots (DBS) are used for our IMB-MS methods. The methods have been designed for adaptation to high-throughput protocols to facilitate their transfer to clinical laboratories. These methods will be validated using a cohort of Washington State agricultural workers with characterized OP exposures to chlorpyrifos or azinphos-methyl. The IMB-MS protocols purely BChE and APH from as low as 25 μL of plasma or RBCs, respectively, or from DBS. The use of DBS will facilitate sample collection, shipping, and archiving as well as the analysis of already archived samples. The IMB-MS protocols have significant advantages: they do not require a pre-exposure measurement, they can detect low levels of exposure, they can be automated, and they provide information on both the OP and percentage modification of the active site serines. Supported by NIH (P42ES04696, R01ES009883, ES09601/EPA-R826886, P41GM103533); the PNASH Center (U50CH07544-10); and by financial support from the CDC (Atlanta, GA).

117 Toxicometabolomics Approach to Prediction of Hepatotoxicity by Troglitazone/LPS in Rats

K. Kim1, 2, J. Kim1, 2, S. Ryu1, D. Nam1, S. Kim1, 2 and S. Kim1, 2. 1Pharmacy, Dankook University, Cheonan, Chungnam, Republic of Korea, 2Pharmacology, CKD Research Institute, Yongin, Gyeonggi, Republic of Korea and 3Chemistry and Chemistry Institute for Functional Materials, Pusan National University, Busan, Busan, Republic of Korea.

Troglitazone (TGZ) is a thiazolidinedione antidiabetic agent which is the synthetic ligands for the peroxisome proliferator-activated receptor γ (PPAR γ). However, it was withdrawn from the market in 2000 due to liver injury in humans. In this study, we endeavored to discover surrogate biomarkers which are correlated with hepatotoxicity induced by TGZ using urinary proton nuclear magnetic resonance (1H NMR) spectral data. A procedure of 1H NMR urinary and serum analysis using pattern recognition was proposed for early screening of the hepatotoxicity of TGZ with lipopolysaccharide (LPS) in rats. Alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were the highest in 6 hours and hepatic inflammation, in histopathology, was observed in 2 hours. All treated animals were divided into two groups of responder and non-responder based on the ALT and AST levels because the levels of ALT and AST were not changed dose-dependently after treatment of TGZ (2 g/kg, p.o.). In urinary analysis, 1H NMR spectroscopy did not show different clustering between responder and non-responder in global metabolic profiling through principal component analysis (PCA). However, it was significantly separated in orthogonal projections to latent structures-discriminant analysis (OPLS-DA). In targeted profiling, endogenous metabolites of phenylacetylglycine, glucose, acetate, 2-oxoglutarate, formate, creatine, citrate, 3-indoxysulfate, lippurate, acetone, phenylalanine, glycine, betaine, cis-aconitate, and tyrosine were selected as putative biomarkers for hepatotoxicity by TGZ. In serum analysis, pattern recognition was similar to the results of the urinary analysis, and then we could select putative 6 endogenous metabolites such as ethanol, glucose, alanine, glutamine, lactate, and 3-hydroxybutyrate. According to these results, toxicometabolomics can be used to predict or screen hepatotoxicity caused by TGZ in urine and serum of rats.
Pro-inflammatory signals upregulate expression of cell surface αM integrin CD11b on eosinophils, favoring cell adhesion to airway epithelium in chronic disorders such as asthma. Absence of CD16B (CD16-) is used to differentiate eosinophils from other granulocytes (CD16+B+), in humans. However, in cynomolgus macaques (CM), alternative methods must be used to identify eosinophils due to the absence CD16B expression on granulocytes in this species. To resolve this, we used the inherent autofluorescence of CM eosinophils to differentiate them from other granulocytes, and monitored CD11b up-regulation \textit{ex vivo}, following IV administration of either 1 or 10 mg/kg ACRA. Blood samples were collected on day-1, pre-dose, 2, 8, 15, and 28, and 43 days and exposed, \textit{ex vivo}, to increasing concentrations of a pro-inflammatory cytokine for 30 min at 37°C. Samples were acquired on a flow cytometer following red blood cell lysis and staining with anti-CD11b allophycocyanin-conjugated antibody. CD11b median fluorescence intensity on eosinophils, identified by their granularity and autofluorescence, was reported for each sample. Animals given 10 mg/kg of ACRA had complete suppression of eosinophil activation over 43 days (plasma levels > 10,000 ng/ml). Suppression of eosinophil activation returned to baseline in animals dosed with 1 mg/kg of ACRA after 28 days, when drug plasma levels were ≤ 240 ng/ml, the EC50 derived from \textit{in vivo} eosinophil CD11b activation assays. Thus, although some understanding of target coverage was known from \textit{in vitro} studies, the eosinophil PD assay applied in this PK study provided valuable information about target coverage. The identification of potential hazards is a key outcome of toxicity studies. With the introduction of omics-technologies into toxicological research, questions have been raised concerning the sensitivity of these methods. We have developed the MetaMap® Tox database with toxicity and metabolome data of 500 reference compounds obtained from rat studies. Plasma metabolome analysis was performed after 7, 14 and 28 days. We have evaluated the predictive performance of MetaMap®Tox using 78 substances for which the predicted mode of action based on metabolomics was compared to the actual outcome of the guideline studies. Overall, 85% of the effects observed with classical parameters have also been predicted by the metabolome data. Out of 45 compounds that did show effects in classical parameters in male animals, 36 compounds (80%) showed the same effect in the metabolome and could be considered as correctly positively predicted. Out of 35 not showing any effect in the classical parameters, 30 substances (86%) did not show an effect on the metabolome (correctly negatively predicted), whereas 5 compounds (14%) did show effects in the metabolome (false-positive predictions). The numbers for female animals are 36 out of 42 correct positive predictions (86%, based on 42 compounds showing toxicity in classical parameters) and 6 out of 42 false negative predictions (14%), 30 out of 36 correct negative predictions (83%, based on 36 compounds showing no effects in classical parameters) and 6 out of 36 false positive predictions (17%). In conclusion our analysis indicates that metabolome data can be used to predict toxicological effects in rats. Since metabolome data often provides a deeper mechanistic insight into the effects observed, metabolome analysis gives an added value for systemic toxicity testing.
Global gene expression studies of liver from carcinogen-exposed animals using RNA-Seq can provide insights into regulatory genes and critical pathways that might lead to hepatocellular carcinoma. We recently conducted RNA-Seq analysis on liver RNA from male F344 rats exposed to 1 ppm aflatoxin B1 (AFB1) in feed for 90 days, prior to the appearance of tumors. Among the more than 1,000 differentially expressed genes, we found a total of 49 potentially novel Cufflinks-assembled transcripts of which 21 transcripts had Ensembl annotation and 28 transcripts did not. Ten of these novel AFB1 altered transcripts were validated by PCR and specific reverse transcriptase primer extension for eventual assembly into expression systems. Data showed a 5-fold increase in the stem cell marker, Sox-9, and the increased reads revealed a longer transcript than predicted for the rat Esenbl transcript or mouse and human orthologs. Similarly, AFB1 produced a 50-fold increase in the p53-regulated transcript, Eda2R (ectodysplasin A2 receptor), for which an extensive, unannotated 3’-region became evident. The set of 28 unannotated, novel transcripts showed AFB1 altered expression ranging from a 5-fold decrease to 659-fold increase. We previously reported two unannotated transcripts from this dataset, termed HAFT1 and HAFT2 (hepatic aflatoxin altered transcripts 1 and 2). Here, we selected 8 other unannotated novel Cufflinks transcripts from RNA-Seq data for PCR amplification and cloning for which partial sequence was obtained that correctly mapped back to each chromosomal location. One of these included a low copy transcript increased 281-fold in AFB1 that contained at least 4 exons in an unannotated region of Chr16 flanked by Fgfr1 and Tac1 genes. Rapid amplification of cDNA ends (RACE) procedures was used to determine complete cDNA sequence for cloning, expression and cellular function. Complete sequencing of such transcripts permitted the way for a new set of biomarkers for chemical hepatocarcinogenesis prior to tumor formation.

Adam8 belongs to a disintegrin and metalloprotease family of genes. This protein has been implicated in a various cellular processes including cell-cell adhesion, muscle development, neurogenesis and asthma. Recently a hepatic global gene expression analysis of the liver was undertaken to identify specific genes that mediate 2-aminoanthracene (2AA) toxicity in the liver. Findings from this study were to assess if serum microRNAs could be used as biomarkers of melamine and cyanuric acid-induced kidney toxicity. Male Fischer 344 rats were a fed diet fortified with equal amounts of melamine and cyanuric acid (0, 180, or 240 ppm each) for 28 consecutive days. Nephrotoxicity, as assessed by increased blood urea nitrogen (BUN) and serum creatinine versus control, was observed in the 240 but not 180 or 0 ppm dose group. Serum samples from the three dose groups were prepared from terminal blood and checked for hemolysis prior to evaluating microRNA expression. Equal volumes of nonhemolytic sera were pooled from a minimum of 3 animals per dose group. Using a PCR array, the relative expression of 373 microRNAs was measured. Based on the screening data, 30 microRNAs were modulated by approximately 4-fold compared to the control. To validate these data, the expression of the 30 microRNAs was measured by quantitative real-time PCR in each of the three individual samples per dose group. Circulating levels of rno-miR-144-3p were down-regulated in sera of rats dosed with 240 ppm melamine and cyanuric acid in comparison to the control group. The down-regulation of rno-miR-144-3p was further confirmed using a larger sample size (n = 12 per dose group; P < 0.025). These data suggest that rno-miR-144-3p may be a minimally-invasive biomarker of kidney injury induced by melamime and cyanuric acid. It is at least as sensitive as the currently used biomarkers BUN and serum creatinine. Future studies will evaluate the expression of rno-miR-144-3p following exposures to additional nephrotoxicants.

The liver and kidney are fundamentally important tissues for drug metabolism, disposition, and excretion. Growing evidence suggests epigenetic mechanisms of gene regulation may play a role in susceptibility to certain toxicities and adverse drug reactions. microRNAs continue to show promise as biomarkers. While relatively immature compared to other genomic resources, growing knowledge of individual miRNAs and their putative gene targets allows for large scale inquiry into genome-wide miRNA expression. miRNA expression in liver and kidney tissues was examined in F344 rats during their life cycle. Animals were evaluated at 2, 5, 6, 8, 15, 21, 52, 78, and 104 weeks of age in both sexes (n=5) using Agilent 8x15k rat miRNA microarrays. 263 and 275 miRNAs were found to be expressed in the liver and kidney, respectively, in at least one age and sex. 221 miRNAs were commonly expressed in both liver and kidney, including criteria of 4.5 fold change and ANCOVA (PDR 5%) revealed 249 (94%) differentially expressed miRNAs (DEMs) in the liver, while 210 (76%) were differentially expressed in the kidney. Of the 305 total DEMs, 154 miRNAs were differentially expressed in both tissues. A notable age difference in expression consisted of 28 miRNAs showing 2

**122b CD1X on Dendritic Cells: A Biomarker of Metallic Allergens and Metallic Nonallergens In Vivo**

Y. Mu1, A. M. Keene1, H. Degheidy1, Z. Zhang1, C. Li2, C. Ghosh6 and J. C. Kwekel7. 1Biomolecular Screening Branch, NIEHS, Research Triangle Park, NC and 2Department of Systems Biology/Personalized Medicine Branch, FDA/National Center for Toxological Research, Jefferson, AR.

The CD1 family is a large multigene family that expresses multiple members on cell surface of numerous cell types, including dendritic cells (DCs). Some CD1 family members are expressed on dendritic cells and are currently used as a biomodulator to predict allergic responses to medical device materials. The cells were exposed for 24 hr to the following metal allergens and non-allergens for biomarker identification and development by employing flow cytometry. Interestingly, of 16 selected cell surface markers (CD1a, CD1X, CD44, CD54, CD68, CD80, CD86, CD102, CD184, CD197, CD206, HLA-DR, TLR-9), we found a new functionality for the protein CD1X on DC. The expression was down-regulated significantly following exposure to 8 metallic allergens (ammonium hexachloroplatinate(IV), cobalt(II) chloride, nickel(II) sulfate, nickel(II) chloride, mercury(II) chloride, beryllium(II) sulfate, gold(I) chloride, potassium dichromate(VI)) while the expression of CD1X was increased by 4.5 fold change and ANCOVA (PDR 5%) revealed 249 (94%) differentially expressed miRNAs (DEMs) in the liver, while 210 (76%) were differentially expressed in the kidney. Of the 305 total DEMs, 154 miRNAs were differentially expressed in both tissues. A notable age difference in expression consisted of 28 miRNAs showing 2
week-specific expression in the liver but not in the kidney. The genes encoding 26 of these 28 miRNAs are located on rat chromosome 6. Nine miRNAs showed sex differences in both tissues and only 1 miRNA (miR-22) showed a similar expression pattern in both tissues; male-specific up-regulation at 21 weeks of age. miR-22 has been shown to post-transcriptionally inhibit PGC-1α, PPARα, and Sirt1, key regulators in metabolism pathways. These results comprise one of the first large-scale comparisons of global miRNAs in the liver and kidney over the rat life cycle that may impact susceptibility to adverse drug reactions.

122e Next-Generation Sequencing of Plasma, Urine, and Tissue microRNA from Sprague-Dawley Rats Treated with Acetaminophen or Cisplatin

MicroRNAs (miRNA) are short single-stranded RNA sequences comprising of approximately 22 nucleotides that have a role in the post-transcriptional regulation of genes. The identification of tissue specific or enriched miRNAs may be useful as novel safety biomarkers. Recent work has demonstrated that both the presence and magnitude of miRNA in biofluids (e.g., plasma and urine) can be associated with tissue-specific damage. This study is the first to use next generation sequencing to analyze changes in miRNA profiles of plasma, urine and tissue samples of rats treated with either a hepatotoxicant (Acetaminophen [APAP]) or a nephrotoxicant (Cisplatin). To verify tissue-specific damage, an analysis of histopathology and serum chemistry was performed. In animals treated with APAP, eight miRNAs were significantly (p<0.05) altered in the liver, 45 in plasma and none in urine. Consistent with the literature, levels of miR-122 (193-fold) and miR-192 (63-fold) were significantly (p<0.001) upregulated in plasma from these animals. Histopathology and increases in liver enzymes demonstrated liver necrosis for APAP-dosed rats without a concomitant kidney injury. In Cisplatin-treated animals, 20 miRNAs were significantly (p<0.05) altered in the kidney, nine in plasma and six in urine. Also consistent with the literature, levels of miR-34a were significantly (p<0.004) upregulated in the kidney (6.1-fold) and plasma (7.2-fold); a significant (p<0.002) 10.0-fold increase in the expression of miR-378 in the urine has not been previously reported. Histopathology and changes in serum markers for kidney injury confirmed kidney but not liver damage in Cisplatin-treated rats. We next plan to use qPCR to validate the next generation sequencing of urine miRNA. Taken together, comparative analysis of urine, plasma, and tissue miRNA demonstrated the utility of miRNA as biomarkers of organ injury and identified miR-378 as a potential novel urine marker for Cisplatin-induced injury.

122f Circulating microRNAs As Potential Non-Invasive Biomarkers in Patients with Crohn’s Disease

MicroRNAs (miRNAs) are a class of small, non-coding RNAs that negatively regulate gene expression, processes that appear to be involved in the pathogenesis of human diseases and toxicities. Circulating miRNAs offer great potential as biomarkers for disease detection because of their remarkable stability in blood and their characteristic expression in different diseases and toxicities. Differential expression of miRNAs has been described in multiple autoimmune-associated diseases. Recently, unique miRNA expression profiles have been described in the intestinal epithelial cells and in the peripheral blood of patients with Crohn’s disease (CD). We hypothesized that miRNAs may be involved in the homeostatic regulation of CD-associated inflammatory responses and their disease-associated dysregulation could be detected in circulating miRNA signatures. Specific miRNAs with important roles in regulating key pathogenic mechanisms in CD inflammation were selected to assemble a Taqman assay panel for screening of plasma from CD patients (Montreal classification, B1-B3) and healthy volunteers. We found that the profile of a number of circulating miRNAs is capable of distinguishing healthy volunteers (HV) from CD patients. In particular, miR-182 levels were upregulated in the CD subjects (B3 vs HV, p=0.006). Interestingly, tumor necrosis factor (TNF)-like ligand 1A (TL1A) is a direct regulated target of miR-182. Numerous genome wide association studies have linked several polymorphisms of the TL1A gene to CD, and inflamed intestinal tissue from patients with inflammatory bowel disease show high expression levels of TL1A. Additionally, an intestinal enriched miRNA, circulating miR-194, was upregulated in the CD subjects (B3 vs HV, p=0.001). The results described here have implications for the use of circulating miRNA profiles as potential non-invasive biomarkers for CD detection.

122g Novel Kidney Injury Biomarker Panels to Detect Nephrotoxicity in Mouse Models

W. Zheng1, R. Maheshwari1 and V. Sabbatini2,3. 1EMD Millipore, St. Charles, MO, 2Brigham and Women’s Hospital, Boston, MA and 3Harvard Medical School, Boston, MA. Sponsor: P. Hewitt.

Kidney is the primary organ for drug toxicity. The application of kidney injury biomarkers has greatly improved the detection of nephrotoxicity during drug development and will accelerate the speed to bring more effective and safe drugs to market. Over the past decade, a panel of novel urinary kidney biomarkers has been approved by the FDA, EMA and PMDA to detect acute nephrotoxicity in preclinical rat studies. Even though mouse models are widely used in drug development process, lack of reliable assays to quantitatively assess multiple protein markers in small volumes of mouse urine has limited the application of these markers in mouse models.

In the present study, we developed multiplexed immunoassays for two panels of mouse kidney injury biomarkers. Furthermore, we validated the sensitivity and specificity of these assays in two different mouse kidney injury models. To induce kidney injury, BALB/C mice were subjected to either bilateral ischemic reperfusion (I/R) for 30 minutes or one dose of cisplatin treatment. Urine specimens were collected and analyzed for urinary protein markers with MILLIPLEX® MAP Mouse Kidney Injury Magnetic Bead Panels. There was a significant increase in many of the novel markers in both I/R and cisplatin treated mouse models reflecting tubular damage. In conclusion, we have developed novel multiplexed assays for mouse urinary kidney biomarkers and validated them in both ischemia and drug induced kidney injury models in mice. The simultaneous measurement of these proteins with multiplex technology offered a robust and convenient method to study these biomarkers in small volume of mouse urine samples.

122h Validation of an Immunoassay for Analysis of Oxytocin in Sheep Plasma to Support Progress towards a Novel Drug Delivery Strategy for the Treatment of Postpartum Hemorrhage

E. Weber1, T. Nett1, V. Oliver2, P. Lambert2 and M. McIntosh3. 1Bioanalytics Group, EndoLogics, LLC, Fort Collins, CO and 2Drug Delivery Disposition and Dynamics, Monash University, Parkville, VIC, Australia. Sponsor: W. Hanneman.

Postpartum hemorrhage is the single largest contributing factor to global maternal mortality, with the burden occurring overwhelmingly in low income countries (WHO & UNICEF 2012). Monash University is working to develop a heat stable and non-injectable oxytocin (OXT) product that can be simply administered by all levels of healthcare personnel.

In support of Monash University’s pre-clinical program, we have validated a radioimmunoassay for the detection of OXT (oxRIA) in sheep plasma, and generated preliminary data on the dose pharmacokinetics (PK) of OXT in sheep, after intravenous (IV) delivery. Validation of the oxRIA, and subsequent studies were carried out using OXT Radioimmunoassay Kits (Phoenix Pharmaceuticals, Inc.). The mean lower limit of quantification for the oxRIA, over three assays, was 760 fg. Recovery of OXT in biological matrix was determined by adding standard OXT at three concentrations to sheep serum, with six replicates at each concentration. After correction for extraction efficiency (69.1%, 0.70% CV), the amounts of OXT recovered from serum was >99%. Slope of the regression line was 1.0986 and r-value was 0.9596. Mean intra- and inter-assay coefficients of variations were 4.6% and 7.5% respectively, over six assays.

To assess the PK of IV-dosed OXT, six sheep were administered 10 IU (~160μg) OXT directly into the jugular vein. Following injection, blood was sampled at ten time points, and plasma concentrations of OXT were determined. Half-life (t1/2) of OXT1 was determined to be ~5 min.

In conclusion, we have shown the oxRIA is reliable for analysis of OXT in sheep serum. The assay was used to assess the t1/2 of OXT delivered to sheep IV, and this value agreed favorably with the t1/2 of OXT reported for other species. On-going pre-clinical studies include the evaluation of both the PK and pharmacodynamics of OXT formulations administered by intramuscular (IM) injection, pulmonary and nasal delivery.
Males and females exhibit different morbidity and mortality across a wide range of conditions which suggests basic pathophysiology may control the incidence of multiple disease processes. Women suffer disproportionately higher rates of many of these diseases, particularly autoimmune and inflammatory diseases. Inflammatory processes induce oxidative stress and reduce cellular antioxidant capacity. This investigation examined the relationship between oxidative stress and inflammatory marker expression and gender in addition to determining the effect of confounders such as drug use, lifestyle and medical history. These conditions are linked to physiological changes that may alter the expression of certain biomarkers of inflammation and oxidative stress. Urine specimens (n=62) were assayed for Myoglobin, C Reactive Protein, Myeloperoxidase, Estradiol, Testosterone, Malondialdehyde, 8OHdG, and Interleukins 1α and 6 using ELISA. Laboratory reference ranges for urine, serum and plasma do not typically differentiate between genders. More importantly, gender-based ranges of urinary concentrations have not been determined for many oxidative stress (OS) and inflammatory cytokines linked to common chronic diseases. Multivariate regression analysis suggest predictors of oxidative marker expression may include gender, preexisting disease and drug use. The results suggest significant gender-based differences may exist in the expression of inflammatory and oxidative biomarkers in the urine of drug users. This work has been supported in part by the Agency for Community Treatment and Services of Tampa and the Laboratory of Occupational and Public Health Toxicology.

125 Identification of MHC Haplotypes Associated with Drug-Induced Hypersensitivity Reactions in Cynomolgus Macaques

The occurrence of immune-mediated drug hypersensitivity reactions (IDHRs) can have a significant impact on therapeutic drug use and development. While the mechanism(s) and risk factors are not fully understood, an association between specific human leukocyte antigen (HLA) alleles and IDHR has been described for some drugs (e.g. abacavir and HLA B*57:01). However, whether such an association exists between IDHR and major histocompatibility complex (MHC) alleles from other species has not been described. In this study, genomic DNA samples were obtained from 62 cynomolgus macaques from several preclinical toxicology studies (with and without IDHR) and genotyped using microsatellite analysis to determine the MHC haplotype for each animal. Of the 62 macaques, 9 animals had clinical evidence of IDHR (manifested as skin lesions). The M1, M2, M3, M4, M5, M6, and M7 haplotype frequencies in the MHC regions were identified to be 17%, 8%, 15%, 19%, 2.4%, 7.3%, and 2.4%, respectively in these monkeys. Recombinant MHC haplotypes and undetermined MHC alleles were represented (2-test for trend, P < 0.05) with the occurrence of IDHR (skin lesions) in this population. These data suggest that cynomolgus macaques may be a good preclinical model for studying mechanisms underlying IDHR. Additionally, genetic haplotype analysis is warranted to determine the potential polymorphism(s) that may be functionally important in IDHR in cynomolgus macaques.

126 Defective TGFβ Signaling in Dermal Dendritic Cells Leads to Their Reduced Lymph Node Migration and Contact Hypersensitivity Responses with Ultraviolet B Irradiation
A. Ravindran1, K. Breech1, J. Mohammed2, and A. Glick1. 1Veterinary and Biomedical Sciences, The Pennsylvania State University, State College, PA and 2Dermatology, University of Minnesota, Minneapolis, MN.

Transforming Growth Factor-β1 (TGFβ1) is an important immunoregulatory cytokine in the skin critical for the development of epidermal dendritic cell (DC) subset-Langerhans cells (LCs). However, the role of TGFβ signaling for the immunomodulatory function of LCs or other skin-resident DC subsets-CD207- dermal DCs (dDCs) and CD103+ CD207+ dDCs in response to Ultraviolet B (UVB) irradiation is not clear. Mice expressing a dominant negative TGFβ Type II receptor (DNR) specifically in CD11c+ DCs displayed reduced steady-state migration of all three DC subsets compared to WT C57BL/6 mice. Acute UVB-induced migration of dermal DC subsets, CD207- and CD207+ dDCs in DNR to skin-draining lymph nodes (SDLNs) was reduced in DNR compared to WT mice, which correlated with a reduced percentage of p-Smad2+ and CD86high dermal DCs in DNR with UVB. There was no significant difference in UVB-induced migration of LC subset between DNR and WT mice. In addition, the UVB-induced migration of CD207- and CD207+ dDCs in a chronic UVB model as well as migration of CD207- subset in an ear explant assay was suppressed in DNR compared to WT mice with no difference in LCs. Consistent with reduced
steady state and UVB-induced migration of dermal DC subsets, ear thickness response measured in a contact hypersensitivity model (CHS) with and without UVB, was reduced in DNR mice compared to WT with an associated reduction in memory effector differentiation and IFNγ, IL17 and IL2 cytokine profile of CD4+ and CD8+ T cells. Together, these results suggest that TGFβ signaling in DCs is important for UVB-induced skin inflammation and optimal response to hapten sensitization in a CHS model, both mediated through the DC-T cell arm of the immune response.

127 Alteration of Cytoskeletal Molecules in a Human T Cell Line Caused by Continuous Exposure to Chrysotile Asbestos

T. Otsuki1, M. Maeda2, H. Matsuaki, S. Lee1, N. Kumagai-Takei1 and Y. Nishimura1.1Hygiene, Kawasaki Medical School, Kurashiki, Japan and 2Agricultural and Life Science, Okayama University, Okayama, Japan.

We have been investigating the immunological effects of asbestos, since the silicosis patients who had exposed silica, the core chemical of asbestos. SiO2, often complicate the autoimmune diseases such as Rheumatoid arthritis, SSc, and ANCA-related vasculitis. Therefore, we are considering asbestos may possess the immunological effects, although the physical fibrous form is differed from particulated silica. We considered the target of asbestos may be the anti-tumor immunity, since the major complications of asbestos-exposed patients are the cancers. In this report, we investigated alteration of protein expression among MT-2 original cells that had no contact with asbestos, and six chrysotile-continuously exposed independent sub-lines using ProteinChip and two-dimensional gel electrophoresis (2DGE) assays. Further confirmation of the changes in protein expression due to asbestos exposure was obtained after the 2DGE method indicated protein modification of β-actin. β-actin was upregulated in mRNA, as were the levels of protein expression and phosphorylation. Moreover, a binding assay between cells and chrysotile showed that various molecules related to the cytoskeleton such as vimentin, myosin-9 and tubulin-P, as well as β-actin, exhibited enhanced bindings in asbestos-exposed cells. The overall findings indicate that the cell surface cytoskeleton may play an important role in inducing the cellular changes caused by asbestos in immune cells, since fibers are not incorporated to the cells and how the alterations of cytoskeleton determined cell destiny to cause the reduction of tumor immunity is important to consider the biological effects of asbestos. Further studies to target several cytoskeleton-related molecules associated with the effects of asbestos will result in a better understanding of the immunological effects of asbestos and support the development of chemo-prevention to recover anti-tumor immunity in asbestos-exposed patients.

128 Analysis of Blood DcR3 Concentration and Its Correlation to Clinical Parameter of Autoimmune Diseases in Silicosis Patients

S. Lee1, Y. Nishimura1, S. Yamamoto1, T. Hatayama2, H. Matsuaki1, N. Kumagai-Takei1, H. Hayashi1, M. Kusaka1, W. Fujimoto2 and T. Otsuki1.1Hygiene, Kawasaki Medical School, Kurashiki, Okayama, Japan and 2Agricultural and Life Science, Okayama University, Okayama, Japan.

Silicosis patients frequently complicate with autoimmune diseases. Dysregulation of apoptosis, particularly in the Fas/Fas ligand (FasL) pathway, has been considered to play a role in the pathogenesis of autoimmune diseases. DcR3 is known as an intracellular decoy receptor that binds FasL and inhibits FasL-induced apoptosis. Initial studies showed that DcR3 expression is elevated in cancer cells, however, later work showed that DcR3 expression is also increased in inflammatory diseases, where serum DcR3 levels correlate with disease progression (Linn WW & Hsieh SL 2011). Our previous report showed DcR3 mRNA expression increased in PBMC of silicosis patients (Otsuki T et al. 2000). In this study, we analyzed blood DcR3 expression and correlation to clinical parameter of autoimmune diseases.

Plasma samples that included 19 of healthy volunteers (age 42.94±7.95, mean 8: female 11), 20 of silicosis patients (age 74.85±5.35, mean 19: female 1), 25 of systemic sclerosis patients (age 62.32±12.06, mean 3: female 1) were provided from Kawasaki Medical School hospital and Kusaka hospital (Bizen, Okayama, Japan) and Kusaka Hospital, Bizen, Okayama, Japan. All factors were analyzed with ELISA. Statistic analysis was performed using SPSS. DcR3 blood level was remarkably increased in silicosis patients compare to healthy volunteers. This result suggested that blood DcR3 increment may cause complication of autoimmune diseases through impair Fas/FasL pathway in silicosis patients. Furthermore this study showed there are no correlation between plasma DcR3 and any other clinical parameter of autoimmune diseases in silicosis patients. This result indicated plasma DcR3 elevation means impairment of immune system rather than directing particular autoimmune disease.

129 FoxO1 Regulates Apoptosis Induced by Asbestos in the Human T Cell Line MT-2

H. Matsuaki1, S. Lee1, M. Maeda2, N. Kumagai-Takei1, Y. Nishimura1 and T. Otsuki1.1Hygiene, Kawasaki Medical School, Kurashiki, Okayama, Japan and 2Agricultural and Life Science, Okayama University, Okayama, Japan.

Asbestos is known to cause malignant mesothelioma and lung cancer. Recent studies indicate the implication of tumor immunity in development of various tumors including malignant mesothelioma. Thus, human T cell line MT-2 cells were cultured to asbestos for longer than 8 months and resultant cells were designated MT-2Rst. Gene expression analysis revealed that the amount of forkhead transcription factor FoxO1 mRNA decreased after long term exposure to asbestos in MT-2 cells. According to the reduction of FoxO1, pro-apoptotic Foxo target genes, Puma, Fas ligand, and Bim, were down-regulated in MT-2Rst cells. Furthermore, ΔFvRNA-mediated knock-down of FoxO1 reduced number of apoptotic cells after treatment with asbestos in parental MT-2 cells. On the other hand, over expression of FoxO1 does not affect on asbestos-induced apoptosis in MT-2Rst cells. These results suggest that FoxO1 play an important role in regulating of asbestos-induced apoptosis, and the presence of multiple pathways regulating resistance to asbestos in MT-2Rst cells.

130 Contribution of Autoantibodies to Fiber-Induced Fibrosis

K. Serve, C. N. Zebedee, C. Davis, K. Ng and J. C. Pfau. Biological Sciences, Idaho State University, Pocatello, ID.

Non-malignant pleural abnormalities arising from asbestos exposure may manifest as pleural plaques, diffuse pleural thickening, or pleural effusions. Clinical observations suggest amphibole, but not chrysotile, exposures are linked to diffuse pleural thickening and progressive loss of lung function. Recent research suggests that factors such as pathogenic autoantibodies and fiber-induced tissue damage contribute to these different clinical outcomes. In order to study the contribution of these factors to pleural disease, we used microscopy to quantify collagen deposition within the pleura and peritoneal cavities of mice exposed to amphibole or chrysotile asbestos or to the carcinogenic fiber erionite. Multiphoton microscopy was used to analyze collagen density of the lung visceral pleura or peritoneal tissue (i.e. diffuse collagen deposition) and the dissection microscope was used to assess localized collagen plaques. Mouse sera were examined for anti-nuclear antibodies (ANAs) to determine potential correlations with collagen density. Intra-tracheal exposure to fibers resulted in an overall increase of ANAs compared with saline control exposures, with the highest ANA level associated with erionite exposure. Erionite exposure was also associated with the highest collagen density within the peritoneal cavity while amphibole was associated with the highest collagen density within the pleural cavity. Collagen density was slightly increased in amphiboile-exposed, ANA-positive mice compared to ANA-negative mice; however, there was no significant correlation between ANA presence and pleural plaques. Further study is needed regarding the possible contribution of anti-fibroblast and anti-mesothelial autoantibodies to collagen deposition, since these antibodies are shown to directly increase collagen production by pleural and peritoneal cells. Overall, these data suggest that fiber exposure increases diffuse collagen deposition within the pleural and peritoneal cavities, with autoantibodies potentially contributing to diffuse, but not localized, collagen deposition.

131 Antinuclear Autoantibodies and IL-17 Are Induced in C57BL/6 Mice Following Amphibole, but Not Chrysotile, Exposure

J. C. Pfau1, A. Ferro2, C. N. Zebedee1, C. Davis1 and K. Ng1. Biological Sciences, Idaho State University, Pocatello, ID and 2College of Osteopathic Medicine, Pacific Northwest University of Health Sciences, Yakima, WA.

Exposure to amphibole asbestos has been shown to increase production of autoantibodies in mice and humans and to increase the risk of systemic autoimmune disease. However, epidemiological studies of chrysotile exposure have not indicated an increased risk for autoimmunity. To explore these apparently different responses to asbestos exposures in mice, and to suggest possible mechanistic explanations for the difference, C57BL/6 mice were exposed intratracheally to amphibole or chrysotile asbestos, or to saline only. Serum antinuclear antibodies (ANA), antibodies to extractable nuclear antigens (ENA), serum cytokines, and immunoglobulin isotypes were evaluated 8 mo after the final treatment. The percentages of FoxO1, pro-apoptotic Foxo target genes, Puma, Fas ligand, and Bim, were down-regulated in MT-2Rst cells. Furthermore, ΔFvRNA-mediated knock-down of FoxO1 reduced number of apoptotic cells after treatment with asbestos in parental MT-2 cells. On the other hand, over expression of FoxO1 does not affect on asbestos-induced apoptosis in MT-2Rst cells. These results suggest that FoxO1 play an important role in regulating of asbestos-induced apoptosis, and the presence of multiple pathways regulating resistance to asbestos in MT-2Rst cells.
overall percentages of T and B-cells in the spleen or lungs of exposed mice. Chrysotile induced a significant increase in the normally rare populations of suppressor B-cells (CD11c+, CD5+, CD11d+) in both the spleen and lungs. Overall, the results suggest that while there may be an inflammatory response to both forms of asbestos, there is an immunosuppressive response in only the amphibole-exposed, but not the chrysotile-exposed mice. These data have critical implications in terms of screening and health outcomes of asbestos-exposed populations.

132 Effect of Perinatal BPA Exposure on Spleen and Serum Pro-Inflammatory Cytokines in Weaned Rats

A. Kelly1, D. R. Mierke1, R. N. Sadowski1, L. M. Wise2 and S. N. Laveigne1.
1Comparative Biosciences, University of Illinois, Urbana, IL and 2Psychology, University of Illinois, Urbana, IL.

Bisphenol A (BPA) is an environmental endocrine disruptor, well known for its reproductive and neurotoxicity, but it can also interact with immunity and inflammation. We have shown that perinatal exposure to BPA and gender affect MHC II levels in spleens of weaned rat. We here report the effect of perinatal BPA exposure (400μg/kg/day) on spleen and serum levels of 3 key pro-inflammatory cytokines (IL-1β, IL-6, TNFα) in both female and male rats. Oral exposure lasted throughout pregnancy and until PND9; rats were then humanely euthanized at weaning. Spleens and sera were collected, snap frozen, and stored at -80°C. Cytokines levels were measured using a multiplex approach. Spleen IL-1β was similar between females and males in both vehicle and BPA groups, but was lower in BPA-treated animals for both genders. Spleen IL-6 was similar between females and males in the vehicle group, but was higher in BPA males compared to vehicle males. Spleen TNFα was low and not affected by BPA. Serum IL-1β was lower in males compared to females in both vehicle and BPA groups, but was higher in BPA males compared to vehicle males. We did not detect any IL-6 or TNFα in these rat sera. Finally, there was no correlation between serum and spleen levels for each cytokine, but spleen cytokine levels correlated with each other. In conclusion, it appears that perinatal exposure to BPA affects peripheral pro-inflammatory cytokines, with some gender-specific effects. In addition, serum did not appear to be an adequate spleen surrogate tissue for IL-1β, IL-6, or TNFα.

133 Perinatal Exposure to Bisphenol A Alters Immune Cell Differentiation at Systemic and Intestinal Level in Young Offspring Rats

Aims: Previous data in rats showed that perinatal exposure to bisphenol A (BPA) altered intestinal immune homeostasis in young offspring, weakening host defenses to intestinal infection. We aimed to investigate whether developmental immunotoxicity during BPA perinatal exposure resulted from early alteration in immune cell differentiation. Methods: Dams were treated with BPA [5 μg/kg/d] or vehicle (corn oil) from day 15 of gestation until weaning (postnatal day 21). Immune cells from spleen, mesenteric lymph node (MLN) or jejunal lamina propria were harvested from female offspring at PND25. Analysis of immune cell frequency for T regulatory (Treg) and T helper (Th) cells, or dendritic cell (DC) was performed by flow cytometry using specific cell markers. Total and E. coli-specific IgA responses in PND25 offspring were also measured. Results: Perinatal BPA treatment decreased frequency of Treg cells (0.33+/−0.04 vs 0.39+/−0.02% of total splenocytes in controls, p<0.02) and of T cells in spleen (p<0.01) and MLN (p<0.04). These data were associated with a decrease in migratory DC frequency at systemic level (0.09+/−0.01 vs 0.16+/−0.04% of total splenocytes in controls, p<0.04), as well as in the gut and associated MLN (p<0.04). Moreover, the decline in DC and Th cells questioned the ability of BPA-exposed rats to induce cell response. As expected, a decrease in E. coli-specific IgA response (p<0.0001) was observed in serum of BPA-exposed rats, while total IgA were not impacted. Conclusion: This study shows that perinatal exposure to BPA at a dose close to the estimated dietary exposure in human (0.3-0.9 μg/kg/day, 95th percentile, European Food Safety Agency 2013) impacted the frequency of antigen presenting cells in young offspring with consequences on T helper differentiation. This led to a decline of T regulatory cells concomitant to altered IgA response toward microbiota, two important actors for systemic and local immune homeostasis.

134 Transmaternal Exposure to Bisphenol A, but Not Phthalates, Accelerates Diabetes Type 1 Development in NOD Mice

1Food, Water and Cosmetics, Norwegian Institute of Public Health, Oslo, Norway and 2Air Pollution and Noise, Norwegian Institute of Public Health, Oslo, Norway.

In nodules, two important actors for systemic and local immune homeostasis.

Type 1 diabetes (T1DM) is an autoimmune destruction of insulin producing beta cells in the pancreas with a genetic predisposition that can be triggered by environmental factors. We have previously shown that bisphenol A (BPA) accelerates the spontaneous diabetes development in the diabetes-prone NOD mice. Here, we hypothesized that oral exposure to a combination of the rapidly metabolized endocrine disruptors BPA and phthalates, which is relevant for human mixed exposures, might give a further effect on diabetes development in NOD mice. A possible link between the development of T1DM and exposure through drinking water from before birth and throughout life to BPA (1mg/l), a mixture of phthalates (DEHP 1mg/l, DBP 0.2mg/l, BBP 10mg/l and DiBP 20mg/l) and a combination of BPA and the phthalate mixture was investigated in NOD mice. Presently, BPA exposure resulted in increased prevalence of diabetes and decreased number of tissue resident macrophages. Interestingly, BPA exposure also impaired the phagocytic activity of peritoneal macrophages. None of these effects were observed after phthalate exposure alone or together with BPA. Exposure to BPA alone or in combination with phthalates resulted in decreased cytokine release (TNFα, IL-6, IL-10, IFNγ, IL-4) from in vitro stimulated splenocytes, indicating a systemic change in immune function. We conclude that BPA, but not phthalates or the combination of BPA and phthalates, accelerates the diabetes development in NOD mice, possibly via decreased number and function of macrophages in pancreatic islets.

135 Total Blood Mercury, Fish Consumption, Proximity to Alluvial Arsenic Deposits, and Serum Autoantibodies among the Cheyenne River Sioux Tribe Members

1Community Environmental Health Program, University of New Mexico, Albuquerque, NM; 2Molecular Genetics and Microbiology, University of New Mexico, Albuquerque, NM; 3Environment and Natural Resources, Cheyenne River Sioux Tribe, Eagle Butte, SD; 4Research Nurses Group, Missouri Breaks Industrial Research, Eagle Butte, SD and 1The Scripps Research Institute, La Jolla, CA.

Mercury (Hg), known to induce autoimmune in rodents, is a ubiquitous toxicant on the Cheyenne River Sioux Tribal (CRST) lands. Mercury exposure happens through fish consumption (FC), a part of Native culture that supports subsistence. Our goals were to ascertain whether total blood Hg levels (THg) reflect Hg exposure via FC, smoking, and to determine if THg is associated with the production of anti-nuclear antibody (ANA) and specific auto-antibodies (sAuAb). We recruited 75 people who consume fish from CRST waters. Hg exposure via FC and smoking were assessed using questionnaires. Blood samples were collected and THg was assessed by mass spectrometry (ICP-MS). Immunofluorescence was used for serum ANA. Native, denatured DNA, chromatin and histone sAuAbs and other diseases sAuAbs were measured by ELISAs. We modeled these immune measures using demographic (age, gender) and exposure predictors. Female gender, age and FC were significant predictors of THg; self-reported smoking was not. 31% of participants tested positive for ANA stained stronger than ≥2+. Even ANA was not significantly associated with THg, the interactions of gender with THg and close proximity to As deposits were statistically significant. Also, female gender, age and FC were significantly associated with elevated sAuAb. Although FC resulted in detectable body burden of Hg, THg alone did not explain ANA or sAuAb in this population. We are working with CRST communities to investigate the relationships among FC, complex metal exposures and the community’s immune responses.
Inorganic mercury (Hg2+) is a potent immunomodulator that has been implicated as a factor contributing to autoimmune disease in animal models as well as in humans. At this time a mechanistic understanding of how Hg2+ depresses immune function remains elusive. Furthermore, while studies clearly demonstrate an association between Hg2+ exposure and increased risk of autoimmune disease on a population level, there are currently no biomarkers that can be utilized to identify Hg-induced autoimmunity. Recently there has been increased appreciation of the involvement of B cells in autoimmune disease. We have employed advanced proteomic and multicolor phosphoflow cytometric approaches to investigate the interaction of Hg2+ with immature (T1 and T2) and mature mouse B cells. Deficits in the B Cell Receptor (BCR) signaling pathway of T1 and T2 B cells is known to be associated with autoimmune disease. Lyn is an Src family protein tyrosine kinase known to be intimately involved in the initiation and regulation the BCR signaling pathway in all B cells. Lyn kinase activity is both positively and negatively regulated by phosphorylation of several strategic tyrosine residues. Results from both the proteomic and phosphoflow approaches have converged on supporting the hypothesis that altered Lyn phosphorylation and functionality consequent to mercury exposure may be key interrelated phenomena mediating immunotoxicity of mercury intoxicated B cells and the emergence of an autoimmune B cell repertoire in mercury intoxicated individuals. This being the case, expression of specific Lyn phosphorylation profiles in B cells may be useful biomarkers of Hg-induced autoimmunity in Hg2+ exposed individuals. Supported by NIH grant ES019228.

**136 Altered Lyn Phosphorylation May Be a Key Mediator of Autoimmunity Associated with Mercury Intoxication of B Cells**

A. J. Rosenspire1, J. Caruso2, R. Gill1, P. M. Stemmer3, N. Caruthers2 and M. J. McCabe1.1 Immunology and Microbiology, Wayne State Univ, Detroit, MI; 2Institute of Environmental Health Science Research, Wayne State University, Detroit, MI and 3Environmental Medicine, University of Rochester Medical Center, Rochester, NY.

**137 Modeling Mechanism by Which Trichloroethyleno Inhibits Liver Repair in Mouse Model of Autoimmunity**

S. Erickson1, K. Gilbert1, B. Reisfeld1, T. Zutlinen2,3, M. Kreps1 and S. J. Blossom4. 1University of Arkansas for Medical Sciences/Arkansas Children’s Hospital Research Institute, Little Rock, AR and 2Colorado State University, Fort Collins, CO.

Chronic exposure to industrial solvent and water pollutant trichloroethylene (TCE) in female MRL+/+ mice generates disease commensurate with human autoimmune hepatitis. The current study was initiated to investigate why TCE-induced autoimmunity targeted the liver. The time- and dose-dependent effects of TCE on pro-inflammatory events in liver and macrophages from female MRL+/+ mice were examined. Compared to other tissues the liver has an unusually robust capacity for repair and regeneration that protects against pathology. Consequently, the impact of TCE on these hepatoprotective events were also examined. The addition of TCE to drinking water for 12 weeks induced a dose-dependent decrease in macrophage production of IL-6 at both the transcriptional and protein level. Although often regarded as a pro-inflammatory cytokine, IL-6 is primarily protective in the liver. TCE had little effect on liver expression of pro-inflammatory genes (Tnfa, Saa2 or Ccl2) until the end of a 40-week exposure. Instead, TCE suppressed hepatic expression of genes involved in IL-6 signaling (Il6r, gp130, and Egr1). Linear regression analysis confirmed liver histopathology in the TCE-treated mice correlated with decreased expression of Il6r. A toxicodynamic model was developed to define the effects of TCE on IL-6 signaling and liver pathology under different levels of exposure and rates of repair. This study underscored the importance of longitudinal studies in mechanistic evaluations of immuntoxicants. It showed that later-occurring liver pathology caused by TCE was associated with early suppression of hepatoprotection rather than an increase in conventional pro-inflammatory events. This information was used to create a novel toxicodynamic model of TCE-induced liver inflammation.

**138 Activation of Poly(ADP-Ribose)Polymerase-1 in Trichloroethylene-Treated MRL+/+ Mice: Potential Role in Autoimmunity**

H. Ma, W. Wang and M. Khan. Pathology, University of Texas Medical Branch, Galveston, TX.

The mechanisms by which trichloroethylene (TCE) induces/exacerbates an autoimmune response are not well understood. Previously, we have shown that TCE exposure leads to oxidative stress which contributes to TCE-mediated autoimmune. This study was aimed to further assess the role of oxidative stress in TCE-induced autoimmunity by assessing the role of poly(ADP-ribose)polymerase-1 (PARP-1, which is mainly involved in DNA repair, and apoptosis by depleting NAD+ and ATP). To achieve this, groups of female MRL+/+ mice were given TCE, N-acetylcysteine (NAC) or TCE + NAC for 6 weeks (TCE, 10 mmol/kg, i.p., every 4th day; NAC, 250 mg/kg/day through drinking water). TCE exposure led to significant increases in serum levels of anti-nuclear (ANA) and anti-dsDNA antibodies. TCE treatment also led to significant increases in the levels of 8-hydroxy-2′-deoxyguanosine (8-OHdG) in kidney (1.7 fold) and liver (1.6 fold) compared to controls, suggesting increased oxidative DNA damage. TCE-induced DNA damage was also associated with significant increases in PARP-1 levels which were 2.8- and 2.9-fold higher in kidney and liver, respectively. Remarkably, NAC supplementation not only attenuated DNA damage and its repair (reduced 8-OHdG and PARP-1 levels), but also the TCE-mediated autoimmunity as evident from significantly reduced serum ANA and anti-dsDNA. These results suggest that TCE-induced oxidative DNA damage along with increased PARP-1 levels may play a role in TCE-induced autoimmunity. Attenuation of PARP-1 activation in TCE-mediated autoimmunity via increased apoptosis of the cells. Supported by NIH ES016302.

**139 Evaluation of Nitrosative Stress in the Pathogenesis and Prevention of Autoimmunity Mediated by Trichloroethene**

G. Wang, J. Wang and M. Khan. Pathology, University of Texas Medical Branch, Galveston, TX.

Exposure to trichloroethene (TCE), a ubiquitous environmental contaminant, has been linked to a variety of autoimmune diseases (ADs) including SLE, scleroderma and hepatitis. Mechanisms involved in the pathogenesis of such ADs are largely unknown. Earlier studies from our laboratory suggested the contribution of oxidative/nitrosative stress in TCE-induced autoimmunity, and N-acetylcysteine (NAC) supplementation provided protection against autoimmunity by attenuating oxidative stress. This study was undertaken to evaluate the role of nitrosative stress in TCE-mediated autoimmunity. Groups of female MRL+/+ mice were given TCE, NAC or TCE + NAC for 6 weeks (TCE, 10 mmol/kg, i.p., every 4th day; NAC, 250 mg/kg/day through drinking water). TCE exposure led to significant increases in serum levels of anti-nuclear (ANA) and anti-histone antibodies. TCE exposure also led to significant induction of iNOS and increased formation of nitrotyrosine in the sera and livers. Proteinomic analysis (2D gel followed by mass spectrometry) identified several nitrated proteins in the liver of TCE-treated mice, also suggesting an overall increase in nitrosative stress. Furthermore, TCE exposure led to decreased GSH levels and increased NF-κB p65 expression. Remarkably, NAC supplementation not only ameliorated the TCE-induced nitrosative stress, reduced GSH levels and NF-κB p65 activation, but also the markers of autoimmunity, as evident from decreased levels of autoantibodies in the sera. These findings provide further support the role of nitrosative stress in TCE-induced autoimmune response. Attenuation of TCE-induced autoimmunity in mice by NAC provides an approach for designing preventive and/or therapeutic strategies. Supported by NIH ES016302.

**140 Docosahexaenoic Acid Consumption Suppresses Silica-Induced Pneumonitis and Glomerulonephritis in Lupus-Prone NZBWF1 Mice**

M. Bates1, C. Brandenberg1, L. Langouy1, L. Bramble1, A. Holiar1, J. R. Harkema1 and J. J. Pestka1. 1University of Michigan State University, East Lansing, MI and 2University of Montana, Missoula, MT.

Exposure to environmental agents such as silica is suspected to contribute to initiation and exacerbation of autoimmunity in genetically predisposed individuals. In prior work, we observed in lupus-prone mice that intranasal exposure to crystalline silica induced a marked inflammatory response in the lungs characterized by elevated pro-inflammatory cytokines, perivascular lymphocytic infiltration, and secretion of IgG, as well as comparable systemic effects that resulted in early onset of glomerulonephritis. Consumption of the n-3 polyunsaturated fatty acid (PUFA) docosahexaenoic acid (DHA) has been demonstrated to prevent inflammation and progression of autoimmunity in both animal and human studies, suggesting that diet is an important factor in autoimmune disease-prone individuals. The purpose of this study was to test the hypothesis that DHA consumption can prevent silica exacerbated lupus nephritis. Lupus-prone NZBWF1 mice were fed a modified AIN-93G diet supplemented with 0, 1, 3 or 6% DHA-enriched algcl oil for 2 wk prior to intranasal silica exposure (1 mg weekly for 4 wk) and maintained on experimental diets until sacrifice. Diets supplemented with 3% and 6% DHA markedly repressed perivascular lymphocytic infiltration in lungs of silica-treated mice. Repressed pneumonia was temporally related to reduced pro-inflammatory cytokines, IgG secretion, and autoantibodies to dsDNA in both bronchoalveolar lavage fluid and plasma. The anti-inflammatory effects of DHA were
further reflected in the kidneys of lupus-prone mice by delayed onset of proteinuria and reduction of glomerulonephritis. The percent energy intake from 3% and 6% DMA-enriched AIN-93G diet were comparable to 2.7% and 5.5% respectively, of dietary intake or pharmacological supplementation in humans. Taken together, these results suggest that consumption of the n-3 PUFA, DHA, might be effective in preventing silica-induced acceleration and exacerbation of autoimmunity.

141 Early Immunomodulatory Effects of Dermal Triclosan Exposure in Mice

N. B. Marshall, S. E. Anderson, K. L. Anderson, C. M. Long, E. Lukomska and B. J. Meade. CDC/NIOSH, Morgantown, WV and 2Immunology and Microbial Pathogenesis Graduate Program, West Virginia University, Morgantown, WV.

It has recently been shown that dermal application of the commonly used anti-microbial compound triclosan, enhanced allergic responses in a mouse asthma model. To help elucidate the mechanisms of this augmented allergic response, we investigated the early immune-related effects of dermal triclosan exposure in mice. Triclosan was applied daily to the dorsal surface of the ears of BALB/c mice at concentrations ranging from 0%-3%, and leukocytes were examined in different organs over time using flow cytometry. Examination of the draining lymph nodes revealed a dose-dependent increase in cell numbers and enhanced GATA-3, IL-4, IL-21 and IL-17 expression suggesting enhanced Th2- and Th17-like effector T cell polarization. Effects on antigen presenting cells were also observed including increased expression of MHC class II, CD80 and CD86. In mice sensitized to ovalbumin (OVA) and subsequently challenged with OVA through pharyngeal aspiration on day 7, mice exposed to triclosan had increased cell numbers in the bronchoalveolar lavage and mediastinal LN by 24 hours compared to vehicle-treated mice. Interestingly, the introduction of OVA into the airway of triclosan-exposed mice was associated with increased swelling of the ear tissue along with an influx of CD11b+ cells and dramatic increase in TSLP and TNF-alpha expression. Taken together, the early immunomodulatory effects of triclosan suggest an adjuvant-type effect that involves CD4 T cells and antigen presenting cells which may contribute to the augmentation of allergic responses.

142 An Immunologic Role of microRNA 210 in a Murine Model of Dermal Toluene-2, 4-Diisocyanate Sensitization

C. M. Long1,2, N. B. Marshall1, P. D. Siegel1, B. J. Meade1, E. Lukomska1, K. L. Anderson1, D. Bezehold1 and S. E. Anderson1. 1Center for Disease Control and Prevention-National Institute for Occupational Safety and Health (CDC-NIOSH), Morgantown, WV and 2Immunology and Microbial Pathogenesis Graduate Program, West Virginia University, Morgantown, WV.

Diisocyanates, such as toluene 2, 4-diisocyanate (TDI) are the principal cause of occupational asthma induced by low molecular weight chemicals. Recently, the study of immune regulation by microRNAs has revealed the importance of these regulatory molecules in allergic disease. Our laboratory has shown that mirRNA 210 (miR-210) expression increases in the draining lymph nodes (DLN) following dermal exposure to TDI in a murine model, however, the role of miR-210 in allergic disease is unknown. These studies were conducted to elucidate the functional role of miR-210 during sensitization to TDI. Female BALB/c mice were dermally exposed to TDI (4%) or vehicle. RNA was isolated from specific cellular subsets (T-cells and B-cells) at four days post exposure and analyzed for miR-210 expression using real-time quantitative polymerase chain reaction analysis. A statistically significant increase in miR-210 expression occurred in the DLI CD4+ cell population of TDI-exposed mice. Confirmed (foxxp3) and predicted (runx1, runx3, smad4, and stat6) miR-210 transcription factor targets were identified using computational algorithms. Augmentations in foxxp3 protein expression and decreases in runx1 and foxxp3 mRNA occurred concurrently with expression of miR-210 following dermal TDI exposure. Understanding the immunologic mechanisms of allergic disease is critical for the development of preventative and therapeutic strategies and these studies suggest a functional role for miR-210 in the regulatory T cell pathway and ultimately in the pathogenesis of TDI sensitization.

Human exposure to arsenic in drinking water is known to contribute to many different health outcomes such as cancer, diabetes, and heart disease. Several epidemiological studies suggest that T cell function is also altered by drinking water arsenic exposure. However, it is unclear how individual responses differ to various levels of exposure to arsenic. Our laboratory has recently identified differential responses of human peripheral blood mononuclear cell (HPMBC) T cells as measured by polyclonal T cell activation following sodium arsenite exposure. Certain healthy individuals exposed to low concentrations (0.1-100 nM) of arsenic in vitro showed a dose-dependent suppression at low concentrations of arsenite, whereas other individuals were not suppressed at low concentrations. In a series of 30 normal donors, we found that three individuals were sensitive to low dose sodium arsenite-induced inhibition of T cell proliferation produced by phytohemagglutinin (PHA) and anti-CD3/anti-CD28. There also appeared to be a correlation with the amount of IL-2 produced by these cells in culture. Current studies suggest that donors who are sensitive to As+3 may be even more sensitive to monomethylarsonious acid (MMA+3) at concentrations of 0.1-100 nM. Our studies demonstrate for the first time that low doses of As+3 and MMA+3 are immunosuppressive to HPMBC T cells in some individuals.

144 Association of Pro-Inflammatory and Apoptotic-Related Genes Expression with Lymphocyte DNA Telomere Length (TLT) in a Mexican Population Exposed to Arsenic

Long term exposure to inorganic arsenic (iAs) leads to a sustained inflammatory response. Chronic inflammation is frequently associated with oxidative stress which may cause telomere dysfunction, leading to apoptosis or, on the opposite side, to cells malignant transformation. It has been reported that during acute inflammation telomere length increase temporarily, maybe as a strategy to assure cell expansion and insult elimination. However, telomere length shortening has been reported in peripheral blood lymphocytes as a marker of accumulated effect of oxidative stress and inflammation. In this work we evaluated the expression of inflammatory and apoptotic related genes and its association with leucocyte telomere length (TLT) in a Mexican population chronically exposed to iAs (n=128) in drinking water. Results showed a positive association between iAs exposure and granulocyte and macrophage colony stimulating factor (GM-CSF) gene expression (p=0.00305) and TLT was positively associated with urinary concentration of DMA III-V (p=0.044), but only when variables corresponding to Apaf-1, TGF-β e IL-8 gene expression were included in the multivariate model. These preliminary results suggest that inflammatory responses may contribute to lymphocyte telomere dysfunction and it could represent a mechanism associated with an increased risk for iAs-related diseases development in exposed populations.

145 Inhibition of Early T Cell Cytokine Production by Arsenic Occurs Independently of Nrf2

K. R. VanDen Berg2 and C. E. Rockwell2. 1Pharmacology and Toxicology, Michigan State University, East Lansing, MI and 2Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Nuclear factor erythroid 2-related factor 2 (Nrf2) is a stress-activated transcription factor that induces the expression of a variety of cytoprotective genes. Nrf2 has also been shown to mediate immunosuppressive effects in multiple inflammatory models. Upon activation, Nrf2 dissociates from its repressor protein, Keap1, and translocates to the nucleus to induce the expression of Nrf2 target genes. This Nrf2-Keap1 interaction can be disrupted by the environmental toxicant and chemotherapeutic agent arsenic trioxide (ATO). The purpose of this study was to determine the effects of ATO on early events of T cell activation and the role of Nrf2 in those effects. The Nrf2 target genes Hmox-1, Nqo-1, and Gclc were all

F. T. Lauer1, D. MacKenzie1, E. Beswick1, A. J. Gandolf2, L. G. Hudson1, K. Liu1 and S. W. Bushel1. 1Pharmaceutical Sciences, University of New Mexico College of Pharmacy, Albuquerque, NM, 2Pharmacology and Toxicology, University of New Mexico College of Pharmacy, Albuquerque, AZ.
found to be upregulated by ATO treatments (1-2 μM) in splenocytes derived from wild-type, but not Nrf2-/−, mice, suggesting that Nrf2 is activated by ATO in splenocytes. ATO was also found to inhibit IFNγ and IL-2 production in wild-type splenocytes activated with the T cell activator, anti-CD3/anti-CD28. However, ATO also inhibited IFNγ and IL-2 production in Nrf2-null mice, suggesting that the inhibition is independent of Nrf2. In contrast, ATO had little effect on either protein or mRNA expression of the cell surface receptors CD25 and CD69. Collectively, this study suggests that although ATO activates Nrf2 in splenocytes, inhibition of early T cell cytokine production by ATO occurs independently of Nrf2. (This work is supported by NIH grant: ES018885)

**145a Cross-Reactivity of Halogenated Platinum Salts**

D. M. Lehmann1, E. H. Boykin1, C. Copeland1, L. B. Copeland1, S. J. Quell2 and W. Williams3. 1NIH/ERL, U.S. EPA, Research Triangle Park, NC and 2Student Contractor, Youngsville, NC.

Halogenated platinum (Pt) salts are well-known respiratory sensitizers associated with the development of asthma. People may be exposed to a variety of platinum compounds in different contexts (e.g., occupationally, automobile exhaust). Published reports suggest that sensitization to one Pt compound may result in hypersensitivity reactions to other Pt compounds. We investigated the potential for this type of cross-reactivity using a mouse model of Pt hypersensitivity. Mice were sensitized through application of 100 μL 1% ammonium hexachloroplatinate (AHCP) in DMSO to the shaved back on days 0, 5 and 19, and 25 μl to each ear on days 10, 11 and 12. Unsensitized mice received vehicle. On day 24, mice were challenged by intratracheal aspiration (IA) with saline or 100 μg ammonium tetrachloroplatinate (ATCP) in saline. Before and immediately after dosing, airway responses were assessed using whole body plethysmography (WBP). On day 26, changes in ventilatory responses to methacholine (Mch) aerosol were assessed by WBP. All mice dosed with AHCP demonstrated significant increases in total serum IgE, suggesting the animals were sensitized. An immediate airway response (IAR) was observed in mice sensitized and challenged with AHCP. Dose-dependent increases in Mch responsiveness occurred in mice sensitized and challenged with AHCP. Bronchoalveolar lavage fluid (BALF) harvested from mice sensitized and challenged with AHCP contained an average of 5% eosinophils compared to less than 0.5% in control mice (p < 0.05). When challenged with 100 μg ATCP, AHCP sensitized mice also exhibited an IAR. Compared to control mice, BALF harvested from the lungs of ATCP challenged mice also contained elevated numbers of eosinophils and were responsive to Mch aerosol. Our data demonstrate that ATCP can trigger allergic lung responses in AHCP sensitized mice. This abstract does not represent EPA policy.

**145b Contact Sensitizing Potential of 2-Ethylhexyl p-methoxycinnamate in Female BALB/c Mice**

R. P. Frawley1, D. R. Germolec2, B. McIntyre3, M. J. Smith3, K. L. White1 and T. L. Guinn1. 1National Toxicology Program, NIEHS, Research Triangle Park, NC and 2Virginia Commonwealth University, Richmond, VA.

2-Ethylhexyl p-methoxycinnamate (EHMC) is a common, active ingredient in sunscreens that absorbs in the ultraviolet B range. EHMC has been detected in both the plasma and urine of humans 3-4 hours after topical application. Published reports suggest that EHMC may be a contact sensitizer or irritant in humans, and may modulate immune responses related to hypersensitivity. The objective of this study was to evaluate the direct hypersensitivity potential of EHMC in female BALB/c mice following dermal exposure using the ICCVAM-validated local lymph node assay (LLNA) in combination with a measurement of irritancy (IRR), and the mouse ear swelling test (MEST). EHMC was applied to the dorsa of both ears in exposed insects at concentrations equal or greater than 80 and 120 μg/L/L, respectively. The LC50 values for toluene and thinner at 24 h exposure were 129.66 μg/L/L, respectively. RT-PCR analysis performed on insects exposed to thinner revealed the activation of glutathione-S-transferase, an oxidative stress marker. Toluene alone, in addition to glutathione peroxidase, also overexpressed other genes such as hypoxia-inducible factor 1 α, DNA Ligase IV and delta-9 desaturase. These results suggest T. castaneum is a suitable alternative animal model for the study of toxicological effects of volatile aromatic compounds. This insect may help predicting the toxicity of volatile organic chemicals, as it reproduces some of the effects observed in mammalian model systems. Grant from University of Cartagena. Program to Support Research Groups (2013–2014). K.C. is sponsored by the National Program for Doctoral Formation (Colciencias, 567-2012).

**148 Screening of Compounds That Alter Sleep-Wake State Alteration in Zebrafish**

A. Alzualde and A. Muriana. BBD BioPhenix S.L., San Sebastian, Spain.

The zebrafish is emerging as alternative to mammalian animal models. Although it is more phylogenetically distant from humans than mammals, zebrafish are veritably that display other advantageous characteristics including embryo transparancy, which allows direct visualization and evaluation of internal organs or small size, which allows to manipulate them easily and to use 96- and 384-well plates to

**146 Identification of Chemical-Specific Toxicity Transcript Profiles In Vitro Using a Comprehensive or a Custom-Made Microarray**

L. M. Naciff1, Y. Shan1, X. Wang1, K. N. De Abreu2, R. Adams2, J. F. Tiesman3, R. S. Serrivati1, E. W. Carney3, B. A. Wessman2, R. S. Thomas2 and G. Daston1. 1Procter and Gamble, Cincinnati, OH, 2The Hamner Institutes for Health Sciences, Research Triangle Park, NC and 3The Dow Chemical Company, Midland, MI.

We have demonstrated that it is possible to define chemical mode of action (MOA) by assessing chemical-specific changes in gene expression in a small number of cell types enriched in relevant pathways for such MOA. For looking more cost effective approaches to gain information to define MOA for chemicals of interest, we have evaluated the transcriptional profile elicited by 34 chemicals in Ishikawa (uterine) and MCF7 (breast cancer) cells, using two platforms: a conventional microarray-based method (U219, Affymetrix) and a custom approach which measures the expression levels of approximately 1000 landmark genes, and uses a computational model trained to infer the response of the other genes (L1000; Genometry). Each of the 34 chemicals was tested at 3 doses and at 3 different time points. In order to compare the two platforms, Affymetrix U219 chip ID was converted to U133A chip ID, since the latter array was used to derive the probes for the L1000 array, using Affymetrix best match list. The same number of up or down regulated genes from each platform were used to query the cMap database (Broad Institute). Of the 34 chemicals evaluated, 23 are represented in the database. For those chemicals, data from either platform was specific enough to identify matches in the database for the same chemical or comparable agents acting via the same mechanism or mode of action. For chemicals not in the database, the highest ranking connections are with agents that act via the same MOA. For example, the transcriptional signature of bisphenol A, a weak estrogen, matched the one elicited by other estrogens in the database, most prominently with estradiol and genistein. These results support a conclusion that if the L1000 array may be useful as a cost-low alternative source of cMAP data. We are comparing data obtained with the same 34 chemicals tested in two additional cell types to further test this idea.
array embryos. The model is ideal to be used as a predictive tool in Drug Discovery, being able in a high extent to compare the results with those obtained in mammals. Increasing knowledge in zebrafish gives more support to this alternative model. Physiological, biochemical and behavioral daily rhythms are regulated by circadian clock. The sleep-wake cycle is a well-studied output of the circadian clock. Apart from having many biological advantages, zebrafish are diurnal and present highly conserved circadian and sleep regulation systems, so they have been postulated also as a good model for circadian rhythm studies. Behavioral profiling in zebrafish reveals a conserved vertebrate neuropharmacology and identifies regulators of rest/wake states. For screening purposes, working with zebrafish larvae has many advantages in terms of rapidity and throughput.

The main objective of this study was to validate a protocol to detect compounds with potential to alter rest/wake states in zebrafish. For this purpose, zebrafish larvae were exposed to melatonin and other reference drugs as barbiturates and benzodiazepines directly in 96 well plates. After treatment larvae movement was tracked during 24 hours automatically. Diurnal and nocturnal locomotor activity and responsiveness of larvae are the main endpoints related to sleep states. This study supports the use of zebrafish in order to detect compounds that alter the sleep-wake states.

### 149 Studying Obesogens Using Zebrafish

C. W. McCollum1, A. Riu1, C. L. Pinto1, M. Grimaldi2, A. Hillenweck3, D. Zalko4, L. Bernard4, V. Lauter4, P. Balaguer4, M. Bondesson1 and J. Gustafsson1. 1CNRCS - Biology & Biochemistry, University of Houston, Houston, TX. 2Université de Montpellier 1, INSERM U896, IRCM, Montpellier, France. 3Research Center in Food Toxicology, INRA, UMR 1331, Toxalim, Toulouse, France and 4Molecular Zoology Team, Institut de Genomique Fonctionnelle de Lyon, ENS de Lyon, Lyon, France.

There is a growing prevalence in adult and childhood obesity, which leads to medical complications such as heart diseases, diabetes and other metabolic abnormalities. More than 35% of adults and roughly 17% of children in the U.S. are obese, with a projected increase in obesity prevalence in 2030 estimated at 33%. Recently, the American Medical Association officially classified obesity as a disease. Human health has been shown to be affected by the increasing presence of environmental pollutants in forms of industrial products (pesticides, drugs, plasticizers, etc.), some of which have been reported to lead to obesogenic effects in animal models. Indeed, exposure in utero to tributyltin (TBT) has been shown to predispose obesity in mice. Previously, we reported tetrabromobisphenol A (TBBPA) and tetrachlorobisphenol A (TCBPA), both commonly used as flame retardants, activate human and zebrafish peroxisome proliferator-activated receptor gamma (PPARγ) in vitro and induce adipogenesis in 3T3-L1 preadipocytes. PPARγ, highly expressed in adipose tissues, promotes adipogenesis and regulates lipid metabolism. To further investigate the link between environmental pollutants and obesity, we have utilized zebrafish as an obesogen model. We describe the metabolic fate of TBBPA and TCBPA to better assess the use of zebrafish as a vertebrate model for mamma- lian endocrine disruption. Additionally, we explore in vivo and in vitro activation of both human and zebrafish PPARγ by pharmaceutical human PPARγ ligands, TBBPA, TCBPA and TBT. We also show that TBBPA, TCBPA and TBT act as obesogens and promote lipid accumulation in zebrafish larvae, as well as induce late-onset obesity.

### 150 Effects of LXR Activation on Lipid Metabolism and Visual Function in Zebrafish

C. L. Pinto, A. Riu, J. Gustafsson, M. Bondesson and P. Jonsson. Center for Nuclear Receptors & Cell Signaling, University of Houston, Houston, TX. Sponsor: D. Zalko.

Liver X receptor (LXR), a ligand-activated transcription factor, is a key regula- tor of multiple pathways involved in lipid, cholesterol and carbohydrate metabo- lism. While there are two LXR isoforms in mammals, LXRα (NR1H3) and LXRβ (NR1H2), only one LXR gene with higher sequence similarity to mammalian LXRα has been reported in zebrafish (ζLXR). LXR has been shown to be expressed at early developmental stages in zf, suggesting a primordial role of LXR. To assess the effects of LXR activation during zf development, zlf larvae were exposed to the LXR agonists T0901317 (2μM) and GW3965 (1μM) from 4 to 6 days post-fertilization (dpf), and RNA was extracted for microarray and qRT-PCR analyses. Microarray data demonstrated several conserved effects of the LXR ligands with mammalian models, including upregulation of known mammalian LXR target genes, and sev- eral genes involved in fatty acid and cholesterol biosynthetic pathways. These pathways could potentially be used to assess the effects of environmental compounds target- ing LXR in zebrafish. Our data shows that LXR plays an important role in lipid metabolic pathways during zf development and supports zebrafish as an alternative model for LXR-related studies involving lipid metabolism. Moreover, ζLXR exposure to the LXR ligands resulted in regulation of genes associated with eye development and visual perception, including photoreceptor and lens-specific genes, suggesting that LXR may also play a role in eye development and visual function in zebrafish.
Effects of Methymercury on Dopaminergic Neuron Development in Zebrafish Larvae

Methymercury (MeHg) is a well known neurotoxin capable of altering the structure and function of the central nervous system. Many signs of MeHg toxicity, including hypoesthesia and tremors, are similar to that of many neurodegenerative diseases, most notably Parkinson’s disease (PD). The disease is pathologically characterized by the progressive loss of dopaminergic (DA) neurons in the midbrain, resulting in the reduction of dopamine secretion and the development of movement disorders. Wild type zebrafish (ZF; Danio rerio) and the transgenic strain (Tg(dat:EGFP)), expressing green fluorescence protein (GFP) in DA neurons of the ventral diencephalon, were used to evaluate the effects of environmentally relevant concentrations of MeHg on the progression of PD-like phenotypes. Three day old ZF larvae were exposed to either 0.06 or 0.3 μM MeHg for 48h. Preliminary data from whole-mount immunostaining for thyrosine hydroxylase and live fluorescence imaging of dopamine transporters suggested disruption of the typical horseshoe pattern of DA neurons in MeHg exposed wild type and Tg(dat:EGFP) larvae. The effects of MeHg on DA neurons appeared to be dose correlated. Preliminarily locomotor assessments also showed a decreased mobility in MeHg exposed fish. There appeared to be a trend of reduced swimming activities in the 0.06 μM MeHg treated larvae, similar to those treated with 250 μM of 6-hydroxydopamine hydrochloride, a positive control for PD-like phenotype. Morphological changes such as endema, curvature of the spine, and hemorrhages confirmed MeHg toxicity in the exposed fish. mRNA expressions of parkin, PINK1, and LRRK2 genes associated with the recessive familial PD, were also determined. The preliminary results suggest that exposure to MeHg may increase the predisposition to neurodegenerative diseases, particularly PD, in a zebrafish model.

The Challenge of Studying Exposure in Zebrafish Embryos

The embryonic and/or larval zebrafish model is rapidly gaining popularity to study toxicity of new compounds. Various characteristics warrant the zebrafish as an ideal non-mammalian whole organism model that could bridge gaps between in vitro cell systems and complex higher animal models. A drawback of the zebrafish model is that the chorion, a shell that protects the embryo in its earliest days, can act as a barrier for test compounds which might result in false negative test outcomes. However, using whole-organism homogenates to analyze total body burden might not give a realistic picture of the internal exposure of the embryo since compounds might stick to the outside of the chorion. Furthermore, in larvae, this approach will not give any information about the biodistribution of compounds. In the present project we studied the uptake and biodistribution of a series of test compounds with different physical and chemical properties. Hereto, zebrafish embryos and larvae were treated with radioactive labeled test compounds for different time periods. By using autoradiography of serial microscopic sections, it was shown that both molecular weight and logP influenced the passage through the chorion, the uptake into the embryo and the biodistribution of the compounds. In general, total body burden analysis of compounds with a high molecular weight suggested considerable uptake by larvae, these compounds did not pass the epithelial cells of the gastrointestinal tract and stayed in the lumen. Consequently, internal exposure to these compounds was limited. By testing the biodistribution of more compounds and taken into account the physical chemical properties of a compound, the predictability of the zebrafish model will be improved.

High-Content Screening Assay for Identification of Chemicals Impacting Cardiovascular Function in Zebrafish Embryos

Targeted assays are needed to better evaluate effects of chemicals on organogenesis and begin classification of chemicals by toxicologically relevant modes-of-action. Using transgenic zebrafish (fli1:egfp) that stably express enhanced green fluorescent protein (eGFP) within vascular endothelial cells, we have developed and optimized a 384-well based high-content screening (HCS) assay that enables us to screen and identify chemicals affecting cardiovascular function at sub-lethal, non-teratogenic concentrations. Following static exposure of one embryo per well from 5-72 hours post-fertilization (hpf), automated image acquisition procedures and custom analysis protocols are used to quantify body length, circulation, heart rate, pericardial area (a biomarker for cardiac looping defects), and intersegmental vessel area within freshly hatched live embryos. After optimizing 72-hpf anesthesia procedures, we evaluated each endpoint across four independent control plates containing 384 initial embryos per plate. Survival and imaging success rates across these plates ranged from 93-99% and 42-74%, respectively. Criteria were then defined for assay success and analysis of treatments, and 10 chemicals were screened for targeted effects on cardiovascular function. Compared to existing zebrafish-based assays, this method provides a comprehensive discovery platform with 1) increased sample sizes; 2) broad concentration-response format; and 3) the ability to identify chemicals that target cardiovascular function at non-teratogenic concentrations.

A New Transgenic Zebrafish Model to Predict Organ Toxicities in Mammals

Zebrafish have many attractions for toxicity testing: they are cheap and easy to breed under laboratory conditions, can readily be exposed to chemical and pharmacological compounds and are susceptible to genetic manipulation. Reference compounds with known or no in vivo liver toxicity were tested on larval and adult zebrafish as well as isolated liver microsomes and the effects compared to available in vitro (hepatocyte) and in vivo (clinical/preclinical) data. Uptake and metabolism of compounds was analysed by LC/MS. To maximize test compound throughput, transgenic reporter lines have been generated based on our analysis of the transcriptional response of zebrafish larvae to a set of reference compounds. One potential limitation of the zebrafish is the functional divergence of its bioactivation and detoxification systems compared to those of preclinical mammalian models used in drug development: testing with human CYP3A4 specific substrates revealed differences in their metabolism between zebrafish and human. To circumvent this limitation we have generated “humanized” transgenic zebrafish using either a human Bacterial Artificial Chromosome (BAC) containing the human CYP3A4 locus or the human CYP3A4 cDNA cloned downstream of a liver specific promoter. Enzyme activity studies with the human CYP3A4 substrate, midazolam,
showed a significant increase in 1-hdyroxy-midazolam metabolite generation in
these transgenic lines compared to wild-type. The metabolic and transcriptional
response of the “humanized” fish to a set of test compounds has been compared to
that of wild-type fish. The results will be presented and discussed in the context of
the utility of the humanized line for pre-clinical safety testing.

Novel System for Express Screening of Organ/Tissue-Specific
Toxicity in Live Juvenile and Adult Zebrafish

S. Revskoy. Pharmacology, Toxicology Research Laboratory, UIC, Chicago, IL.
Sponsor: A. Lyubimov.
We propose a cost-effective high throughput-screening model for in vivo testing of
organ/tissue-specific toxicity and efficacy in real time in adult zebrafish whose internal organs/tissues are selectively labeled with an endogenously expressed fluorescent
protein, which is released into circulation upon toxic destruction of the organ/
tissue. Thus, the fluorescence can be detected in off-site tissues as a result of the fluorescent protein molecules release from damaged cells followed by the fluorescent
protein diffusion and distribution via circulation from the targeted organ to neighbor and distant tissues. This ectopic fluorescence can be detected and quantitatively
assessed in vivo by a comparison of fluorescence in the non-targeted tissue in untreated/non-transgenic fish vs. treated fish, wherein the change is indicative of the
toxic/pharmacological activity. The accuracy of detection of ectopic fluorescence
has further been enhanced by using optically transparent zebrafish strains (sheer or
casper) expressing fluorescent proteins in targeted organs, e.g. liver, pancreas, heart,
brain etc. With multiple reporter fluorescent proteins the measurements are carried
out in different spectral conditions specific for each reporter. This technology has
been tested using DEN toxicity towards liver and pancreas in transgenic zebrafish
harboring DsRed2- and GFP-tags in liver and pancreas, respectively. Transgenic
zebrafish (i.e., an optically transparent strain) with high levels of a fluorescent reporter in hepatocytes has responded to hepatotoxic compound DEN by releasing
DsRed2 fluorescent protein into circulation. As a result fluorescence has been accumulated in areas distant from the liver, such as tail, fin and others. In contrast,
DEN had no effect of GFP release from pancreas. This assay is non-invasive and
can be carried out on the same fish multiple times for monitoring time-course toxicity. The same strategy will be applied to an assessment of pharmacological effects
of antitumor drugs on syngeneic and allogeneic tumors, growing in fish.

Cytotoxicity of Natural Toxins Mediated by the Organic
Anion Transporting Polypeptide (OATP1B3)

V. Charoensuk, D. Huang, L. Xie and D. W. Kinniburgh. Physiology &
Pharmacology, Alberta Centre for Toxicology University of Calgary, Calgary, AB,
Canada.
Microcystins (MCYSTs) are natural toxins that inhibit serine-threonine protein
phosphatase. The protein phosphatase inhibition assay (PPIA) has been used in our
laboratory as a screening method to detect MCYSTs in lake water since 2007. We
recently developed a novel assay using the real-time cell analyzer (RTCA, Roche
xCELLigence) for detecting MCYST cytotoxicity. The assay is based on the fact
that MCYSTs toxicity requires the active uptake of MCYSTs into the cytoplasma
membrane which is mediated by the organic anion transporting polypeptides
(OATPs). The aims of this study were (1) to investigate differential cytotoxicities
of other natural toxins that possibly presented in water including nodularin, tautomycin, and MCYST analogues and (2) to observe the role of transporters in the
toxicities of these natural toxins.
The wild type Chinese hamster ovarian cells (CHO/WT) and CHO with
OATP1B3 expression (CHO/OATP1B3) were exposed to the toxins using the
RTCA method. After 48h of incubation, no toxic effect was observed in CHO/
WT, while growth inhibition was demonstrated in CHO/OATP1B3. Coincubation of toxins with the known substrates of OATPs, taurocholate (TC) and
bromosulfophthalein (BSP), inhibited the uptake of toxins through the OATP1B3
transporter and decreased the cytotoxic effects. The in vitro analysis of inhibition
on purified protein phosphatase, PP1, was also performed to compare the differential potencies of the toxins. Inhibition concentrations at 50% (IC50) from both
cytotoxicity and PPIA were compared.
In conclusion, we demonstrated that some natural toxins, such as nodularin, tautomycin and MCYSTs, require the active uptake by the OATP1B3 to induce cytotoxicity. The cytoxicity potencies are not necessarily related to the PP1 inhibition
potencies.

Development of an In Vitro Assay Measuring Estrogenic
Responses for Use in Chemical Safety Assessment

R. Alyea, C. Le Sommer, P. Balbuena, S. Ross, P. D. McMullen,
M. E. Andersen and R. A. Clewell. The Hamner Institutes for Health Sciences,
Research Triangle Park, NC.
To support the vision outlined in the 2007 report “Toxicity Testing in the 21st
Century: A Vision and A Strategy”, our laboratory is evaluating key cell response
networks to develop proof of concept safety assessments for a series of prototype
compounds and networks, including the estrogen receptor (ER)-mediated uterine proliferation pathway. We evaluated the ability of a human uterine epithelial
adenocarcinoma cell line (Ishikawa) to recapitulate in vitro phenotypic responses
to ethinyl estradiol (EE), including proliferation, epithelial-to-mesenchymal transition (EMT), and transcriptional activation of key ER-mediated genes (PGR,
ALPP, GREB1). Cells were treated with vehicle (ethanol; EtOH) or EE (18 doses,
10-14 to 10-6M) for 1-6 days and cell viability was measured. This phenotypic
anchor, an approximate 1.2 fold increase in cell viability, helped inform the dose
range selection of EE that caused no effect, minimal effect, or maximal effect,
which were then used to further examine transcriptional responses encompassing
several earlier time points (6, 12, 24, 72 hours) as an indicator of transcriptionally
mediated precursor events. The lowest concentration at which we observed gene
expression changes was 1pM at 12, 24, and 72 hours, the same dose at which
we observed a phenotypic effect. Interestingly, DEPTOR, a negative regulator
of mTOR, is upregulated at these low doses. EMT, an additional in vivo and in
vitro phenotypic outcome associated with estrogen signaling, occurred at doses and
times similar to those inducing proliferation (day 3; 10pM). Our results suggest
that EE induced increased cell viability, EMT, and transcriptional activation occur
at similar doses and are consistent with in vivo responses providing evidence that
Ishikawa cells are an adequate platform for evaluating estrogen mediated cellular
response networks.

A Robotic MCF-7:WS8 Cell Proliferation Assay to Detect
Agonist and Antagonist Estrogenic Activity

W. Casey1, C. Z. Yang2, M. Stoner2, G. J. Kollessery2, A. Wong2 and
G. D. Bittner2, 3. 1NICEATM, National Institute of Health, Research Triangle Park,
NC, 2CertiChem, Inc., Austin, TX and 3Neurobiology Section, School of Biology,
University of Texas in Austin, Austin, TX.
Endocrine disrupting chemicals with estrogenic (EA) or anti-estrogenic (AEA) activity have been extensively reported to possibly have many adverse health effects.
We have developed robotized assays using MCF-7:WS8 cell proliferation (or suppression) to detect EA (or AEA) of 78 test substances supplied by the Interagency
Coordinating Committee on the Validation of Alternative Methods (ICCVAM)
and the National Toxicology Program’s Interagency Center for the Evaluation of
Alternative Toxicological Methods (NICEATM) for validation studies. We also
assayed ICI 182,780, a strong estrogen antagonist. Chemicals to be assayed were
initially examined for solubility and volatility to determine optimal assay conditions. For both EA and AEA determinations, a range-finder assay was conducted
to determine the concentration range for testing, followed by a comprehensive
assay. Test substances with potentially positive results from an EA comprehensive
assay were subjected to an EA confirmation assay that evaluated the ability of ICI
182,780 to reverse chemically-induced MCF-7 cell proliferation. The AEA assays
examined the ability of chemicals to decrease MCF-7 cell proliferation induced by
non-saturating concentrations of 17β-estradiol (E2), relative to ICI or raloxifene
(RAL), also a strong estrogen antagonist. To be classified as having AEA, a saturating concentration of E2 had to significantly reverse the decrease in cell proliferation produced by the test substance in non-saturating E2. We conclude that our
robotized MCF-7 EA and AEA Assays have accuracy, sensitivity, and specificity
values at least equivalent to validated test methods accepted by the US EPA and the
Organisation for Economic Co-operation and Development (OECD).

Evaluation of the p53-Mediated DNA Damage Response
Toxicity Pathway Using Chemicals with Distinct
Mechanisms of DNA Damage

R. A. Clewell1, B. Sun1, Y. Adeleye2, P. L. Carmichael2, P. D. McMullen1,
S. Pendse1 and M. E. Andersen1. 1Institute for Chemical Safety Science, The
Hamner Institutes for Health Sciences, Research Triangle Park, NC and 2SEAC,
Unilever, PLC, Colworth Science Park, Sharnbrook, Bedfordshire, United Kingdom.
As part of a larger effort to provide proof of concept in vitro only risk assessments,
we have developed a suite of high throughput assays for key readouts in the p53
DNA damage response toxicity pathway: double strand breaks (p-H2AX), fixed
chromosomal damage (micronuclei; MN), p53 activation (p53, p-p53), p53 tran-

38     SOT 2014 Annual Meeting


scripational regulation (MDM2, WIP1, p21) and cell fate (cell cycle, apoptosis). 18 point dose-response curves were generated for protein and cell fate endpoints in a p53 competent cell line (HT1080) for 3 mechanistically-distinct chemicals: etoposide, methylmethane sulfonate, and quercetin. Gene array analysis was also performed for each chemical at 7 doses, and determined those with no effect, minimal effect, or maximal effect on MN response. Evaluation of cellular response across chemicals and doses revealed two important observations. 1) The p53 transcriptional program is chemical dependent. At similar levels of DNA damage, the three chemicals cause very different protein and cellular responses (apoptosis vs. arrest). Together with previously published CHIP-seq studies, our transcriptional data indicate that these different responses are determined very early (i.e., prior to transcriptional activation) and are likely a result of differential kinase activation and augmentation of the general p53 transcriptional response by co-regulators. 2) The p53 transcriptional response does not prevent permanent DNA damage induction at low doses. MN induction occurs at doses equal to, or lower than, doses required to activate p53-mediated gene transcription. This observation is important because it indicates that any protective effect of p53 is likely due to p53’s activity as a recruitment factor for repair proteins at the site of DNA damage. We are currently evaluating the role of post-translational p53 activities (repair center formation) in the prevention of permanent DNA damage at low chemical doses.

163 Embryonic Stem Cells Carrying a Transgenic BMP-Reporter Construct: A Useful Tool for the Identification and Analysis of Teratogenic Compounds In Vitro

Embryonic stem cells (ESC) are used as a tool for the identification of teratogenic modes of action in the analysis of chemicals or pharmaceuticals. In particular, the embryonic stem cell test (EST) has been scientifically validated previously and is now used for screening purposes. The differentiation of ESC into various tissues is regulated by a set of essential signaling pathways, including the TGF, Wnt, and Shh pathways as well as tyrosine kinase receptors mediating FGF or EGF signaling. For some of these essential signaling pathways, transgenic reporter mice have been developed that allow the in vitro analysis of pathway activity during embryonic development. We have isolated and characterized embryonic stem cells from transgenic mice carrying a EGFP transgene under the control of a BMP responsive element that has been shown to nicely recapitate in vitro BMP activity (Monteiro et al. 2008). During the differentiation of ESC into cardiomyocytes, we analyzed the differentiation process using quantitative RT-PCR, FACS, quantitative EGFP measurements, and the functional analysis of contracting cardiomyocytes. Our results show that the activity of the reporter gene can be used for the detection of teratogenic activities of valproic acid, retinoic acid, and 6-aminonicotinamide in vitro. In addition, these cells provide a useful tool to characterize the molecular mechanism underlying the activity of chemicals or pharmaceuticals on the differentiation process during early embryonic development.

164 Cyclosporin A Pharmacokinetics in In Vitro Systems

P. Bellw1n, T. Schmidt1, G. Tru1is2, C. Savary1, C. Parmentier1 and W. Deka1n1.

The immunosuppressant Cyclosporin A (CsA) is administered to reduce graft rejections after transplantation in patients, but it is also nephro-, hematopoietic diseases, and neurotoxic. Hepatotoxicity is related to elevated CsA blood levels and CYP3A4/5 activity in patients. Nephro- and hepatotoxicity can be diminished by drug monitoring and adjusted CsA administration. In this work, Cyclosporin A was used as a model compound to assess the kinetic profiles in three liver models (primary human hepatocytes [PHH], primary rat hepatocytes [PRH] and HepaRG cells) after repeated dosing. Cells were treated for up to 14 days with a high (TC10) and a non-toxic concentration (1/10th of TC10) specifically determined for each model. CsA concentrations were measured by LC-MS/MS in the treatment solutions, cell culture media, cell lysates and plastic binding samples at 5 specific time points on the first and the last treatment day. Comparisons across the models revealed three different kinetic profiles. Both PHH and HepaRG cells significantly metabolized CsA and a no bioaccumulation was observed after repeated dosing. Instead, CsA accumulated in PRH. Comparison of kinetics in HepaRG cells and PHH indicated the difference between a cell line and a primary cell culture, with the latter showing biological variability between different human donors. These results underline the interspecies difference for the CYP3A4 metabolism route between human and rat hepatocytes, which can also be observed in vivo.

165 Utilizing Human Population-Based In Vitro Model to Investigate Pesticide Mixtures and Drug/Metabolite Pairs

N. Abdo1, P. Marlot2, P. Munir2, D. Shea1, F.A. Wright1 and J. Rusyn1.

1UNC at Chapel Hill, Raleigh, NC, 2University of Liverpool, Liverpool, United Kingdom and North Carolina State University, Raleigh, NC.

A population-based human in vitro model offers exceptional opportunities for evaluating the potential hazard, mode of action, and population variability in response to chemicals. Challenges remain that require further assessment to increase the utility of the information obtained from this model. This study was designed to address two of these challenges: limited metabolic capacity of lymphoblasts and the potential to screen complex mixtures. We selected lymphoblast cell lines from 4 racially and geographically diverse populations based on availability of genome sequence and basal RNA-seq. For the mixture experiment, 146 cell lines were exposed to pesticide mixtures (organochlorine pesticide environmental mixture extracted from a passive surface water sampling device, or a mixture of 36 currently used pesticides). For the drug/metabolite experiment, we exposed 331 cell lines to Carbamazepine, Sulfamethoxazole, or two major metabolites of each drug. Concentration-response cell viability data was used to derive a 10% effect (or no-effect) level for each compound/cell line. We found that a mixture of pesticides currently in-use was less toxic but more variable than a mixture of organochlorine pesticides. A significant correlation between pesticide mixtures indicates that cells that were sensitive to one pesticide mixture were likely sensitive to the other. Significant population differences were found for the currently used pesticide mixture. For drug/metabolite pairs, we observed a wide range of inter-individual variability in cytotoxicity. Significant pairwise correlations of EC10 were found for each drug and its two metabolites. We found statistically significant and/or suggestive associations between genetic variants and cytotoxicity of each drug/metabolite. These data provide the opportunity to establish population-based confidence intervals in cytotoxicity, as well as probe candidate susceptibility pathways.

166 Toll-Like Receptor 4 Signaling Heterogeneity in Different Cell Models Can Impact Data Interpretation and Toxicity Testing

B. Franz1, M. Davidson2, N. Hibbard1 and J. M. McKim1.

1CerTox, Inc, Kalamazoo, MI and 2Kalamazoo College, Kalamazoo, MI.

Toll-like receptor (TLR) mediated pro-inflammatory signaling in response to pathogen-associated molecular patterns (PAMPs) and endogenous ligands has been implicated in a diverse array of destructive immunopathological consequences. Divergence and heterogeneity in TLR4 surface expression and signaling in immortalized cell models may present advantages or limitations in experimental applications. The aim of the present study was to evaluate TLR4 functionality in in vitro models of diverse human tissue origin: THP-1 acute monocytic leukemia, HepG2 hepatocellular carcinoma, Caco2 colorectal adenocarcinoma, and H295R adrenocortical carcinoma. LPS-mediated induction of the TLR4 pathway was assessed by seeding cells into 96-well plates at 10,000 cells/well followed by 24 hr equilibration at 37°C, 5% CO2. Cells were exposed to LPS (0.1, 1, 10, 100, 1000, and 10,000 ng/mL), an antagonist naloxone (1, 10, 100, and 1000 μM), or LPS + naloxone for a period of 24 hr. Media was collected for IL8 ELISA quantitation. The THP-1 cell line exhibited a clear concentration-response to LPS, reaching a maximum of 375 pg/mL IL8 at 10,000 ng/mL LPS. HepG2 cells showed a small increase at the highest LPS exposure (150 pg/mL IL8 at 10,000 ng/mL LPS). Caco2 (>50 pg/mL IL8 at 10,000 ng/mL LPS) and H295R (<5 pg/mL IL8 at 10,000 ng/mL LPS) cells also showed minimal effects. These data indicate concentration-dependence of THP-1 to LPS and attenuation of LPS-mediated activity by simultaneous naloxone exposure (e.g., 60 pg/mL IL8 at 10,000 ng/mL LPS + 1000 μM naloxone). IL8 expression exhibited by the other in vitro models indicates low background production of the cytokine and an apparent lack of LPS concentration-dependent upregulation. Interestingly, naloxone appears to inhibit the expression of IL8 in the absence of LPS stimulation in all cell lines tested, with the exception of the monocytic THP-1. In conclusion, selection of a cell line can greatly influence the data obtained and subsequent interpretations regarding the role of TLR4 in any observed effects.

SOT 2014 ANNUAL MEETING 39
167 Assessing Cellular Stress via Hif-1α and Nrf2 Signaling Using Protein Stability and Transcriptional Reporters
A. Landreman, M. Rober, M. Bratz, J. Wilkinson, C. A. Zimprich, J. Hartnett, B. Binkowski and M. Cong. Promega Corporation, Madison, WI.

The signaling pathways involved in the cellular stress response have been identified as useful screening targets for assessing potential compound toxicity that can be studied in a variety of in vitro cell model systems. We have used reporter gene assays to study two specific pathways involved in cellular stress response: hypoxia and antioxidant response as mediated by Hif-1α and Nrf2 transcription factors, respectively. For both pathways we tested the hypothesis that monitoring stability of the transcription factor protein directly using novel protein fusion reporters would accurately reflect changes in transcriptional activity as measured by the expression of a reporter being driven by response element containing promoters. Assessment was performed in transiently transfected human induced pluripotent stem cell (iPSC)-derived cardiomyocytes (iCell® Cardiomyocytes) followed by treatment with cobalt chloride or 1,10-phenanthroline (Hif-1α) and D.L-sulforaphane or tert-butylhydroquinone (tBHQ) (Nrf2). Results demonstrate that changes in the signal from the protein reporter consistently reflect the observed changes in transcriptional activity at similar exposure concentrations. In addition, treating HEK293 cells stably transfected with Hif-1α or Nrf2 response element reporter constructs with the chemical inducers described above demonstrate that transcriptional induction can be multiplexed with a cell viability assay allowing for direct measurement of both reporter gene and cell viability from the same assay well. As toxicity assessment efforts continue to move towards utilizing more physiologically relevant in vitro model systems, the ability to monitor cellular stress using reporters closer to the primary signaling event, such as the stability of the transcription factor protein directly, may be a useful complement to more traditional transcriptional reporter assays. In addition, the ability to multiplex reporter and viability assays may be valuable, particularly when utilizing limited cell types such as iPSC or primary cells.

168 Characterization of a 3D Scaffold-Free Culture of Human Breast Carcinoma Cells to Understand Estrogenic Endocrine Disruption
M. M. Vantangoli, S. Petren and K. Boekelheide. Pathology and Laboratory Medicine, Brown University, Providence, RI.

The use of scaffold-free agarose hydrogels provides a system in which cells form spheroids, initiating contact with other cells and the matrix. We have demonstrated the use of this system to culture MCF-7 human breast cancer cells. MCF-7 cells within this model self-aggregate and develop into differentiated spheroids, possessing a defined luminal space. As shown by transmission electron microscopy, cells in MCF-7 spheroids display tight junctions, desmosomes and apical/basal polarity. MCF-7 cells grown in 3D display increased expression of breast-differentiation markers including cytokeratin 18 (KRT18). When compared to 2D cultures, 3D cultures show a reduced fold induction of mRNA of estrogen responsive genes (GREB, PGR and CTSD) following estradiol exposure in concentration response and time course studies. The expression of e-cadherin (CDH1) was downregulated in 2D cultures following estradiol exposure. Interestingly, CDH1 mRNA was increased in 3D cultures as soon as 2 hours post-exposure as demonstrated by RT-PCR and Western blotting. We propose to use this system to assess the molecular and phenotypic changes associated with exposure to endocrine disrupting compounds (EDCs), including diethylstilbestrol, bisphenol A and genistein. The use of a differentiated scaffold-free 3D culture system offers a unique opportunity to study the phenotypic and molecular changes associated with exposure to EDCs. 3D cell culture models are intriguing due to their ability to bridge the gap between animal models and traditional 2D cell culture. 3D models allow for the growth of human cells in an environment that is closer to the in vivo environment compared to tissue culture plastic. While many 3D models rely on scaffolded matrices for the growth of cells at low densities, scaffold-free models allow cells to aggregate and maximize cell-cell contact, free of the influence of surrounding matrix.

169 Effects of Phenylethylamines on Huh-7 Human Hepatoma Cells Studied with Untargeted Global Metabolomics
T. J. Flynn, Y. Liu and S. Pugh Bishop. 1. Division of Toxicology, US Food and Drug Administration, Laurel, MD and 2.Oak Ridge Institute for Science and Education, Oak Ridge, TN.

Phenylethylamines such as β-phenylethylamine (PEA) and N,N-dimethylphenylethylamine (DMPEA) are found in products marketed as dietary supplements. While the major safety concern with this class of compounds is cardiovascular toxicity, the hepatotoxicity of some phenylethylamines such as methamphetamine and MDMA is well established. PEA and DMPEA were initially screened in Huh-7 cells at concentrations from 5 to 1000 μg/mL for 48 hours. Significant cytotoxicity was observed at 500 μg/mL and above for both compounds. PEA but not DMPEA showed a significant dose-related increase in reactive oxygen species as concentration increased. LCMS-based metabolomics studies were conducted on cells treated with PEA or DMPEA at 100 μg/mL for 48 hours. Examination of the supernatant culture medium identified several putative metabolites of both PEA and DMPEA. The most prominent metabolite for both compounds was N-phenylacetyl glutamine suggesting that the major pathway for both compounds was through oxidative de-ammoniation by monoamine oxidase to phenylacetaldelyde. Significant (p<0.05, fold change=1.5) metabolic changes in the supernatant medium from PEA treatment included increased release of mevalonic acid from the cells, suggesting increased activity of the cholesterol synthesis pathway. Significant metabolic changes in the supernatant medium from DMPEA treatment included; increased utilization by cells of amino acids from the medium for cellular function and protein synthesis pathways; and, decreased release of creatine and 1-methylhistoimtanide from cells, suggesting decreased flux through intracellular bioenergetic pathways. These findings suggest that PEA and DMPEA are extensively metabolized by Huh-7 cells and that these compounds and/or their metabolites can alter liver metabolism in ways that could lead to liver toxicity.

170 An Integrative Approach for the Prediction of Acute Oral Toxicity: Past and Future

The model presented assesses results of mechanism-based in vitro assays and relevant physical-chemical properties to predict an LD50 value, the standard measure of acute oral toxicity. The uniqueness of such a model is that it can serve multiple purposes, at a multidisciplinary level (Chemistry, Biology and Safety Evaluation): to rank-order compounds and guide the design or identification of hits for further testing, to identify potential subcellular targets and hypothetical mechanisms of acute oral toxicity, and to provide an estimate of acute oral toxicity for labeling purposes. Such a testing strategy has been implemented using a series of 57 compounds in the frame of a long-range research program with CeeTox, Inc. (SOT 2010, 2011, 2012 and 2013). The predictive performance of our model was assessed using a set of 100 public domain compounds. Chemicals were defined as toxic (T) or non-toxic (NT) on the basis of an in vivo LD50 threshold of 500 mg/kg, a value that could be acceptable for early efficacy testing. We showed that the overall concordance was above 85%, the sensitivity and the specificity being 87% and 89% respectively. To expand the applicability domain of the model and anticipate the complexity and diversity of cosmetic products, a set of reactive and non-reactive proprietary compounds was evaluated. The model remained highly predictive of the 39 chemicals categorized as non reactive (sensitivity = 83%, specificity = 94%) while for the 43 reactive compounds, the model could not be applied. This study is a clear demonstration that one way to address acute oral toxicity is to combine multiple, mechanism-based parameters and key chemical properties. However, further efforts are needed to fully handle the complexity of cosmetic ingredients. Incorporating SAR and metabolism for example, could be a way to expand the applicability domain of this model.

171 DNA Damage and Adduct Formation by Prototype Metabolic Activation-Dependent DNA-Reactive Carcinogens in Chicken Embryo-Fetal Liver
G. M. Williams1, A. M. Jeffrey1, J. Duan1, K. D. Brunnenmann1, B. Ó Horgan2, E. H. Veer3 and U. Descl4. 1Chemical Safety Laboratory, Dept of Pathology, New York Medical College, Valhalla, NY and 2Boehringer Ingelheim Pharma Gmbh & Co., Biberach an der Riss, Germany.

Prototype metabolic activation-dependent DNA-reactive carcinogens and structurally related, mutagenic, but less potent carcinogens or noncarcinogens were evaluated in the chicken egg genotoxicity (CEGA) assay, which provides a non-animal intact and aseptic test organism. In the assay, 3 daily doses, 48, 24 and 3 hr prior to termination, were administered to 9 to 11 day old embryo-fetuses and livers were harvested for measurement of two endpoints, DNA breaks using the alkaline single cell gel electrophoresis (comet) assay and DNA adducts using the N-2-hydroxy-1,4-nucleoside phosphate (NPL) assay. The effects of two carcinogens of different structures requiring distinct pathways of bioactivation, 2-acetylaminofluorene (AAF), aflatoxin B1, benzo[a]pyrene (BaP), and diethylthiuramoxide, were compared to their structurally related noncarcinogens fluorene (FLU) and benzo[a]pyrene (BeP) or...
weak carcinogens, alflaxatin B, and nitrosodiethanolamine. The four prototype carcinogens produced DNA breaks, whereas less poter carcinogens and noncarcinogens yielded borderline or negative results, respectively. AAF and BaP also produced DNA adducts, whereas none was found with FLU or BeP, consistent with comet results. Thus, the CEGA, using comet and NPL, is capable of detect- ing the genotoxicity of diverse carcinogens while not yielding false positives for non-carcinogens.

172 Genetic Deletions in Mitochondrial Cholesterol Transporters Result in Germline Defects in C. elegans

D. W. Ferreira and P. Allard. Institute for Society and Genetics, University of California, Los Angeles, Los Angeles, CA.

Basic DNA replication and mitochondrial machinery are conserved in the nem- atode C. elegans. Because of this, it is a prime organism to investigate the contribu- tions of individual mitochondrial cholesterol transporters to normal cholesterol homeostasis within the developing germline. Previous studies performed by our laboratory and others indicate that Bisphenol A (BPA) causes defects in the de- veloping germline of both C. elegans and rodents models. In C. elegans, defects are prevented by the addition of cholesterol to the treatment medium. To investigate whether inhibiting cholesterol uptake affects germline development, we have char- acterized several strains of C. elegans with null deletions in one or more mitochondri- al cholesterol transporters. Preliminary experiments in adult C. elegans lacking either functional Steroid Acute Regulator Protein (StAR) or 18kDa translocator protein (TSPO) orthologs show an increase in the incidence of apoptosis in germ cell nuclei relative to control worms as determined by acridine orange staining. Furthermore, DAPI staining of mutant worms uncovered the presence of gaps in the pachytene region of the gonad, where germ cell nuclei are normally present. Closer examination of StAR mutant worms revealed a reduction in Syp-1 (a synap- tonemal complex protein) immunofluorescence, indicating incomplete synopsis of chromosomes during germ cell meiosis. Overall fertility was also affected in these worms as measured by a decrease in total brood size. Together, the data collected in cholesterol transport mutants show similar defects in the germline as BPA treated worms. Future studies will investigate the relationship between cholesterol and BPA uptake within the germline of C. elegans.

173 Validation of the Yeast Androgen Screen for Identification of Endocrine Active Substances That Interact with the Androgen Receptor

B. van Ravenwaay1, T. Ramirez1, C. Wojtakiewicz1, H. Hiner1, C. Schönlaub1, H. Hollert2, S. Brosch1, O. Zierau1, G. Vollmer1, M. Jäger4, A. H. Poth4, Dresden, Germany, 4Harlan CCR, Rossdorf, Germany and 5University of

Humans are occupationally and environmentally exposed to large numbers of chemicals that have not been adequately tested for toxicological effects, including endocrine disrupting potential. The quantitative high-throughput screening (qHTS) paradigm has provided a more efficient and cost-effective alternative to traditional toxicity tests for profiling environmental chemicals for toxicity. The U.S. Tox21 program has screened a library of approximately 10K chemicals in three independent runs for estrogen receptor alpha (ERα) agonist and antagonist activity using two types of ER reporter gene cell lines, one with an endogenous full length ERα (ER-luc; BG1 cell line) and the other with a transfected partial receptor consisting of the ligand binding domain (ER-β; ERTr β-lactamase cell line), in a qHTS format. Concentration-response data were analyzed by three Tox21 partners (NCCG, EPA, and NTP) using different analysis approaches to determine activity. The ability of the two assays to correctly identify ERα agonists and antagonists was evaluated using a set of 39 reference compounds with known ERα activity. Although both assays demonstrated adequate (i.e. >85%) predictivity, the ER-α assay was more sensitive and the ER-β assay more specific. The qHTS assay results were compared with results from previously published ERα binding assay data and showed >80% consistency. Actives identified from both the ER-α and ER-β assays were analyzed for structure-activity relationships (SARs) revealing known and potentially novel ERα active structure classes, e.g. steroid hormones and flavonoids. The results demonstrate the feasibility of qHTS to identify envi- ronmental chemicals with the potential to interact with the ERs signaling pathway and the two different assay formats improve the confidence in correctly identifying these chemicals.

173c Developing Osteoblasts As an Endpoint for the Mouse Embryonic Stem Cell Test

The mouse Embryonic Stem cell Test (mEST) is a promising in vitro assay for detecting potent embryotoxicity; however, the addition of another endpoint may improve the predictive value of the test. Differentiation of mouse embryonic
stem cells (mESCs) to osteoblasts was examined as such an endpoint. A number of variables such as culture conditions, starting cell number and genetic background of the cell lines were investigated. Direct plating of D3 ESCs in the presence of ascorbic acid, β-glycerophosphate and dexamethasone resulted in the most consistent and robust differentiation to osteoblasts which was detectable by alizarin red staining as early as culture day 7. Differentiation continued to increase up to at least culture day 14 as indicated by levels of osteocalcin mRNA and other osteoblast lineage specific markers. The 14 day D3 culture system was then used to test the predictivity of osteoblast differentiation as an endpoint in the mEST; determination of cytotoxicity was performed as in the validated mEST using both the D3 and ST3 cell lines; osteocalcin mRNA was used as the differentiation endpoint in the osteoblast system. We have tested seven compounds used in the mEST validation experiments using the prediction model developed in the validation study. These compounds include 5-fluorouracil (CAS NO. 51-21-8), diphenhydramine hydrochloride (CAS NO. 147-24-6), metformin hydrochloride (CAS NO. 133073-73-1), lithium chloride (CAS NO. 7447-41-8), acetylamide (CAS NO. 79-06-1), valproic acid (CAS NO. 1009-66-5), and penicillin G (CAS NO. 69-57-8). Our results show that this osteoblast EST can correctly classify the embryo toxicity for all of the tested compounds. These results suggest that differentiation to osteoblasts may be used as an additional endpoint for the mEST. Future work will focus on compounds that were misclassified by the validated mEST and compounds which produce limb defects.

**173d Analysis of High-Throughput, High-Content Data in a C. elegans-Based Toxicity Assay**

To quantitatively assess the effects of chemical exposures on transcription, an automated high-throughput in vivo toxicity assay was developed. This assay measures changes in the levels and cell-specificity of expression of individual genes in C. elegans. Transcriptional responses of archetypal stress-inducible target genes were measured by qRT-PCR in response to: juglone, an oxidative stressor; N-methyl-N′-nitro-N-nitrosoguanidine, a DNA damaging agent; cadmium, a heavy metal; chlorpyrifos, an organophosphate neurotoxin; and tunicamycin, an endoplasmic reticulum stressor. Genes were selected that were significantly upregulated in response to at least one toxicant, had large dynamic ranges (i.e., low constitutive levels of expression), and demonstrated a mechanically relevant response. Individual strains of transgenic C. elegans that express fluorescent proteins under the control of cyp-35A2, gst-4, hsp-16.2, hsp-16.4, hsp-4 and mlf-2 were exposed to six concentrations of each toxicant. Fluorescence data were measured from images (N=12 per replicate) acquired using a high content imager and subsequently analyzed using CellProfiler’s Worm Toolbox; high-throughput imaging analysis software designed for use with nematodes. Image analysis yielded a large number of highly variable nematodes at each concentration. A robust Bayesian method was used to compare the fluorescent intensity in control animals to the highest concentration of toxicant for each gene/toxicant combination. Parameters describing the distributions of nematode intensities were estimated using Markov chain Monte Carlo methods, and the difference in the means of the control and treated distributions were compared. A threshold for significance was set based on the 95% highest density interval for the difference in means and visual confirmation of fluorescence. The results obtained using this novel image-based assay were consistent with the density interval for the difference in means and visual confirmation of fluorescence. means were compared. A threshold for significance was set based on the 95% highest density interval for the difference in means and visual confirmation of fluorescence. The results obtained using this novel image-based assay were consistent with the density interval for the difference in means and visual confirmation of fluorescence.

**173f A High-Throughput Microscopy Pathway in Toxicity Reporter Platform for Chemical Safety Assessment**

S. Wink, B. van de Water and S. Hiemstra. Division of Toxicology, LACDR, Leiden University, Leiden, Netherlands.

Chemicals react or interact with cellular components leading to a perturbation of signal transduction networks as the cells try to reestablish homeostasis. In case these perturbations are detrimental to cells adaptive stress responses are activated. However, if cellular stress is too severe these adaptive stress responses are unable to reestablish homeostasis and a threshold will be reached where the cell activates cell death responses to avoid cell community-level detrimental effects. We anticipate that high content imaging of critical cellular stress response hallmarks in the development of specific toxicities will be instrumental to assess toxicological hazard. To this end we have developed a set of endogenously regulated BAC-based GFP reporter HepG2 cell lines that enable the live cell visualization of dynamic responses of cellular adaptive stress response programs, including reporters for oxidative stress (Keap1, Nrf2 and Srxn1), DNA damage response (P53BP1, p53, p21 and Mdm2) and the unfolded protein response (ATF4, XBP1, BiP and CHOP). We have carefully characterized these reporters with respect to induction of GFP fusion products and dependence on the anticipated transcriptional control by RNAi mediated knockdown. Moreover, each adaptive stress response reporter is preferentially activated by their respective model compounds (oxidative stress: iodoacetamide, diethylmaleate; DNA damage: cisplatin and etoposide; UPR: thapsigargin and tunicamycin). As a next step we applied these HepG2 reporter cell lines to assess the activation of cellular stress responses by 150 compounds that are associated with drug-induced liver injury. All compounds were evaluated at 1, 5, 10, 50 and 100 Cmax and evaluated for the induction of Srxn1-GFP (Nrf2 activation) or CHOP-GFP (UPR activation). We identified specific sets of DILI compounds that strongly activate both, one or none of the stress response reporters. We anticipate that our cellular stress response reporters in combination with HCl may play a key role in future safety assessment of chemicals.

**173e Quantitative Model of Systemic Toxicity Using ToxCast and ToxRefDB**

L. Truong1, G. Ouédraogo2, S. Losel-Joubert2 and M. T. Martin1. 1EPA - NCCT, Durham, NC and 2L'Oreal, Paris, France.

EPA's ToxCast program profiles the bioactivity of chemicals in a diverse set of ~700 high throughput screening (HTS) assays. In collaboration with L'Oreal, a quantitative model of systemic toxicity was developed using no effect levels (NEL) from ToxRefDB for 633 chemicals with HTS data, chemical fingerprints, and a subset with reverse toxicokinetic (RTk) data. Floor and ceiling performance based models were generated using HCA to define clusters of similar NEL values using 4.6 OMU, a 1/5th order reduction in model uncertainty based on our performance baselines. HTS data was then incorporated into the model using 74 groups of assays based on biology (e.g. response data, gene families), technology annotation (assay mechanisms, signal directions), and assay confounders (oxidative stress, cytotoxicity). For each assay grouping, a mean activity value was computed and adjusted for confounders. Incorporating HTS data with read-across resulted in a 4.2 OMU, a total reduction in model uncertainty of 2/5th. RTk steady-state concentrations were then incorporated to adjust in vitro concentration (uM) to in vivo dose (mg/kg/day). Although RTk values were only available for a subset of the total chemical set (211), including RTk further lowered the overall model uncertainty to 3.7 OMU, roughly 3/5th of the total model uncertainty we expect to be able to reduce. Herein, we have identified a model that incorporates HTS (dynamics), read-across (chemistry) and RTk (kinetics) to predict systemic NEL, harnessing and incorporating the power of both new and existing data. This abstract does not necessarily represent EPA policy.

**173g Transcriptomic Characterization of Mouse Embryonic Stem Cell Differentiation and Its Modulation by Thalidomide**

X. Gao, J. Yourick, V. Topping, K. Belgrave and R. Sprando. Division of Toxicology, Office of Applied Research and Safety Assessment, U.S. Food and Drug Administration, Laurel, MD.

The Tox21 program calls for transforming toxicology testing from traditional in vivo tests to less expensive and higher throughput in vitro methods. In developmental toxicology, a spectrum of alternative methods has been developed including cell line based tests. In particular, embryonic stem cells (ESCs) have received widespread attention as a promising alternative model for developmental toxicity assessment. Here, we characterized gene expression changes during mouse ESC differentiation and their modulation by thalidomide. C57BL6 ESCs were allowed to differentiate spontaneously and RNA of solvent controls was collected at 0, 24, 48, 72, 96, 120 and 168 h after embryoid body (EB) formation; RNA of thalidomide-exposed EBs were collected at 24, 48 and 72 h. Samples were hybridized to Affymetrix Mouse Gene 2.0 ST Array; using a stringent cut-off criteria of Bonferroni-adjusted p < 0.05 and fold change > 2.0, a total of 1501 probesets were found differentially expressed among the solvent controls at different time points. Out of these probesets 1032 were mapped on the DAVID database as annotated genes, and gene ontology (GO) analysis showed these regulated genes were mostly involved in differentiation-related processes such as development, metabolism, morphogenesis, cell differentiation, cell organization and biogenesis, embryonic development, and reproduction. Principal component analysis (PCA) based on these genes showed that the unexposed solvent controls appeared in chronological order in the PCA plot, which when connected by the regression curve formed a differentiation track. The thalidomide-exposed cultures appeared to deviate from this differentiation track, suggesting its modulating effects on the differentiation process.
The differentiation track defined in this study may be further explored as a baseline for developmental toxicity testing, with compounds causing significant deviation from the differentiation track being predicted as potential developmental toxins.

173h Performance of the BG1Luc and ER β-Lactamase Estrogen Receptor Transactivation Assays in Tox21

L. Rinckel1, W. Casey1, R. Huang1, L. Hsieh1, K. Shockley1, M. Xia1, R. R. Tice1 and P. Ceger1.1, NIH, Durham, NC; 2JTS, Inc, Durham, NC and 3NCGC, Rockville, MD.

Two estrogen receptor (ER) transactivation (TA) assays, the BG1Luc and HEK293 ER β-lactamase (ER-blα) methods, were adapted for use in the U.S. Tox21 high-throughput screening program. Both in vitro assays detect substances with ER agonist or antagonist activity. BG1Luc endogenously expresses full-length ER (α and β) and is stably transfected with a plasmid containing four estrogen responsive elements (ERE) upstream of a luciferase reporter gene. ER-blα is a mammalian one-hybrid system stably expressing a β-lactamase reporter gene under the control of the GAL4 DNA-binding site and a fusion protein consisting of the human ERα ligand-binding domain and the GAL4 DNA-binding domain. Approximately 10,000 chemicals were tested three times in both assays in agonist and antagonist modes. To differentiate true ER agonists from cytotoxic substances, cell viability was determined. Concentration-response data (N=15) were analyzed to evaluate the performance of the two assays. The assay data quality was high in both agonist and antagonist modes as indicated by acceptable signal to background ratio (2.5 to 8), CV (<10.5%), reproducibility (outcome matches across triplicate runs, ≥0.878), and Z’ factor (≥0.4). Sensitivity and specificity of the assays were compared to ER TA performance standards that were developed with the OECD for the BG1 manual method. Sensitivity was 100% for BG1 agonist, 85% for ER-Blα agonist, and 100% for both agonist and antagonist assays. Agonist and antagonist specificity were 100% for BG1 and ER-Blα. Reference standard values were: estradiol EC50 30 pM for BG1 and 275 pM for ER-Blα, and hydroxytamoxifen IC50 71 nM for BG1 and 6 nM for ER-Blα. Understanding the differences behind the performance of these assays is critical to their acceptance and utilization by both regulators and industry. This project was funded in whole or in part with Federal funds from the NIEHS, NIH under Contract No. N01-ES-35504.

173i Functional Assays and Alternative Species: Using Larval Zebrafish in Developmental Neurotoxicity Screening

S. Padilla1, M. Callaham2, R. C. MacPhail3, D. L. Hunter1, K. A. Jarema1, K. F. Jensen1, J. Olina and A. Tennant1. 1ISTD, U.S. EPA, Research Triangle Park, NC; 2Albert Einstein College of Medicine, Bronx, NY; 3TAD, U.S. EPA, RTP, NC and VA Tech, Blacksburg, VA.

The U.S. Environmental Protection Agency is evaluating methods to screen and prioritize large numbers of chemicals for developmental toxicity. As such, we are exploring a behavioral testing paradigm, which can assess the effects of sublethal and subteratogenic concentrations of developmental neurotoxicants on 6 day larval zebrafish (Danio rerio). This assay simultaneously tests individual zebrafish under both light and dark conditions in a 96-well plate using a video tracking system. By controlling the duration and intensity of light, we are able to detect changes in locomotion during light-dark transitions, and adaptation to both light and dark during the approximate 1.5 hour testing period. Multiple chemicals at several concentrations (≥120 µM nominal concentration) can be tested in large numbers of larvae using this method. We have evaluated a training set of chemicals (22) that are generally considered positive (n=16) or negative (n=6) controls for developmental neurotoxicity in mammals. Many of the developmentally neurotoxic compounds perturbed behavior at subteratogenic doses (e.g., lead, hepta-chlor, chlorpyrifos, chlorpyrifos oxon), while many non-neurotoxic compounds did not (e.g., acetaminophen, saccharin, glycolosate). Exposure to developmental neurotoxicants altered the overall activity level in light and dark conditions, and/or the activity pattern. The zebrafish neurodevelopmental assay using this training set of chemicals had a sensitivity of 0.875 and a specificity of 0.833. The training set results, therefore, indicate that careful evaluation of zebrafish larval behavior is capable of identifying mammalian developmental neurotoxicants. This abstract may not necessarily reflect official Agency policy.

173j Effects of ToxCast Phase I Chemicals on Steroidogenesis in H295R Human Adrenocortical Carcinoma Cells

M. T. Martin1, A. L. Forrester1, D. L. Filer1 and C. Tookey1. 1ORD/NCCRT, USEPA, Research Triangle Park, NC and 2CerTox, Inc., Kalamaazoo, MI.

A delicate balance of steroid hormones is essential for proper development and reproduction. Disruption of steroidogenesis by environmental toxicants results in altered hormone levels causing adverse reproductive and developmental effects. H295R human adrenocortical carcinoma cells were used to evaluate the effect of chemicals on steroidogenesis. Using a 96-well format, cells were pre-stimulated with 100M forskolin for 48 hr to induce steroidogenesis followed by chemical exposure for 48 hr. Media were removed and 13 hormone analytes were quantified by HPLC-MS/MS including progesterone (PREG), progesterone (PROG), glucocorticoids, androgens, and estrogens. Initially, 31 unique ToxCast Phase I chemicals (primarily pesticides) were tested at a single non-cytotoxic concentration. 220 chemicals were found to alter the levels of at least one hormone analyte. Based on the single concentration analysis, 96 chemicals disrupting 46 hormones were selected for six-point concentration-response evaluation (0.006 – 100 µM). Concentration-dependent disruption of at least one hormone was observed with 68 of the selected chemicals. By evaluating the effects of chemicals on 13 hormones this assay provides valuable mechanistic insight into the possible targets for chemical perturbation in the steroidogenic pathway. For example, ≤10 chemicals altered PREG or 17αOH-PREG while 27 and 35 chemicals had an effect on PROG and 17αOH-PROG levels, respectively. These results demonstrate that the chemicals evaluated likely do not target CYP17a hydroxylase activity. However, 33 chemicals altered testosterone levels and 38 chemicals concentration-dependently altered estradiol levels revealing significant disruption of subsequent dehydrogenation and aromatization steps. Cumulatively, these results suggest CYP17a lase and hydroxysteroid dehydrogenase activity are the most likely targets for the disruption of steroidogenesis by the subset of ToxCast Phase I chemicals evaluated. This abstract does not necessarily reflect USEPA policy.

173k In Vitro Safety Profile of Personal Care Products—Use of an In Vitro Testing Platform Based on a Reconstructed Vaginal Tissue Model

C. Moudgal1, L. Strazdas1, D. Sheehan2, D. Wolfeinger2, N. Wilt3, G. Costin4, S. Ayehunie5 and A. Armento1. 1The Clorox Company, Pleasanton, CA; 2Institute for In Vitro Sciences, Inc. (IIVS), Gaithersburg, MD; and 3MatTek Corporation, Ashland, MA.

One of the common goals of this industry is to confirm the safety of their products. Ethical concerns have led to the use of alternative testing methods in lieu of tradi- tional testing methods. Several studies have shown good correlation between alter- native test methods, traditional testing methods and human exposure. In the current study, the safety profile of three products with potential for vaginal exposure was assessed using the reconstructed human vaginal EpiVaginal™ model (MatTek Corporation, USA); the assay negative control (sterile, deionized water) and positive control (1% Triton® X-100) were tested alongside. To increase the confidence in the test outcome, histopathology evaluation was conducted to assess the extent of cellular damage. Two liquid products were directly applied to the EpiVaginal™ tissues, while the wet wipe product was placed in direct contact with the tissue. Vaginal irritation expressed as ET50 values (3.32 and 12.71 hours) showed a higher irritation potential for the liquid formulations compared to the wipes (24 hours). The lower irritation potential of the wipe product may be related to the availability of a rather limited amount of the liquid formulation in the wipes compared to the liquid formulations. Histology evaluations showed good correlation between the ET50 and change in tissue structure. The results of this in vitro test methodology confirmed the safety profile of the products, should vaginal exposure occur during use. This two-endpoint testing platform (viability and histology) provided not only a correlative interpretation of the data, but also indication of the structural changes of the tissues exposed to the test article that are relevant to human exposure. Future plans include further exploring the capability of this in vitro testing platform for screening products before entering clinical trials.

173l Chemotherapeutic Class-Specific Neurotoxic Effects on Rat DRG Cells Using High-Content Analysis

H. Behrsing1, F. Cutili1, J. Hamre1, M. A. Davis1 and L. Guo1. 1Leidos Biomedical Research, Inc., Frederick, MD and 2Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD.

We exposed primary rat dorsal root ganglion (DRG) to peripheral neuropathy (PN)-causing drugs and evaluated cell-based changes using high content analysis (HCA). Neuron-specific BIII tubulin was stained along with other cell markers

SOT 2014 ANNUAL MEETING 43
to evaluate subcellular changes following DRG culture exposure to PN-causing drugs. Cultures consist of mostly non-neuronal cells (e.g., Schwann and satellite cells), but neuronal and support cell growth is highly interlaced. Nuclear, neu- rite/process (N/P), and Nissl changes were evaluated at 0, 24 or 72 hr following drug exposure (0.003-30 μM, 24 hr). Drug inter- and intra-class-specific changes were identified for anti-tubulin drugs (hyperstabilizers and destabilizers), alkylating agents, a proteasome inhibitor, and other anti-cancer drugs (doxorubicin, lapatinib, birinapant, and thalidomide). Destabilizers all caused varying loss of N/P and Nissl area staining, but drug-specific variations on other marker responses were found. Hyperstabilizers caused mild N/P loss, increased alpha tubulin intensity, de- creased Nissl area, but had no effect on Nissl intensity. At 10 and 30 μM, cisplatin and oxaliplatin (but not carboplatin) caused Nissl marker changes, but N/P and cell loss was delayed. At different concentrations doxorubicin and lapatinib caused similar nuclear, Nissl, N/P, and cell loss. Thalidomide and birinapant caused no significant changes at any concentration tested. Interestingly, different classes of drugs showed differential effects on non-neuronal cells. The use of HCA with specific markers has allowed us to class-rank the drugs tested. Moreover, this complex culture model demonstrates concordance with reported morphological changes induced by these classes of agents in vivo. Funded by NCI Contract No. HHSN26120080001E.

173m Effect of Nicotine on Zebrafish Embryos: High-Content Analysis to Assess Developmental Toxicity

Zebrafish embryos represent one of the only vertebrate model systems amenable to high throughput toxicity screening. Nicotine, a drug of abuse, has been reported to have many adverse effects on the developing nervous system. Several studies have shown that zebrafish adults and embryos are ideal for monitoring nicotine effects. Previously, we reported that nicotine alters the expression of biomarkers of endocrine function in zebrafish embryos. This observation is concordant with mammalian and human data depicting nicotine as an agent that can modulate hormone levels. Additionally, nicotine exposure has been shown to affect the ner- vous system of zebrafish larvae and juveniles generating abnormal arborization of axons, suggesting a defective path-finding signaling process. Here, we report auto- mated fluorescent image acquisition of hhb-GFP transgenic embryos that express green fluorescent protein as a reporter in their motoneurons and axons, to detect nicotine’s effects. The experiment is performed in vivo using embryos arrayed in 384-well plates. Post-acquisition image analysis provides average motoneuron axon lengths for control and experimental groups. The data show no significant dif- ference in the ventral axon length between the control and the nicotine-treated groups when the embryos were treated at 28 hours post-fertilization for 24 hours. However, nicotine-treated embryos were slightly and significantly smaller than the controls. These observations are in agreement with previous studies reporting that nicotine promotes arborization (axon pathfinding) but does not have any drastic effect on axonogenesis. Protocol # E0735901.1

173n 4-Vinylcyclohexene-Induced Changes in Gene Expression and Antioxidant Status Is Mediated via Oxidative Stress in Drosophila melanogaster
A. O. Abolaji1,2, J. P. Kamdém3, T. H. Lugokenskia2, T. K. Nascimento2, E. P. Waczuk2, E. O. Farombi1 and J. B. Rocha2. Department of Environment, National Institute for Occupational Safety and Health (NIOSH), Morgantown, WV, 1Department of Biochemistry, University of Complutense de Madrid, Madrid, Spain. 2Department of Biochemistry, University of Ibadan, Ibadan, Nigeria and 3Duke University, Durham, NC.

4-Vinylcyclohexene (VCH) is a by-product of pesticides, plastic, rubber, flame-retardants and tyre productions. The ovotoxicity of VCH has been reported in animal models. However, there is dearth of information on the possible involvement of oxidative stress in the toxicity of this occupational chemical. Thus, this study was designed to investigate the effect of VCH on selected genes expressions, antioxidant status and oxidative stress markers in Drosophila melanogaster model. Flies (both genders) of 1- to 3- days old were orally treated with different concentrations of VCH (10 μM-1mM) in the diet for 5 days. Subsequently, the survival and negative geotaxis assays in the flies were determined, as well as the quantification of reactive oxygen species (ROS) generation. In addition, the real time RT-PCR expressions of selected oxidative stress and antioxidant mRNAs genes of HSP27, 70 and 83, SOD, Nrf2, MAPK and catalase were determined. Furthermore, we evaluated selected enzyme concentrations such as catalase, GST, δ-ALA-D and acetyleholinesterase (Ache). Our data showed that VCH oral exposure is accompanied by the reduction in negative geotaxis. Also, VCH caused significant inductions of the mRNA of SOD, Nrf2 and MAPK genes expressions, which was associated with increased ROS production, altered activities of antioxidant enzymes (GST and catalase), and inhibition of δ-ALA-D and Ache concentrations (p < 0.05). These data imply that, VCH mechanism of toxicity is mediated by oxidative damage, as evidenced by the alteration in the oxidative stress-antioxidant balance. Thus, D. melanogaster has provided further insights into the mechanism of VCH-induced toxicity.

173o Similar Toxicity of Three Fluorocompounds to the Nematode Caenorhabditis elegans
W. A. Boyd1, J. R. Rice1, D. Chandra2, M. Smith1, P. K. Den Besten2 and J. H. Freedman1. 1NIH, Research Triangle Park, NC, 2UCSF, San Francisco, CA and 3Social & Scientific Systems, Inc., Durham, NC.

Fluorides are commonly added to drinking water in the United States to de- crease the prevalence of dental caries. However, the use of fluorides in drinking water has been controversial, primarily due to unresolved toxicological questions. Silicofluorides, such as sodium hexafluorosilicate (Na,SiF₆) and fluoroalumic acid (H₃SiF₆), are the compounds most used for fluoridation, although fluoride salts such as sodium fluoride (NaF) are also used. Interestingly, only the toxicity of sodium fluoride has been examined and not that of the more often-used sili- cofluorides. In the present study, the toxicities of sodium fluoride, sodium hexa- fluorosilicate, and fluoroalumic acid were compared in the alternative toxicological testing organism Caenorhabditis elegans using three quantitative, high-throughput toxicological assays: growth, reproduction, and feeding. Within each assay, the toxicities of the three fluoride compounds varied considerably when expressed as millimoles of compound, seemingly indicating that sodium fluoride was less toxic than the silicofluorides. However, both silicofluorides contain 6 fluoride ions per molecule. Thus, when toxicity was expressed in parts per million (ppm) fluoride, all three fluoride compounds produced concentration–response toxicity profiles with almost identical EC50s and LECs, suggesting that silicofluorides have toxicities similar to sodium fluoride.

173p Using Acute Toxicity, Transcriptomics, Metabolomics and Lipidomics to Understand Effects of Chemical Flame- Retardants on Eco-Indicator Daphnia magna
L. D. Scanlan1, A. Loguinov1, P. Antczak2, Q. Teng3, H. Stapleton4, F. Falkam6 and C. Völkel6. 1U.C. Berkeley, Berkeley, CA, 2University of Liverpool, Liverpool, United Kingdom, 3Duke University, Durham, NC and 4United States EPA, Athena, GA.

The effects of legacy flame-retardant (FR) chemicals octa and penta brominated diphenyl ether (PBDE) and pentaBDE replacement formulation Firemaster550® (FM550) were analyzed on freshwater crustacean Daphnia magna, an ecological keystone species used in fresh water quality assessment. Acute 48-hour LC50 values were determined for penta and octaBDE and for five FM550 formulations and related compounds: FM550, bis (2-ethylhexyl) tetraborophosphate (BEH-TEBP), triphenyl phosphate (TPHP), Firemaster® BZ-54 (BZ54) and the non-brominated BEH-TEBP analog bis (2-ethylhexyl) phthalate (BEHP). Microarray transcriptomics, HNMR-based metabolomics, and lipidomics were utilized to investigate mode of toxicity. Nominal LC50 values ranged from 58 μg/L (pentaBDE) to 3.96 mg/L (octaBDE) and were not correlated to LogKow. Microarray gene expression analyses performed at 1/10 LC50 found that BEH-TEBP and BZ54 caused similar gene expression patterns while the responses to other FRs were distinct. OctaBDE, BZ54 and BEH-TEBP caused changes in the expression of signal transduction genes located in the cellular membrane, but affected different signal systems and therefore caused different biological effects. PentaBDE affected protein synthesis and turn-over and FM550 appeared to cause nutritional dysregulation. Results indicate that hydrophobic FR compounds affect Daphnia in unique ways, not via a general narcotic mechanism.

174 Exposure to 2, 3, 7, 8-Tetrachlorodibenzo-p-Dioxin (TCDD) Induces Expression of Prostaglandin E2 Receptor 4 (EP4) Gene in the Developing Anteroventral Perventricular Nucleus (AVP)
I. Del Pino Sam1,2 and S. Peterson1. 1Veterinary and Animal Sciences, University of Massachusetts, Amherst, MA and 2Toxicology and Pharmacology, Universidad Complutense de Madrid, Madrid, Spain.

Developmental exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) interferes with masculinization of gonadotropin release patterns, most likely by blocking estradiol (E2)-dependent sexual differentiation of the anteroventral periventricular nucleus (AVP). The process of sexual differentiation involves both cell death and alterations in neurite outgrowth, but the underlying molecular mechanisms are unclear. It has been reported that dendritic spine number and shape is modified...
by TCDD. PGE2 induces formation of dendritic spines on preoptic area (POA) neurons through its EP receptor interaction. EP receptors have been implicated in sexual differentiation of dendritic outgrowth and synaptogenesis in other brain regions, and neonatal activation of EP2 and EP4 receptors are both necessary and sufficient for the organization of male sexual behavior in the preoptic area (POA). To date, no work has examined whether similar processes specifically regulate differentiation of the AVPV, a nucleus in the rostral POA. To determine whether these EP receptors are altered by TCDD in the AVPV, we administered vehicle or TCDD 600 ng orally to rat dams on the first post-partum day. Pups were euthanized the following day (PND2) and AVPV regions microdissected from frozen sections. Using QPCR, we found that only the EP2 and EP4 receptors were differently expressed in both sexes and only EP4 receptor was significantly upregulated by TCDD in males. These findings suggest that TCDD may interfere with masculinization of the AVPV by increasing EP4 receptor.

Neonatal Exposure to Pesticides in Mice Alters Neuroprotein Levels Important for the Developing Brain

Pesticides are used for plant protection and are divided into different chemical classes. In this study we investigate developmental neurotoxic effects of three different classes of pesticides; organophosphate (chlorpyrifos), carbamate (carbaryl) and organochlorine (endosulfan). It has been recognized that the developing mammalian brain has critical periods when the brain is more sensitive to toxic insults. When these insults occur during a period of rapid brain growth they can cause developmental neurotoxic effects and may alter adult susceptibility to other toxicants. Therefore, timing of exposure is of significance.

We have recently seen that these pesticides can induce behavioral neurotoxic effects. Therefore the aim of the present study was to explore if neonatal exposure to these pesticides can affect neuroprotein levels e.g. calcium/calmodulin-dependent kinase II (CaMKII), growth-associated protein-43 (GAP-43), glutamate receptor-1 (GluR1), postsynaptic density protein 95 (PSD95), synaptophysin and tau, which are important for normal development, of the mouse brain. Male NMRI-mice were exposed, on postnatal day 10, to a single oral dose of 5 mg chlorpyrifos/kg bw, 0.5-20 mg carbamate/kg bw or 0.1-0.5 mg endosulfan/kg bw and control animals received a 20% fat-emulsion vehicle. The animals were euthanized 24h after exposure and the neuroprotein levels in hippocampus and cerebral cortex were analyzed. Significant increased levels of GAP-43, GluR1 and tau, and significant decreased levels of CaMKII and synaptophysin compared to control was seen. The neurotoxic effects differed between the brain regions. The results from the present study show that a single oral exposure to pesticides, during a critical period of brain development, can cause developmental neurotoxic effects, shown as changed neuroprotein levels. The neurotoxic effects are in line with previous behavioral studies. Further investigations on the developmental neurotoxic effects of pesticides are needed to understand the mode of action and assess the effects of low dose interaction of mixtures.

Arsenic Inhibits Hedgehog Signaling during P19 Cell Differentiation

J. Liu1 and J. L. Bain1, 2. Biological Sciences, Clemson University, Clemson, SC and 2Environmental Toxicology, Clemson University, Clemson, SC.

Arsenic is a toxicant found in ground water the world, and human exposure mainly comes from drinking water or from crops which are irrigated by contaminated water. It can be leached into a liquid that comes in contact with plastics, suggesting concerns about the health risk of human exposure. Previous animal studies have suggested that maternal exposure to phthalates during fetal and/or neonatal periods may cause reproductive and developmental toxicities in offspring due to their actions as endocrine disrupting chemicals (EDCs). DEHP is converted to the presumed toxic metabolite, MEHP, by lipase enzymes in the gastrointestinal tract. Upon ingestion, DEHP is rapidly metabolized to MEHP by pancreatic lipases in the lumen of the gut in both rodents and humans, before being further converted into oxidative metabolites and glucuronidated for excretion in the urine and faeces. Since DEHP is converted to MEHP in the gastrointestinal tract, it remains unclear whether DEHP is harmful to fetal brain development by parenteral routes of exposure. We therefore gave DEHP to pregnant Sprague-Dawley rats by gavage and to assess whether DEHP have direct impact on the neural cells viability and patterning of dendrites in fetal rat. DEHP treatment results in induction of oxidative stress leading to disrupt the developmental processes of the central nervous system. MTS was used to examine DEHP reduce dose dependent cell viability. With using immunofluorescence microscopy, malformation of neural morphology in fetal brain was detected. Therefore, our data summarized that DEHP is cytotoxic to the fetal neural cells and requires induction of ROS to exert their developmental alternation effects.

Contribution of DEHP in Malformation of Fetal Brain Development

C. Tsen1, 2, 3, Y. Chuang1, Y. Yang2, S. Tong2, Y. Chen1, Y. Chang1, C. Lin1 and M. Chan1, 2, 3. 1Biocience Technology, Chung Yuan Christian University, Chung-Li, Taiwan and 2Center of Nanotechnology, Chung Yuan Christian University, Chung-Li, Taiwan.

DEHP, Di(2-ethylhexyl)phthalate, a phthalate plasticizer used most often in the world. It can be leached into a liquid that comes in contact with plastics, suggesting concerns about the health risk of human exposure. Previous animal studies have suggested that maternal exposure to phthalates during fetal and/or neonatal periods may cause reproductive and developmental toxicities in offspring due to their actions as endocrine disrupting chemicals (EDCs). DEHP is converted to the presumed toxic metabolite, MEHP, by lipase enzymes in the gastrointestinal tract. Upon ingestion, DEHP is rapidly metabolized to MEHP by pancreatic lipases in the lumen of the gut in both rodents and humans, before being further converted into oxidative metabolites and glucuronidated for excretion in the urine and faeces. Since DEHP is converted to MEHP in the gastrointestinal tract, it remains unclear whether DEHP is harmful to fetal brain development by parenteral routes of exposure. We therefore gave DEHP to pregnant Sprague-Dawley rats by gavage and to assess whether DEHP have direct impact on the neural cells viability and patterning of dendrites in fetal rat. DEHP treatment results in induction of oxidative stress leading to disrupt the developmental processes of the central nervous system. MTS was used to examine DEHP reduce dose dependent cell viability. With using immunofluorescence microscopy, malformation of neural morphology in fetal brain was detected. Therefore, our data summarized that DEHP is cytotoxic to the fetal neural cells and requires induction of ROS to exert their developmental alternation effects.

Developmental Vulnerability of Rat Hippocampal Neural Stem Cells to the Neurotoxicant Methylmercury (MeHg)

M. Obiorah1, K. B. Sokolowski2 and E. DiCicco-Bloom1, 2. 1Neuroscience and Cell Biology, Rutgers RWJMS, Piscataway, NJ and 2Toxicology, Rutgers University, Piscataway, NJ. Sponsor: J. Richardson.

The developing brain is sensitive to environmental neurotoxicants such as methylmercury (MeHg), to which humans are exposed via tainted seafood. Studies implicate association of perinatal exposure with learning, memory and IQ deficits in children, suggesting hippocampal dysfunction. Using single-cell analysis, we showed that after 24 hours, a single, low exposure (0.05/1g) adversely affects neurogenesis in postnatal day 7 (P7) rat hippocampus (akin to 3rd trimester in humans), a period of major neural stem cell (NSC) proliferation. NSC proliferation continues but wanes during prepubescence (P14) and adolescence (P21). Yet, the period of developmental vulnerability and lasting consequences of exposure on future neurogenesis remain undefined. To define developmental vulnerability, we injected s.c P14 and P21 rats once with a low or high (5ug/g) MeHg dose and sacrificed 24h later, pulsing with S-phase marker EdU 2h before sacrifice. S-phase cells at P14 were not vulnerable to the low dose, but the high dose reduced mitotic cells in the dentate gyrus hilus by 29% without inducing cell death (cleaved caspase-3) or altering the size of the intermediate neural progenitor pool (Tbr2+ cells). These results indicate that P14 rats retain some vulnerability to MeHg. In contrast, P21 exposure (24 or 48 h) had no effect on S-phase cells nor apoptosis at either time point. To determine long-term effects of early exposure, P7 rats were injected once with MeHg and assessed with BrdU analysis. Significant increased levels of GAP-43, GluR1 and tau, and significant decreased levels of CaMKII and synaptophysin compared to control was seen. The neurotoxic effects differed between the brain regions. The results from the present study show that a single oral exposure to pesticides, during a critical period of brain development, can cause developmental neurotoxic effects, shown as changed neuroprotein levels. The neurotoxic effects are in line with previous behavioral studies. Further investigations on the developmental neurotoxic effects of pesticides are needed to understand the mode of action and assess the effects of low dose interaction of mixtures.

Human Embryonic Stem Cells and Their Neuronal Descendants Exhibit Differential Sensitivity to PBDEs

J. F. Robinson, N. Larroque, M. McMaster and S. J. Fisher. Department of Obstetrics, Gynecology, & Reproductive Sciences, University of California, San Francisco (UCSF), San Francisco, CA.

Polybrominated diphenyl ethers (PBDEs) are ubiquitous environmental pollutants of major concern due to their possible effects on human neurodevelopment. At a cellular level, the potential mechanisms include disrupting proliferation and dif-
fermentation, perturbing thyroid hormone signaling, and/or generating oxidative stress. Additional studies are needed to understand the molecular bases of PBDE-induced neurotoxicity and the potential developmental risks associated with these exposures. Knowledge gaps include: 1) PBDE effects in human model systems; and 2) windows of vulnerability to PBDE exposure. In this study, we used human embryonic stem cells (hESCs; UCSC4) and their progeny, neuronal progenitors (NPGs), to investigate the dose-dependent effects of two commonly used PBDE congeners (BDE-47 and -99). The approaches included a combination of assays for assessing cell viability, death, proliferation, differentiation and thyroid hormone receptor (THRA, THRB) expression. PBDEs had dose-dependent toxic effects on both cell types with NPGs exhibiting greater sensitivity than hESCs. NPG responses included reduced expression of FOXA, a transcriptional regulator of neural development. In line with previous studies using rodent cell models, BDE47 and -99 significantly reduced THRA and increased THRB expression in NPGs. For example, 25 μM BDE47 and -99 exposure for 24 h upregulated THRB mRNA levels by 22- and 18-fold, respectively. In summary, our results imply that human exposures to PBDEs during the early embryonic period may alter neurogenesis and that sensitivity varies during development. Follow-up studies are focusing on the mechanisms underlying differences in sensitivity of hESCs vs. NPGs and the relevance of our results to human in vivo brain development.

180 Alterations of Postnatal Development of Feedback Inhibition and Basic Excitability in the Hippocampus of Rats Prenatally Exposed to Valproic Acid

Y. Fueta1, Y. Sekino2 and S. Ueno1. 1Department of Environmental Management and Control, University of Occupational and Environmental Health, Kitakyushu, Japan, 2Division of Pharmacology, National Institute of Health Sciences, Tokyo, Japan and 3Department of Occupational Toxicology, University of Occupational and Environmental Health, Kitakyushu, Japan.

There is a concern about the impact of exogenous chemical substances on the neuronal development of children. Current developmental neurotoxicity guideline (TGC426) is mainly based on zebrafish animal studies such as behavior and patholog-ical examinations, without any electrophysiological testing. Valproic acid (VPA), used as an antiepileptic drug and a mood stabilizer, is known to produce animal models of autism spectrum disorder. We aimed to clarify whether prenatal VPA affects early postnatal development of neuronal circuitry with our electrophysiological approach. VPA was orally administered to the pregnant day 15 Wistar rats with different concentrations of 0 (control, saline only), 150, 300 or 600 mg/kg. On the days of PND 13, 14 and 15, field potentials were recorded from the CA1 area of hippocampal slices obtained from the control and VPA groups to test development of the local circuits. Stimulation/response curves of field excitatory postynaptic potential and those of population spike (PS) enhanced at PND14 and 15 in the VPA-300 group, indicating an enhancement of spike generation or glutamatergic synaptic transmission. The ratios of paired-pulse responses of PS were almost equal to 1 in the control group, showing a lack of feedback inhibition, but decreased in the VPA-300 group from PND15 to 15, suggesting a developed feedback inhibition. Our results provide the evidence that prenatal VPA exposure enhances inhibitory circuits and then potentiates basic excitability in the hippocampal CA1 area. The present results were similar to those obtained from prenatal exposure to an industrial chemical 1-bromopropane, suggesting its electrophysiological evaluation may be useful for developmental neurotoxicity to predict producing a neuropathology after growth.

181 Neurobehavioral Effects of Developmental Exposure to 2, 2', 4, 4'-Tetrabromodiphenyl Ether (BDE-47) and Mechanistic Exploration Using Whole-Genome Transcriptional Profiling

D. E. Haggard, M. T. Simonich, L. Truong, S. M. Buel, B. C. Goodale and R. L. Tanguy. Department of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR

Polybrominated diphenyl ethers (PBDEs) are a class of high production volume flame retardants used in a variety of consumer products that are considered ubiquitous environmental pollutants. 2,2',4,4'-tetrabromodiphenyl ether (BDE-47) is one of the predominant PBDE congeners found in environmental and biological samples. Developmental exposure to PBDEs, including BDE-47, is associated with neuronal and developmental effects in humans and wildlife; however, the exact mechanism is unknown. We utilized the embryonic zebrafish to assess the development and neurobehavioral responses induced by developmental BDE-47 exposures. Zebrafish were exposed at 6 hours post fertilization (hpf) and general mortality and malformation were assessed at 24 and 120 hpf. We subsequently examined the effects of BDE-47 exposure on photo-motor response in 24 hpf embryos using our lab-derived Photo-motor Response Assessment Tool (PRAT), and we investigated effects on 120 hpf photo-induced larval locomotion using the ViewPoint Zebrafish system. We also ascertained the consequences of developmental BDE-47 exposure on adult zebrafish cognitive development using an active avoidance learning assay. Developmental exposure to BDE-47 up to 20μM resulted in no overt toxicity. BDE-47 exposure led to a dose-dependent increase in activity in the locomotor assay. Adult zebrafish cognition was negatively affected by developmental BDE-47 exposure, as measured by a decrease in the learning rate in the active avoidance task. To explore the mechanism by which early life-stage BDE-47 exposure initiates the observed behavioral effects, whole transcriptome RNA sequencing was performed on embryonic zebrafish exposed from 6-48 hpf. We observed distinct gene expression changes induced by BDE-47 compared to control animals, and functional analyses revealed possible mechanisms important in the behavioral effects of BDE-47.

182 An Automated High-Content Screen for Migration of Neural Crest Precursor Cells

Cell motility is fundamental to development of neural-crest-derived structures in the embryo. Using neural crest stem cells (NCSCs) derived from induced pluripotent stem cells (iPS) cells, we developed a scalable high content screening (HCS) assay to measure the effect of chemicals on NCSC migration. The assay format involves “scratching” a confluent cell monolayer with a Teflon-coated pin tool (V&P Scientific, CA). In order for the assay to be routinely performed on hundreds of test chemicals, the pin tool incorporates 384 elements so that each well is scratched in parallel and reproducibly. The pin tool creates a cell-free region in each well that is 600 microns in diameter. Importantly, “scratching” did not appear to damage the culture surface, which might prevent cell migration due to removal of serum proteins or introduction of grooves running perpendicular to the cell borders. We showed that removal of the cells with the pin tool was spatially consistent well-to-well enabling automated image analysis to assess cell migration into the cell-free region. In order to control for false positives (i.e. pro-proliferative chemicals that lead to an increase in cell count within the cell-free region and cytotoxic chemicals (i.e. chemicals that lead to overall cell loss), cell density outside of the “scratched” region was measured and compared to neutral controls. The scalability of this assay enabled us to rapidly screen the NC22 library of FDA-approved drugs as well as several reference compounds such as Cytochalasin D and paclitaxel. Not only did the imaging-based format of this assay enabled large-scale screening via fixed-end-point screening, but it also allowed follow-up screens that incorporated staining for markers such as Sox10, and in some cases live-cell imaging to measure alterations in directional persistence for individual cells.

183 Molecular Analysis of Rat Palatal Development

J. Wright1, I. Vicharos-Rodriguez1, J. Dixon1, M. Rattray1, E. Barnes2 and M. J. Dixon1. 1Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom and 2Jealott’s Hill International Research Centre, Syngenta, Bracknell, United Kingdom.

Development of the secondary palate involves cell growth, adhesion, differentiation and apoptosis. Cleft palate, which results from failure of these processes, involves interplay between teratogenic and genetic factors. A diverse range of molecules increases the incidence of cleft palate in the rat, data derived from this species are used in human risk assessment during development of New Chemical Entities. A deeper understanding of the molecular perturbations that lead to cleft palate would refine the utility of the rat in assessing risks to human health. Rat palatal shelves initiate from the maxillary processes on embryonic day (E)13 and grow lateral to the tongue during E14 and E15. During E16 the palatal shelves re-orientate to a horizontal position above the tongue and fuse via their medial edge epithelia by E17. While it is believed that the molecules driving palatogenesis in the rat are identical to those underlying mouse palatal development, this assumption has not been verified. To profile the genes expressed during palate development, we performed RNA-seq analysis of palatal shelves dissected from rat embryos at eight developmental stages between E14.5 and E17 and recovered ~90 μg of RNA from each pair of palatal shelves. Sequence analysis generated an average of 54 million reads from each sample, ~85% of which mapped to unique positions in the rat genome. To calculate gene expression levels we mapped reads to the transcriptome and used a Bayesian deconvolution algorithm to infer transcript expression levels. Transcript levels for each gene were combined to obtain gene expression levels which showed a dynamic range of five orders of magnitude. Strong, temporally-coherent signals were observed for thousands of genes. Comparison of the expression profiles of a subset of genes that play an essential role in mouse palate development with their rat orthologues indicated similar expression patterns suggesting that the principal underlying pathways are conserved between mouse and rat.

Congenital heart defects and cardiovascular disease cause significant morbidity and mortality. Researching heart formation will increase our understanding of the processes that underpin these conditions. Our research has focused on the epicardium, the epithelial layer that covers the heart. Epicardial cells (EPDCs) migrate into the myocardium where they differentiate into fibroblasts and smooth muscle cells essential for the development of the coronary vasculature. EPDCs also provide signals required for myocardial proliferation and functionality. However, the precise mechanisms that regulate epicardial cell biology remain unclear.

The EHC mouse has a recessive embryonic lethal mutation in Myh10, and as a consequence develops multiple cardiac defects, including abnormal epicardial cell morphology and no functional coronary network. The localization of Wilms Tumour 1 (WT1), a marker of both epicardial cells and EPDCs, was explored using immunohistochemistry (IHC). Embryonic day 14.5 EHC embryos were genotyped by DNA sequencing: hearts were frozen and sectioned using a cryostat. Sections were stained using an anti-WT1 rabbit polyclonal antibody and fluorescence labeled anti-rabbit secondary antibody. Abnormal clusters of WT1 positive cells were observed at the interface between the epicardium and myocardium, suggesting EHC and EPDCs have reduced ability to migrate into the subepicardial space. We are currently investigating the cell specific requirement for Myh10 by generating myocardi al Myh10 knock out embryos (MHC Creflox/flox). Initial IHC results show NMIIB protein localisation is reduced in the embryonic myocardium, indicating Myh10 ablation in cardiomyocytes. Preliminary data indicates that Myh10 expression in cardiomyocytes is not required for coronary vessel development. The findings in the EHC mutant will improve our understanding of the complexities of embryonic coronary vessel development and the potential for abnormalities to arise.

Intravenous Infusion in the Juvenile Rat

L. Allais, N. Truchot, P. Vignaud, S. David, D. Ravelo and J. Briffaux, WIL Research Europe-Lyon, St Germain-Nuelles, France.

Toxicology studies in juvenile animals are part of non-clinical development of pediatric therapeutics and could be conducted in various species, the rat still being the most commonly used species. Most of the administration routes are technically feasible in the juvenile rat but more complex methods of administration, such as intravenous infusion, require challenging design adaptations. A feasibility study was first performed in close collaboration with our animal welfare group to develop continuous intravenous infusion in the juvenile rat surgically implanted with a catheter on postnatal day (PND) 21. Following anaesthesia with isoflurane, a catheter was implanted into the posterior vena cava via the femoral vein. The pups were continuously infused (24 h/day) with sterile physiological saline for 4 weeks. The technical challenges, such as the length of the catheter and the implantation site, associated with infusing a juvenile rat during a phase of rapid growth were investigated. The feasibility study was then followed by a complete juvenile study using a higher number of animals (20 males and 20 females). Half of the rats was necropsied at 7 weeks of age after the end of the 4-week infusion period and the other half was retained without further infusion for up to 11 weeks of age. Standard toxicity and developmental endpoints such as clinical observations, growth, food intake, clinical pathology, sexual maturation, auditory and pupillary reflexes were evaluated throughout the study. Two behavioral tests (open field and water maze) were also conducted during the observation period. The in-life results were compared with background data from non-catheterized animals at a similar age and histology results at 7-week and 11-week sacrifice time-points were compared with those from catheterized rats used in general toxicology studies.

The present evaluation demonstrated that a 4-week continuous intravenous infusion period is feasible using equipment, procedures and welfare practices adapted to the juvenile rat and did not interfere with the growth or development from PND 21 to 11 weeks of age.

Social Housing of Mature Males in a Nonhuman Primate Breeding Program

S. M. Henwood, J. Edwards and F. Gruenig, Toxicology, Covance Laboratories Inc., Madison, WI.

The cynomolgus monkey (Macaca fascicularis) is the preferred species for nonhuman primate (NHP) developmental toxicity studies for biopharmaceuticals. Social housing of NHPs has become mandatory in many countries. The revised USDA regulations require social housing of all social species, which includes NHPs. Although social housing of females and juvenile male NHPs is easily achieved, pair-housing of sexually mature adult males is considered challenging and even more so for male breeder animals. We have implemented a Three Pillar Concept for conducting developmental toxicity studies in NHPs, which addresses pen housing, training, and behavioral assessment of animals for selection of compatible cage mates. This Concept has been applied to our male breeder program. The assessment of social ranking by observance of aggressive and submissive behaviors allows the development of a hierarchical structure with ranking of animals as alpha, submissive, or subordinate. Assessment must be done by a trained animal behaviorist with an understanding of social structure of primate societies. Following establishment of ranking on the dominant-subordinate spectrum, a three-phase approach is used to ensure sustainable commingling pairs. An appropriate familiarization period is key to establishing successful pairs. Effects following initial pairing of males, such as delayed body weight gain, are transient. During active mating, the male pair is separated and housed individually. The female is placed in the male cage for up to 48 hours. Following completion of the mating period, the female is removed and the male commingling pair is reunited. Careful monitoring and management is critical to ensure successful commingling pairs and to minimize aggression. Challenges are mainly related to appropriate training, experience, and timing. To date, we have established 16 male breeder pairs with mature males with body weights up to 15 kg. This demonstrates that sexually mature breeding males can be socially housed successfully even during an ongoing mating program.

The Role of the Epicardium in Cardiogenesis: Insights from the EHC Mouse

E. Barnes, C. J. Wright, L. Ridge, G. Tenin and K. Hengstes, Syngenta, Jealott’s Hill International Research Centre, Bracknell, United Kingdom and Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.

The findings in the primate (NHP) developmental toxicity studies for biopharmaceuticals. Social housing of sexually mature adult males is considered challenging and even more so for male breeder animals. We have implemented a Three Pillar Concept for conducting developmental toxicity studies in NHPs, which addresses pen housing, training, and behavioral assessment of animals for selection of compatible cage mates. This Concept has been applied to our male breeder program. The assessment of social ranking by observance of aggressive and submissive behaviors allows the development of a hierarchical structure with ranking of animals as alpha, submissive, or subordinate. Assessment must be done by a trained animal behaviorist with an understanding of social structure of primate societies. Following establishment of ranking on the dominant-subordinate spectrum, a three-phase approach is used to ensure sustainable commingling pairs. An appropriate familiarization period is key to establishing successful pairs. Effects following initial pairing of males, such as delayed body weight gain, are transient. During active mating, the male pair is separated and housed individually. The female is placed in the male cage for up to 48 hours. The Non-Obese Diabetic (NOD) Mouse As A Model for Diabetic Pregnancy

C. Kappen and J. Salbaum, Developmental Biology, Pennington Biomedical Research Center, Baton Rouge, LA and Regulation of Gene Expression, Pennington Biomedical Research Center, Baton Rouge, LA.

Diabetes in pregnancy is a well-known risk factor for neural tube defects (NTDs). In previous work, we used streptozotocin induction of diabetes in the mouse as a model of type 1 diabetes during pregnancy. We reported that embryonic gene expression is altered under diabetic conditions, and we also observed a general increase in variability of expression levels. To determine whether this is a general feature in diabetic pregnancies, we employed a model of spontaneous type 1 diabetes occurrence, the non-obese diabetic (NOD) strain of mice. In this strain, litters in diabetic dams exhibit NTDs at a rate of ~40%, with no malformations found in normoglycemic pregnancies. Gene expression profiling by microarrays and next-generation sequencing, at two different developmental time points, also indicated greater variation of gene expression levels within the group of diabetes-exposed embryos. On the basis of these findings, we propose a variation-based theoretical model to explain the incomplete penetrance of the NTD phenotype in diabetic pregnancies of inbred strains in mice. We also illustrate the discovery-advancing power of this paradigm. Beyond genetic models, our concept has broad impact for incomplete penetration of outcomes from teratogen/toxin exposures in general, and for prevention strategies.

Fetal Myocardial Reduction in Hyperglycemic Mouse Pregnancy Is Associated With Dysregulated Expression of the Antiapoptotic Gene BCL-2 in the Developing Heart: Preliminary Results

S. D. Holladay, J. C. Gutierrez, M. R. Prater, N. Navarrette and R. M. Congal, Vet Biosciences & Diagnostic Imaging, University of Georgia, Athens, GA and Biomedical Sciences & Pathobiology, Virginia Tech, Blacksburg, VA.

A growing number of environmental contaminants may adversely affect fetal development through disruption of glucose homeostasis. We previously detected significant late-gestation ventricular myocardial reduction in fetal mouse hearts collected from pregnant mice dosed with streptozotocin, which is toxic to insulin-producing beta cells of the pancreas and induces hyperglycemia. Flow cytometric analysis of the myocardial cells showed an enhanced rate of apoptosis, suggesting dysregulated cell death as a mechanism associated with the myocardial defect. The present study therefore examined expression of the anti-apoptotic gene Bcl-2 in fetal myocardium from hyperglycemic mouse dams on days 14 and 17 of gestation. The hyperglycemia was induced in female Rockefeller (inbred CD1) mice, 6 to 8 weeks old, by pre-breeding streptozotocin (STZ) injection. Expression of Bcl-2 in the fetal myocardium from diabetic dams was decreased by 53% and 51% at GD14 and 17, respectively. These results suggest maternal hyperglycemia may damage the developing myocardium by altering expression of gene pathways that regulate cell death.
For the functional inhibition studies, BeWo cells and cells overexpressing the wild-type BCRP in the placenta and 2) direct inhibition of glyburide transport by BCRP. Pregnant women that express the common C421A-BCRP variant and/or consume soy may be at an elevated risk for drug-induced neonatal hypoglycemia. Support: ES020522, ES005022, ES007148, and an AFPE Predoctoral Fellowship.

Impact of Fatty Acids on Human UDP-Glucuronosyltransferase 1A1 Activity and Its Expression in Neonatal Hyperbilirubinemia

R. Fujisawa, A. Shibuya and T. Itoh. School of Pharmacy, Kitasato University, Tokyo, Japan.

While breast milk has been known as a cause of neonatal hyperbilirubinemia, the underlying mechanism of breast milk-induced jaundice has not been clarified. Here, the impact of fatty acids on human UDP-glucuronosyltransferase (UGT) 1A1 — the sole enzyme that can metabolize bilirubin — were examined. Oleic acid, linoleic acid, and docosahexaenoic acid (DHA) strongly inhibited UGT1A1 activity. Forty-eight hours after a treatment with a lower concentration of DHA (10 mg/kg), total bilirubin significantly increased in neonatal hUGT1G1 mice, which are human neonatal jaundice models. In contrast, treatments with higher concentrations of fatty acids (0.1–10 g/kg) resulted in a decrease in serum bilirubin in hUGT1G1 mice. It was further demonstrated that the treatment with higher concentrations of fatty acids induced UGT1A1, possibly by activation of peroxisome proliferator-activated receptors. Our data indicates that activation of peroxisome proliferator-activated receptors would increase UGT1A1 expression, resulting in reduction of serum bilirubin levels in human infants.

Genistein Reduces Human Placental BCRP/ABCG2 Transporter Expression and Function In Vitro: Potential Risk for Fetal Drug Exposure

K. M. Bircsak 1, 2, Q. Wang 1, Y. Lin 1 and L. M. Aleksunes 1. Department of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ and 2Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ.

Pregnant women with gestational diabetes are often treated with the hypoglycemic agent, metformin. The aim of this study was to determine the effect of the soy isoflavone, genistein, on the placental circulation by the breast cancer resistance protein (BCRP/ABCG2) expressed on placental syncytiotrophoblasts. The purpose of this project was to determine the effect of the soy isoflavone, genistein, on the 1) regulation (protein and function) of BCRP in the placenta and 2) direct inhibition of glyburide transport by BCRP in cell-based systems. Human choriocarcinoma BeWo cells were incubated with genistein (0–10 μM) for 48 h and collected for western blot and functional analysis. For the functional inhibition studies, BeWo cells and cells overexpressing the wild-type (WT) or functionally-reduced variant (C421A) of BCRP were incubated with increasing concentrations of genistein (0–100 μM) for 1 h. Retention of BCRP substrates Hoechst 33342 or BODIPY-glyburide was quantified with an automated fluorescence cell counter. Genistein reduced the protein expression of BCRP and increased the cellular retention of Hoechst up to 40% in BeWo cells at 48 h. In the direct inhibition studies, genistein enhanced the accumulation of Hoechst in placental BeWo cells (50%) and both BCRP-overexpressing cells (WT and C421A, 300%), with a trend for the C421A-BCRP cells to accumulate even more Hoechst in the presence of genistein. Interestingly, genistein increased the accumulation of BODIPY-glyburide up to 70% only in the C421A-BCRP cells. In conclusion, genistein decreases the placental expression and direct transport of glyburide by BCRP. Future studies with the common C421A-BCRP variant and/or consume soy may be at an elevated risk for drug-induced neonatal hypoglycemia.
194 Ethanol (EtOH) Alters the Redox Environment, Histiotrophic Nutrition Pathways (HNP), and the Thiol Proteome during Rat Organogenesis

J. L. Jilek1, K. E. Sant1, K. H. Cho1, M. S. Reed2, J. Pohl2, J. M. Hansen3 and C. Harris1.

1Environmental Health Sciences, University of Michigan, Ann Arbor, MI, 2Biotechnology Core Facility Branch, Centers for Disease Control, Atlanta, GA and 3Division of Pulmonary, Allergy/Immunology, Cystic Fibrosis and Sleep, Department of Pediatrics, Emory Medical School, Atlanta, GA.

Ethanol is a known teratogen involved in the etiology of structural and functional defects by mechanisms that include redox regulation and related disturbance of the actin cytoskeleton, although, modes of action are not well defined. This study uses the rat whole embryo culture (rWEC) model to further elucidate the relationships between embryonic nutrition, redox environment and observed changes in the thiol proteome following EtOH exposures (1.5–6.0 mg/ml). Soluble thiol concentrations (GSH and Cys) and their respective intracellular redox potentials (Eh) were determined using HPLC. EtOH reduced GSH and Cys concentrations in embryo (EMB) and visceral yolk sac (VYS) tissues, and also in yolk sac fluid (YSF) and amniotic fluid (AF). These changes were accompanied by greater oxidation as indicated by increasingly positive Eh values. Disruption of nutrient transport and cytoskeletal dynamics has been previously shown following EtOH exposure. EtOH reduced HNP activity in rWEC as measured by the clearance of FITC-albumin from the culture media. A significant decline in total FITC clearance was observed at all doses, showing an optimal >50% change at the high dose. EtOH-induced changes in protein concentrations within the thiol proteome were measured in EMBs and VYS using isotope-coded affinity tags (ICAT). Decrease for specific proteins involved in cytoskeletal dynamics and endocytosis (α-actin, α-tubulin, cubulin, and actin-related protein) and in proteins involved in nuclear trafficking (Ran and RanGAP) were observed. This study suggests that EtOH can alter redox environments, HNP activities, and concentrations of the thiol-reactive proteins involved with cellular transport systems, which all may collectively contribute to EtOH-induced developmental toxicity during early organogenesis.

195 Two Alleles of Med31 Provide a Model to Study Defects in Cellular Proliferation and Endochondral Ossification

K. Wolton1, J. Wright1 and K. Hengtges1. University of Manchester, Manchester, United Kingdom and 2Syngenta, Berkshire, United Kingdom.

Over 400 different skeletal dysplasias have been characterised and represent a significant global health concern, with incidence rates estimated around 1 in every 4000-5000 live births. Understanding the mechanisms which govern early skeletal development in the embryo is key to developing potential therapeutics.

We have isolated two separate mouse lines with mutations in the Mediator complex gene Med31 derived from an ENU mutagenesis screen. The first mouse is null for the Med31 protein during development, and displays delays in the development of the limbs. Using a combination of wholemount staining for the mitotic marker phospho-histone H3 on E10.5 embryos and immunohistochemistry on E16.5 parafomaldehyde fixed sections using the Ki-67 antigen, we have confirmed that the mutants have cell proliferation defects which contribute to delays in bone ossification.

The second mouse line has a Med31 missense mutation (Y57C), confirmed by genomic sequencing, which we predict affects the ability of the Med31 protein to interact with Med7N within the Mediator complex. Individual null or Y57C heterozygous mice are phenotypically normal, whilst double mutants, of the genotype ‘Med31 null/ Med31 Y57C’ show delays in limb development similar to Med31 null mice, when stained with Alcian blue and Alizarin red in skeletal preparations.

To further understand the function of Med31 in the context of cellular proliferation in the developing limb, we have developed a cell culture knock out model, in which we reduce Med31 expression using shRNA transfection into the mesenchymal cell line C3H10T1/2. We will use a combination of cell culture and whole embryo models to further elucidate the function of Med31 in limb development.

196 The Effects of Thalidomide on Fgf8, Bmp4 and Hoxa11 Expression in the Limb Bud in Rabbit Embryos

Thalidomide (TM) induces limb defects in humans and some animal species including rabbits. Although the mechanism of TM-induced limb defects has been investigated for a long period, the limb development-related genes expressions have not been vigorously characterized in rabbits. In this study, we investigated the Fgf8, Bmp4 and Hoxa11 expressions in the limb buds in TM-treated Klkl/JW rabbit embryos on gestation day (GD) 10, 11 and 12 by whole mount in situ hybridization. It has been reported that Fgf8 and Bmp4 expressions were changed in the limb bud in TM-treated rabbit and chick embryos, respectively. Hoxa11 was selected because Hoxa11 knockout mice showed morphological changes at the ulna and radius and the radius malformation was observed in TM-induced rabbit fetuses. On GD 10 and 11, growth retardation of the whole body was induced by TM treatment. The expression lengths of Fgf8 on GD 10 and 11 in the forelimb bud were significantly or tended to be decreased in the TM-treated embryos, which was correlated to the growth retardation and was not considered to be directly relevant to the teratogenic effect of TM on the forelimb. Hoxa11 is not expressed on GD 10. The TM-induced characteristic changes in the expression pattern of Hoxa11 on GD 11 and Bmp4 on GD 10 and 11 were not noted. On GD 12, there was no effect of TM on growth retardation. The expressions of Fgf8 and Bmp4 were not changed by TM on GD 12, while Hoxa11 expression was narrowed by TM at the anterior region and was not changed at the middle and posterior regions in the forelimb bud and in all regions in the hindlimb bud. The anterior region was located on the radial side and the radius malformation was observed in the TM-treated rabbit fetuses. Therefore, the decrease in the Hoxa11 expression on GD 12 was related to the limb defects induced by TM and can be a good marker for early prediction of the teratogenic effect of TM on the forelimb.

197 Humoral Immunity and Lymphocyte Immunophenotyping Control Background Data in Mainland and Indonesian Cynomolgus Monkey Infants

S. Onda1, N. Yee1, N. Lalayeva1, R. E. Watson1, N. Makori1, S. Graza1, P. Franklin1, T. Beck1, K. Fukuzaki1 and R. Nagata2. Safety Assessment, SNBL USA, Ltd., Everett, WA and 2Shin Nippon Biomedical laboratories, Ltd., Tokyo, Japan.

Background: Lymphocyte immunophenotyping (LIP) and T-cell dependent antibody response (TDAR) are the most common tests in assessing potential developmental immunotoxicology in pre- and postnatal developmental (PPND) studies. Background data from Mainland (ML, China and Cambodia) and Indonesian Island (IL) Cynomolgus monkeys were compared in order to accurately assess the presence or absence of test article-related changes in treated monkeys from different sources.

Methods: Control data were analyzed retrospectively from a total of 14 and 10 PPND studies for LIP and TDAR data, respectively. Blood samples for LIP by flow cytometry in infants were collected throughout the postnatal period and analyzed for total CD3+ T cells, CD3+CD4+ Helper T cells, CD3+CD8+ Cytotoxic T cells, CD3+CD20+ B cells, and CD3+CD16+ or CD3+CD159a+ Natural Killer (NK) cells. To evaluate TDAR, keyhole limpet hemocyanin (KLH) was injected twice, and primary and secondary IgM and IgG levels in serum were measured by ELISA.

Results: IL monkeys generally had higher absolute counts and relative percentages of NK cell populations, and lower circulating B cell numbers when compared to ML monkeys. IgM levels elevated rapidly after the 1st and 2nd doses, with peak IgM concentrations in IL 24-27% lower than that observed in ML. IgG levels were determined using HPLC. EtOH reduced GSH and Cys concentrations in embryo (EMB) and visceral yolk sac (VYS) tissues, and also in yolk sac fluid (YSF) and amniotic fluid (AF). These changes were accompanied by greater oxidation as indicated by increasingly positive Eh values. Disruption of nutrient transport and cytoskeletal dynamics has been previously shown following EtOH exposure. EtOH reduced HNP activity in rWEC as measured by the clearance of FITC-albumin from the culture media. A significant decline in total FITC clearance was observed at all doses, showing an optimal >50% change at the high dose. EtOH-induced changes in protein concentrations within the thiol proteome were measured in EMBs and VYS using isotope-coded affinity tags (ICAT). Decrease for specific proteins involved in cytoskeletal dynamics and endocytosis (α-actin, α-tubulin, cubulin, and actin-related protein) and in proteins involved in nuclear trafficking (Ran and RanGAP) were observed. This study suggests that EtOH can alter redox environments, HNP activities, and concentrations of the thiol-reactive proteins involved with cellular transport systems, which all may collectively contribute to EtOH-induced developmental toxicity during early organogenesis.

Discussion: Blood samples were collected throughout the postnatal period and analyzed for total CD3+ T cells, CD3+CD4+ Helper T cells, CD3+CD8+ Cytotoxic T cells, CD3+CD20+ B cells, and CD3+CD16+ or CD3+CD159a+ Natural Killer (NK) cells. To evaluate TDAR, keyhole limpet hemocyanin (KLH) was injected twice, and primary and secondary IgM and IgG levels in serum were measured by ELISA.

Results: IL monkeys generally had higher absolute counts and relative percentages of NK cell populations, and lower circulating B cell numbers when compared to ML monkeys. IgM levels elevated rapidly after the 1st and 2nd doses, with peak IgM concentrations in IL 24-27% lower than that observed in ML. IgG levels were determined using HPLC. EtOH reduced GSH and Cys concentrations in embryo (EMB) and visceral yolk sac (VYS) tissues, and also in yolk sac fluid (YSF) and amniotic fluid (AF). These changes were accompanied by greater oxidation as indicated by increasingly positive Eh values. Disruption of nutrient transport and cytoskeletal dynamics has been previously shown following EtOH exposure. EtOH reduced HNP activity in rWEC as measured by the clearance of FITC-albumin from the culture media. A significant decline in total FITC clearance was observed at all doses, showing an optimal >50% change at the high dose. EtOH-induced changes in protein concentrations within the thiol proteome were measured in EMBs and VYS using isotope-coded affinity tags (ICAT). Decrease for specific proteins involved in cytoskeletal dynamics and endocytosis (α-actin, α-tubulin, cubulin, and actin-related protein) and in proteins involved in nuclear trafficking (Ran and RanGAP) were observed. This study suggests that EtOH can alter redox environments, HNP activities, and concentrations of the thiol-reactive proteins involved with cellular transport systems, which all may collectively contribute to EtOH-induced developmental toxicity during early organogenesis.

Discussion: Blood samples were collected throughout the postnatal period and analyzed for total CD3+ T cells, CD3+CD4+ Helper T cells, CD3+CD8+ Cytotoxic T cells, CD3+CD20+ B cells, and CD3+CD16+ or CD3+CD159a+ Natural Killer (NK) cells. To evaluate TDAR, keyhole limpet hemocyanin (KLH) was injected twice, and primary and secondary IgM and IgG levels in serum were measured by ELISA.
Development and Validation of an Analytical Method for Monobutylphthalate, a Metabolite of Di-n-Butylphthalate, in Harlan Sprague-Dawley Rat Pup and Fetus by Ultra-Performance Liquid Chromatography-Tandem Mass Spectrometry (UPLC-MS/MS)

Di-n-butyl phthalate (DBP) is a common plasticizer used in a variety of consumer products. Exposure to DBP is widespread, and its potential toxicity has been, and continues to be, investigated. The objective of this work was to develop and validate a method to quantitate mono-n-butyl phthalate (MBP), the major metabolite of DBP, in rat pup and fetus. Samples were prepared by spiking 0.5 g of pup or fetus homogenate with 25 mL of water, 25 mL of internal standard solution (MBP-d4 in water), and 300 mL of 0.1% formic acid in water. Analyte extraction was achieved by the addition of 1 mL of acetonitrile, vortex mixing, and centrifugation. The supernatant was filtered, submerged into liquid nitrogen, and centrifuged to facilitate lipid separation. The method was successfully validated over the range 50-5000 ng/g in pup, with cross-validation for fetuses. Validation parameters included linearity (r ≥ 0.99), recovery (mean recovery = 100%), sensitivity (limit of detection = 9.4 ng/g, experimental limit of quantitation (ELOQ) = 50 ng/g), precision (relative standard deviation ≤ 10%), and accuracy (relative error ≤ 10%). Background phthalate interference was detected in both pup and fetus, but MBP peak area ratios for the blanks were ≤ 40% of those for the ELOQ standards, demonstrating acceptable selectivity. Stability was established for frozen matrix samples stored at -20°C for 60 days, matrix samples subjected to freeze-thaw (3 cycles over 3 days), and also ambient and refrigerated extracts for 3 days. It was also demonstrated that pup samples as high as 7,500 ng/g and fetus samples as high as 25,200 ng/g could be accurately quantitated by diluting into the calibration range. The method is being applied for quantitation of MBP in pup and fetus samples from rats administered 0, 300, 1000, 3000, or 10,000 ppm DBP in feed.

Developmental Toxicity Assessment of Multiwall Carbon Nanotubes in Pregnant Mice after Intratracheal Instillation

N. Kobayashi, T. Numano, R. Kubota, Y. Ikarashi and A. Hirase. 1National Institute of Health Sciences, Tokyo, Japan, 2DIMS Institute of Medical Science Inc., Ichinomiya, Aichi, Japan, and 3Department of Molecular Toxicology, Nagaoya City University Graduate School of Medical Sciences, Nagaoya, Aichi, Japan.

In order to evaluate the developmental toxicity of multi-wall carbon nanotubes (MWCNTs) via inhalation exposure, we conducted an intratracheal instillation study of MWCNTs in pregnant mice. MWCNTs (MWCNT-7) dispersions were prepared by ultrasonication using an ultrasonic bath for 30 min. In order to compare the biological effect of dispersion media, we used two different media, mouse serum and 2% (w/v) of sodium carboxymethyl cellose (CMC-Na) solution. The MWCNT dispersions in serum were administered to pregnant Crl:CD1(ICR) mice on gestation day 9 at dosage of 0, 3.0, 5.0 and 7.0 mg/kg bw (mouse serum). The MWCNT dispersions in 2% CMC-Na solution was administered at dosage of 5.0 mg/kg bw. Ten pregnant mice per group were evaluated and dissected on gestation day 17. Decreased body weights in all MWCNT exposed pregnant mice were observed, although there were no clear dose-dependent changes. No statistically significant difference was observed between the control group and MWCNT exposed groups in the numbers of corpora lutea, dead fetuses (early or late resorption), and live fetuses, or sex ratio. Body weight of fetuses and placental weights were significantly decreased in the most MWCNT exposed groups, although no clear dose-dependency was observed. Furthermore, external malformations (i.e., oligodactyly, extensive contractures, kinked tail, cleft lip, and cleft palate) were observed in all MWCNT exposed groups. The fetuses with external malformations were derived from the same litters. The equivocal dose-dependent effects may be due to a litter dependent toxic mechanism. These results suggested that the intratracheal exposure of MWCNT resulted in teratogenic effects in mice in spite of different dispersion media. Further examinations are needed to clarify the mechanism of the developmental toxicity by MWCNTs.

Elucidation of a Novel Molecular Mechanism of Dioxin Toxicity

N. Fujisawa, W. Yoshio and G. Tohyama. Graduate School of Medicine, The University of Tokyo, Tokyo, Japan.

Exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) exerts a variety of toxicity. Beside the essential role of aryl hydrocarbon receptor (AhR), the molecular basis of TCDD toxicity has been elusive. Recent in vitro experiments showed that TCDD activates cPLA2 via a different pathway from transactivation of AhR target genes. Thus, there is a research need to elucidate the possible involvement of this alternate pathway in the manifestation of TCDD toxicity in vivo. First, we administered TCDD to fetuses, lactational pups, and adults of wild-type or cPLA2 KO mice to find out the manifestation of toxicity. Next, among a variety of dioxin toxicity, we studied the molecular mechanism of toxicity by focusing on the neonatal hydronephrisis. Finally, using AhRα mice, we investigated the role of AhR localization into nucleus with regard to the alternate pathway. Fetal toxicity: cPLA2α (+/-) pregnant mice were administered TCDD on gestational day (GD) 12.5, and onset of hydronephrisis and cleft palate and changes in fetal survival rate were examined on GD18.5. cPLA2α was found to be an important part in the manifestation of neonatal and fetal hydronephrisis, and at the same time in the reduction of TCDD-induced fetal lethality. Neonatal toxicity: cPLA2α (+/-) dams and AhRα(-) dams were orally administered TCDD on postnatal day (PND) 1. Pups were sacrificed on PNDs 7 and 14 to examine the development of hydronephrisis. Hydronephrisis was not developed in either cPLA2α KO or AhRα(-) mice. Adult toxicity: cPLA2α (+/-) and cPLA2α (-/-) mice aged 12 week old were injected i.p. with TCDD. Hepatotoxicity and thymic atrophy were examined on day 8. In adult mice, cPLA2α was found not to be associated with the manifestation of these kinds of TCDD toxicity. In conclusion, using different stages of mice, neonatal hydronephrisis was found to be a good model to study the molecular basis of a novel pathway in the induction of TCDD toxicity. The nuclear localization of AhR was suggested to play an essential role in the activation of the novel pathway.

Evaluation of the Sodium Valproate-Induced Developmental Abnormalities and Its Mechanisms in Zebrafish

Sodium valproate (VPA) is known to induce developmental abnormalities such as spina bifida, craniofacial anomalies and developmental neurotoxicity (DNT) in mammals. In the present studies, we evaluated the VPA-induced developmental abnormalities in zebrafish and analyzed the mechanisms of the abnormalities focusing on the craniofacial anomaly and DNT. [Study 1] Zebrafish (Tupfelf Longfin) were exposed to VPA at 75 μM from 5 to 144 hours post fertilization (hpf), and morphological evaluation was conducted at 144 hpf. Additionally, gene expression analysis of dkie2, a marker for neural crest cells, was performed by in situ hybridization on staged embryos. VPA-treated larvae showed abnormal findings in the notochord and lower jaw, corresponding to the phenotypes observed in VPA-exposed mammals, and the lower jaw anomaly was accompanied with a decrease in dkie2 expression in the hyoid arch. These results imply that the VPA-induced morphological anomaly in the lower jaw is related to morphogenesis failure of the neural crest-derived structures in zebrafish. [Study 2] Zebrafish were exposed to VPA at 40 μM from 5 to 144 hpf. After VPA-free period for 24 hours from 144 hpf, locomotor activity was evaluated under 10 minutes light and dark cycles, and gene expression analysis of tyrosine hydroxylase (th), a marker for dopaminergic neuron, was performed on staged embryos. VPA-treated larvae showed an increase in locomotor activity during the dark period and a decrease in th expression in the hypothalamus. These results imply that the VPA-induced DNT is related to inhibition of the dopaminergic neuron development in zebrafish. In conclusion, our studies revealed that VPA induces some developmental abnormalities in zebrafish and suggested that inhibition of the neural crest-derived cranial and dopaminergic neuron development is related to these developmental abnormalities.

Evaluation of Teratogenicity of IMiD® Compounds Using the Zebrafish Developmental Toxicity Assay

J. Y. Hui, P. J. Sherratt, B. D. Jeffy, K. Tang and D. J. Fort. 1Celgene Corporation, Summit, NJ and 2Fort Environmental Laboratories, Stillwater, OK.

IMiD immunomodulatory analogues are analogues of thalidomide that represent a promising class of drugs for the treatment of inflammatory, autoimmune, and cancerous diseases. To investigate the usefulness of the zebrafish developmental toxicity
203 Expression of Glyoxylase 1 (glo1) throughout Zebrafish Embryonic Development and Alterations following Atrazine Exposure

G. A. Ryan1, G. L. Weber1, S. M. Peterson1, M. M. Sepulveda2 and J. L. Freeman1, 1Health Sciences, Purdue University, West Lafayette, IN and 2Department of Forestry and Natural Resources, Purdue University, West Lafayette, IN.

Atrazine, a commonly used herbicide in the Midwest, is an endocrine disruptor and a suspected carcinogen. Although atrazine was recently banned by the European Union for widespread contamination risks in potable water supplies, this herbicide is still commonly used in the United States with a current maximum contaminant level (MCL) of 3 ppb in drinking water. The health risks associated with this MCL are currently being reviewed by the Environmental Protection Agency, however the mechanisms of atrazine toxicity are not well defined. In this study transcriptomics was first used to identify genes with altered expression following exposure to 0, 0.3, 3, or 30 ppb atrazine during embryogenesis with the zebrafish model system. This analysis showed that expression alterations were enriched with genes associated with neuroendocrine development and function, cell cycle regulation, and carcinogenesis. From this list of genes, glyoxylase 1 (glo1) was targeted for further study. glo1 is part of the glyoxylase system which converts methylglyoxal to S-D-lactoylglutathione. Upregulation of glo1 is linked to cell proliferation and is associated with various cancers in humans. To further our understanding of this genetic target, expression was analyzed at five developmental time points (24, 36, 48, 60, and 72 hpf). In situ hybridization was used to characterize spatial gene expression of glo1 throughout development under normal conditions and after exposure to 0, 0.3, 3, or 30 ppb atrazine. glo1 was found to be ubiquitously expressed at each time point with most of the staining concentrated in the brain. A high level of expression was also observed in the liver. Real time quantitative PCR (qPCR) of 35 cycles was used to further investigate the developmental expression of glo1 and its deregulation by atrazine exposure. qPCR was first used to profile expression throughout embryogenesis in control conditions at 12, 24, 36, 48, 60, and 72 hpf. Expression of glo1 was developed in the zebrafish model system. This is a potential carcinogen. Visceral defects were observed with atrazine and pan-caspases were observed during embryogenesis. This study showed that expression during the first 12 hours (2-14 hpf) was critical in producing pectoral fin defects. Development of the pectoral fin shares a similar molecular pathway as those of tetrapod limbs; however pectoral fin defect was only observed with atrazine in the ZFDA. These data with the IMID compounds show a lack of concordance of developmental defects between zebrafish and other species commonly used for EF evaluation because limb malformations have been reported with atralidomeline and pomalidomide in rabbits, and with lenalidomide in non-human primates.

204 Deregulation of miRNA-126 Expression in Developing Zebrafish Exposed to the Herbicide Atrazine

K. Schlotman, S. Wirbisky, G. J. Weber and J. L. Freeman, Health Sciences, Purdue University, West Lafayette, IN.

Atrazine is a commonly used herbicide in the United States that is reported to frequently contaminate drinking water sources. Studies have indicated atrazine to adversely impact the neuroendocrine and reproductive systems and to be a potential carcinogen. The current maximum contaminant level for atrazine in drinking water set by the US Environmental Protection Agency is 3 parts per billion (ppb); however, levels higher than 3 ppb are often reported. Ongoing studies in our laboratory are investigating the immediate and latent adverse health outcomes associated with a developmental atrazine exposure and identifying the generic and epigenetic mechanisms of atrazine toxicity using the zebrafish model system. MicroRNAs (miRNAs) are epigenetic regulators that post-transcriptionally control the translation of mRNA. To identify if an embryonic atrazine exposure would alter miRNA expression, a unique microarray platform containing all known zebrafish and human miRNAs was designed. Zebrafish embryos were exposed to 0, 0.3, 3, or 30 ppb atrazine through 72 hours post fertilization (hpf), and miRNA expression was analyzed using the microarray platform. Expression of 18 zebrafish and 9 human miRNAs were significantly altered in response to atrazine exposure. One of the most robustly changed miRNAs was miR-126, a miRNA associated with angiogenesis and tumorigenesis. To further investigate the developmental expression of miR-126 and its deregulation by atrazine exposure, quantitative PCR (qPCRs) was first used to profile expression throughout embryogenesis in control conditions at 12, 24, 36, 48, 60, and 72 hpf. Expression of miR-126 was measured during six developmental time points specific with an increase in expression after 12 hpf and a peak in expression at 36 hpf. Following a decrease in expression at 48 hpf, expression levels were significantly higher at 60 and 72 hpf. Deregulation of miR-126 following exposure to 0, 0.3, 3, or 30 ppb atrazine at all six developmental time points was also analyzed to further our understanding on the impacts of atrazine exposure on miR-126 expression.

205 Exposure to Chemicals Found in Umbilical Cord Blood Alters Kisspeptin/GPR54-GnRH Pathway Expression and Development in the Zebrafish Embryonic Development Model

J. P. Craggs and D. Schlenk, Environmental Sciences, University-California, Riverside, Riverside, CA.

There are numerous positive and negative inputs that affect the development of the hypothalamus–pituitary–gonadal axis during fetal and early-life stages. Therefore, alterations in reproductive function that manifest later in life, such as the earlier onset of puberty could be a result from perturbations or exposures during critical neuronal developmental time-points. Recent work has identified Kisspeptin (KISS), expressed in the arcuate nucleus (ARC) region of the brain, that are vital for the central regulation of gonadotrophin releasing hormone (GnRH) neurosecretory activity and timing of puberty. At present, there is little research examining the effect of chemicals found in the umbilical cord blood on KISS mRNA levels or on the development of KISS positive gonadotropes in any developmental vertebrate model. The goal of this study is to use the developing zebrafish embryo model to determine the impact of individual chemicals and low-level mixtures of compounds that are present in the umbilical cord blood on KISS-NK-DYN-GnRH signaling system. Embryos were exposed to several compounds at concentrations reported in umbilical cord blood. KISS 1 and 2, GPCR54-1 and 2, and GNRH3 mRNA expression was measured at 2 hour intervals for the first 24 hours. We first identified mRNA expression of two orthologs of KISS 1 and 2 and GPCR54-1 & 2 during initial stages of development. This is subsequently followed by GnRH exposure at 23 hpf. Initial exposures to either estradiol or the anti-diabetic drug metforin increased mRNA expression of KISS 1 and 2 as well as shifted the timing of expression. Our results indicate that there is a shift in timing and mRNA expression that may impact GnRH neuronal signaling and development.

206 Induction of Vitellogenin in Thracemyx scripta Exposed to Atrazine

E. R. Thomas1 and R. Valverde2, 1Biological Sciences, Southeastern Louisiana University, Hammond, LA and 2Biological Sciences, Southeastern Louisiana University, Hammond, LA. Sponsor: A. Hoberman.

Due to their ubiquitous presence, persistence, and tendency to bioaccumulate, endocrine disrupting chemicals (EDCs) may cause significant impacts on the health of wildlife. Atrazine, a commonly used pesticide in the United States, is a type of EDC that is causing much concern due to the recent finding that it may cause adverse effects at low doses. This study focuses on the estrogenic effects of atrazine (2-Chloro-4-ethylamino-6-isopropylamino-s-triazine). Since it has been shown that atrazine caused two male American leopard frogs (Rana pipiens) to have oocytes that were vitellogenic, we hypothesized that exposure to atrazine may result in the induction of vitellogenin in hatching red eared slider turtles (Trachemyx scripta). Vitellogenin is the egg yolk precursor protein that is typically found when female oviparous vertebrates are reproducitively active. Because males also carry the gene that codes for vitellogenin, this protein is a reliable biomarker in oviparous vertebrates for exposure to estrogenic compounds. Hatchling male and female T. scripta received intraperitoneal injections of one of four different concentrations of atrazine (0.0001, 0.01, 0.1, or 1 ng/g bm), estradiol-17B in two doses (1 or 1000ng/g bm), or vehicle (saline) only. Plasma vitellogenin concentration was measured using an ELISA developed specifically for T. scripta vitellogenin. Significant production of vitellogenin occurred in turtles in both the estradiol groups as well as the atrazine groups in a dose response manner. Our data shows that exposure to low doses of atrazine causes induction of vitellogenin in the turtle and demonstrates the potential for this compound to act as an EDC. 

Developmental Exposure to Benzo[a]pyrene Affects Behavior and Energetics in Larval and Adult Zebrafish

A. Knecht, R. L. Tanguay and L. Truong, Dept. of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous environmental contaminants present in urban air, dust, and soil resulting from incomplete combustion of organic materials or fossil fuels. It is widely recognized that PAHs pose risks to human health, especially for the developing fetus and infant, where PAH exposures have been linked to in-utero mortality, lower intelligence, and cardiovascular effects. Using the zebrafish model, we evaluated the developmental toxicity of PAH exposures. Zebrafish embryos were exposed from 6-120 hours post fertilization (hpf) to B[a]P, BaA, BEZO, and 9,10-PHEQ concentrations that caused no observable morphological toxicity. Using the Seahorse Extracellular Flux Analyzer, we measured in vivo respiration in 26hpf embryos exposed to PAHs. Exposure to B[a]P, BaA, BEZO, and 9,10-PHEQ caused decreased oxygen consumption rates, indicative of mitochondrial damage. Developmental B[a]P and BaA-Q exposure also resulted in hyperactive swimming at 120hpf. To determine if behavioral and physiological effects persisted, a subset of exposed animals were raised to adulthood in chemical-free water and assessed for learning and energetic deficits. Preliminary results indicate B[a]P-dependent deficiencies in learning and performance in an active avoidance conditioning test. To determine if adult physiological function is altered by developmental PAH exposure, a swim tunnel respirometer was used to measure total oxygen consumption. Animals developmentally exposed to B[a]P demonstrate a significant increase in oxygen consumption rates. Finally, to explore what transcriptional events are occurring prior to the onset of developmental toxicity, mRNA expression changes in B[a]P-exposed embryos were examined with whole-genome RNA-seq at 48hpf. Collectively, these data demonstrate that developmental PAH exposure results in a number of non-cancer endpoints and we are now positioned to identify the mechanisms underlying these complex responses. This research was supported by NIEHS grants P42ES016465 and P30ES002010.

Effects of Benzo[a]pyrene and Cyp19B Knockdown on Early Zebrafish Development

K. M. Alharthy, P. T. Booce, J. Corrales, C. Thornton, W. Dong and K. L. Willett, Department of Pharmacology and ETRP, University of Mississippi, University, MS and Nicholas School of the Environment, Duke University, Durham, NC.

Benzo[a]pyrene (BaP) is a ubiquitous environmental contaminant that is an endocrine disrupting and carcinogenic PAH. Previously we found that BaP significantly decreased fish brain aromatase (CYP19B) expression, a key enzyme in steroidogenesis. We hypothesized that BaP deregulates the steroid hormone hypothalamo-pituitary-gonadal feedback loop adversely affecting development and physiology. Here, we consider whether the toxicities observed following BaP exposure are comparable to those following transient CYP19B knockdown during early development. One-cell zebrafish embryos were injected with a CYP19B morpholino or the Genetools control-MO. Other non-injected embryos were exposed to nominal waterborne concentrations of BaP (0, 10 & 50 μg/L) for 96 hours post-fertilization (hpf). BaP and CYP19B knockdown resulted in a number of similar phenotypic endpoints. Cumulative mortality of zebrafish larvae was significantly increased by 5, 6, and 20% for low BaP, high BaP, and CYP19B knockdown, respectively, compared to controls. Hatching efficiency was significantly decreased by all treatments at 48 hpf. In a treatment-blinded morphological assessment of larvae at 96 hpf, the body length, optic vesicle, and swim bladder inflation of larvae were significantly decreased while pericardial and abdominal edema were increased by high BaP and CYP19B knockdown. The incidence of normal larval body, tail and pectoral fin shape was significantly decreased in both treatments. To identify the effects of BaP and CYP19B knockdown on primordial germ cell (PGC) migration, in-situ hybridization was done on embryos at the 25 somite stage; preliminary results suggest that BaP may affect PGC migration. Zebrafish were collected at 2B, 32, 35 & 52 days post-fertilization to determine if gonad maturation was delayed. Results suggest BaP effects in zebrafish embryos are similar to the effects observed by aromatase knockdown. Supported by NIEHS R03 ES018962.

Developmental Exposure to Benzo[a]pyrene Affects Behavior and Energetics in Larval and Adult Zebrafish

K. L. Willett, R. L. Tanguay and L. Truong, Dept. of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous environmental contaminants present in urban air, dust, and soil resulting from incomplete combustion of organic materials or fossil fuels. It is widely recognized that PAHs pose risks to human health, especially for the developing fetus and infant, where PAH exposures have been linked to in-utero mortality, lower intelligence, and cardiovascular effects. Using the zebrafish model, we evaluated the developmental toxicity of PAH exposures. Zebrafish embryos were exposed from 6-120 hours post fertilization (hpf) to B[a]P, BaA, BEZO, and 9,10-PHEQ concentrations that caused no observable morphological toxicity. Using the Seahorse Extracellular Flux Analyzer, we measured in vivo respiration in 26hpf embryos exposed to PAHs. Exposure to B[a]P, BaA, BEZO, and 9,10-PHEQ caused decreased oxygen consumption rates, indicative of mitochondrial damage. Developmental B[a]P and BaA-Q exposure also resulted in hyperactive swimming at 120hpf. To determine if behavioral and physiological effects persisted, a subset of exposed animals were raised to adulthood in chemical-free water and assessed for learning and energetic deficits. Preliminary results indicate B[a]P-dependent deficiencies in learning and performance in an active avoidance conditioning test. To determine if adult physiological function is altered by developmental PAH exposure, a swim tunnel respirometer was used to measure total oxygen consumption. Animals developmentally exposed to B[a]P demonstrate a significant increase in oxygen consumption rates. Finally, to explore what transcriptional events are occurring prior to the onset of developmental toxicity, mRNA expression changes in B[a]P-exposed embryos were examined with whole-genome RNA-seq at 48hpf. Collectively, these data demonstrate that developmental PAH exposure results in a number of non-cancer endpoints and we are now positioned to identify the mechanisms underlying these complex responses. This research was supported by NIEHS grants P42ES016465 and P30ES002010.
anti-oxidant pathways. Therefore, we explored the potential for these compounds to produce adverse developmental effects using zebrafish (Danio rerio) as a model vertebrate. We specifically tested the hypothesis that flavonoids exhibit effects on development through ER-dependent and -independent mechanisms. Embryos were exposed to 5 μM of each flavonoid (epigallocatechin, biocianin A, 5-epi-epigallocatechin, epigallocatechin-3-gallate, and kempferol), 1-50 μM, from 6 hours post fertilization (hpf) to 120 hpf. Effects included yolk-sac and pericardial edemas, axial defects, fin dysmorphogeneis and craniofacial abnormalities. Two compounds (S-equol and biocianin A) induced estrogen-responsive genes (vitellogenin, cyc19a1b, lbh) indicative of nuclear ER activation. Co-exposure with the ER antagonist tamoxifen significantly inhibited induction of these genes, but did not rescue against developmental toxicity. We also observed spastic pectoral fin and caudal tail movements for all compounds, which is suggestive of neurotoxicity, and not apoptotic of estrogen action. We therefore assessed acute effects on neurobehavior in naive 120 hpf larvae challenged with a battery of 24 flavonoids. All induced hyperactive swimming behavior suggesting flavonoids have stimulatory properties at these concentrations. These results taken together indicate that although the estrogen receptor mediates some effects on gene expression, developmental toxicity and neurobehavioral effects are likely not a result of nuclear ER action. This research is supported by NIEHS grants P30 ES00210, RC4 ES019764 and T32 ES07060.213 Combined Effects of Selenomethionine and Osmotic Stress on the Unfolded Protein Response and Apoptosis during Embryonic Development

A. J. Kupcso1 and D. Schlenc21. Environmental Toxicology, University of California-Riverside, Riverside, CA and 2Environmental Sciences, University of California-Riverside, Riverside, CA.

Pregnancy-Induced Hypertension (PIH) can lead to increased risk of adverse fetal and maternal outcomes by generating hypoxic stresses for the mother and developing fetus. Although osmotic stress may not have direct lethal effects, it may alter the toxicities of xenobiotics during development. Organic forms of selenium, such as selenomethionine (SeMet), are often taken as dietary supplements, yet alter the toxicities of xenobiotics during development. Measuring CYP1A mRNA and protein expression as bio-markers for AHR activation, we determined that mTIP principally interacts with SeMet but may also bind with AHR1A and AHR1B to induce CYP1A expression. However, triple knockdown of all AHR isoforms failed to prevent mTIP-induced cardiac toxicity even though there was no detectable CYP1A expression. These results suggest that mTIP causes AHR-independent toxicity through a pathway that is also antagonized by CH223191.

ATF4, IRE1 and BiP were up-regulated in a time-dependent manner after 4 and 8 hours and BiP continued to increase at 12 hours. Osmotic stress without SeMet induced IRE1 and ATF6 after 24 hours. These results indicate embryo lethality may occur through apoptosis and the unfolded protein response and that osmotic stress may compound these effects.

214 Ethanol Exposure during Medaka (Oryzias latipes) Embryogenesis: Impact on Cannabinoid Receptors

A. K. Dasmahaptra1,2 and I. A. Khan31. National Center for Natural Product Research, University of Mississippi, University, MS, 2Department of Pharmacology, University of Mississippi, University, MS and 3Department of Pharmcognosy, University of Mississippi, University, MS.

Developmental ethanol exposure is able to induce Fetal Alcohol Spectrum Disorder (FASD) phenotypes in medaka (Oryzias latipes). This study investigated possible expression of cannabinoid receptor (cnr) mRNAs during medaka embryogenesis and variability to ethanol-induced FASD phenotypes. Data base searching (GenBank, Ensembl) indicates that medaka genome includes three human orthologs CNR (cnr1a, cnr1b and cnr2). A quantitative real-time PCR (qPCR) technique was used to analyze the expression of these three cnr during medaka embryogenesis and their response to ethanol. Embryos at different stages of development and hatchings were utilized for RNA extraction followed by qPCR analysis of cnr1a, cnr1b and cnr2 mRNAs at the message level. Moreover, fertilized medaka eggs (Iwamatsu stage 10) were exposed to ethanol (300 mM) either for 2 days or for 6 days followed by cnr1a, cnr1b and cnr2 mRNA analysis. qPCR analyses indicate that the expression of all three, cnr1a is developmentally regulated and only cnr2 mRNA showed maternal expression. The mRNA concentrations of all cnr were found to be enhanced after 3 dpf and attained maximal level either prior to or after hatching. Embryos exposed to ethanol (300 mM) two days are unable to produce any significant effect in cnr gene expression immediately after ethanol removal; however, if these embryos were maintained in clean hatching solution without ethanol for another four days (6 dpf), only cnr1a mRNA was reduced significantly. Expression of other two cnr mRNAs (cnr1b and cnr2) either in 2 dpf or in 6 dpf remained at the same level as in controls. Six dpf exposure of the embryos to ethanol (300 mM) is also showed significant reduction in cnr1a mRNA content; however, cnr1b and cnr2 mRNAs maintained the same status as in the controls. Among the three, ethanol disrupts the expression of only cnr1a that may probably lead the development of FASD phenotypes in medaka.

215 PAH Exposure in Early Xenopus Embryos Alters Cardiac Function and Aryl Hydrocarbon Receptor (AhR) Signaling

The incomplete combustion of fossil fuels results in deposition of the polyaromatic hydrocarbons (PAHs), pyrene (PYR) and phenanthrene (PHE), into air, soil, and water. These common and persistent contaminants are also present in tobacco smoke, coal tar sealant, and weathered crude oil and have been detected at significant levels in human milk and cord blood. Surprisingly little is known about their toxicity to humans, particularly during development. To gain a better understanding of potential risks to humans, we characterized the effects of PHE and PYR exposure on cardiac function and AhR signaling using embryos of X. laevis, an important model of vertebrate development. We exposed albino embryos, at the onset of gastrulation, to 0.25, 2.5, or 25 μM PHE or PYR for 120 h and recorded the cardiac activity at various stages of heart development using an inverted dissecting microscope, Leica™ video camcorder, and recording and editing software (Camtasia™ and Image™) to determine heart rate, interbeat variability, and contractility. The mRNA levels for the two CYP1A genes, CYP1A6 and CYP1A7, and for the AHR gene (AhR repressor) were quantified for whole embryos exposed for 96 h to PYR at 0.5 and 25 μM. At stage 42 (72 h, during heart valve formation), PHE treatment (2.5 and 25 μM) was associated with decreased heart rate and increased interbeat variability (P < 0.01), a measure of arrhythmia, while exposure to PYR at these same doses led to increases in both heart rate and contractility (P < 0.01). These two PAHs have distinct impacts on cardiac signaling, suggesting the Xenopus heart may serve as an excellent developmental system for investigating PAH-induced alterations in signaling. In addition, exposure to 0.5 μM, but not 25 μM, PYR for 96 h was associated with 2-3 fold increases in CYP1A6 and AHR mRNA levels (P < 0.01), indicating activation of AhR signaling, a pathway essential to normal development, and a possible low-dose effect for PYR.
Innovative toxicity test systems that are translational to effects in humans and that allow reduction, refinement and replacement (3Rs) of vertebrates to assess chemical safety are urgently needed for ethical, scientific and economic reasons. Whereas cell culture systems may have predictive value, they lack the multicellular or multi-organ complexity of whole organisms. In addition, in view of developmental and reproductive toxicology (DART), they lack a complete life cycle. Therefore, we have compared D. discoideum (slime mold), C. elegans (nematode) and embryos of D. rerio (zebrafish) as possible systems to test for DART. These systems have gained attention as highly promising 3R alternatives since they have highly conserved gene-ontologies, tissue types and molecular responses. We have performed a combinatorial knowledge and experimental based comparison to align D. discoideum, C. elegans and D. rerio in order to identify common denominators as translational biomarkers for DART. We exposed the three systems to 4 compounds, the kinase inhibitor H89, antimicrobial agent mofloxicaine, boric acid and valproate. Interestingly, although individual species showed species specific phenotypic effects upon compound application, these phenotypes were indicative of alterations in conserved and expected core molecular pathways, like PKA and inositol signaling. Individual test systems further showed differences in sensitivity to compounds. In all test systems, RNA-sequencing revealed that alterations in gene expression profiles are additive between test species and that they represent genes that have orthologs in humans. We concluded from these findings that the combinatorial use of surrogate systems may be a valuable tool for predictive DART testing. Further validation includes benchmarking of well known DART toxicants and building of a Weight of Evidence platform.

**219 Exposure to Pyrene and Phenanthrene Alters Normal Pigmentation in Xenopus laevis Embryos**

Pyrene (PYR) and phenanthrene (PHE) are among the most abundant of the polycyclic aromatic hydrocarbons (PAHs) deposited into the environment. Despite the observation that both are present in human milk and cord blood, little is known about their developmental toxicity. Our lab uses a well-established amphibian model of vertebrate development, the African clawed frog *Xenopus laevis*, to assess the developmental impacts of PYR or PHE exposure. Melanophores are the amphibian cellular equivalent of human melanocytes that produce the brown-black pigment melanin. Embryos, at the onset of gastrulation, were exposed to 0, 0.25, 2.5, or 25 μM PHE or PYR for 96 hr and melanophore number and dendricity (branched or Dalmatian spot appearance) were observed. By 96 hr, melanophore dendricity was drastically reduced in embryos exposed to 25 μM of either PHE or PYR (P<0.001), effects that were not reversed after return to control conditions for 24 hr. In addition, while there was no effect at 96 hr on melanophore number (or density), the distance migrated by the melanophores was reduced in embryos exposed to either PHE or PYR at 25 μM (P<0.01). Loss of dendricity can disturb the dispersal and transfer of melanin to surrounding keratinocytes, thus interfering with UV protection in the skin. Melanophores could serve as an accessible indicator cell system for potential PAH-induced negative impacts on developing tissues, particularly for other neural- and vascular-relevant receptors, etc. Interestingly, many off-targets involved in cell cycle and spindle apparatus formation, like histone deacetylase, microtubules formation, etc. With these additional models it was possible to significantly improve the ratio of identified DART positive compounds.
Secondary, non-mammalian in vitro assays were used for the prediction of DART, mainly results from the FETAX (Frog Embryo Teratogenesis Assay Xenopus) and ZETA (Zebrafish) assays. The predictivity of these in vitro assays when used as single results were similar to the in silico models. But a combined in silico in vitro approach was able to identify and evaluate compound inducing DART effects with sensitivities up to 75% and specificities around 70%, depending on the in silico models used and available in vitro results. These validation results showed that an integrated testing strategy of in silico models and in vitro assays is able to predict the in vitro DART inducing potential of drug candidates effectively and early in development.

221 Transgenerational Effects of the Endocrine-Disrupting Herbicide Atrazine in Zebrafish
J. L. Freeman, G. J. Weber, S. Wirbisky and M. M. Sepulveda. Purdue University, West Lafayette, IN and 2Forestry and Natural Resources, Purdue University, West Lafayette, IN.

Atrazine, an agricultural herbicide that is a common contaminant of potable water supplies, is implicated as an endocrine disruptor and potential carcinogen. Ongoing studies are defining the genetic and epigenetic mechanisms of an embryonic exposure to atrazine, assessing the later in life adverse health outcomes in the exposed generation, and transgenerational effects using the zebrafish model system. Embryos were exposed to environmentally relevant concentrations of atrazine shortly after fertilization through the end of embryogenesis. Transcriptional profiles immediately following the exposure identified expression alterations in genes associated with neuroendocrine function, cell cycle regulation, and carcinogenesis. Adults developmentally exposed to atrazine had a significant difference in the number of pairs that successfully bred and was coupled to a distinct alteration in reproductive system. Embryos were exposed to environmentally relevant concentrations of atrazine shortly after fertilization through the end of embryogenesis. Transcriptional profiles immediately following the exposure identified expression alterations in genes associated with embryonic and tissue development and with neurological and ophthalmic diseases. Furthermore, the beta-estradiol pathway was predicted to be inhibited. The F2 were raised to maturity and significant differences in reproductive function outcomes were observed with the number of pairs that successfully bred and was coupled to a distinct alteration in reproductive phenotype in the exposed females. To determine if adverse effects were passed onto progeny, an unexposed generation was created from adults developmentally exposed to atrazine to assess paternal and/or maternal inheritance (F2). RNA-sequencing of the F2 at the end of embryogenesis revealed enrichment of expression alterations in genes associated with embryonic and tissue development and with neurological and ophthalmic diseases. Furthermore, the beta-estradiol pathway was predicted to be inhibited. The F2 were raised to maturity and significant differences in reproductive function outcomes were observed with the greatest impacts in the cross of the males developmentally exposed to atrazine with control females. No significant differences were observed in the F3 larvae in regards to survivorship, hatching or morphological analysis of whole larvae, head, or eye length. Overall these results indicate that transgenerational effects on the female reproductive system are most pronounced in progeny from the males developmentally exposed to atrazine. Overall these results indicate that transgenerational effects on the female reproductive system are most pronounced in progeny from the males developmentally exposed to atrazine.

222 Evaluation of Teratogenic Effect of BMP2-Inducible Kinase Inhibition in Zebrafish by Using Morpholinio Antisense Oligonucleotides

Bone morphogenetic protein 2 (BMP2) has regulatory role in attenuating the program of osteoblast differentiation. BMP2 inducible kinase (BIKE2) is a serine/threonine protein kinase upregulated during BMP2 activation. Since there are no published reports related to BIKE2 inhibition inducing embryo malformation, we evaluated roles of BIKE2 in embryo development in zebrafish using morpholino antisense oligonucleotides (oligos) targeting BIKE2 and p53. (Anti-p53 mitigates morpholino-associated apoptosis/toxicity in embryos). Zebrafish embryos (2-32 cell stage) were micro-injected with BIKE2 antisense, or non-sense control oligonucleotides and subsequently evaluated for developmental malformations 5 days post fertilization/post-injection. Craniofacial, heart, and profound axial malformations, including caudal dygenesis and ectopic tails were observed in groups injected with BIKE2 morpholino antisense oligos. The spectrum of malformations was similar to the “super-dorsalization” phenotype previously reported with BMP2 inhibition. Compared with control non-sense oligos, malformations were significantly higher in embryos containing antisense BIKE2 oligos (5% in control vs 20% using a single BIKE2 antisense oligo, and 37% using a combination of two BIKE2 antisense oligos, respectively). Compounds that bind with high affinity and specificity to BIKE2 also caused teratogenic effects indicating skeletal abnormalities consistent with gene targets downstream of BMP2 and/or involved in dorsalization using RT-PCR. Reductions of the gene products ostepherin (regulating osteocyte precursors for bone cell differentiation), pax2a (required for midbrain–hindbrain boundary formation, which affects dorsal expansion), ev1, a (ventral signal required for normal mesodermal progenitor cells development), and krox-20 (required for hindbrain formation and specification) were observed. Together these studies indicate that inhibition of BIKE2 has teratogenic effect on zebrafish embryo development.

223 Tributyltin (TBT) Exposure Promotes Zebrafish Sexual Differentiation
C. L. McGinnis, K. Kosior, J. Kowalski and T. Lombardi. Quinnipiac University, Hamden, CT.

Tributyltin (TBT), an antifouling agent, has been implicated in the masculinization of fish species worldwide, however the molecular mechanism is still not completely understood. Our lab has previously examined the actions of TBT as an endocrine disruptor in zebrafish (Danio rerio) and determined, in vitro, that TBT inhibits zFER specific activity in a dose dependent manner and may potentially act through the RXR portion of the PPAR-RXR (peroxisome proliferator-activated receptor gamma - retinoid X receptor alpha) heterodimer. Additionally, zebrafish were exposed to increasing concentrations of TBT and sex differentiation genes were analyzed via qPCR. Results from qPCR focused our experimental efforts on the candidate gene, SRY-box containing gene 9a (Sox9a). Sox9a is a key regulator in mammalian testis differentiation, where it is shuttled to the nucleus upon differentiation; this appears to be a conserved mechanism across fish, marsupials and placental mammals. Developing zebrafish were exposed to 1µM and 2.5µM TBT from 10 days post hatch (dph) to 90 dph and sampling was done at 25, 40, 60 and 90 dph. Fish were treated three times per week with TBT, estrogen, testosterone, or vehicle. Following treatments, tissues were fixed in 4% PFA, processed, paraffin imbedded, and then immunohistochemical (IHC) analysis was performed to assess Sox9a nuclear or cytoplasmic localization.

223a Mitochondrial Uncoupling Disrupts Neurodevelopment in Zebrafish Embryos
S. Chan, J. Bestman, J. J. Rahn and K. D. Stackley. Drug Discovery and Biomedical Sciences, Medical University of South Carolina, Charleston, SC. Sponsor: R. Di Giulio.

Caloric restriction is a proven method for weight loss and possible lifespan extension. However, caloric restriction is detrimental in early development as malnourished mothers produce offspring with low birth weights, developmental delay and neurodevelopmental defects, which have been linked with diseases in later life. Inhibiting mitochondrial energetics, such as through exposure to uncouplers like 2,4-dinitrophenol (DNP), mimics caloric restriction. DNP disrupts the proton gradient needed for ATP synthesis by oxidative phosphorylation, and is a common environmental toxicant in automobile exhaust, industrial waste and pesticides. DNP is also seen as an illicit weight-loss drug, particularly with women of childbearing age due to its ready availability online. Thus it is important to analyze the effects of exposures to mitochondrial toxins such as DNP on the developing embryo, as a potential cause of some birth defects and neurological disorders. We use zebrafish embryos to study the effects of mitochondrial uncoupling on embryonic development, as breeding pairs produce hundreds of transparent embryos that develop rapidly outside of the mother and hatch within 3 days post-fertilization (dph). Here we show that mitochondrial uncoupling by DNP disrupts embryonic development, causing developmental delay and neurodevelopmental defects. The development of the primary motor neurons and retinal layers were particularly impacted, which may explain the locomotor defects observed in DNP exposed embryos. Biochemically, we observed that mitochondrial ATP turnover was decreased throughout embryonic development. Likewise, protein oxidation and other markers of oxidative stress response were decreased. As reactive oxygen species (ROS) are required for nervous system development, we propose that the neurodevelopmental defects we observe are likely due to decreased ROS signaling in embryos.

223b Relative Developmental Toxicity of Pentachlorophenol and Pentachloroanisole in Zebrafish (Danio rerio)
Y. Cheng and L. Chan. University of Ottawa, Ottawa, ON, Canada.

Pentachlorophenol (PCP) and pentachloroanisole (PCA) are widely distributed chlorinated aromatic compounds and have been found in the environment and human populations. The objective of this study is to characterize and compare the effects of PCP and PCA on development using a fish model. Zebrafish embryos were exposed to 0.1, 1, 10, 100, 500, 1000 µg/L PCP and PCA respectively for 96 h. The sub-lethal and lethal effects were studied through malformation observation, LC50 testing for survival rate at 96 hpc and EC50 testing for hatching rate at 72 hpc. The mRNA gene expression changes related to brain growth and thyroid
hormone regulating pathways were investigated. LC50 at 96 hpf was 3.04 µg/L for PCP << 336.0 µg/L for PCA, and EC50 for hatching at 72 hpf was 2.74 µg/L for PCP << 339.1 µg/L for PCA, indicating that the developmental toxicity of PCP was at least 100 times higher than that of PCA. Other sub-lethal effects, such as yolk deformation, malformation of tail, scoliosis, hemorrhage and pericardial edema, were observed. Both PCP and PCA showed hyperactivity effects similar to that of triiodothyronine (T3) resulting in increased mRNA expressions of Synaptophysin (SYN), Isothyroid Deiodinase type II (Dio2), Isothyroid Deiodinase type III (Dio3), Thyroid hormone receptor alpha 2 (THRαa) and Thyroid hormone receptor beta (THRβ). Our results on the relative developmental toxicity of PCP and PCA and the possible underlying mechanisms will be useful to support further research in human populations.

The interaction between regulatory pathways is an important mechanism by which organisms can adapt to their environment and respond to endogenous stress. One interaction that recently has been identified in adult mammals, cell culture, and fish embryos is that occurring between the aryl hydrocarbon receptor (Ahr) and members of the nuclear factor erythroid-2 related factor (Nrf) family. Each transcription factor regulates numerous downstream genes involved in the cellular response to toxicants and oxidative stress; they each also play a role in normal development. In zebrafish embryos, where there are six nrf genes, developmental gene expression of all nrf has been shown to be altered in the absence of Ahr1B protein using morpholino knockdown. The mechanism of this altered transcriptional response by Ahr1B has been explored using Chromatin Immunoprecipitation (ChIP) in zebrafish embryos to test the hypothesis that Ahr1B is binding directly to cis-promoter elements to regulate the developmental transcription of nrf genes. Using ChIP coupled with PCR, Ahr1B has been shown to directly bind to XREs on the promoter of each nrf gene in the presence of TCDD, confirming its role as a transcriptional regulator of the entire nrf gene family. This research highlights the importance of the TCDD-Ahr-Nrf gene battery during the most sensitive life stage, the embryo, and provides a better understanding of how combinatorial molecular signaling can protect embryos from potentially embryotoxic events following toxicant exposure.

As part of the chemical screening and prioritization research program of the US EPA, the ToxCast Phase II chemicals were assessed using a vertebrate screen for developmental toxicity. Zebrafish embryos (Danio rerio) were exposed in 96-well plates from late-blastula stage (6hr post fertilization, pf) through day 5pf (1-2 days post-hatch). All exposures were by immersion and renewed daily. The 700 chemicals included food additives, consumer use product ingredients, pesticides, failed pharmaceuticals, and “green” plasticizers (http://epa.gov/ntct/toxcast/chemicals.html). Intra- and inter-plate replicates were included for quality control. Developmental toxicity was initially assessed using a single nominal concentration of 80 µM: positives and a selection of negatives were confirmed by concentration-response determinations. On day 5pf, larvae were moved from exposure solution to a control solution without chemical, and on day 6pf were assessed for overt toxicity (i.e., death, non-hatching and dysmorphology; n=4 embryos per chemical). Dysmorphology was a combined score using both in-life observation and brightfield, high-content image analysis. Overt toxicity was noted with 46% of the chemicals tested compared to 62% positive chemicals when the ToxCast Phase I library, consisting of mostly pesticide active ingredients, was previously tested. As with the Phase I library, the octanol-water partition coefficient (logKow) of the Phase II library chemicals was positively correlated with overt toxicity: there were 18% positive chemicals with logKow 0-4; 41% positive chemicals with logKow 0 to 4; and 67% positive chemicals with a logKow >4. All chemicals positive at the single concentration were further assessed for potency using a Dose-Response Study (8-point, semi-log concentration curve: n=3 embryos per concentration). These data demonstrate the utility of zebrafish in medium-throughput chemical testing programs for detection of adverse developmental outcomes. This abstract may not necessarily reflect official Agency policy.

Polycyclic aromatic hydrocarbons (PAHs) are known to induce developmental defects in vertebrates, and exposures of fish embryos to PAHs have been shown to cause cardiac deformities. However, the mechanisms underlying this toxicity remain unclear. The aryl hydrocarbon receptor (AHR), a transcription factor, is activated by and mediates toxicity of some PAHs. Exposure to a simple PAH mixture consisting of an AHR agonist (benzo(a)pyrene-BaP) and fluoranthene (FL), an inhibitor of cytochrome p50 (CYP1) - a gene induced by activation of the AHR - results in pericardial effusion and an elongated heart. Knockdown of AHR2 prevents this toxicity. In this study, we used a microarray analysis to identify genes involved in this toxicity. To determine the role of AHR2 by knocking down this gene, we used zebrafish embryos injected with a control morpholino and AHR2 morpholino. Embryos at 36hpf were then exposed to DMSO, 100 µg/L BaP, 500 µg/L FL, or 100 µg/L BaP + 500 µg/L FL. We extracted heart tissues at various time points (2h, 6h, 12h, and 18h) for RNA. Overall data showed that gene expression differences between the AHR knockdown and control embryos decreased over time, suggesting that the AHR mediated gene expression due to PAHs decrease within 18 h of exposure. Furthermore, despite BaP + FL resulting in a deformed heart, this mixture resulted in smaller effect on overall gene expression compared to BaP or FL alone. Differentially expressed genes by BaP + FL in AHR knockdown and control embryos were primarily involved in Ca2+ cycling, cardiac muscle contraction, suggesting that PAH affects on cardiac muscle function may underlie the structural deformities. Furthermore, several genes such as Pdlim1 - a gene involved in cardiac looping – that were identified may play a direct role in underlying cardiac abnormality in fish. Ingenuity pathway analysis on transcriptomic data suggested that FOS signaling pathway might be playing a key role in mediating AHR-dependent cardiac toxicity.

Background: Lead exposure has been associated with high blood pressure. Oxidative stress and inflammation have also been independently associated with high blood pressure. Objective: We examined the association of blood lead levels, serum gamma-glutamyl transferase (GGT), and serum C-Reactive Protein (CRP) levels with systolic blood pressure (SBP), diastolic blood pressure (DBP), and hypertension in adult participants in the National Health and Nutrition Examination Survey (NHANES) 2007-2010. Methods: The outcome of interest were SBP and DBP, hypertension, blood lead levels, serum GGT, and serum CRP. Serum CRP, serum GGT, and blood lead were log normal transformed. Blood lead was also analyzed using weighted quartiles. Linear regression, logistic regression and multilog procedures were used with a priori covariates age, race/ethnicity, gender, education, smoker status, alcohol use, diabetes, body mass index, and serum creatinine. Results: Higher SBP statistically correlated with blood lead and serum GGT in all adults and in male and female subgroups. Blood lead and serum GGT were associated with hypertension when all individuals were entered in the model and in the female subgroup after stratification. Elevated serum CRP was associated with serum GGT and with DBP, but not with blood lead, SBP, or hypertension. Conclusions: This study demonstrates a possible biological pathway through which lead induces hypertension and increases SBP. Our results indicate that lead may work through a direct mechanism as well as through the indirect mechanism of oxidative stress in order to affect these outcomes.

Background: Exposure to environmental chemicals may play a role in the development of obesity. There is evidence that environmental exposures are associated with obesity in children and adults.

223c Transcriptional Regulation of the Nuclear Factor Erythroid-2 Related Factor (NRF) Family by the Aryl Hydrocarbon Receptor (AhR)

223f Serum Gamma Glutamyl Transferase Is Associated with Higher Blood Pressure and Lead-Induced High Blood Pressure: A Model Pathway Using NHANES 2007-2010

223g Association of Urinary Dichlorophenols with Increased Body Weight Measures and Obesity in Children and Adults: Analyses of NHANES 2007-2010

Background: Exposure to environmental chemicals may play a role in the development of obesity. There is evidence that environmental exposures are associated with obesity in children and adults.
Objective: To examine the association of urinary levels of the environmental pesticides 2,5-dichlorophenol (2,5-DCP) and 2,4-dichlorophenol (2,4-DCP) and the environmental phenoxytriclosan with body weight outcomes in children, adolescents and adults participating in the National Health and Nutrition Examination Survey (NHANES) 2007-2010.

Methods: We performed multivariate linear and logistic regression to analyze the association of BMI z-score, waist circumference, and obesity with urinary pesticide concentration in children and adolescents. We conducted the same analyses in adults with the outcomes of BMI, waist circumference and obesity.

Results: We found a statistically significant positive association (p<0.05) between 2,5-DCP and BMI z-score and obesity in children and adolescents. In adults, there was a statistically significant positive association (p<0.05) between 2,5-DCP and BMI, waist circumference, and a non-monotonic association with obesity. However, a statistically significant relationship between 2,4-DCP and body weight outcomes was not found in adults. No associations were found between the body weight outcomes and any of the body weight outcomes for either children or adults.

Conclusions: We found an association between dichlorophenols and increased body weight measures in both children/adolescents and adults. Additionally, we found an association between dichlorophenols and obesity in children/adolescents and a non-monotonic response in adults.

223h Airway Inflammation Markers in Exhaled Breath from Children Are Linked with Exposure to Black Carbon

S. De Prins1,2, E. Doms1, M. Van Poppel1, L. Int Panis1,3, E. Van de Mieroop4, S. De Prins1,2, E. Dons1, M. Van Poppel1, L. Int Panis1,3, E. Van de Mieroop4, S. De Prins1,2, E. Dons1, M. Van Poppel1, L. Int Panis1,3, E. Van de Mieroop4, S. De Prins1,2, E. Dons1, M. Van Poppel1, L. Int Panis1,3, E. Van de Mieroop4, S. De Prins1,2, E. Dons1, M. Van Poppel1, L. Int Panis1,3, E. Van de Mieroop4.

The current study assessed the associations between airway oxidative stress and inflammation markers and BC exposure in primary school children in a Western European urban area.

In 130 children 6-12 years old, the fraction of exhaled nitric oxide (FeNO), exhaled breath condensate (EBC) pH, 8-iso prostaglandin and IL-1β were measured in two seasons. Acute BC exposure on the sampling day was assessed using BC measurements at a central monitoring site. Land use regression (LUR) models were applied to estimate weekly and seasonal average BC exposure. Associations between biomarkers and exposure were tested using linear mixed effects regression models. Next to single exposure models, models combining multiple exposures were analyzed. Oxidative stress and inflammation markers were associated with BC levels, independent of gender, age, allergy status, parental education level and meteorological conditions on the sampling day. Depending on the considered single or multiple exposure model, IQR increases in acute BC exposure ($100 ng/m^3$) were linked with higher 8-iso prostaglandin ranging from 5.9 (95% CI 0.1-12.0) to 9.4% (95% CI 2.1-17.2). Increased FeNO levels ranging from 12.1 (95% CI 2.5-22.8) to 15.2% (95% CI 4.4-27.0) were associated with IQR increases in weekly BC exposure (1730 ng/m^3). IQR increases in acute and weekly BC were linked with increases in IL-1β between 19.3 (95% CI 1.3-40.5) and 42.8% (95% CI 11.2-83.2).

Acute BC exposure was associated with airway oxidative stress while weekly and acute exposure was linked with airway inflammation. The association between BC exposure and IL-1β in EBC reflects activation of cells involved in first line defense mechanisms of the airways such as airway epithelial cells and macrophages, as was previously suggested by in vitro studies.

223i Arsenic Level in Drinking Water and Lung Cancer Mortality among 127 United States Counties from 1950 to 1979

S. H. Lamm1, E. K. Dissen1, M. Feinleib2, J. Li1,2 and E. Hatef1,2.

Background: Studies from Asia and Latin America found arsenic to be a risk factor for bladder and lung cancers in areas with high levels of arsenic (> 100-200 ug/L) in drinking water. Evidence for cancer risk at the < 100 ug/L arsenic levels found for bladder and lung cancers in areas with high levels of arsenic (> 100-200 ug/L) in drinking water was supported by a study in Diepenbeek, Belgium and 4Provincial Institute of Hygiene, Antwerp, Belgium.

School of Medicine, Macon, GA and 2Department of Mathematics and Computer Science, Fort Valley State University, Fort Valley, GA.

We hypothesized that greater longevity may influence age-adjusted incidence of two selected mesenchymal cancer types since enhanced robustness in older age groups may more accurately reflect age-related cancer trends. Using SEER 9 registry data we examined age-adjusted pleural mesothelioma (PM) and soft tissue sarcoma (STS) incidence rates for 1973 through 2010 in conjunction with concurrent changes in age distribution of the US population. The overall age-adjusted rate per 100,000 person-years for PM significantly (* p<0.05) increased by 185%* from 1973 to its peak value in 1992, then decreased by 18% from 1992 to 2010. The 75 yr age group dominated the early PM trends, increasing by <600%* for 1973-1992, and again by 19%* for 1992-2010. In contrast, the 0-74 yr age group showed a 96%* increase in age-adjusted PM for 1973-1992, and then declined by 47%* for 1992-2010. By comparison, overall age-adjusted STS rates were increased by 17%* for 1973-1992 and again by 29%* for 1992-2010. The 75+ yr age group dominated the STS trends in both intervals, increasing by 43%* for 1973-1992, and again by 41%* for 1992-2010, while the 0-74 yr age group showed only 11% (n.s.) and 25%* increases in these respective intervals. The SEER 9 registry exhibits significant increases in the 75+ yr population at risk from 1973 (3.7%) to 1992 (7.4%) and again for 2010 (10.1%). We conclude that the continuing shift toward greater longevity since 1992 may help to explain the greater elevation in age-adjusted PM and STS rates among the increasingly robust 75+ yr age group. Regulatory controls on asbestos may explain the 47% decline in PM for the 0-74 yr age group from 1992 to 2010, while the 19% increase in the 75+ yr age group may represent a longevity effect that is apparent for both PM and STS.
nostic methods and changes in disease classification since 1992 also may contribute to these trends, and the issue of longer latency for asbestos-related PM should be examined further.

226 Aflatoxin Exposure Associates with Abnormal Liver Function and Infections with HIV and TB in Uganda

M. Kang1, L. Tang1, P. M. Nkurunziza2, R. Mwバンanaka3, A. Nkwot4, J. Ssek2, C. C. Whalen and J. Wang1. 1University of Georgia, Athens, GA, 2MRC Uganda Unit, Entebbe, Uganda and 3Rakai Health Program, Rakai, Uganda.

Aflatoxins (AF) exposure is a serious global health threat. The epidemic of liver disease and infections with HIV and TB was associated with AF exposure in Ghana; however, the correlation between AF exposure and the progression of these epidemic diseases has not been firmly established in other African populations. In this study we assessed AF-lysine adduct level in serum samples collected from a normal human group (n=267), a group with abnormal liver function (n=132), a group with HIV infection (n=536), and a group with HIV/tuberculosis co-infection (n=62) in Uganda. AF-lysine adduct was measured via high-performance liquid chromatography (HPLC)-fluorescence detection with a limit of detection of 0.4 pg/mg albumin. Median serum AF-lysine adduct level was 1.54 pg/mg albumin (range=0.45-253.11) among normal human group; median serum AF-lysine adduct level was 2.88 pg/mg albumin (range=0.54-153.06) among the group with abnormal liver function; median serum AF-lysine adduct level was 3.19 pg/mg albumin (range=0.41-167.04) among the group with HIV infection; and the median serum AF-lysine adduct level was 8.90 pg/mg albumin (range=0.54-70.41) among the group with HIV and tuberculosis co-infection. Groups with abnormal liver function (p<0.01), HIV infection (p<0.01), and HIV/tuberculosis co-infection (p<0.001) had significantly higher AF-lysine adduct levels than that in the normal human group. Patients with severe HIV progression, dependent on CD4+ T cell counts, had a significant higher adduct level than those with minor progression (P-trend=0.0062). In addition, the adduct level was synergistically increased in HIV patients infected with tuberculosis compared to the HIV patients without tuberculosis and non-infected normal group (P-trend=0.0001). This study confirms previous findings and implies that mitigation of AF exposure not only can reduce liver diseases, but also an innovative strategy to reduce the spreading of HIV and tuberculosis in epidemic sub-Saharan African countries.

227 A Systematic Review of the Epidemiologic Evidence on Low-Level Arsenic Exposure and Cognitive Function in Children: Applicability for Risk Assessment

The U.S. Environmental Protection Agency is currently revising their 1988 non-cancer and cancer risk assessments for inorganic arsenic. Cognitive function in children is an endpoint for which several recent studies bear consideration in deriving a non-cancer reference dose (RfD). We conducted a systematic review of the epidemiologic literature for scientific evidence on possible neurobehavioral effects at lower exposure levels in children. Eleven cross-sectional, case-control, and cohort studies were identified that report on the association between low-level arsenic exposure and cognitive function in older children (e.g., >5 years) was observed overall. A population-based randomized trial from Matlab, Bangladesh (Hamadani et al. 2011), provided the best evidence for informing a quantitative risk assessment (results reported separately), with supporting evidence from another region of Bangladesh. In this study, verbal and, to a lesser extent, full-scale IQ scores were inversely associated with log urinary arsenic levels in girls, but not boys, at age 5 years. It remains unclear whether the findings in the available literature are applicable to similar child populations in the United States. Standard cognitive test measures have not been developed for Bangladesh, and issues such as differences in cultural practices, poor nutrition, adequate correction for maternal IQ, presence of other neurotoxicants in some studies, and dietary deficiencies in Bangladesh greatly limit generalizability to U.S. populations.

228 Clinical and Molecular Features of Myelodysplastic Syndrome following Benzene Exposure

P. Kerz1 and D. Pratt2. 1Pacific Coast Toxicology, Reseda, CA, 2Summit Toxicology, Superior, CO and 3School of Public Health, University of Colorado, Aurora, CO.

Chronic exposure to benzene is associated with several possibly related and overlapping hematopoietic diseases such as aplastic anemia (AA), myelodysplastic syndrome (MDS), and acute myeloid leukemia (AML). Recent reports indicate that MDS developing subsequent to benzene exposure may represent the main risk of hematologic disease associated with benzene, and that MDS may develop following exposures to benzene at lower concentrations than previously reported. In addition, cytogenetic abnormalities long assumed to be induced by benzene such as aneuploidy or loss of all or part of chromosomes 5 or 7, which are associated with some forms of therapy related MDS/AML, may not be associated with benzene exposure after all. We have compiled MDS cases from the peer-reviewed literature with documented benzene exposure and describe the clinical and molecular features of benzene-associated MDS (BZ-MDS). We believe such analysis will help to clarify the etiology and pathogenesis of the disease. We report that BZ-MDS cases frequently feature hypoplastic bone marrow, clear indications of an autoimmune mechanism, marked eosinophilia, relatively young age at diagnosis, and increased survival relative to de novo MDS. In addition, cytogenetic features frequently seen in therapy-related MDS (tMDS) do not appear to be prominent features of BZ-MDS. These results highlight a need for additional study of BZ-MDS and suggest a picture of BZ-MDS that is distinct from both tMDS and de novo disease.

229 The Biomarkers of Exposure to ARsenic (BEAR) Pregnancy Cohort in Mexico: Arsenic Methylation Linked to Poorer Birth Outcomes

J. E. Laine1, K. Bailey1, M. Rubio-Andrade1, A. F. O’Hara2, L. Smeester3, Z. Drobna4, A. H. Herring5, M. Styblo4, G. G. Garcia-Vargas6 and R. Fry7. 1Department of Environmental Sciences and Engineering, UNC, Chapel Hill, NC, 2Department of Epidemiology, UNC, Chapel Hill, NC, 3Facultad de Medicina, Universidad Juarez del Estado de Durango, Gómez Palacio, Mexico, 4Department of Nutrition, UNC, Chapel Hill, NC and 5Department of Biostatistics, Gillings School of Global Public Health, UNC, Chapel Hill, NC.

Exposure to inorganic arsenic (iAs) from drinking water is a global public health problem yet much remains unknown about the extent of exposure in susceptible populations, including pregnant women and children. Higher prenatal iAs exposure has previously been associated with a greater risk of adverse pregnancy outcomes and later life health effects. Our objective for this study was to establish the Biomarkers of Exposure to ARsenic (BEAR) prospective pregnancy cohort in order to better to understand the effects of iAs exposure and iAs metabolism during pregnancy on maternal-fetal health, with the ultimate aim of increasing awareness and reducing potential exposures to iAs. Concentrations of iAs in drinking water (DW-iAs) and maternal urinary concentrations of iAs and its metabolites (U-iAs) were determined. Birth outcomes were recorded and analyzed for their relationship to DW-iAs, U-iAs, and concentrations and proportions of individual urinary arsines. DW-iAs for the study subjects ranged from 0.9 to 236 μg/L. More than half of the women (53%) had DW-iAs that exceeded the World Health Organization’s recommended guideline of 10 μg/L. DW-iAs was significantly associated with U-iAs. Overall, neither DW-iAs nor U-iAs were associated with any birth outcomes. However a significant inverse relationship was observed between urinary concentrations and proportions of MMAs and birth weight with an average decrease of 25 g. Biomonitoring results demonstrate that pregnant women in Gómez Palacio are exposed to potentially harmful levels of DW-iAs. A relationship between iAs metabolism and adverse birth outcomes were established.

230 A Cross-Sectional Study of Blood Level Lead and Attention-Deficit/Hyperactivity Disorder by Parental Socioeconomic Status amongst Korea Children

H. Kwon2, O. Yi1 and D. Kim3. 1National Health Insurance Services, Health Insurance Policy Research, Seoul, Republic of Korea, 2Department of Preventive Medicine, Dankook University College of Medicine, Cheonan, Republic of Korea and 3Department of Public Health Promotion Research Institute for Health and Social Affairs, Seoul, Republic of Korea. Sponsor: I. Park.

Background: It has been reported that blood lead level increases the risk of ADHD of children.

Objective: We estimated the effect of blood lead level on ADHD controlling for parents’ socioeconomic status (SES).
Methods: Whether or not blood lead level was associated with ADHD by parental SES was evaluated using information on 3,666 school aged children in Korea. Associations between parental SES and the blood lead level were examined by estimating fixed effects model.

Result: After adjustments for potential confounding variables, children with mother in the lowest education (Odds Ratio (OR): 2.38, 95% CI=1.40-4.03) and those living in the most deprived area (OR=1.29, 95% CI =1.01-1.66) were significantly more likely to be associated with ADHD.

Conclusion: Our findings suggest that the association between blood lead level and ADHD vary by characteristic of parental SES.

Keywords: ADHD, blood lead level, SES

231 Cumulative Risk Assessment of Urban Air Toxics: A Pilot Study in San Antonio, Texas

D. Procotor, M. Suh, J. A. Tachovsky, L. Abraham, G. Hixon, G. Brothby and S. Campleman. 1ToxStrategies, Mission Viejo, CA, 2ToxStrategies, Austin, TX, 3ToxStrategies, Houston, TX, 4ToxStrategies, Richmond, CA and 5Electric Power Research Institute, Palo Alto, CA.

A pilot cumulative risk assessment project was conducted to test a modeling strategy for estimating the community health burden potentially associated with air toxics while simultaneously accounting for background air toxics, criteria air pollutants, and non-chemical stressors in an urban population of San Antonio, TX. Generalized additive models (GAMs) were used to quantitatively evaluate the potential association between airborne exposure to certain air toxics (lead, arsenic, antimony, cholormethane) generated by two coal-fired electricity generating units (EGUs), background levels of these air toxics, PM2.5, ozone, and social stressors on all cancer and heart disease mortality for 34 census tracts within the 10-mile radius of the EGUs. Four demographic and socioeconomic indicators (i.e., percent African American, percent female, age, and poverty) were significantly associated with all cancer and heart disease mortality, accounting for 70.6% and 79.1% of the variance, respectively. Accounting for these four demographic and socioeconomic indicators in the GAMs, concentrations of the four EGU-specific air toxics were not significantly associated with either all cancer or heart disease mortality in the study area. However, arsenic from non-EGU related on-road and non-road sources was significantly associated with all cancer mortality (88.8% of the residualized variance), PM2.5, lead from non-point sources, and ozone were significantly associated with heart disease mortality (88.1% of the residualized variance). With 17.9 and 21.27 degrees of freedom for cancer and heart disease, respectively, the GAMs were highly complex and non-linear. Although this pilot study has several limitations, it utilizes an innovative approach to quantitatively assess cumulative risk from non-chemical and chemical stressors and may serve as a preliminary model for future analysis.

232 Weight-of-Evidence Evaluation of the Respiratory Effects Associated with Diacetyl

B. L. Finley, J. S. Pierce, K. Neier and L. J. Roberts. 1Cardno ChemRisk, Brooklyn, NY and 2Cardno ChemRisk, Chicago, IL.

Recent case reports and epidemiologic investigations have concluded that diacetyl inhalation in the workplace may be associated with serious adverse respiratory effects, including the relatively rare and lethal disease bronchiolitis obliterans (BO). The concern stems from a series of cases of fixed obstructive lung disease consistent with BO that were reported in eight former employees from the Gilster-Mary Lee microwave popcorn plant in Jasper, Missouri. However, over 100 volatile organic compounds were identified in air samples collected in the workplace, and the majority of the cohort was non-occupationally exposed to respiratory irritants, including known inducers of BO. A weight of evidence analysis was conducted to determine if the suggested associations between diacetyl and BO and pulmonary function decrements (e.g., fixed obstruction, decline in FEV1 and FVC) satisfy the Bradford Hill criteria of causation. Based on our analysis, none of the criteria were met. Specifically, no statistical estimate for BO has been reported in the literature and inconsistent associations have been reported between diacetyl exposure and various pulmonary function deficits (across studies and within a single cohort). Furthermore, temporality cannot be established because baseline medical evaluations were not performed on any of the worker cohorts, and none of the epidemiology investigations demonstrate the presence of an exposure-response relationship that can be attributed to diacetyl. In addition, the lack of deep lung effects observed in experimental animals exposed to concentrations of diacetyl that are orders of magnitude higher than the occupational setting contradicts the hypothesis that diacetyl is the probable cause for lung disease in these workers. Thus the weight of evidence does not support the hypothesis that exposure to diacetyl causes BO and/or pulmonary function decline.
Identification of heat-related health risks is of critical importance for outdoor workers, particularly in the Deep South, where heat indices often reach high stress levels in the summertime. We hypothesize that significant differences in vulnerability to heat-related health risks exist in urban groundkeeper populations due to the urban heat island effect and that volatile organic compound (VOC) exposure will be heightened for groundkeepers at urban sites in close proximity to roads with high traffic volumes or major point source industries, particularly when temperatures are high. We set out to determine whether a small, inexpensive temperature/sunlight monitor attached to the shoe could be used to estimate heat exposure. We recruited 21 groundkeepers to wear temperature/sunlight and passive VOC monitors for 7 consecutive days during the summer. Urban and rural non-occupationally exposed participants were also recruited (N=60). In response to an exit survey, most participants (86%) found wearing the monitor on their shoe was very comfortable and reported the monitor was not hard to remember to wear (81%). When data from the individual monitors were compared to data from the closest weather station, weather stations overestimated average heat exposure. In contrast, daily maximum temperatures from a nearby weather station underestimated maximum temperatures experienced by urban participants. A small proportion of the samples analyzed suggest elevated time-weighted average toluene and benzene exposure for non-smoking participants when compared to ambient levels measured in the recent Birmingham Air Toxics study and estimated benzene levels for at least two participants are over the EPA chronic inhalation reference concentration for cancer risk. The investigation contributes to exposure research by determining the effect of microclimates within urban settings on assessing the heat and VOC related health risks associated with outdoor work in the summertime.

**235 Measuring Personal Exposure to Heat and Volatile Organic Compounds in Groundkeepers**

**236 Mechanisms for the Development of Rat Lung Tumors following Inhalation Exposures to MDI**

A. Poole1, A. H. Chappelle1 and M. A. Collins1. 1International Oecoytane Institute, Manchester, United Kingdom and 2Toxicology Advice & Solutions, Wollerau, Switzerland.

Although the endpoint of greatest concern after inhalation exposure to methylene diphenyl diisocyanate (MDI) (101-68-8) is occupational asthma, it has been suggested that evidence from cancer incidence and mortality studies of workers is insufficient to determine if exposure to MDI is causally associated with cancer. Chronic administration (17 h/d) of MDI aerosol results in proliferative and fibrotic responses and low incidence of bronchoulveolar (BA) adenomas in rats. This poster reviews, evaluates and characterizes studies investigating early events of MDI pulmonary toxicity. Evidence indicates compensatory homeostatic mechanisms leading to pulmonary tumors. Key events include continued exposures to respirable MDI aerosols, localized particle deposition at concentrations depleting protective biomolecules in fluid lining the lung surface, and exposure duration. Once deposited in the BA region, MDI particles interact chemically with biological macromolecules, including surfactant and other proteins, reducing their concentrations in the lung lining. To maintain normal homeostasis increased synthesis of secretory protein is induced. As the increased synthesis becomes maximized but demand for protective proteins is maintained there is a secondary, compensatory response characterized by an increase in cell replication resulting in BA hyperplasia in the terminal bronchioles and ultimately, after prolonged exposure/cellular stress, to the development of adenomas. The observation that MDI particulates do not accumulate in the lung at doses producing lung tumors, together with the lack of chronic inflammatory response at lower exposures, supports a non-genotoxic, compensatory response of the lung to maintain homeostasis. In conclusion, while the intrinsic properties of respirable MDI might pose a similar hazard for disease in both rat and humans, for humans the risk situation is entirely different. Rat lung tumors after chronic exposure to MDI are not predictive of the potential for human carcinogenicity.

**237 Is There Evidence of an Increased Risk to Human Health from Low-Level Exposure to Benzene?**

S. A. Fiebelkorn and C. Meredith. Group R&D, British American Tobacco, Southampton, United Kingdom.

Benzene is a volatile chemical used in industry and present in petrol, exhaust fumes and tobacco smoke. Several epidemiological studies have demonstrated an association between occupational benzene exposure and increased leukaemia risk, in particular acute myeloid leukaemia (AML). However, there is still some uncertainty as to the risk to the general population from low-dose benzene exposure. The main route of human exposure is via inhalation of benzene present in the environment or tobacco smoke. Smoking can contribute up to 90% of an individual’s exposure. In order to investigate the risk associated with low-dose exposure, potency estimates for benzene have been generated from individual occupational studies and meta-analysis data, and an exposure assessment for three population sub-groups, non-smokers, light smokers and heavy smokers carried out. Subsequently, various techniques including life table analysis have been used to evaluate risk of leukaemia and AML. The use of epidemiological data to generate a margin of exposure (MOE) was investigated and suggested benzene may be a high priority for risk management actions based on lifetime exposure estimates and its potency as a leukaemogen. Further assessment using meta-analyses data resulted in estimates of the excess lifetime risk of leukaemia at up to 0.006% for non-smokers and up to 0.06% for heavy smokers. For AML this was 0.003% for non-smokers and 0.03% for heavy smokers. The contribution of benzene to smoking induced leukaemia was estimated at between 8 and 26% (UCL 12-33%). For AML this contribution was estimated at 15 to 31% (UCL 28-60%). The estimates for AML are subject to some uncertainty due to limitations of the available data and further work would be required to confirm these findings. Future work may also include the use of alternative modelling techniques for epidemiological data, the use of biomarker data and further investigation of benzene metabolites and target tissue dose. It may also be possible to apply these methods to additional tobacco smoke toxicants and other smoking related disease endpoints.

**238 Mode of Action and Lack of Human Relevance of Benzo[alpha]pyrene (Benzo[alpha]pyrene)-Induced Thyroid Follicular Cell Adenomas in Male Han Wistar Rats**

R. Green2, P. P. Parsons2, R. C. Peffer2, J. Wight2 and R. Currie2. 1Product Safety, Syngenta Crop Protection, LLC, Greensboro, NC and 2Jeallott, Syngenta Ltd., Bracknell, Berkshire, United Kingdom.

Benzo[alpha]pyrene (Benzo[alpha]pyrene) is a novel succinate dehydrogenase inhibitor fungicide (FRAC class C2). In a 2-year dietary administration study with Han Wistar rats (10, 25, 100 and 600[µg]/[400µg] ppm), an increased incidence of benign thyroid follicular cell adenomas was observed in males in the 600 ppm group only (17% vs. 2% in controls). There were no treatment-related increases in the incidence of any other tumour type in the rat or mouse. Specific mode of action (MOA) studies were conducted and, in conjunction with the regulatory toxicology studies, demonstrate a MOA for induction of thyroid follicular cell adenomas. The MOA of benzo[alpha]pyrene (BaP) is based on the following key events: 1) Induction of hepatic UDPglucuronosyltransferase. 2) A decrease in circulating T3/T4 levels. 3) A compensatory increase in circulating thyroid stimulating hormone (TSH) via the hypothalamus-pituitary-thyroid (HPT) axis. 4) Increased proliferation in thy-
Arsenite and Methyl Methanesulfonate Co-Exposures Induce Synergistic Cellular Responses Associated with Carcinogenic Pathways

P. Balbuena1, B. Sun1, S. Ross1, L. Recio2, L. Winter1, H. H. J. Clewell1 and  K. Nohara1.

The Hamner Institutes for Health Sciences, Research Triangle Park, NC and 1Integrated Laboratory Systems, Research Triangle Park, NC.

Formaldehyde (FA) is used in both industrial applications and consumer goods, and exposure is associated with irritation of the nasal epithelium as well as pathologies such as hyperplasia, metaplasia and squamous cell carcinoma. This work presents a mode of action (MOA) analysis, conducted to examine the interdependence and collective contribution of these and other effects to upper respiratory tract (URT) carcinogenesis. Data were sorted by species and endpoint and evaluated for consistency in specificity, plausibility and coherence across multiple data-streams. DNA damage in the nasal passages is evident within days of exposure in animals, consistent with the clastogenicity observed in the nasal/buccal epithelium of humans after months to years of exposure. In conjunction with genotoxicity, FA elicits other effects in the respiratory epithelium, such as changes in cell proliferation rates, and cytotoxicity following cilastasis and mucous flow interruption, which progresses to regenerative proliferation at higher concentrations. As related events, genotoxicity, cytotoxicity and proliferation likely interact in a feed-forward manner, with each contributing to the amplification of initiated clones as a function of increasing FA exposure. For example, at low exposure levels both genotoxicity (DNA-protein crosslinks) and irritation may occur at the cellular level, triggering metaplastic transition and transient proliferation at the tissue level. This proliferative burst may indirectly augment direct FA genotoxicity and trigger an outgrowth of nascent clones. Sustained regenerative proliferation may further enhance cellular genotoxicity and promote the expansion of mutant cells. By evaluating the potential for complementarity, this integrated analysis highlights the relationships and relative contributions of cytotoxicity, proliferation and genotoxicity to URT carcinogenesis. The views expressed are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.
243 Significant Nonlinearity of Lung Cancer Risk in Relation to Arsenic in Drinking Water in Northeastern Taiwan

K. T. Bogen1, C. Chen1 and J. S. Tsai2. 1Health & Environmental, Exponent, Oakland, CA; 2Health & Environmental, Exponent, Seattle, WA and 1Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan.

Carcinogenic effects of ingested inorganic arsenic (InAs) have been addressed by ecological studies of increases in skin, lung, and bladder cancer in impoverished villages in southwest Taiwan and elsewhere. More recently, increased lung cancer incidence (LCI) was shown in a cohort of 6,888 residents of 3,901 households located in 18 villages in northeast Taiwan who were followed for 11 years [Chen et al. Environ Res 2010; 110(5):455–462]. That study estimated InAs exposure from thousands of household-well-specific measurements classified into five categories (range: undetectable [≤0.15] to >3,000 μg/L), and adjusted by age, gender, education, and consumption of cigarettes and of alcohol. A parallel cohort study by Chen et al. (2010) showed similar effects for bladder cancer. To refine dose-response analysis, the combined LCI and exposure data were re-binned into six exposure categories using residents who did not drink well water as the reference group (~16% of all residents and all person-years of exposure). Log adjusted relative risk (RRadj) was modeled as log(RRadj) = b * log(1 + X) + c * log(1-X), with exposure (X) defined as InAs concentration or as cumulative InAs exposure. Good fits to the re-binned data (p > 0.7, chi-square test) were obtained using each dose metric, but the estimated initial-slope parameter b is significantly negative in each case (2-tail p = 0.043 and 0.029, respectively), consistent with estimates of RRadj ≤ 1 at InAs levels ≤55 μg/L and <1,720 μg/L, respectively. This appears to be the first reported observation of a statistically significant hormetic dose-response relationship (i.e., with one significantly negative initial slope) for a single chemical carcinogen based on epidemiology data. Further analysis of potential confounding factors affecting non-drinkers of well water in this study is needed to better assess the nature and magnitude of any low-dose nonlinearity of LCI that occurred in this cohort.

244 Arsenic and Cadmium-Transformed UROtsa Bladder Cells Stably Expressing SPARC Will Reduce SPARC Expression during the Formation of a Tumor Heterotransplant

J. R. Danilev2, A. Slusser1, A. R. Klinger1, J. L. Larson1, X. Zhou2, S. H. Garrett1, B. Somir1 and D. A. Sene1. 1Basic Sciences, University of North Dakota, Grand Forks, ND and 2Pathology, University of North Dakota, Grand Forks, ND.

SPARC, secreted protein acidic and rich in cysteine, is an extracellular matrix protein that can bind to structural molecules such as type I collagen yet SPARC’s role in the matrix is a non-structural one. SPARC functions to regulate cell signaling, migration, angiogenesis, and cell proliferation acting more like a cytokine than a matrix molecule. SPARC clearly has a strong role in cancer however, in some types of cancers SPARC is elevated and in others reduced. Our previous studies showed that in an environmental model of bladder cancer utilizing the UROtsa cell line SPARC was drastically reduced in cells transformed with arsenic or cadmium and that this reduction occurred early in the transformation process upon exposure to low doses of either metal. In this study, SPARC was stably transduced into 2 arsenic and 2 cadmium UROtsa cell lines thereby re-establishing SPARC mRNA and protein levels comparable to those in the UROtsa parent cell line. These SPARC-expressing cells were then injected into nude mice and the resulting tumor heterotransplants were characterized. Results showed there were again non-detectable levels of SPARC protein by immunohistochemistry. In Western analyses SPARC levels were barely detectable if at all in the heterotransplants generated with SPARC-expressing cells. Real time PCR analyses showed that SPARC mRNA was being expressed in the tumors but when compared to the expression of the vector blasticidin transcript (BSD), the ratio of SPARC to BSD was reduced in the heterotransplant tumors compared to the cell lines. The possibility of down regulation of SPARC mRNA via miRNAs is being determined. In conclusion, the results of this study show that despite being stably transfected, SPARC expression is greatly reduced in heterotransplants. Therefore, shutting down SPARC protein expression appears to be strongly advantageous to tumor formation.

245 Peroxisome Proliferator-Activated Receptor-β/δ (PPARβ/δ) Inhibits Cell Proliferation and MMP-2-Mediated Tumorigenesis in Human Testicular Embryonal Carcinoma Cells

F. Yao1, L. Chen1, B. Zhu1, F. Gonzalez2 and J. M. Peters3. 1Department of Veterinary and Biomedical Sciences and The Center of Molecular Toxicology and Carcinogenesis, the Pennsylvania State University, University Park, PA and 2Laboratory of Metabolism, National Cancer Institute, Bethesda, MD.

Testicular germ cell tumors are most prevalent in young adult men ages 15–40 years, and arise as a result of abnormal testicular development. Peroxisome proliferator-activated receptors β/δ (PPARβ/δ) regulates a variety of biological processes but the function of PPARβ/δ in carcinogenesis remains controversial. Stable human testicular cancer cell lines (NT2/D1 and Ter2a) that constitutively over-express PPARβ/δ were produced to effectively examine the role of this receptor in human cancer models. Over-expression and/or ligand activation of PPARβ/δ increased expression of angiopoietin-like protein 4 (ANGPTL4) mRNA, a known PPARβ/δ target gene. Over-expression of PPARβ/δ inhibited cell proliferation in both NT2/D1 and Ter2a cells compared to controls. Ligand activation of PPARβ/δ both in NT2/D1 and Ter2a cells over-expressing PPARβ/δ caused a significant decrease in clonogenicity compared to controls. Over-expression and/or ligand activation of PPARβ/δ had no effect on either staurosporine-induced or UVB-induced poly(ADP-ribose) polymerses (PARP) cleavage; however, an increase in annexinV-positive NT2/D1 and Ter2a cells over-expressing PPARβ/δ, indicative of increased apoptosis, was found using flow cytometric analysis. Over-expression and/or ligand activation of PPARβ/δ inhibited MMP2 and MMP9 activities, presumably associated with the decreased invasion and migration in NT2/D1 and Ter2a cells. The MMP2/9 inhibitor SB-3CT suppressed the PPARβ/δ antagonist GSK3787-enhanced gelatinolytic activities, invasion, and migration in NT2/D1 control and/or over-expressing PPARβ/δ cells. This finding confirms a definitive requirement of PPARβ/δ in MMP2/9-mediated metastasis in vitro. Combined, these novel observations demonstrate the inhibitory effect of activating or over-expressing PPARβ/δ on tumorigenesis in human testicular cancer cells.

246 Ligand Activation of Peroxisome Proliferator-Activated Receptor-β/δ (PPARβ/δ) Attenuates Liver Tumorigenesis in HBV Transgenic Mice

G. Balandasamy1, L. R. Kramer1, B. Kang2, F. Gonzalez3 and J. M. Peters3. 1Pennsylvania State University, University Park, PA; 2Non-clinical Research Institute Chennon Co., South Korea; 3Department of Medicine and 4Laboratory of Metabolism, NCi, Bethesda, MD.

PPARβ/δ can inhibit pro-inflammatory activities in the liver. Since chronic inflammation often precedes liver carcinogenesis, the role of PPARβ/δ in modulating liver cancer was examined. Male hepatitis B virus (HBV) transgenic mice, which develop hepatocellular injury around 2-3 months of age, followed by hyperplasia and neoplasia by 9-12 months of age, eventually developing hepatocellular carcinoma by 18 months, were used for this study. Whole liver was isolated from 7-month-old mice treated with PPARβ/δ ligand for three weeks (short term study). Ligand activation of hepatic PPARβ/δ in these mice attenuated pro-inflammatory genes, tumor necrosis factor-alpha (Tnfα) and inducible nitric oxide synthase (iNos) mRNA. In addition, serum levels of alanine amino transaminase (ALT) were also attenuated in ligand treated HBV mice. These effects were not observed in the control mice. Prolonged PPARβ/δ ligand treatment (8 months long term study) of HBV mice of the same age showed attenuation of tumor multiplicity and average number of liver foci as compared with the control group. Ligand activation of PPARβ/δ in liver of HBV mice increased expression of the PPARβ/δ target gene, angiopoietin-like 4 (Angptl4) mRNA. Western blot analysis of whole liver from these HBV mice showed reduced NF-kB activation indicated by attenuated expression of phosphorylated p65 and phosphorylated IκB protein levels in ligand activated liver tissues. In addition, protein levels of the cell proliferation marker CYCLIN D1 and the oncogene c-MYC were significantly attenuated in livers of ligand treated HBV mice as compared to controls. Combined, results from these studies suggest that PPARβ/δ inhibits hepatic inflammation, and has the potential to attenuate hepatic tumorigenesis.
Ligand Activation of Peroxisome Proliferator-Activated Receptor-β/δ (PPARβ/δ) Inhibits TGFβ1-Induced Epithelial-Mesenchymal Transition (EMT) in a Human Lung Cancer Cell Line

K. C. Pasmantik, A. Pidathala, B. Zhu, F. Gonzalez and J. M. Peters

Department of Veterinary and Biomedical Sciences, Penn State University, State College, PA and Laboratory of Metabolism, National Cancer Institute, Bethesda, MD.

PPARβ/δ regulates fatty acid catabolism, glucose homeostasis, cellular differentiation and numerous anti-inflammatory activities, but the role of PPARβ/δ in carcinogenesis remains controversial. Surprisingly, the role of PPARβ/δ in metastasis has not been extensively investigated to date in any cancer model. Thus, the present study examined the role of PPARβ/δ in tumor growth factor-β-1 (TGFβ1) stimulated lung cancer cells in stable cell lines over-expressing PPARβ/δ in the presence or absence of a potent PPARβ/δ ligand. Ligand activation of PPARβ/δ in A549 cells over-expressing PPARβ/δ resulted in a significant increase of epithelial markers, (e.g; E-CADHERIN and OCCCLUDIN) with a concomitant decrease in mesenchymal markers, including N-CADHERIN and VIMENTIN without affecting the parent and A549-Mig1 vector control cells. Further, ligand activation of PPARβ/δ increased E-CADHERIN and suppressed VIMENTIN mRNA levels in A549 cells over-expressing PPARβ/δ. Migration and invasion is a known phenotype associated with cells undergoing metastasis. Ligand activation of PPARβ/δ inhibited TGFβ1-induced migration and invasion in A549 cells over-expressing PPARβ/δ, indicating an anti-metastatic effect of PPARβ/δ. Furthermore, MMP-2 and MMP-9 mRNA levels were decreased by ligand treatment in cells over-expressing PPARβ/δ. Ligand activation of PPARβ/δ in A549 cells over-expressing PPARβ/δ not only inhibited TGFβ1-induced morphology but also reversed TGFβ1-induced expression of E-CADHERIN and VIMENTIN protein. Interestingly, the PPARβ/δ antagonist GSK3878 in treatment A549 cells over-expressing PPARβ/δ prevented ligand-induced inhibition of EMT, indicating that PPARβ/δ is required for the inhibition of EMT. Collectively, these results suggest that ligand activation of PPARβ/δ could be a potential therapeutic target for lung cancer metastasis.

Evidence the PPAR Beta/Delta and BCL6 Pathway Is Involved in Pancreatic Cancer Development and Progression

R. W. Smith, J. D. Coleman, J. T. Thompson, B. Prokopczyk and J. Vanden Heuvel

Veterinary and Biomedical Sciences, Penn State University, State College, PA and Pharmacology, Penn State University, Hershey, PA.

The nuclear receptor Peroxisome Proliferator-Activated Receptor-β/δ (PPARβ/δ) regulates expression of genes involved in inflammation, metabolism, and cancer directly or in concert with the transcriptional repressor B-Cell Lymphoma 6 (BCL6) in the pancreas. Ligand-dependent activation of PPARβ/δ causes the dissociation of BCL6 from the complex, which in turn suppresses genes involved in inflammation and invasion. In this study we have examined the mRNA expression of several cancer biomarkers, as well as PPARβ/δ and BCL6 target genes in human pancreatic tissue of matched normal and tumor biopsies as well as the LSL-Kras(G12D); Pdx-δ/ mice. mRNA expression was higher in tumors than in surrounding tissue in humans and was augmented in Kras(G12D) expressing mice compared to non-recombinant counterparts. There was no change in BCL6 expression. BCL6 target genes, MCP1 and NFkB1 involved in inflammation, and VCA1 mRNA in cell adhesion showed significant increases in both human tumors and in pancreas from Kras(G12D) expressing mice. MMP9, another BCL6 target responsible for regulation of cell migration and metastasis, also showed elevated expression from normal tissue in humans. Increased expression of PPARβ/δ, in tumors and in pre-neoplastic lesions may sequester the transcriptional repressor BCL6 and hence play an important role in cancer development and progression and suggests means for treating pancreatic cancer.

Ligand Activation of PPARβ/δ Inhibits Invasion and Formation of Three-Dimensional Spheroids of the LNCaP Prostate Cancer Cell Line

P. Krishnan and J. M. Peters

Penn State University, University Park, PA.

Prostate cancer is second to lung cancer in causing death from cancer in American men. The American Cancer Society estimates that about 240,000 new cases of prostate cancer will be diagnosed and about 30,000 men will die of prostate cancer in 2013. Our group has shown that ligand activation of PPARβ/δ plays a role in inhibiting skin cancer and colon cancer. The hypothesis that ligand activation of PPARβ/δ will inhibit prostate cancer progression was examined in these experiments. To study the role of PPARβ/δ, human PPARβ/δ was over expressed in LnCaP cells using the Mig1 retroviral system. Western blot analysis showed about 3 times the expression of the PPARβ/δ compared to the parent LnCaP cell line and the control Mig1 infected LnCaP cells. The LnCaP cells were treated with the highly specific PPARβ/δ agonist GW7042 (0.01 to 10 μM) and the invasion was measured using the xCELLigence system. Invasion was dose-dependently decreased following ligand activation of PPARβ/δ in LnCaP cells over-expressing PPARβ/δ compared to the parent LnCaP cells and LnCaP-Mig1 control cells. To mimic in vivo tumor growth, the LnCaP cells were plated as three dimensional (3D) hanging drops and then plated in poly(2-hydroxyethyl methacrylate) (Poly-HEMA) coated wells and treated with transforming growth factor-β1 (2 ng/mL) and tumor necrosis factor-α (10 ng/mL) for 96 h. Morphological analysis showed that LnCaP cells and LnCaP-Mig1 control cells formed microspheres which were not seen in LNCAp cells over-expressing PPARβ/δ. The initial clonogenic assay results showed a dose dependent decrease in the number of clones formed in the LnCaP cells. Combined, these results suggest that activation of PPARβ/δ may play a role in preventing and/or treating prostate cancer. Analysis of the role of PPARβ/δ activation in inhibiting epithelial to mesenchymal transition by studying the changes in the marker proteins like E-CADHERIN, VIMENTIN and N-CADHERIN in this 3D spheroid model are underway.

Does PCE Cause Non-Hodgkin’s Lymphoma?

D. G. Dodge and B. D. Beck

Gradient, Bend, OR and 4Gradient, Cambridge, MA.

Tetrachloroethylene (PCE) is a volatile, chlorinated hydrocarbon used as a solvent in the dry cleaning and textile-processing industries and as an agent for degreasing metal parts. It is also a widespread environmental contaminant. In 2012, US EPA classified PCE as ‘likely to be carcinogenic in humans by all routes of exposure’ based, in part, on epidemiologic evidence associating PCE exposure and Non-Hodgkin’s Lymphoma (NHL). We critically analyzed human, animal, and mechanistic evidence, including epidemiologic studies published subsequent to US EPA’s analysis, to address the question of whether PCE causes NHL in humans. A number of epidemiologic studies of populations exposed to PCE have been conducted, principally in laundry and dry cleaning workers and populations exposed to chlorinated solvents in drinking water. Most of the studies addressing a potential association between PCE exposure (or imperfect surrogates such as occupation) and NHL do not report statistically significant results, including those with higher quality exposure-assessment methodologies. Limitations (e.g., lack of an exposure-response

Uncoupling-Induced Metabolic Reprogramming Provides Insights into Skin Cancer Resistance

A. Solmonson, S. M. Nowinski, M. Keaton, E. Morin-Kensicki, J. E. Rundhaug and E. M. Miller

Metabolic reprogramming is a hallmark of tumorigenesis and malignancy across a variety of cancer types. Reduced oxidative phosphorylation and increased ATP synthesis by glycolytic upregulation is thought to provide both the energy and metabolic precursors necessary to meet the increased biosynthetic and energetic demands associated with malignancy. We hypothesized that since uncoupling protein-3 (UCP3) dissipates the mitochondrial electrochemical proton gradient, it may lead to the consumption or depletion of biosynthetic substrates necessary for carcinogenesis. In support, previous studies from our lab have shown that mice expressing a keratin 5-UCP3 transgene are completely resistant to chemically- and Ras-induced skin carcinogenesis; however the metabolic consequences of UCP3 overexpression in relation to cancer resistance are unclear. To examine the metabolic changes associated with UCP3 expression and this profound skin cancer resistance, we performed metabolomic analysis of more than 350 metabolites in epidermis from K5-UCP3 and wild type FVB/N littermate mice. Results of this analysis show significant UCP3-dependent changes in metabolites indicative of increased energy harvesting via glycolysis, breakdown of phospholipids and increased beta oxidation. Consistent with decreased energy reserve, K5-UCP3 epidermis exhibits increased uncoupled respiration, decreased ATP and increased AMP levels, which correspond to increased AMP Kinase (AMPK) activation (Thr172 phosphorylation). Taken together, these data suggest that uncoupling proteins might provide a means to oppose the metabolic demands of tumorigenesis and suggest that targeting mitochondrial uncoupling may be a novel and effective strategy in cancer prevention and treatment.
gradient, small numbers of cases, internal inconsistencies, and potential exposure misclassification) in many of the positive studies weaken the evidence of a causal relationship. In experimental animals, high doses of PCE have been associated with a number of cancers. Potentially the most relevant of these to NNL is monoclonal cell leukemia (MNCL) in aging F344 rats in more than one study. Though the etiology and mode of action of MNCL in F344 rats is not established, some factors suggest that it should not be considered a reliable indicator that PCE poses a carcinogenic hazard to humans. For example, while MNCL is extremely common in F344 rats, it is rare in other rat strains and not seen in mice. Although F344 rats are genetically predisposed to develop MNCL, there is no such predisposition in humans toward the development of the human leukemia that most resembles MNCL in F344 rats. We conclude that weak epidemiologic data and lack of human-relevant animal data indicate PCE is not likely to cause NHL in humans.

252 Bisphenol A Induces Prostate Cancer Progression and Differential Gene Expression
E. Ricke1, A. B. Theberge1, M. A. Moses2 and W. A. Ricke1. 1Global Environmental Health Sciences, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA and 2Environmental Medicine, University of Rochester, Rochester, NY. Sponsor: R. Peterson.

Introduction and objectives: Estrogen in combination with androgen has been shown to induce prostate diseases including prostate cancer. Bisphenol A (BPA), a small molecule used to manufacture polycarbonate plastics, is one of the most prominent EDCs and has been identified as a xenoestrogen. Humans are exposed to BPA as it leaches from food and beverage containers made of polycarbonate. Our goal was to determine if BPA could substitute for estrogen in inducing prostate cancer progression in a tissue reconstitution model. Furthermore, we wanted to determine if cells induced from cancers would have different gene expression signatures indicative of hormonal regimen used.

Methods: Tissue recombinants composed of BPH1 + rUGM were surgically grafted to the renal capsule of adult male athymic mice that were subcutaneously inoculated with either 25 mg estradiol (E2) or T+BPA (25 mg) and grown for 4 weeks. Grafts were excised at necropsy and BPH1 cells were isolated. RNA was collected from BPH1-BPA and BPH1-E2 as well as parental BPH1 cells. Gene expression profiles were created using quantitative PCR.

Results: BPA induced tissue recombinants composed of BPH1 + rUGM to develop into cancer similar to that of E2. Changes for INHBA expression increased in BPH1-BPA over BPH1 and BPH1-E2 cells (BPH1: 100%, BPH1-E2: 52%, BPH1-BPA: 190%). Conversely, BPH1-BPA showed lower expression than BPH-1 and BPH1-E2 for PPARY (BPH1: 100%, BPH1-E2: 901%, BPH1-BPA: 83%). Whereas, CTNNB1 expression was higher in BPH1-E2 and BPH1-BPA compared to BPH1 cells (BPH1: 100%, BPH1-E2: 201%, BPH1-BPA: 182%). Lastly, there was minimal change in expression between cell lines for CDH1 (BPH1: 100%, BPH1-E2: 90%, BPH1-BPA: 105%).

Conclusions: These data support the concept that BPA acts as an estrogen to promote prostate cancer progression. Although, BPA induced cancers share some similarities with E2 induced cancer, BPA may have a distinct tumor gene expression profile that may distinguish it from other cancers.

253 hTERT-Immortalized Renal Proximal Tubule Epithelial Cells: Characterizing a Model System for Testing the Role of Cadmium and Benzo[a]pyrene in the Development of Renal Cancer
B. R. Simon1, M. J. Wilson1 and J. K. Wicksb. 1Global Environmental Health Sciences, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA and 2Biomedical Sciences, Tulane University School of Medicine, New Orleans, LA.

In order to elucidate the mechanisms by which the heavy metal cadmium (Cd) acts as a co-carcinogen, we aim to characterize a newly developed cell line derived from renal proximal tubule epithelial cells (RPTEC) of a healthy male donor. The RPTEC/TERT1 cell line has been immortalized with the human telomerase (hTERT) subunit only and does not exhibit chromosomal abnormalities. We have conducted controlled exposure experiments designed to demonstrate toxicological responses in RPTEC and to assess their potential to develop into renal subtypes. urothelial and urothelial like cancer in these cells, which will serve as a model for renal cell carcinogenesis. We are conducting exposure experiments to mixtures of the common environmental contaminants, Cd and benzo[a]pyrene (BaP). Our studies are the first to provide information regarding toxicological responses in this novel RPTEC/TERT1 cell line. A significant increase in the expression of genes coding for BaP metabolizing enzymes (CYP1A1, CYP1B1) occurred in a dose- and time-dependent manner at 3, 6, and 24 hours post exposure. Likewise, a significant increase in the heavy metal responsive gene MT2A was observed following exposure to Cd. The presence of BPDE-DNA adducts confirms that the RPTEC/TERT1 cell line responds to BaP consistent with what is known regarding these cell types in a normal, healthy kidney. Future studies will be conducted to test mutagenesis under conditions of co-exposure to Cd and BaP. We hypothesize that Cd inhibits DNA repair processes, therefore, causing BPDE-DNA mutations to become fixed in the genome which may lead to carcinogenesis.

254 Chronic Alcohol Intake Promotes Tumor Growth in a Diethylnitrosamine-Induced Hepatocarcinogenesis Mouse Model through Increased Wnt/β-catenin Signaling
K. E. Mercer1, L. Hennings2, N. Sharma3, C. Chandler1, R. Wynne4, M. J. Ronis3,5 and T. M. Badger1,3. 1Pediatrics, UAMS, Little Rock, AR, 2Pathology, UAMS, Little Rock, AR and 3Arkansas Children’s Nutrition Center, Little Rock, AR.

Ethanol (EtOH) metabolism is involved in both initiating and promoting mechanisms in hepatocellular carcinoma progression in chronic alcoholics. In this study, we developed a mouse model to test the hypothesis that chronic EtOH consumption promotes tumor growth irrespective of EtOH-related initiating mechanisms. Male mice received a single dose of diethylnitrosamine (DEN) on postnatal day 13, and were assigned to either an EtOH-liquid diet, a control liquid diet pair-fed (PF) to the EtOH group, or a standard chow diet 47 days post-DEN injection. After 16 wks of EtOH feeding (5.0% v/v) we observed a 2-4 fold increase tumor multiplicity, but not tumor incidence in EtOH+DEN treated mice compared to PF+DEN and chow+DEN groups, p<0.05, which corresponded to a 4-fold increase in hepatocyte proliferation in EtOH+DEN non tumor liver tissues, p<0.05. In the EtOH+DEN non tumor liver tissues, we also observed a significant increase in β-catenin expression and changes in β-catenin localization when compared to DEN treated PF and chow controls. More important, in a separate rodent model of alcoholic liver disease, prolonged feeding of EtOH alone significantly reduced hepatic retinol and retinoic acid concentrations, increased cytosolic β-catenin expression, phosphorylated (Ser 21/9) GSK3b expression, and increased nuclear accumulation of β-catenin in rat hepatocytes, p<0.05. In addition, RNA analysis using a targeted Wnt PCR array revealed a significant up-regulation of soluble Wnts, transcription factors associated with a proliferative phenotype, and β-catenin targets associated with disease progression, p<0.05. These findings suggest a link between alcohol-related retinoid depletion, up-regulation of Wnt/β-catenin signaling, and tumor growth and progression in our mouse model of HCC. Supported by NIH AA018282.

255 Orally Administered Nicotine Induces Urothelial Hyperplasia in Rats and Mice
P. R. Dodman, L. L. Arnold, K. L. Pennington and S. M. Cohen. Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE.

Tobacco smoking is a major risk factor for multiple human cancers including urinary bladder carcinoma. Tobacco smoke is a complex mixture containing chemicals that are known carcinogens in humans and/or animals. Aromatic amines a major class of DNA-reactive carcinogens in cigarette smoke, are not present at sufficient high levels in tobacco smoke to fully explain the incidence of bladder cancer in cigarette smokers. Other agents in tobacco smoke could be excreted in urine and enhance the carcinogenic process by increasing urothelial cell proliferation. Nicotine is one such major component, as it has been shown to induce cell proliferation in multiple cell types in vitro. However, in vivo evidence specifically for the urothelium is lacking. We previously showed that cigarette smoke induces increased urothelial cell proliferation in mice. In the present study, urothelial proliferative and cytotoxic effects were examined after nicotine treatment in mice and rats. Nicotine hydrogen tartrate was administered in drinking water to rats (52 ppm nicotine) and mice (514 ppm nicotine) for 4 weeks and urothelial changes were evaluated. Histopathologically, 7/10 rats and 4/10 mice showed simple hyperplasia following nicotine treatment compared to none in the controls. Rats had an increased mean BrdU labeling index compared to controls, although it was not statistically significantly elevated in either species. Scanning electron microscopic visualization of the urothelium did not reveal significant cytotoxicity. These findings suggest that oral nicotine administration induced urothelial hyperplasia (increased cell proliferation), possibly due to a mitogenic effect of nicotine and/or its metabolites.
Colorectal cancer (CRC) occurs more prevalently in developed countries where it is the second highest cause of cancer-related mortality. Only 15-20% of CRC cases have a genetic pre-disposition, while the remaining 80-85% are caused by environment and lifestyle. Epidemiological studies have suggested a strong link between diet and CRC. Western-style diets can induce local colonic inflammation, which is also strongly associated with CRC development. Benzo[a]pyrene (BaP) and 2-aminon-1-methyl-6-phenylimidazo[4,5-b]pyridine (PhIP) are dietary pro-carcinogens found in meats cooked at high temperatures common in Western-style diets and require metabolic activation to their genotoxic agents by cytochromes P450 (CYP) 1A and 1B1 enzymes. We previously observed overexpression of CYP1B1 and pro-inflammatory cytokine interleukin-6 (IL6) in malignant tissue retrieved from CRC patients, indicating that inflammation and changes in metabolic competency occur in CRC tissue. To further understand the link between diet, inflammation and CRC, we investigated the effect of IL6, BaP and PhIP on human colon epithelial cell lines HCT116 and SW480 grown as 2D and 3D cultures. We measured DNA damage using the micronucleus (MN) assay and determined CYP1A1 and CYP1B1 expression along with associated micro-RNA (miRNA) changes. In both cell lines, MN frequency was increased dose-dependently with BaP and PhIP treatment while pre-treatment with IL6 further enhanced DNA damage. Induction of CYP1B1 gene expression was shown following IL6 treatment while CYP1A1 expression was not changed. Additionally, treatment with IL6 decreased expression of miR-27b, a miRNA known to target CYP1B1 mRNA. Taken together, these data demonstrate that exposure of colon cells to IL6 alters metabolic competency of the cells through epigenetic changes. Similar events occurring in colorectal epithelial cells could lead to increased dietary pro-carcinogen-induced DNA damage, thereby contributing to colorectal carcinogenesis.

Triclosan is a broad spectrum anti-bacterial agent widely used in many personal care products, household items, medical devices, and clinical settings. Human exposure to triclosan is mainly through oral and dermal routes. Although it has been reported that long-term oral exposure of mice to triclosan induces liver tumors, the dermal carcinogenicity of triclosan in either animals or humans is unknown. In this study, using mouse epidermal JB6 Cl 41-5a cells, triclosan within a narrow range of concentrations (3 - 6 μM), stimulated anchorage-dependent cell growth in a concentration- and time-dependent manner. Higher concentrations of triclosan (8 μM) inhibited cell growth, which was due to necrotic cell death. Although triclosan failed to promote anchorage-independent cell transformation in a soft agar colony formation assay, enhanced cell proliferation was demonstrated by a substantial increase in the percentage of BrdU positive cells and an elevation in the protein levels of cyclin A, even at a concentration that triggered necrosis. Western-blotting analysis revealed that triclosan transiently induced the activation of extracellular signal-regulated kinase 1/2 (ERK1/2), c-Jun N-terminal kinase (JNK), and p38 MAP kinase (p38). Pre-treatment with the MEK1/2 inhibitor PD184352 blocked triclosan-mediated the phosphorylation of ERK1/2 and substantially suppressed triclosan-stimulated cell proliferation, whereas the JNK inhibitor SP600125 or p38 inhibitor SB203580 had little or no effect on triclosan-stimulated cell proliferation. These data suggest that triclosan stimulated mouse epidermal cell proliferation in an ERK1/2-dependent manner and raises concerns about potential dermal carcinogenicity of triclosan.

There are increasing epidemiological and experimental studies supporting the activity of metformin, the most commonly used anti-diabetic drug, as an anti-tumor agent. However the mechanisms associated with the anti-neoplastic activity of metformin remain unclear. De novo lipogenesis is considered as one of the hallmarks of cancer and fatty acid synthase (FAS), which plays a major role in lipogenesis is a negative prognostic factor for patient survival in pancreatic cancer. A key transcriptional regulator of FAS is SREBP (Sterol Regulatory Binding Protein) which is one of the downstream effectors of mTOR signaling. Treatment of Panc28 and L3.6pl pancreatic cells with 5-15 mM metformin decreased phospho-mTOR (p-mTOR) but not mTOR protein and this was accompanied by decreased expression of SREBP and FAS. Previous reports have linked IGF1 to activation of mTOR in pancreatic cancer cells and knockdown of IGF1 by RNA interference decreased mTOR signaling; moreover, metformin also decreased IGF expression suggesting the mTOR inhibition by metformin is due to IGF1 downregulation. Previous reports suggest that IGF1 expression is regulated by specificity protein Sps (transcription factors (TFs)) and we have shown that metformin decreases expression of Sp1, Sp3 and Sp4 transcription factors in pancreatic cancer cell lines. The role of Sp transcription factor in regulating IGF1 and mTOR was further investigated by knockdown of Sp1 (Sp1), Sp3 (Sp3), Sp4 (Sp4) or their combination (Sp1/3/4) by RNAi and this resulted in decreased expression of IGF1 and inhibited mTOR signaling and its downstream effectors in pancreatic cancer cell lines. These data indicate that metformin blocks lipogenesis in pancreatic cancer cells through downregulation of Sp transcription factors and Sp regulated IGF1, resulting in inhibition of mTOR signaling.

Triclosan is a broad spectrum anti-bacterial agent widely used in many personal care products, household items, medical devices, and clinical settings. Human exposure to triclosan is mainly through oral and dermal routes. Although it has been reported that long-term oral exposure of mice to triclosan induces liver tumors, the dermal carcinogenicity of triclosan in either animals or humans is unknown. administration did not further modulate the observed receptor-dependent effects. Ligand activation of PPARβ/δ or PPARγ also reduced cell growth in stable cell lines over-expressing these receptors. An analysis of clonal expansion also revealed that elevated expression of PPARβ/δ reduced plating efficiency; furthermore, ligand activation of PPARβ/δ (but not PPARγ) conferred resistance to a dose-dependent manner. Collectively, these observations demonstrate that both PPARβ/δ and PPARγ decrease human malignant melanoma cell line proliferation. These results also demonstrate the utility of the Mig1G model to dissect the functions of PPARβ/δ and PPARγ, including the targeting of these receptors for potential malignant melanoma therapies.

### 261 The Trichloroethylene-Associated P81S VHL Hotspot Mutation Alters Tumor Microenvironment: Metabolic Reprogramming, DNA Damage Response, and Radiation Resistance

M. C. DeSimone1, W. Rathmell2 and D. W. Threadgall3-2
1Biological Sciences, NCSU, Raleigh, NC, and 2Lineberger Comprehensive Cancer Center, UNC, Chapel Hill, NC.

Occupational exposure to trichloroethylene (TCE), a solvent found in contaminated groundwater, has been associated with the P81S hotspot mutation in the von Hippel-Lindau (VHL) tumor suppressor gene in cases of clear cell renal cell carcinomas. There remain considerable mechanistic gaps in the kidney cancer risk assessment of TCE due to lack of appropriate model systems. We purport that specific mutations in VHL that uniquely alter its protein function may provide a selective growth advantage to somatic cells harboring these mutants, leading to clonal expansion. For this study, we developed a stem cell model system to study the unique biology of the P81S mutation. VHL deficient (Vhl−/−) mouse embryonic stem cells were generated that stably express either wild-type, P81S, or R167Q human VHL protein and were examined in vitro under hypoxic conditions for hypoxia-inducible transcription factor family stabilization and E3-ubiquitin ligase complex formation. To examine the microenvironmental stress response, cell lines grown as teratomas were examined for size, proliferation, and apoptosis, which were subjected to whole genome microarray analysis, and proliferation, and exposure to 5Gy ionizing radiation to quantify apoptotic response. The P81S mutation disrupts VHL-E3 complex formation in vitro, and in vivo, teratomas gained a growth advantage resulting from apoptotic resistance, not enhanced proliferation. Transcriptomic analysis suggests that a key component of this survival advantage is metabolic reprogramming and disabling of the DNA damage response, conferring radiation resistance. This work demonstrates a novel interaction between VHL and the ATM-mediated DNA damage response network, and highlights the potential of the TCE-associated P81S VHL mutation to initiate an adaptive response required for selective tumor growth through effects on metabolic diversification, apoptosis suppression, and alteration of the DNA damage response.

### 262 Hydrolysis of DNA-Protein Crosslinks Forms Formaldehyde-DNA Adducts

Y. Lai and J.A. Swenberg, Department of Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Formaldehyde causes squamous cell carcinomas in the nasal passages of rats and has been classified as a known human carcinogen by IARC. The primary genotoxic effects of formaldehyde include the formation of DNA-protein crosslinks (DPCs) and hydroxymethyl DNA adducts. Formaldehyde induced DPCs showed a rapid loss in lymphocyte cultures and no accumulation was observed in rats after repeated exposures. Previous research indicated that formaldehyde induced DPCs were lost through spontaneous hydrolysis rather than DNA repair. In this study, we investigated hydrolytic degradation of formaldehyde induced DPCs with deoxyguanosine linked to cysteine (dG-Ch2-Cys), glutathione (dG-Ch2-GSH) and N-terminal acetylated 12-mer human O6-alkylguanine DNA methyltransferase peptide (dG-Ch2-AGT). Under physiological pH and temperature conditions, the determined half-life for dG-Ch2-Cys and dG-Ch2-GSH was 11.6 min (R2 = 0.9807) and 87.8 min (R2 = 0.9935), respectively. The degradation kinetics of dG-Ch2-AGT consisted of an initial rapid degradation rate with half-life of 7.4 min followed by a much slower degradation rate with half-life of 90.7 min (R2 = 0.9987). During the hydrolysis of DPCs, dG could be directly formed if bond cleavage occurs between dG and methylene (N2-dG-Ch2-bond). However, no dG was detected in the first 3 min, 20 min and 10 min incubation for dG-Ch2-Cys, dG-Ch2-GSH and dG-Ch2-AGT, respectively. On the other hand, N2-hydroxymethyl-dG (HO-Ch2-dG) was readily formed and increased rapidly after initiating reaction for all tested crosslinks, suggesting cleavage of the Ch2-Cys bond, but not the N2-dG-Ch2 bond. HO-Ch2-dG can be degraded to dG following incubation for longer time periods. Thus, the mechanism of DPCs hydrolysis involved the production of HO-Ch2-dG before forming end product of dG. These results suggest that DPCs are likely to be an important source of formaldehyde DNA monoadducts and that monoadducts represent a biomarker of both direct attack of DNA and a breakdown product of DPC.

### 263 Differential Gene Expression Analysis of TPA/UVC Co-Treated TK6 Cells Reveals a Novel Gene Signature Important in Carcinogenesis by Combining DNA Damage and Tumor Promoting Pathways

K. P. Gloyve1, Z. Chen2, L. K. Markell1 and X. Han1
1Harkell, DuPont, Newark, DE and 2IGCT, DuPont, Wilmington, DE.

Environmental and chemical carcinogens have been shown to act as both initiators and promoters of cancer. In the present study, we attempted to reveal critical pathways in chemical carcinogenesis that were triggered from converging processes of initiation (via UVC irradiation) and promotion (via 12-O-tetracosanoylphorbol acetate (TPA) treatment) in cultured TK6 cells. We have previously shown that TPA-pretreated TK6 cells undergo a synergistic increase in apoptosis and delayed yH2AX clearance following DNA damage induced by UVC-irradiation. To elucidate the cellular pathways responsible for the synergistic interaction between TPA-pretreatment and UVC-irradiation we analyzed the global transcriptional profile with RNA-sequencing. Differential expression analysis revealed significantly deregulated genes associated with the combination of TPA-pretreatment and UVC-irradiation (TPA+/UVC) compared to either stress alone (TPA+/UVC- or TPA-/UVC+). To focus our analysis on genes specific to the combined exposure, we filter the gene list for those that occurred in a TPA-dependent dose responsive trend and significantly up- or down-regulated in the TPA+/UVC+ cells compared to TPA-/UVC- and TPA-/UVC+. We found a set of 84 genes (46 up, 38 down) specific to the combined exposure that are significantly deregulated and likely responsible for the increased sensitivity to UVC-induced DNA damage. Major up-regulated genes include TNFSF4, GDF15, ATF3, SERPINE1, IL29, LIF, FOS, IFNG, SNAI1, NOXA and AADD34a. Major down-regulated genes include PO2UAF1, PAX5, GBP1, SP1, ASK1, GBP6, LYN, TRAF5 and CLI4C. Overall, most genes were connected to pathways important in inflammatory driven carcinogenesis including TNFG, Interferon-γ, TGFβ, API1 and p53. Here we show that TPA-pretreatment causes an increased sensitivity to UVC-induced DNA damage which is accompanied by an exacerbation of immune/inflammatory pathways that may be important for tumor promotion.

### 264 The Aryl Hydrocarbon Receptor Controls Breast Cancer Stem-Like Cell Development and Function

E. A. Stanford1, A. J. Parks2, O. Novikov1-2 and D. H. Sherr1
1Environmental Health, Boston University, Brookline, MA and 2Molecular and Translational Medicine, Boston University School of Medicine, Boston, MA.

In 1940, an American woman’s risk of getting breast cancer was 1 in 14. Since then, the age-adjusted incidence of breast cancer has increased such that 1 in 8 women born this year will be diagnosed with breast cancer in her lifetime. Analyses of known risk factors such as diet, exercise, and hormone replacement therapy do not completely explain the increase in breast cancer incidences or the genesis of breast cancers not associated with inheritance of susceptibility genes. A meta-analysis of over 150 published studies on breast cancer and the environment implicates a number of environmental chemicals, including aryl hydrocarbon receptor (AhR) ligands, in breast cancer risk. Tumor invasion and metastasis following relapse is the cause of death in nearly all breast cancer patients. The cancer stem cell (CSC) theory hypothesizes that cancers and their metastases are driven, to a disproportionate extent, by breast cancer stem-like cells (BCSCLs). BCSCLs are defined by their activity and expression of aldehyde dehydrogenase (ALDH), expression of a set of genes associated with “stemness”, ability to self-renew, expression of genes consistent with epithelial-to-mesenchymal transition (EMT), and resistance to chemotherapeutics. Recent studies have implicated the AhR, a transcription factor involved in tumorigenesis, in the development and/or function of stem cells, which share properties with CSCs. From these studies, we postulated that the AhR may play a role in the development or function of BCSCLs. Here, we present data demonstrating high levels of constitutively active AhR in BCSCLs from aggressive human ER-, PR-, Her2- and inflammatory breast cancers. The results indicate that AhR hyper-activation with exogenous ligands increases and AhR inhibition with pharmacological or molecular agents decreases expression of BCSCL characteristics. Our findings further implicate environmental chemicals in breast cancer risk through increasing breast cancer progression and survival after chemotherapy.
Residual aromatic extracts (RAEs) are petroleum streams derived as by-products during solvent extraction of vacuum tower bottoms (VTB) often used in tire extender oils and specialty petroleum products. Due to process conditions, RAEs may have high levels of polycyclic aromatic compounds (PACs), which are thought to drive carcinogenicity in animal bioassays. To maximize the use of these substances while protecting human health, a more efficient method for separating potentially harmful PACs during vacuum distillation was investigated. This work identifies a correlation between carcinogenicity and boiling point which can identify optimal conditions for vacuum distillation to minimize the toxicity of RAEs. Using the modified Ames assay, samples of VTB, raffinate, and RAE were obtained from five refineries to evaluate relationships between mutagenicity index (MI), PAC content and boiling point by GC distillation (GCD). As expected, a positive linear relationship between MI and PAC content occurred for 3-6 ring PAC (R2=0.72), regarded as the carcinogenic PACs. A negative correlation between MI and boiling point (5% vaporized by GCD, R2=0.72) indicated that lower boiling samples (<470°C) were more likely to be mutagenic. This inverse relationship was further demonstrated by distillation of select samples (MI=0.50±0.07 (n=5)) into low and high boiling range fractions. Mutagenicity and 3-6 ring PAC content were markedly higher in low boiling fractions (MI=2.36±0.55 vs.0.17±0.11, PAC=5.2±0.7 vs. 0.97±0.35%, respectively). These results support the hypothesis that PACs are key contributors to the mutagenic potential of petroleum substances that can be separated by boiling point. Because vacuum distillation can be continuously measured and manipulated at refineries, these findings provide a means to readily monitor and minimize the carcinogenic potential of RAEs in situ to ensure continuous product safety.

In a rodent tumor bioassay, high doses of sodium phenobarbital (NaPB), a constitutive androstane receptor (CAR) activator, produced hepatic tumors. Previous mode of action (MOA) studies have demonstrated that NaPB induces hepatic microsomal cytochrome P450 (CYP) 2B enzymes and hepatic cytoplasmic DNA synthesis in rodents, suggesting that the MOA for rodent liver tumor formation is a mitogenic activity via CAR activation. In this study the effects of NaPB on liver weight and histopathology, hepatic CYP2B activity, hepatic replicative DNA synthesis, and mRNA expressions of CYP2B/3A and selected genes related to cell proliferation, were examined after 1-week treatment with NaPB at 500, 1000, 1500, and 2500 ppm in males of CD-1 mice, Wistar Hannover (WH) rats, and humanized mice (chimeric mice with human hepatocytes). The treatment of humanized mice with 1000-1500 ppm NaPB resulted in plasma levels around 3.5-fold higher than those observed in human subjects given therapeutic dose of NaPB. NaPB produced dose-dependent increases in liver weight, CYP2B activity, and CYP2B3A mRNA in CD-1 mice and WH rats and also produced effects on these parameters in humanized mice. While NaPB produced a dose-dependent increase in hepatocyte replicative DNA synthesis in CD-1 mice and WH rats, no increase in replicative DNA synthesis was observed in humanized mice. In addition, NaPB produced no increases in Ki-67, PCNA, GADD45β, and MDM2 mRNA expression in humanized mice but significantly increased those in CD-1 mice and/or WH rats. Thus, while NaPB could activate CAR/PPARγ, as demonstrated by increased CYP2B3A mRNA levels, NaPB did not increase cell proliferation in human hepatocytes of humanized mice. As human hepatocytes are refractory to the mitogenic effects of NaPB, the data demonstrate that the MOA for NaPB-induced rodent liver tumor formation is not relevant for humans.
265d Integrated microRNA, mRNA, and Protein Expression Profiling Reveals Dysregulated Expression of microRNAs and Their Targets in Rat Kidney Treated with a Carcinogenic Dose of Aristolochic Acid

Aristolochic Acid (AA), is classified as a group 1 carcinogen by the International Agency for Research on Cancer. MicroRNA (miRNA) alterations are involved in the initiation and progression of human cancer, but their roles in AA-induced carcinogenesis remain unknown. In order to search for miRNA regulation and identify their functional targets, we have employed a novel approach integrating miRNA, transcriptome and proteome profiling and a computational target predicting algorithm. We treated rats with 10 mg/kg AA and vehicle control for 12 weeks and eight kidney samples (4 for the treatment and 4 for the control) were used for examining miRNA and mRNA expression by deep sequencing, and protein expression by proteomics. AA treatment resulted in significant differential expres- sion of miRNAs, mRNAs and proteins as measured by both principal component analysis (PCA) and hierarchical clustering analysis (HCA).

Specially, 63 miRNAs (adjusted p value < 0.05 and fold change > 1.5), 6,794 mRNAs (adjusted p value < 0.05 and fold change > 2.0), and 800 proteins (fold change > 2.0) were significantly altered by AA treatment. To investigate the influence of miRNA on these processes, we combined proteomic and transcriptomic data into three groups containing responses indicating translational repression (163), translational activation (236), and transcriptional destabilization (460). Our predicted miRNA targets were further compared and validated from experimentally validated targets in miRTarBase (P = 4.96e-06). Cancer is identified as the top function by ingenuity pathway analy- sis (IPA) for identified 399 targets. Our findings suggest that dysregulated miR- NAs and their targets are involved in kidney carcinogenesis in the AA-treated rats.

266 Refining the Caco-2 Model to Evaluate the Impact of Intestinal Hydrolysis on Parabens Absorption in the Gut

X. Sun, Y. Zhao, J. Dong, H. J. Clewell and M. Yoon. The Hamer Institutes for Health Sciences, RTP, NC.

The oral bioavailability of environmental esters such as parabens can be greatly affected by intestinal hydrolysis, but little is known about this metabolic pathway largely due to lack of relevant experimental systems. The conventional Caco-2 model which overexpresses carboxylesterase-1 (CES-1) is not appropriate to this end, because the CES-2 isosform is predominantly expressed in human enterocytes. In this study, we stably expressed CES-2 in Caco-2 cells, while knocking down CES-1, to appropriately evaluate the impact of hydrolysis on the ab- sorption of parabens. Western blot analysis showed that the expression of CES-2 in the Caco-2/CES-2 cells was comparable to that in human enterocytes. Studies on transport and metabolism of methyl- and butylparabens were performed with the Caco-2/CES-2 cells. The results showed that parabens are rapidly hydrolyzed while the genotoxic absorbed parabens (both butylparaben and WIT butylparaben (10 M) was applied to the apical side, all of the parent compound was converted to p-hydroxybenzoic acid (pHBA) within 30 min, most of which was found in the apical side indicating the location of hydrolysis being at or closer to the apical membrane and the efficient efflux of pHBA into the apical side (i.e., luminal side in the gut). Additional experiments with a general CES inhibitor, bi-par-nitro- phenylphosphate, further supported these findings. An in vitro kinetic model was developed to describe the kinetic behaviors of parabens and pHBA in the Caco-2/ CES-2 cells and extrapolate to humans in vivo. The refined Caco-2/CES-2 system, together with pharmacokinetic modeling can provide accurate estimates of oral bioavailability of parent parabens and their metabolites under different exposure conditions which will contribute to risk assessment and better understanding of human exposure to parabens and other environmental esters (supported by the ACC-IRI).

267 Toxicological Effects of Antibody-Mediated TGF-beta Antagonism in Cynomolgus Monkeys

C. Horvath1, C. Hendriks1, P. Finn2 and L. Andrews1. 1DSAR, Sanofi, Waldham, MA and 2Genzyme Biologics, Genzyme, a Sanofi Company, Framingham, MA.

Transforming growth factor beta (TGF-beta) is a multifunctional cytokine that has an important role in various processes, including cell proliferation and differ- entiation, angiogenesis, and wound healing. Overexpression of TGF-beta can lead to fibrosis and has been linked to chronic conditions such as chronic kidney disease and TGF-beta by the antibody GC1008 may modify this pathologic process. The toxicological impact of chronic TGF-beta neutralization was evaluated in juvenile cynomolgus monkeys. Repeat dose toxicity studies (28 days, 3 months and 6 months) were conducted with GC1008 at dose levels ranging from 0.1 to 50 mg/kg (dosed every other week or every third day). In all studies, the toxicokinetics of GC1008 were highly variable, but adequate exposure was obtained to allow for interpretation of the toxicological findings. When dosed every third day, diminished systemic exposure was observed following 7 doses in a single animal; this animal tested positive for anti-drug antibodies. Across all studies, consistent findings related to treatment with GC1008 were observed. Clinical observations included bleeding, often asso- ciated with eruping teeth, and hematomas. Alterations in hematology parameters included dose dependent, reversible, decreases in red blood cell counts, hemoglo- bin, and hematocrit values. In the 3 and 6 month studies, epithelial cell hyperplasia was noted at varying locations. The epithelial hyperplasia observed in these studies may have been associated with exacerbation of pre-existing background lesions (i.e. periodontitis, rhinitis, cystitis). Overall, these studies have characterized the potential risks associated with chronic neutralization of TGF-beta and suggest that the majority of homeostatic roles of TGF-beta in these normal juvenile primates were not significantly disrupted by antibody-mediated antagonism of this biologically important growth factor.

268 Safety Assessment of Flt3 Ligand: 28-Day Toxicity Studies in Rats and Monkeys

J. I. Thoma1, E. M. Forsberg1, L. E. Gergel3, L. A. Vitale1, B. J. Karalius1, K. M. Borrelli1, H. C. Marsh1 and T. Keler2. 1Celdes Therapeutics, Needham, MA and 2Celdes Therapeutics, Phillipensburg, NJ.

Flt3 Ligand (also referred to as Flt3L, fms-like tyrosine kinase 3 ligand, or CDX-301) is a hematopoietic cytokine which stimulates the proliferation and differen- tiation of various blood cell progenitors. Nonclinical safety was assessed in two GLP-compliant toxicity studies where Flt3L was administered subcutaneously for 28 days to Cynomolgus monkeys and rats (5, 25, 200 and 1600 μg kg-1 d-1). For all animals, mortality, clinical signs, body temperature, body weights, and clinical pathology were recorded throughout the study. Detailed necropsies were performed in a subgroup of animals 48 hours after the last administration of CDX-301 and on the remaining animals after a 2-week recovery period. Selected tissues were collected for histopathology evaluation and bone marrow smears were evalu- ated. Blood samples were collected periodically for the determination of pharma- cokinetics, anti-drug antibodies and, in the monkeys, for immune cell analysis. No gender differences were observed in the pharmacokinetics of Flt3L. Many animals developed anti-Flt3L antibodies, which were neutralizing in some rats. An increase in dendritic cells and monocytes, but not regulatory T cells, was seen in the mon- keys following Flt3L exposure. Flt3L was well tolerated in both monkeys and rats. The most significant test article-related findings were bone marrow hyperplasia (considered a pharmacological effect of Flt3L), an increased severity of chronic in- flammation at the injection site, increased severity of mononuclear cell infiltration

265c The Role of Cancer Stem-Like Cells in Cr(VI)-Induced Malignant Cell Transformation and Tumorigenicity

J. Dai and Z. Zhang, University of Kentucky, Lexington, KY.

Hexavalent chromium (Cr(VI)) compounds are well-known human carcinogens. Epidemiological studies have shown that occupational and environmental exposure to Cr(VI) is associated with a high rate of lung cancer. Cancer is a disease driven by cancer stem cells (CSCs). In the present study, we hypothesize that stem-like cells (SCs) play a key role in the Cr(VI)-induced malignant cell transformation, contributing Cr(VI)-induced lung cancer. Our results show that chronically expo- sure to low dose of Cr(VI) up to six months caused the malignant transformation of human bronchial epithelial BEAS-2B cells. To examine the existence and nature of CSCs in those Cr(VI)-transformed cells, SCs were isolated by collecting floating cells and were enriched by forming spheres under anchorage-independent growth in serum-free medium. The results show that cancer epithelial stem cell biomarkers such as Notch1 and ALDH were highly expressed in SCs as compared to normal BEAS-2B cells and Cr(VI)-transformed BEAS-2B cells. The results from hetero-transported animal study show that SCs were able to form tumors in immune-deficient nude mice at 100 cells, while Cr(VI)-transformed cells failed to grow tumor, indicating potent self-renewal and essential for tumorigenesis of those SCs. Further investigation indicates that those CSCs exhibited apoptosis resistance and reduced capacity of generating reactive oxygen species (ROS), in- dicating of potent cell proliferation/growth and capacity against exicot oxidative stress. Notably, oxygen consumption rate (OCR) was significantly decreased in SCs compared to normal BEAS-2B cells or Cr(VI)-transformed cells, indicating a metabolic alteration in SCs associated with augmented tumorigenicity and potent survival characteristics. The decrease in OCR in SCs might be due to the loss of fructose-1,6-biophosphatase (FBP1) which is a rate-limiting enzyme in gluconeo-genesis. In summary, the present study suggests that CSCs are critical in Cr(VI)- induced malignant cell transformation and tumorigenicity.
in various tissues, and thymic atrophy. Adverse findings were observed only in the 200 and 1600 μg kg−1 d-1 dose groups in either species. Based on these results, 25 μg kg−1 d-1 was determined to be a no observed adverse effect level (NOAEL) for both species.

269 Immune-Mediated Hepatotoxicity in Monkeys following Administration of a Highly Conserved Biotechnological Protein

Drug-induced liver injury (DILI) is a frequent adverse event leading to the attrition of drug candidates during development and to the withdrawal of approved therapeutics from the market. There are several causes of DILI, including immune-mediated. We report an atypical, but clearly immune-mediated drug-related hepatotoxicity in monkeys associated with a recombinant human protein (rhApo2L/TRAIL; dulanermin) formerly in development for the treatment of cancer. The cynomolgus monkey was chosen as the pharmacologically relevant species for the safety assessment of rhApo2L/TRAIL because the sequence identity between the human and cynomolgus monkey proteins was approximately 98%; additionally, rhApo2L/TRAIL bound to human and monkey cognate receptors with comparable affinities. During the course of the toxicology program, hepatotoxicity was observed in repeat-dose monkey toxicology studies. There was a strong correlation between hepatotoxicity and the presence of anti-drug antibodies (ADAs). The human and monkey proteins differ only by 4 amino acids, and the X-ray crystal structure of the human protein indicated that 3 of the 4 distinct side-chains were surface-exposed. We hypothesized that these 3 amino acids could serve as epitopes for the development of cross-species ADAs, resulting in ADA-mediated hepatotoxicity in monkeys. In vitro and in vivo investigative toxicity studies supported the ADA-mediated hepatotoxicity hypothesis and demonstrated that the equivalent autologous monkey protein was well-tolerated. The thorough characterization of the ADA-mediated toxicity in monkeys enabled the successful transition of rhApo2L/TRAIL into human clinical trials.

270 Comparison of Three Methods for the Evaluation of Cytokine Storm Risk in Early- and Clinical-Stage Biopharmaceutical Development

G. dos Santos and E. Clarke. ReachBio LLC, Seattle, WA.

Cytokine Release Syndrome (CRS) and Cytokine Storms (CS) are common and potentially dangerous side effects of anti-T cell antibodies and other immunomodulatory therapies. Therapy-induced CRS occurs quickly following infusion and results in the activation of T cells and the release of a wide range of inflammatory cytokines, including IL2, IL4, IL6, IL8, IL17, TNFα and/or IFNγ. We compared three methods to identify a robust assay that allows for the assessment of potential CRS and CS risk. In Method 1 (Romor, 2011), human PBMCs were pre-incubated for 48 hrs at 1 x 10^6 cells per mL, followed by culture on tissue-culture plastic in the presence of test (anti-CD3 clone OKT3 or anti-CD28 superagonist clone ANC28.1) or control (humanized anti-CD20 or humanized anti-TNFα) antibodies. In Method 2 (Findlay, 2011), human PBMCs were cultured on a HUVEC monolayer in the presence of test or control antibodies. In Method 3, a combination of the first two, human PBMCs were pre-incubated at 1 x 10^6 cells per mL, followed by culture at 1 x 10^6 cells per mL on a HUVEC monolayer in the presence of test or control antibodies. In all studies, supernatants were harvested after 24 hours and evaluated for TNFα and/or IFNγ by ELISA. Using Method 1, no measurable IFNγ production in the presence of any concentration of anti-CD3 or anti-CD28 was detected. Method 2 resulted in the production of ng per mL quantities of IFNγ in the presence of at least 100 ng/mL anti-CD3, but not with anti-CD28 up to 10 μg/mL. Method 3 resulted in the production of ng per mL quantities of IFNγ and high ng/mL quantities of TNFα when > 1 ng/mL anti-CD3 or > 1 μg/mL anti-CD28 was present. Method 2 appears to be the most suitable protocol to assess new antibodies and biologics for stimulation of inflammatory cytokine release and therefore as a potential model for CRS and CS induction. It could be extended to compare cytokine profiles with either human or non-human primates PBMCs and may be amenable to further refinement through lymphocyte subset analysis by flow cytometry.

271 Aerosol and Ocular Toxicity of AERAS-402 in Nonhuman Primates

C. S. Codin1, D. A. Holey2, R. Wachholder2, P. Darrah1, B. Bolton1, M. Douguign3, R. Seder2, M. Roederer2 and D. Sizemore2. 1Smidler Avanza, Gaithersburg, MD, 2Aeras, Rockville, MD, 3Vaccine Research Center, NIAID, Bethesda, MD, 4US Military HIV Research Program, Silver Spring, MD, 5Cruell Holland BV, Leiden, Netherlands and 6Ke aki Technologies, Frederick, MD.

AERAS-402 is a novel tuberculosis vaccine comprised of a recombinant, replication-deficient adenovirus, serotype 35 (Ad35), expressing a fusion protein of three mycobacterial antigens. This study assessed the toxicity of aerosol vaccination with AERAS-402 following three doses of 10^11 viral particles (vp) to Rhesus monkeys and evaluated toxicity following a single ocular topical administration. Twelve monkeys received test article via aerosol inhalation on Study Day (SD) 1, 8, and 15, and subjected to a full gross necropsy on SD 18 or 43. Two monkeys were administered test article via ocular topical application on SD 1, and subjected to a full gross necropsy on SD 43. Four monkeys were administered control article via aerosol inhalation and ocular topical administration on SD 1, 8, and 15, and subjected to a full gross necropsy on SD 18 or 43. Test article-related organ weight alterations on SD 18 were limited to apparent increased absolute and relative lung weights that correlated with microscopic findings in the lung, mediastinal lymph nodes, bronchi-associated lymphatic tissue, and the naso-oropharynx. All effects were expected with vaccination via the aerosol route, considered non-adverse, and completely resolved by SD 43. There were no test article-related organ weight or microscopic pathology findings following ocular delivery. All animals receiving aerosolized vaccine generated neutralizing antibodies to Ad35 and elicited strong, multifunctional CD4+ and CD8+ T cells by SD 43 in the lungs (obtained from BAL fluid). In addition, low-level, peripheral blood T cell responses were shown in 9/12 vaccinated animals on SD 18 which diminished by SD 43. Based on these findings the no-observed-adverse-effect level (NOAEL) is at least 10^11 vp when administered via aerosol inhalation or ocular topical application.

272 Evaluation of Paracetamol Toxicity in the Cynomolgus Monkey

H. Yu1, N. C. Barras1,2, S. Gales1,2, E. Lenz3, D. Weston1, I. Wilson4, T. Parry5, H. Powell5, D. Thurman5, F. J. Qiao6, Q. Qin7 and J. Ren1. 1Center for Drug Safety and Evaluation, Shanghai Institute of Materia Medica, Shanghai, China, 2AstraZeneca Safety Assessment, Alderley Park, United Kingdom and 3AstraZeneca R&D, Burton, MA.

Paracetamol (Acetominophen, APAP) was administered orally in a rising dose protocol to 2 male and 2 female Cynomolgus monkeys to determine the Maximum Toleraed Dose (MTD) for subsequent toxicity investigations. In the subsequent repeat dose study involving 6 monkeys, no dose-limiting toxicity was seen at up to 900 mg/kg/day APAP for 14 days. Toxicokinetic analysis showed that plasma exposure rose, albeit less than proportionally, with increasing dose. There were some fluctuations in clinical chemistry and haematology parameters, but these were not dose-related, and there were no compound-related findings observed microscopically. Both monkeys at 900 mg/kg/day had a 5 cm. gas filled segment in their large intestine that was considered compound-related. Metabolite profiling of the urine showed parent and glucuronidated APAP, but the cysteinyl conjugate which would be anticipated if the monkey has similar metabolism to rats and man was notably absent. This opens the possibility that metabolism in the cynomolgus monkey differs from that in the other species, and shows that the cynomolgus monkey is a poor model for investigating paracetamol-mediated toxicity in humans.

273 Development of a Novel Model of Pseudophakia in Nonhuman Primates to Assess Ocular Particle Movement Risk following Intravitreal Administration of Suspension Formulations

E. A. Thackaberry1, V. Bantseev1, C. Schuetz1, F. Zhong1, E. Budzynski2, M. C. Struck2, C. Trost2, C. Farman1 and E. Bentley4. 1Safety Assessment, Genentech, Inc., South San Francisco, CA, 2Covance Laboratories, Inc., Madison, Madison, WI, 3Department of Ophthalmology and Vision Sciences, University of Wisconsin-Madison, Madison, WI and 4School of Veterinary Medicine, University of Wisconsin-Madison, Madison, WI.

The development of suspensions for intravitreal (ITV) injection carries a risk for particle movement within the eye, leading to visual disturbances or blockage of Schlem’s canal and increasing intraocular pressure (IOP). The risk of such particle movement may be increased in patients with artificial intraocular lenses (IOLs), specifically patients with artificial intraocular lenses (IOLs), termed pseudophakic patients, and pseudophakic patients who have undergone posterior capsulotomies.
To directly evaluate particle movement in a nonclinical setting, a pseudophakic non-human primate (NHP) model was created to mimic clinical procedures for surgical intervention for cataracts. This model was then validated using Triescence®, an approved IV suspension with a history of successful use in pseudophakic patients. The lenses of the right eye of 11 cynomolgus monkeys were removed by aspiration and replaced with FDA-approved acrylate/methacrylate IOLs in the capsular bag. 5/11 animals then underwent a posterior capsulorhexis in the same eye. Following 4-6 weeks of post-surgical recovery, animals were dosed with IV adalimumab. Following IV adalimumab dosing, no significant particle movement was observed in the control (non-treated) eyes or the pseudophakic eyes. A small amount of test article moved into the anterior chamber of 2/5 pseudophakic + capsulotomy eyes only. Movement of Triescence® did not result in increased IOP or any other clinical complications. These results are in line with the clinical performance of Triescence® in these patient populations, and suggest that this pseudophakic NHP model may be appropriate for the assessment of particle movement with novel IV suspensions.

274 Polysomnography Using Video Electroencephalograph, Electro-Oculogram, and Electromyogram Monitored Continuously by Telemetry in Cynomolgus Monkeys

R. Mikaelian¹, S. Authier¹,², M. Pouliot¹, E. Troncy¹, D. Forster¹ and D. Paquette¹. ¹CTIexLAB North America, Lalit, QC, Canada and ²Faculty of Veterinary Medicine, University of Montreal, St-Hyacinthe, QC, Canada.

Medication-induced sleep disturbances are a major concern in drug development as a multitude of prescription drugs cause abnormalities at polysomnography. Rodent sleep architecture (nocturnal) differs from larger mammals (diurnal) which presents higher translational value. Polysomnography is used in clinical diagnostic but is also applicable to cynomolgus monkeys when using telemetry with continuous electroencephalograph (EEG), electro-oculogram (EOG) and electromyogram (EMG) monitoring with video. Sleep stages in cynomolgus monkeys include wake, N1 (somnolence), N2 (sleep characterized by the presence of sleep spindles and K complexes), N3 (deep sleep with slow waves) and rapid eye movements (REM) and are quantified with automated or manual scoring. Optimal cynomolgus data filters included EOG low pass >25 Hz, EEG band pass 0.7-50Hz and EMG high pass >5Hz. As observed in humans, cynomolgus monkeys present a progressive increase in REM sleep duration with a parallel progressive decrease in N3 sleep during the night. REM sleep was characterized by muscle atonia, high frequency (mostly theta) low amplitude EEG in all animals and EOG activity in most but not all epochs. Total sleep time was 70±2.2% of the 12 hour dark cycle. Sleep stages N1, N2, N3 and REM were typically observed in sequence and represented 1.1±0.8%, 65.2±5.3%, 16.0±5.6% and 17.7±2.4% of total sleep time, respectively. Amphetamine (1 mg/kg, PO) significantly reduced total sleep time and all stages. Spectral analysis revealed a significant increase in higher frequency bands after amphetamine. As expected for benzodiazepine, Diazepam (2 mg/kg, PO) significantly reduced N3 sleep compared to control (340%) but with no effect on total sleep time. Video EEG, EOG and EMG by telemetry is a useful non-clinical model to investigate drug induced sleep disturbances.

R. Kubaszky¹, D. Paquette¹, D. Forster¹, M. Pouliot¹, E. Troncy¹ and S. Authier¹,². ¹CTIexLAB, Lalit, QC, Canada and ²Faculty of Veterinary Medicine, University of Montreal, St-Hyacinthe, QC, Canada.

EEG investigations are required to characterize drug induced adverse neurological effects. Seizure liability studies generally aim to: 1) confirm drug-induced seizures are self-limiting, 2) determine plasma level at seizure onset 3) identify prodromal signs which can be monitored in clinical trials 4) confirm that conventional drugs (e.g. diazepam 6 mg/kg, IP for rats and 1 mg/kg, IV for large animals) can treat drug-induced seizures and 5) confirm the NOAEL by absence of paroxysmal activity at lower dose level of the test article. Cynomolgus monkeys, Beagle dogs and Sprague-Dawley rats were instrumented with telemetry implants with EEG electrode placement based on the 10-20 system combined with EMG. After 24 h of continuous video-EEG monitoring, animals received an IV infusion of pentylenetetrazole (PTZ) until convulsions followed by diazepam. A seizure detection protocol with a dynamic spike train threshold was used for the EEG monitoring period (total of 44 h). Spectral analysis quantified absolute and relative amplitudes of EEG frequency bands (delta, theta, alpha, sigma, beta and individual frequencies). The PTZ dose required to induce convolution was 31.2, 35.6, 48.3 mg/kg, in Sprague-Dawley rats, Beagle dogs and cynomolgus monkeys, respectively. Most common prodromal signs included tremors, salivation, emesis, ataxia and nystagmus. Spike trains were detected by computerized analysis in all animals. Seizure peak frequency was 3-6 Hz. Spectral analysis revealed an increase power from higher frequency bands (i.e. theta, alpha, sigma and beta) starting on average at 6 min 9 sec prior to ictus. EEG-video was useful to characterize neurological adverse effects and identify prodromal signs. Computerized EEG analysis was a valuable tool to investigate proconvulsant risks.

276 Comparative Nonclinical Assessments of the Potential Biosimilar PF-06140293 and Adalimumab

M. Deraz¹, S. L. Ripp², C. Ne³, A. M. Shoieb⁴, G. Finch⁵, L. G. Loretol⁶ and M. W. Leach⁷. ¹Pfizer Inc, Cambridge, MA, ²Pfizer Inc, Groton, CT and ³Pfizer Inc, Andover, MA.

Rationale: Adalimumab (Humira®) is a recombinant fully human immunoglobulin (IgG1) monoclonal antibody targeting tumor necrosis factor (TNFα). Adalimumab is approved for the treatment of rheumatoid arthritis, juvenile idiopathic arthritis, psoriatic arthritis, ankylosing spondylitis, Crohn’s disease, ulcerative colitis and plaque psoriasis. To support clinical development, nonclinical studies evaluated the structural, functional and in vivo toxicokinetic (TK) and pharmacodynamic (PD) similarity of PF-06140293 and adalimumab. Methods: Structural similarity was determined by peptide mapping. Cynomolgus monkeys were administered PF-06140293 or adalimumab-EU by subcutaneous (SC) injection at weekly dose levels 0 or 157 mg/kg (total 5 doses) for 1-month. Assessments included mortality, clinical parameters, clinical pathology, TK, anti-drug antibodies (ADA), histopathology and pharmacodynamics. Results: Peptide mapping showed similar chromatographic profiles and consistent measured masses for PF 06140293, the US-licensed (adalimumab-US) and EU-approved (adalimumab-EU) products. The results of comparative functional and binding assessments (TNF-induced inhibition of apoptosis in U937 cells and Fc-based functionality) were also similar. PF-06140293 and adalimumab-EU were well tolerated in cynomolgus monkeys. PF-06140293 and adalimumab-EU-related effects were limited to microscopic observations of decreased cellularity of lymphoid follicles and germinal centers in the spleen. There were no biologically or toxicologically relevant differences in the incidence or severity of these microscopic findings between PF-06140293 and adalimumab-EU groups. Systemic exposure appeared similar, with systemic exposure (Cmax and AUC(168) ratios of PF 06140293 relative to adalimumab-EU ranging from 1.0 to 1.2. These studies supported entry of PF 06140293 into clinical development.

277 A Repeat IV Dose Toxicity Study of Gemcitabine Formulations in Male and Female CD-1 Mice

J. Rivasnas¹, C. S. Godin¹, A. Knill¹, B. Currow¹ and E. Kon¹. ¹Hospira Inc., Lake Forest, IL and ²Smithers Avanza, Gaithersburg, MD.

This study compared the toxicity of Hospira’s Gemcitabine Injection (Test Article) with Gemzar® (Reference Article), when administered to CD-1 mice. Test and Reference Articles were composed of the same cytotoxic active ingredient but Test Article contained additional impurities formed after accelerated degradation. One hundred and sixty mice were assigned to one of eight groups (10 mice/sex/group) and dosed with Vehicle, Test or Reference Article at doses of 0, 100, 500, or 600 mg/kg. Mice were dosed by IV administration via the lateral tail vein on Study Day 1 (SD) and 8. Surviving animals were euthanized on SD 15. Mortality, clinical and post dose observations, body weights, food consumption, ophthalmologic examinations, clinical pathology, gross pathology, organ weights, and histopathology were assessed.

There were no consistent premonitory adverse clinical signs, and no visible lesions at necropsy. There were no adverse effects of the Test or Reference Articles on clinical, cage side, or post dose observations, body weight, food consumption or gross pathology. Treatment with Test and Reference Articles both led to reduced red blood cell count, hemoglobin, hematocrit and absolute lymphocyte counts, increased absolute reticulocyte counts and red cell distribution width, increased absolute and relative spleen weights, decreased absolute and relative thymus and testis weights, increased splenic hematopoiesis and testicular germ cell depletion at doses ≥100 mg/kg. Lymphocytolysis and/or lymphoid depletion of spleen, thymus and lymph nodes were also observed and thymic atrophy was noted at 600 mg/kg. Most observations were of no toxicological significance; however testicular germ cell depletion is adverse due to potential effects on reproductive function. Lymphoid organs and testes are the primary target organs for both articles. In conclusion, the toxicological profile of Hospira’s Gemcitabine Injection containing additional impurities was no different to that of the Reference Article, Gemzar®.
Understanding species differences in placental transfer of Fc-containing biopharmaceuticals (particularly monoclonal antibodies) will improve human risk extrapolation from nonclinical embryo-fetal development toxicity data. Maternal and fetal concentration data from 10, 15, 8 and 34 Fc-containing biopharmaceuticals in the rabbit, rat, mouse and cynomolgus monkey from across 56 species and the associated labor. Additionally, if homogenized tissue is analyzed for ex vivo in rats. Scanners were operated with software validated for the conduct of GLP studies. The coefficients of variation (%CV) were calculated from each series of 4 scans performed on the same animal. X-ray Absorptiometry (DXA) and peripheral Quantitative Computed Tomography (pQCT) were done on four rats and 4 NHPs, 4 times each with repositioning between scans using 2 separate scanners. Legs and arms scans were also performed in NHPs. pQCT scans were performed at the proximal tibia diaphysis for the calf muscle or at the femur diaphysis for the thigh muscle, in vivo and ex vivo in rats. Scanners were operated with software validated for the conduct of GLP studies. The coefficients of variation (%CV) were calculated from each series of 4 scans performed on the same animal. The %CVs obtained for rat WB fat and muscle were below 4% and 1% respectively. The %CVs obtained for NHP WB fat and muscle were 35% and below 2% respectively. Fat mass in NHPs were very low at around 200g explaining the larger variability observed. Similar results were obtained for the two DXA machines. For the right arm, the % CV was below 10% for lean mass (7.3%) and below 11% for fat parameters (g %). For the right leg, the % CV was below 3% for lean mass (2.4%) and below 25% for fat parameters (g %). Additionally, body mass measured by DXA differed by 4% relative to the actual NHP body weight. With pQCT, the % CV was below 4% for lean mass and below 20% for fat parameters. DXA and pQCT provide reproducible non-invasive measurements of fat and muscle mass in NHP which can also be combined with bone densitometry. These data support the use DXA and pQCT densitometry in preclinical studies, to provide comprehensive measures of the body composition in nonclinical drug development programs.

Embryo-Fetal Development (EFD) study designs for risk assessment often include satellite groups for the assessment of toxicokinetics, increasing animal utilization and the associated labor. Additionally, if homogenized tissue is analyzed for ex vivo data, this prohibits a direct comparison of drug levels in the maternal and fetal circulation. Therefore, we have investigated an alternative blood sampling method which allows for collection of fetal blood yet does not hinder visceral or skeletal evaluations for the same fetuses. By collecting from the axillary artery and pooling by litter, sufficiently blood volumes have been obtained from gestation day 21 (GD21) Sprague-Dawley rat fetuses to conduct either toxicokinetic or antibody titer analyses on fetal blood. Clinical pathology and hematologic samples of approximately 1mL were gathered across 24 litters and directly compared. Standard
clinical chemistry (GLU, UN, CREA, AST, ALT, etc.) and hematology (RBC, etc.) parameters indicated that samples collected via the axillary artery were equivalent to blood collected via cardiac puncture. However, cardiac puncture often produces structural damage to at least the thoracic cavity which would negate the possibility of further feline evaluations. It can therefore be concluded that this bleeding procedure offers a way to meaningfully reduce satellite animal requirements without a negative impact on the visceral and skeletal evaluations required of the study design.

283 A Novel Approach for Assessing the Safety of Pharmaceuticals

Too often, prescription medications once thought safe for human use cause adverse health consequences and fail during clinical testing or are recalled after public release. One major problem is the inability of current toxicity assessment methods to detect many toxicities caused by pharmaceuticals during preclinical trials. We have developed a novel toxicity discovery method known as the organismal performance assay (OPA), that is capable of revealing mammalian health consequences. OPAs utilize genetically diverse wild mice (Mus musculus) that compete amongst each other for limited resources in semi-natural enclosures. This assay is sensitive, broad and functional because it demands high performance of most physiological systems in order for individuals to be successful. OPAs have proven powerful in detecting adverse health affects from inbreeding, genetic manipulations and dietary fructose. We tested the safety of Paxil (paroxetine) and Baycol (cerivastatin). Performance of pharmaceutical-exposed mice was analyzed when competing directly against control mice in OPAs. Performance was measured by territoriality, survivorship and reproductive success. We hypothesized that pharmaceutical-exposed individuals will suffer significant fitness declines compared to control individuals. Paxil-exposed breeding pairs took significantly longer to produce their first litter (p<0.05) and these litters were significantly biased towards female offspring (p=0.0021; 39:61 M:F). Paxil-exposed offspring also weighed significantly less than controls (p<0.0001). We detected a significant decline in reproductive success in both sexes and treatments (Paxil F: p<0.001; M: p<0.01, Baycol F: p<0.001; M: p<0.001). Pharmaceutical-exposed males were significantly less dominant than controls (Paxil p<0.0001; Baycol p<0.0001). Baycol-exposed individuals suffered higher mortality (p=0.0116). These pharmaceutical-caused health declines were mirrored by previous animal testing, indicating that OPAs provide superior sensitivity compared to conventional approaches. The data indicate OPAs could be a useful tool in safety testing during pharmaceutical development.

284 Recovery Assessment in Preclinical Drug Safety Testing—A Retrospective Analysis of Value and Timing

We have previously reported the profile of target organ toxicities in first time in man (FTIM) toxicity studies conducted in rodents and non-rodents for 77 AstraZeneca candidate drugs (CDs) across a range of therapy areas (Horner et al., 2013, Reg. Tox Pharm, 65, 334-343). Here, we present a further analysis of which target organ toxicities subsequently recovered after a dose free period and whether that profile differed for CDs that progressed into man and those that did not. We also report which additional target organ toxicities (defined as toxicities in a target organ not previously noted) were observed in chronic (≥3 month) studies conducted to support later stage clinical programmes across the different intended therapy areas (Cardiovascular/Gastrointestinal: CVGI; CNS/Pain: CNSP; Respiratory and Inflammation: RITA; Oncology/Infection: OI). Target organ toxicity was primarily defined as compound-related histopathological changes. Overall, the analyses showed that ≥85% of findings were either fully or partially resolved at the end of the recovery period; lack of recovery in the dog male reproductive tract was the most frequent finding. Interestingly, profiles of recovery were largely similar for those CDs that progressed into man and those that did not and were also similar across therapy areas with the exception of oncology, where more findings persisted at the end of the recovery phase. Compared to observations in chronic studies, >60% of toxicities were identified in the FTIM studies with varying detection rates across the target organs. Overall, these data support inclusion of recovery on the FTIM studies and also demonstrate that chronic toxicity studies provide additional information of great value in risk assessment for longer term dosing in humans.

285 Validation of a CYP1A2 and a CYP3A4 Induction Assay Using Puracyp’s 1A2-DRE™, and DPX2™ Cell Lines: Comparison between the Gene-Reporter Assay and Human Hepatocyte Data

A. Watanyar, J. Enoru, K. Draper and W. DeMaio. Ricerca Biosciences, Concord, ON.

Induction of Cytochrome P450 drug metabolizing enzymes (DME) can lead to rapid elimination of APIs resulting in reduced efficacy and increased metabolism which can potentially lead to formation of toxic metabolites. The FDA routinely requests data on induction of human CYP450 enzymes CYP1A2 and CYP3A4 by new chemical entities in early development. CYP1A2 expression is regulated via the aryl hydrocarbon receptor (AhR), while CYP3A4 is predominantly regulated via the pregnane X receptor (PXR). Human primary hepatocytes are the preferred in vitro model for studying induction of DME, but their use is limited by unpredictable supply of tissues and interindividual donor variability. In this study, two gene reporter assays for evaluating induction of CYP1A2 and CYP3A4 were validated, using Puracyp’s 1A2-DRE™ (a HepG2 derived cell line stably transfected with human AhR gene and a luciferase reporter gene linked to CYP1A2 promoter and the dioxin response element enhancer), and DPX2™ (a HepG2 derived cell line stably transfected with human PXR gene and a luciferase reporter gene linked to the CYP3A4 promoter and enhancer). CYP1A2 inducers rifampicin, phenobarbital, clotrimazole, erythromycin, and phenytoin increased CYP3A4 luciferase activity in a concentration dependent manner, resulting in EC50 and Emax values of 0.56 μM and 50-fold, 9.7 μM and 24.5-fold, 1.9 μM and 27.4-fold, and 3.3 μM and 37.8-fold, respectively. Similarly, CYP3A4 inducers rifampicin, phenobarbital, clotrimazole, erythromycin, and phenytoin increased CYP3A4 luciferase activity resulting in EC50 and Emax values of 0.85 μM and 7.8-fold, 119.8 μM and 5.0-fold, 0.5 μM and 5.0-fold, 10 μM and 4.2-fold and 17.5 μM and 4.0-fold, respectively. Our reporter gene assay data showed good correlation with data generated using human hepatocytes. Therefore, these validated assays can be used in early development for evaluating induction of CYP1A2 and CYP3A4, providing guidance on compound selection and potential for clinical drug-drug interactions.

286 Acute Kidney Injury Biomarkers following Low-Dose Gentamicin Treatment of Rats

G. Marceau1, I. Kołodziejski1, G. Diagne1, J. Tremblay1, S. Thébaud1, M. Toneva2, E. Scrihrner Doering2, C. Kostrub3 and A. Nelson1. 1ITR Laboratories Canada, Inc, Barrie d’Urfe, QC, Canada, 2ALPCO Diagnostics, Salem, NH and 3CK Scientific, Belmont, CA. Sponsor: W. Leg.

Rationale

The use of biomarkers as part of the preclinical assessment of kidney injury is now a well established goal. Published analysis of multiple datasets from the toxicology industry has convincingly identified a panel of urine and serum biomarkers which correlate with drug induced kidney injury. Several biomarkers have been shown to be superior to blood urea nitrogen (BUN) and serum creatinine at detecting renal injury. The present study correlates histopathologic evidence of kidney damage with urinary and serum biomarkers after very low dose regimens of Gentamicin.

Experimental procedures

Male Sprague-Dawley rats received daily subcutaneous injections of Gentamicin sulfate for 15 days at dose levels of 5, 15, and 50 mg/kg/day. Urine samples were collected over 16 hours for biomarker assessment at multiple timepoints (Pre-Tx, Days 4, 10, and 16). Blood was also collected at the end of a fasting period and serum preserved. A panel of biomarkers was tested in urine (Albumin, B2M, clustatin, cystatin C, KIM-1, NAG, NGAL, OPN, RBP) and serum (BUN, creatinine, and cystatin C). Kidney histology was assessed on days 4 and 16.

Results

Increased excretion of urinary biomarkers was observed on Days 10 and 16 of gentamicin treatment, and was associated with histologic changes on Day 16. Serum and urine creatinine and BUN remained unchanged over the treatment period.

Conclusions

As previously reported, creatinine and BUN levels were insensitive to low levels of acute kidney injury. Increased urine excretion of a group of biomarkers was associated with histopathological findings despite the normal values of creatinine and blood urea nitrogen. These biomarkers are candidate diagnostics and potential surrogates to histological evaluation of acute kidney injury.
Clinical Pathology parameters are routinely assessed during the conduct of toxicology studies. This study was conducted to see if there were any differences in hematology, coagulation and clinical chemistry parameters among Sprague Dawley rats sourced from Charles River sites based in the USA, China and Taiwan. Control group data from completed and ongoing toxicology studies were used to see if there were any differences between the three sources of animals. The results from the three data sets were analyzed using the Charles River USA-supplied rat as reference control point. Analysis of the hematology data showed for males slightly lower white blood cell count (WBC), red blood cell count (RBC), hemoglobin (HGB), mean corpuscular hemoglobin concentration (MCHC) and neutrophils and increased mean corpuscular hemoglobin (MCH) for animals from both China and Taiwan when compared to the USA. In addition, decreased group mean lymphocytes and monocytes were observed for animals from China only. For the female rats decreased WBC, RBC, HGB, HCT, MCV, lymphocytes, monocytes and eosinophils and mean platelet volume (MPV) were observed for animals from China only. For both males and females from both China and Taiwan, decreased Prothrombin time were observed when compared to the USA-sourced rat. Differences in clinical chemistry were observed for rats from both China and Taiwan and included a reduced total protein due to a reduced albumin, reduced potassium and increased globulin when compared to the USA rat. The results of the analysis indicated that those rats sourced from Taiwan were closer to those sourced from China in terms of clinical pathology profile. These observed differences between the three sources of animals enforce the need to be consistent in the source of animals for a toxicology development program and also the need for maintaining separate back ground data bases.

Lower Susceptibility to Histaminergic Reactions in Rodents Using Continuous Infusion: Advantages for Safety Assessment of Parenteral Peptide/Protein Drugs

H. van Wijk1, P. Baldrick1 and U. Wimrntzer2. Covance Laboratories Ltd, Harrogate, United Kingdom and Bayer Pharma AG, Wuppertal, Germany. Sponsor: A. Jackson.

Some drugs elicit histaminergic responses in vitro and in vivo, with the rat shown to be particularly sensitive in toxicology testing. As more parenteral therapeutic peptides/proteins are developed a model less prone to histaminergic reactions would offer improved safety testing. Such a model could be continuous vascular infusion via surgically implanted indwelling catheter in rodents and would allow comparison of histamine release response compared to bolus administration. In this study, the sensitivity of mouse and rat to histamine release after bovine pancreatic trypsin inhibitor drug Aprotinin (Trasylol®) given as a bolus or 6hrs intravenous infusion was investigated.

Rodents with implanted indwelling femoral vein catheter were bolus injected with 120.000 or 300.000 U/kg or infused over 6hrs with 240.000 or 300.000 U/kg. After bolus injection, mice developed mild clinical signs, while rats developed clear histaminergic symptoms (cyanosis, swellings, reddening). Reddening was also seen in 1 rat after 300.000 U/kg infusion over 6hrs. Predose histamine levels in mice were markedly (~15-fold) lower than in rats. Induced histamine release was also seen in 1 rat after 300.000 U/kg infusion over 6hrs. Predose histamine levels in mice were markedly (~15-fold) lower than in rats. Induced histamine release was also seen in 1 rat after 300.000 U/kg infusion over 6hrs. Predose histamine levels in mice were markedly (~15-fold) lower than in rats. Induced histamine release was also seen in 1 rat after 300.000 U/kg infusion over 6hrs.

Methylmercury (MeHg) is well known as human neurotoxic agent whose exposure sources are mainly environmental and aquatic-derived food. MeHg is reported to induce central nervous system (CNS) disability. However, the exact mechanism of MeHg-induced neurotoxic effects is still unknown. In this study, to investigate which cell death signaling pathway is related with MeHg-induced cytotoxicity, the effects of MeHg on apoptosis and autophagy were evaluated in human neural stem cells (NSCs). H1.B1.F3. Human NSCs were treated with 1 μM of MeHg for 48 hr and the effect of MeHg on cell signaling pathway was elucidated. MeHg inhibited Akt/mTOR signaling that led to induction of caspase-dependent apoptosis and autophagy in the NSCs. Furthermore, retinoic acid (RA)-induced neuronal differentiation was inhibited by MeHg. Taken together, these results suggest that MeHg inhibits the differentiation of human NSCs by induction of caspase-dependent apoptosis and autophagy.

Verifying Performance of Cell Viability and Apoptosis Assays Applied to 3D Microtissues

T. L. Bus1, M. P. Valley2, K. R. Kupcho2, D. F. Lazar2 and C. A. Zimprich2. 1Cell Health, Promega Corporation, Madison, WI and 2Research, Promega Corporation, Madison, WI.

Multicellular 3D culture systems containing more than one cell type and exhibiting formation of a complex extracellular matrix represent a more physiologically relevant environment for performing in vitro cytotoxicity testing. yet provide a challenge for assay chemistries originally designed for measuring events from 2D monolayers of cells. The approach of this research was to investigate whether increasing detergent concentrations to increase lytic capacity or providing physical disruption of samples would improve the results of cell viability and apoptosis assays applied to microtissues grown using 3D culture models. Results demonstrate that increasing detergent concentration in assay reagents has limits that depend on the source and stability of the luciferase enzyme. Introducing a physical disruption step in the protocol (shaking multi-well plates for 5 minutes at 850 rpm) improves the generation of signal from the luminescent ATP assay applied to microtissues grown in 3D models. Physical disruption also improved signal intensity from measurement of caspase-3/7 activity as a marker of apoptosis. Validation of assays designed for 2D monolayers is necessary prior to application to 3D culture models.
Activation of the Aryl Hydrocarbon Receptor by Endogenous Cinnabarinic Acid Induces Stanniocalcin-2 to Elicit Cytoprotection against ER and Oxidative Stress

D. Carter, A. Joshi, T. Harper and E. J. Ellerlink. Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX.

The Aryl Hydrocarbon Receptor (AhR) is a cytosolic ligand activated transcription factor historically known for its role in xenobiotic metabolism. However, endogenous tryptophan catabolites such as cinnabarinic acid possess the capacity to activate the AhR. Our lab has recently identified stanniocalcin 2 (STC2) as a novel AhR target gene that was induced in an AhR dependent manner after adenosiv infection of mouse primary hepatocytes. We hypothesized that AhR induction of STC2 plays a cytoprotective role in the mouse liver. Here we demonstrate for the first time that cinnabarinic acid activation of the AhR induces STC2 to elicit protection against ER stress and oxidative stress-induced apoptosis in mouse primary hepatocytes. We confirmed AhR activation and AhR targeting of the STC2 gene after cinnabarinic acid treatment by conducting immuno-cytocchemistry and chromatin immuno-precipitation experiments, respectively. Our preliminary data demonstrates that cinnabarinic acid treatment of primary hepatocytes causes significant enrichment of the STC2 protein while decreasing caspase 3 activities in a dose dependent manner. We also show that primary hepatocytes pre-treated with cinnabarinic acid for 24 hours exhibited reduced caspase 3 activities and reduced percentages of TUNEL positive cells after treatments with thapsigargin, hydrogen peroxide or ethanol when compared to non cinnabarinic acid pre-treated cells. Using AhR conditional knockout primary hepatocytes as well as STC2 knockdown using siRNA, we were able to confirm the direct involvement of STC2 in the cytoprotection of mouse primary hepatocytes against ER stress and oxidative stress-induced apoptosis. Our data conclusively demonstrates that AhR induction of STC2 in the liver plays a crucial cytoprotective role against ER stress and oxidative stress-induced apoptosis. Therefore, our goal is to elucidate the cytoprotective mechanism of STC2 in mouse primary hepatocytes.

CYP1B1 Inhibits TRAIL-Mediated Apoptotic Pathway followed by Sp1 Induction

Cytochrome P450 1B1 (CYP1B1) belongs to the CYP1 family and shares the feature as an enzyme for drug metabolisms. It has been reported that CYP1B1 expression is higher in the tumor tissues than the normal ones, especially in hormone-related cancers such as breast, ovarian and prostate cancer cells. To explore the role of CYP1B1 on cancer cell proliferation, we investigated whether CYP1B1 blocks apoptotic pathways. Using Western blot and RT-PCR, the expression of anti-apoptotic factors such as Bcl-2, Bcl-xl, XIAP, survivin and Mcl-1 were examined and showed to be promoted followed by CYP1B1 overexpression or treatment with CYP1B1 inducer, 7, 12-dimethylbenz[a]anthracene (DMBA). These promoting results were reversed when cells were transfected with siRNA for CYP1B1 or treated with a CYP1B1 inhibitor, tetrathromthoxynil (TMS). Moreover, AIE, a widely known pro-apoptotic factor, was showed to be translocated to cytosol from mitochondria after treatment with TMS. The expression of TRAIL, a member of tumor necrosis factor superfamily, was also examined followed by alteration of CYP1B1 expression and it showed similar changes in expression level to pro-apoptotic factors. Sp1, a transcription factor, has been reported to suppress TRAIL expression by binding TRAIL promoter. To identify whether Sp1 mediates the suppression of TRAIL, we examined Sp1 expression after changes of CYP1B1 expression level and it showed that Sp1 is promoted by CYP1B1. Moreover, Sp1 knockdown with specific siRNA showed promotion of TRAIL-related apoptotic factors and these results were matched by chromatin immunoprecipitation. Moreover, attenuation of Sp1 DNA binding activity using mimicrycin A, a well known Sp1 binding inhibitor, resulted in recovery of TRAIL expression formerly suppressed by treatment with DMBA. Taken together, these data suggest that CYP1B1 blocks apoptosis via TRAIL suppression and this is mediated by Sp1 induction.

Intact 20kDa Extracellular Domain of APO2L/TRAIL Bioanalysis by HRMS: A Potential Cancer Therapeutic Protein

Recombinant APO2L/TRAIL (Ap2 ligand/tumor necrosis factor-related apoptosis-inducing ligand), typically analyzed by LBA, was successfully quantified as intact protein by High Resolution Mass Spectrometry (HRMS). The chromatographic separation of intact APO2L/TRAIL for mass spectrometric analyses was found to be challenging with silica columns. Whereas, polymer column greatly improved peak shape and reproducibility. Moreover, the column temperature had an important impact on the amount of APO2L/TRAIL recovered from column upon injection: Increasing the column temperature from 22°C to 70°C increased the recovery by at least 4-time and improved peak shape. Data processing method was optimized to avoid interferences, it was possible to quantitate only the most abundant charge state and isotopomers or the sum of each charge state and isotopomers. APO2L/TRAIL signal was found to have charge state distributions from +12 to +27 with the 6 most intense charge states being from +18 to +23. Monitoring only one charge state (+20), with an XIC of 10mDa, led to variability and unacceptable peak shape. After summation, the 6 most abundant multiple charge states with an XIC window of 10mDa around the most abundant isotopomer, a S/N=8 was observed at the LLOQ. The method showed very good results: dynamic range was linear (weighted to 1/x2) with a correlation of r=0.9960. The assay precision was below 5% and with accuracy between 101-108% for the LLOQ QCs and 3 additional QC levels. This data successfully confirmed the possibility to use HRMS for intact protein quantification without tropic digestion.

Preventive Effect of Nonmitogenic Acidic Fibroblast Growth Factor on Diabetes-Induced Testicular Cell Death and Atrophy

M. Skibba1, C. Zhang2, X. Jiang1 and L. Cai1, 2. 1Pharmacology and Toxicology, University of Louisville, Louisville, KY and 2RCRHR and Department of Pediatrics, University of Louisville, Louisville, KY.

Fibroblast growth factor (FGF) family members in previous studies were shown to prevent various oxidative stress-induced cardiac, neuronal and retinal inquires. Particularly, FGF-1 was found to protect the heart from ischemia-, doxorubicin- and diabetes-induced damage suggesting the potential clinical application. However, long-term use of FGF-1 was restricted for its potential risk of carcinogenesis due to its non-specific proliferating activity. Thus a cluster of amino acids responsible for proliferation were deleted in the native FGF-1 to create a modified non-mitogenic FGF-1 (nmFGF-1). The present study tested if the nmFGF-1 protects male germs cells from diabetes-induced apoptotic cell death and testicular atrophy. Mice were treated with multiple low-doses of streptozocin (STZ) to induce type-1 diabetes and then treated with nmFGF-1 for 6 months. Diabetic mice showed a decrease in testicular weight and an increase in apoptotic cell death (detected by TUNEL staining). Treatment with nmFGF-1 alleviated diabetic effects on testicular weight and apoptotic cell death. Mechanistically, the diabetes induces, the mitochondrial apoptotic pathway due to a significant increase in BAX/Bcl-2 ratio, determined with Western blotting assay. Diabetes also induced mild increases in endoplasmic reticulum stress and associated cell death, reflected by increases in cleaved-caspase 12, CHOP, and GRP-78 expression, and a significant increase in TNF-α-alpha expression as an index of inflammation. All these effects induced by diabetes were attenuated by treatment with nmFGF-1. Therefore, these results suggest that nmFGF-1 is able to prevent the apoptotic-effect of diabetes on the testes via the mitochondrial pathway predominantly, resulting in prevention of diabetes-induced testicular atrophy.

Nelumbo nucifera Leaf Extract-Induced Pancreatic Cancer Apoptosis via JNK/ERK Activation-Regulated Mitochondria-Dependent and ER Stress-Triggered Signaling Pathways

Y. Chen1, C. Su1, T. Lu1, C. Yen3, Y. Chung1, K. Chen2, C. Wu1, S. Liu1 and C. Huang2. 1Department of Physiology and Graduate Institute of Basic Medical Science, China Medical University, Taichung, Taiwan, 2Department of Oncohemato-lymphology, Changhua Christian Hospital, Changhua, Taiwan, 3Department of Public Health, China Medical University, Taichung, Taiwan, 4School of Chinese Medicine, China Medical University, Taichung, Taiwan, 5Department of Occupational Safety and Health, Chang Shou Medical University, Taichung, Taiwan, 6Department of Urology, China Medical University Hospital, Taichung, Taiwan and 7Institute of Toxicology, National Taiwan University, Taipei, Taiwan.

In this study, we investigated the pharmacological effects of N. nucifera leaf in anti-pancreatic cancer and elucidate its molecular mechanisms. The results found that Nelumbo nucifera leaf extract (NNE) significantly caused cytotoxicity in PANC-1 cells with a dose-dependent manner and induced several features of apoptosis signals in PANC-1 cells. NNE was also capable of increasing the protein phosphorylations of JNK and ERK-1/2, but not that p38-MAPK. Transfection of PANC-1 cells with JNK1- and ERK2-specific si-RNA could inhibit JNK-1 and ERK-2 activation and attenuate caspase-3/-7 activity induced by NNE, respectively. Furthermore, exposure of PANC-1 cells to NNE could trigger endoplasmic reticulum (ER) stress indicating by the increase in ER stress-related molecules. Transfection of PANC-1 cells with GRP-78- and GRP94-specific si-RNA could effectively prevented the NNE-induced caspase-3/-7 activity, respectively. More
importantly, quercetin, not that catechin, was the mainly active component of NNE in NNE-induced cytotoxicity and apoptosis in PAN-C-1 cells. In conclusion, these results demonstrate that NNE induces pancreatic cancer cell apoptosis via the JNK/ERK activation-regulated mitochondria-dependent and ER-stress-triggered signaling pathways. And quercetin is the mainly active component of NNE.

297 Most Bioactivation-Dependent Nephrotoxins Induce Apoptotic Death along with Unique Patho-Morphological Characteristics in Mouse Kidneys

Critical issues in the pathophysiology of toxic renal injury includes drug metabolization within target cells, changes in gene expression, oxidative stress, inflammation and various types of cell deaths. Drug-induced nephropathy is often viewed as an endpoint in animal toxicity studies, and the diagnosis of various forms of kidney injury based on clinical data remains very challenging because of the difficulty in interpreting histopathology. Our earlier studies showed that most bioactivation-dependent nephrotoxins cause oxidative stress and apoptotic death. Therefore, this study analyzed the histopathological changes induced by different bioactivation-dependent nephrotoxins [chloroform (CHCl3), diclofenac (DCF), salicyclic acid (SA) and furosemide (FUR)] to profile common and uncommon pathological features to hypothesize whether a subset of changes can be used to categorize nephrotoxins. Mice were administered CHCl3 (1 ml/kg orally), DCFL (300 mg/kg, ip), SA (300 mg/kg, ip) and FUR (500 mg/kg, ip) and sacrificed 24 hours later. PAS or H&E stained kidney sections were examined under a brightfield microscope to assess changes in proximal (PT) and distal tubules (DT). Bowman's capsule, ureter, brush borders, Bowman's space, glomerular congestion and interstitial fibrosis. Results indicated that all the toxins induced nephrotoxicity as judged by elevated serum BUN (5 fold or higher by all toxins), increased BUN/creatinine ratios and tissue MDA levels (fold or higher). Pathomorphologically, the most common features were distorted PTs and DTs along with brush border injury, scattered apoptotic nuclei and abundant inflammatory cells. DCFL showed hypertrophied tubular cells with massive induction of apoptotic nuclei, SA showed degeneration of brush borders with tubular dye accumulation, whereas FUR showed global injury throughout the tissue. Thus, this study may have discerned a novel way of profiling xenobiotic-induced nephrotoxicity [Suppo, by Dept. of Pscs of Manch. Univ. Coll. of Pharm. & AMS Coll of Pharm & HScs, NV]

298 Anthracenyl Isoxazole Amides (AIsMs) As Mitochondrial Modulators of Apoptosis

A. K. Kearns, M. J. Weaver, P. K. Shaw, N. R. Natale and H. D. Beall, Biomedical and Pharmaceutical Sciences, Univ Montana, Missoula, MT.

Development of G-quadruplex ligands for the treatment of solid tumors is an emerging field of research. G-quadruplex structures within the nuclei of cells are the target for these ligands with the goal of inhibiting telomerase and causing replicative senescence or selective apoptosis of tumor cells. We have previously shown that novel anthracenyl isoxazole amides (AIsMs), such as N5C 748994 (A1M), bind telomeric G-quadruplex DNA and exhibit single digit micromolar IC50 values in SNB-19 glioblastoma cells, suggesting their potential as G-quadruplex-directed antitumor agents. However, confocal microscopy with MitoTracker Red showed that A1M was primarily localized within the mitochondria of cells, with less distribution to the nucleus. As a result, the present study was conducted to determine if the AIsMs modulate mitochondrial function in SNB-19 glioblastoma cells. Our hypothesis was that the AIsMs produce cell death via mitochondrial-mediated apoptosis. A1M significantly increased both early and late apoptosis at 5 μM compared to control after 24 hours as measured by Annexin V/flow cytometry. JC-1 staining indicated that mitochondrial membrane potential was significantly reduced by 5 μM A1M while reactive oxygen species generation was increased at the 1 μM level using MitoSox Red, a mitochondrial indicator of superoxide anion. In addition, exposure to 5 μM A1M resulted in caspase-9 activation, an indication of mitochondrial-mediated apoptosis. Although these findings suggest that the mitochondria is one possible target of A1M-associated toxicity, these effects could also be triggered by A1M binding to G-quadruplex in nuclear DNA (via human telomerase catalytic subunit hTERT shuttling) or directly to G-quadruplex in mitochondrial DNA. Further studies on the mechanisms of A1M toxicity are ongoing. Supported by NIH Grant P20RR017670 (HDB).

299 Assessment of an In Vitro Model for Evaluating the Role of PARP in Ethanol-Mediated Hepatotoxicity

J. Cowle1, G. T. Johnson1, M. M. Bourgeois1, A. Mayo-Perez1, S. Morris2 and R. D. Harbison3, 1Environmental and Occupational Health, University of South Florida, Tampa, FL, 2College of Nursing, University of South Florida, Tampa, FL.

This investigation assesses the role of poly(ADP-ribose) polymerase in ethanol-mediated hepatotoxicity using the untransfected HepG2 hepatocellular carcinoma line, an established, well-characterized toxicological model. HepG2 cells were treated with ethanol at concentrations between 100 mM and 800 mM, and assessed for markers of cytotoxicity. PARP-1 activity in total cell protein lysates was quantified as a proxy of apoptotic induction at six hours. Our results demonstrated a 1.43-fold AST activity increase in culture medium isolates of cells exposed to 800 mM without significant effect on cellular viability. PARP-1 activity varied greatly and results for enzyme activity remained inconclusive. The results suggest a high degree of insensitivity to ethanol toxicity and nuclear enzyme activity, demonstrating the metabolic unrelevance of untransfected HepG2 in ethanol toxicosis. There is a need to characterize phase 1 metabolic enzyme expression profiles relevant to ethanol for CYP2E1 and ADH pathways to facilitate constructing toxicological models using transfected, as well as the untransfected HepG2 model.

300 Genotoxicity of DEHP and Its Metabolite

Y. Chang1, C. Tseng1, 2, 3, Y. Chen1, Y. Chuang1 and M. Chao1, 2, 3, 4. 1Bioscience Technology, Chung Yuan Christian University, Chung-Li, Taiwan, 2Biomedical Engineering, Chung Yuan Christian University, Chung-Li, Taiwan and 3Center of Nanotechnology, Chung Yuan Christian University, Chung-Li, Taiwan.

DEHP, Di-(2-ethylhexyl) phthalate, the most common phthalate plasticizer used in manufactures. It can be leached into a liquid that comes in contact with plastics, suggesting concerns about the health risk of human exposure. Several in vivo studies have shown that DEHP can be metabolized in the intestine and converted to MEHP, mono-ethylhexyl phthalate. The metabolite can be absorbed through the vili and travel in the circulation system then causes series damages in endocrine and reproductive system. In addition, investigations also demonstrated an association with elevated induction of rat hepatic cancer, testicular cancer, and developmental toxicity in reproductive system under MEHP exposure. However, the mechanism regarding to carcinogenicity induced by DEHP or its metabolite MEHP remains unclear up to date. We therefore are investigating the cell viability and mutagenicity of DEHP and MEHP in Chinese hamster ovary (CHO) cells. Cytotoxicity and DNA damages induced by these chemicals in nucleotide repair-proficient A549 and repair-deficient UV5, and base excision repair-deficient EM9 cell lines. Results show that the parental chemical, DEHP, as well as MEHP derivatives caused dose-dependent decreases in cell survival, but with very different potencies: MEHP has the high potency; and DEHP lower. Exposure to these compounds induced dose-dependent production of ROS, as determined by cm-H2DCF-DA Fluorescence. Comet assay shows the DNA damages in the trend as same as cytotoxicity, but no difference observed between NER and BER deficient cells exposed to these treatments, even at highly toxic doses. It was noted however that simultaneous exposure of ROS scavenger N-acetylcycteine (NAC) shows the protection against DEHP and MEHP induced DNA damages. In summary, DEHP and MEHP are cytotoxic to the cells and require induction of ROS to exert their genotoxicity effects.

301 Exposure of V79 Hamster Cells to Cadmium Chloride Results in the Production of Double-Strand Breaks and Cell Cycle Changes

J. Comotto, C. Donald and M. Reynolds-Walsh, Washington College, Chestertown, MD.

Cadmium is a ubiquitous metal used in many industrial applications, resulting in widespread environmental pollution. Exposure to this metal occurs through inhalation and can result in numerous respiratory disorders, as well as cancer. Non-occupational exposure occurs through inhalation and the ingestion of cadmium from polluted food and water. This study investigates the effects of cadmium exposure on cytotoxicity, genotoxicity and cell cycle progression in V79 hamster cells. Western-blot analysis of caspase and PARP cleavage were used to determine cytotoxicity while genotoxicity and cell cycle changes were analyzed using H2AX, cyclins A and B, and cyclin dependent kinases 1 and 2. To determine if cadmium damage was cell cycle specific propidium iodide analysis was performed on cells synchronized in G2/M, G0, and S phases, using nucodazole, serum starvation, and aphidicolin treatments, respectively. Genotoxicity was measured following analysis of mutations at the HPRT gene. Results determined that cadmium expo-
sure resulted in a dose-dependent increase in apoptosis and double strand break formation which correlated with a greater uptake of cadmium as measured by ICP/MS. Downregulation of cyclins A and B and cdk1 and 2 occurred indicating there was a cell cycle arrest following cadmium exposure. Cells arrested in G2/M by nocodazole prior to exposure demonstrated increased G0/G1 arrest which was p53-dependent. Collectively, this study indicates that cadmium induces genotoxic lesions and causes alterations in normal cell cycle progression.

**302 Induction of Apoptosis by PQ1, a Gap Junction Enhancer That Upregulates Cx43 and Activates the p38-MAPK Signaling Pathway in Mammary Carcinoma Cells**

T. A. Nguyen and S. N. Shishido. Diagnostic Medicinal/Pathobiology, Kansas State University, Manhattan, KS.

Cell death induced by the gap junction enhancer, PQ1, was studied in mammary carcinoma cells (FMC2u) derived from a malignant neoplasm of a female Pyt transgenic mouse. PQ1 was determined to have an IC50 of 6.5 μM in FMC2u cells, while inducing an upregulation in Cx43 expression. The mechanism behind PQ1 induced cytotoxicity in mammary carcinoma cells is thought to be attributed to the change in Cx43 expression; therefore, the effects of Cx43 modulation in FMC2u cell survival was determined through transfection experiments with Cx43 cDNA, which induced an elevated level of protein expression similar to that seen with PQ1 exposure, or siRNA to silence Cx43 protein expression. Overexpression of Cx43 led to a reduction in cellular viability, while an increase in viability was observed after silencing of Cx43 in FMC2u cells. The mitogen-activated protein kinase (MAPK) family has been implicated in the regulation of cell survival and cell death; therefore, the GJIC-independent function of PQ1 and Cx43 in the MAPK-dependent pathway of apoptosis was explored in mammary carcinoma cells. Both the overexpression of Cx43 and PQ1 treatment stimulated an increase in the phosphorylated form of p38-MAPK, reduced levels of the anti-apoptotic protein Bcl-2, and increased the cleavage of pro-caspase-3. Silencing of Cx43 protein expression led to a reduction in the phosphorylation of p38-MAPK and an increase in bcl-2 expression. These results suggest that PQ1 affects not only GJIC, but also cellular survival via a MAPK-dependent pathway. Cx43 may be the key element in the mechanism of PQ1 induced apoptosis.

**303 Zebrafish Assay Format for Determining Compound-Induced Apoptosis Inhibition and Activation**

P. McGrath. Phylomix, Cambridge, MA.

During development, naturally occurring apoptosis plays an important role in tissue modeling. However, uncontrolled apoptosis is associated with numerous diseases as well as compound toxicity. Here we describe an assay format used to assess compound induced apoptosis inhibition or activation that relies on the presence of developmentally regulated cell death in live 2 day post fertilization (dpf) zebrafish. At 2 dpf, developmental apoptosis present in the hatching gland and nasal placode can be assessed by acridine orange (AO) live dye fluorescence staining. In contrast, at this stage only a few dispersed apoptotic cells are present in the zebrafish tail. By 3 dpf, essentially no apoptosis is visible at any site. Using these inherent assay parameters, in this study, we assessed 4 characterized inhibitors: Ac-DNLD-CHO, Ac-DEVD-CHO, Z-VAD-fmk, and Q-VD-Oph and 3 activators: Staurosporine, Borrélidin, Gambogenic acid, and 1 negative control compound, Buthionine sulfoximine, shown not to affect apoptosis in mammals. Zebrafish (N = 10) were exposed to the MNLC of each compound for 24 hrs, incubated with AO (1 mg/ml), washed and anesthetized. Effects were initially assessed visually followed by quantitative morphometric image analysis. Compared to the DMSO control, significant inhibition (P < 0.05) of developmentally regulated apoptosis in the hatching gland and nasal placode was observed for Ac-DNLD-CHO (73.7 + 22.6%), Ac-DEVD-CHO (99.60 + 0.4%), Z-VAD-fmk (70.9 + 27.7), and Q-VD-Oph (68.60 + 23.5%), and significant activation (P < 0.05) of apoptosis in the tail was observed for Staurosporine (933 + 701%), Gambogenic acid (2692 + 1205%), and Borrélidin (9227 + 6017%). Buthionine sulfoximine, the negative control, did not significantly affect AO staining. Student’s t-test was used to determine significance (P < 0.05). Effects in zebrafish were then compared with results in mammals. The overall correct prediction rate was 100%, considered excellent by ECVM. These data support use of zebrafish as a predictive model for assessing cell death for safety, toxicity and efficacy studies.

**304 Non-Tubulin Mitotic Disruptors Induce Apoptosis in Cancer Cells**

J. C. States, D. J. Saforo, N. A. Klimchak and J. O. Trent. University of Louisville, Louisville, KY.

Disrupting mitosis is a validated approach for cancer chemotherapy. Mitotic disruptors (e.g. taxanes) are common components of combination chemotherapy used to treat cancers of lung and other organs. These agents induce mitotic arrest and apoptosis in cancer cells. Chemotherapeutic success is limited by development of resistant and dose-limiting toxicity. Mitotic disruptors currently in use, and most of the new agents in development, target tubulin. An alternative approach is to target the regulators of mitosis. The anaphase promoting complex/cyclosome (APC/C) is the master regulator of mitosis and cell cycle, and is a novel anti-cancer target. Using an in silico approach, candidate compounds were identified to disrupt APC/C activity. Compounds were tested for ability to induce cytotoxicity in colony forming and AlamarBlue assays and to induce increases in mitotic index in a variety of human cancer, SV40-transformed and diploid cell lines. Compounds containing a 1-amino-propan-2-ol core were found to induce mitotic arrest and cell death as predicted in lung and ovarian cancer cells, malignant melanoma and HeLa cells and SV40-transformed fibroblasts and bronchial epithelia, while sparing normal diploid cells. These results indicate that targeting the disruption of the APC/C is a viable approach for developing a new class of mitotic disruptors useful for cancer chemotherapy.

**305 Salubrinal Differentially Modulates Mitochondrial Dysfunction-Induced by Halogenated Analogs of 3, 3’-diindolylmethane (DIM) in Prostate Cancer Cells**

T. Sanderson1, D. Montes-Grajales2, J. Olivero-Verbel3, S. H. Safe4 and A. Goldberg4. 1INRS-Institut Armand-Frappier, Laval, QC, Canada, 2Environmental and Computational Chemistry Group, University of Cartagena, Cartagena, Colombia and 3Veterinary Physiology and Pharmacology, Texas A&M University, College Station, TX.

We have previously shown that halogenated analogs of 3,3’-diindolylmethane (DIM), termed ring-DIMs, induce apoptosis and necrosis in human prostate cancer cells. We now show that ring-DIMs at toxic concentrations induce endoplasmic reticulum (ER) stress in human prostate cancer cells, and that cell death induced only by 4,4’-dihaloDIMs is abrogated by pre-treatment with the ER stress inhibitor, salubrinal. Salubrinal reduced phosphorylation of eIF2alpha in cells treated with 4,4’-dibromoDIM and did not increase phosphorylation of eIF2alpha in cells treated with 7,7’-dichloroDIM or DIM. We also found that neither CHOP nor ATF4 levels, both indicators of ER stress, were decreased after pre-treatment with salubrinal. The effect of salubrinal appeared to be linked to mitochondrial stability as pre-treatment with salubrinal negated the decrease in mitochondrial membrane potential (MMP) and mitochondrial abundance in cells treated with 4,4’-dibromoDIM. In contrast, salubrinal exacerbated the cytotoxic effects of 7,7’-dibromoDIM, 7,7’-dichloroDIM and DIM by further increasing the loss of MMP and mitochondrial abundance induced by these compounds. We found that an inhibitor of the mitochondrial permeability transition pore, cyclosporine A, prevented the loss of cell viability, MMP and mitochondrial abundance caused by co-treatments of 7,7’-dihaloDIMs with salubrinal. An in silico 3D docking analysis to find binding partners for salubrinal and the ring-DIMs point to targets other than ER stress and eIF2alpha as mediators of salubrinal’s apparently contradictory modulation of cell death induced by the ring-DIMs.

**306 Targeting CamKII in Prostate Cancer Cells: Induction of Mitochondrial Dysfunction and ER Stress by Halogenated Analog of 3, 3’-Diindolylmethane**

A. Goldberg5, A. Beach6, D. Montes-Grajales2, V. Tironenko7, J. Olivero-Verbel3, S. H. Safe4 and J. Sanderson1. 1Toxicology, INRS, Laval, QC, Canada, 2University of Cartagena, Cartagena, Colombia, 3Concordia University, Montreal, QC, Canada and 4Texas A&M University, College Station, TX.

We have previously shown that a series of halogenated analogs of 3,3’-diindolylmethane (DIM), termed ring-DIMs, induce apoptosis and necrosis in androgen-dependent and androgen-independent prostate cancer cells, with 4,4’-dibromoDIM having the greatest anti-cancer activity. To understand the upstream events leading to the activation of caspases in response to treatment with dibhalo-DIMs in androgen-dependent LNCaP and androgen-independent LNCaP C4-2B cells, we monitored the onset of endoplasmic reticulum (ER) stress and the dysregulation of mitochondrial apoptosis. We found that 4,4’-dibromo- and 7,7’-dichloroDIM and DIM itself caused ER stress-dependent upregulation of CHOP and ATF4, while only 4,4’-dibromo- and 7,7’-dichloroDIM increased phosphorylation of eIF2alpha.
Hepatocytes are the primary cell type of the liver providing the majority of the detoxification which increases the potential for cellular dysfunction and death. Though the source of the insult may be caused by several factors, exposure to drugs represents a significant concern warranting FDA guidance on drug-induced liver injury (DILI). In vitro studies are still the gold standard; however, in vitro screening has gained importance for reducing animal exposure, amenable to high-throughput platforms and better equipped to study cellular mechanisms of action. Typically in vitro screening has incorporated primary hepatocytes cultured in a two dimensional (2D) format where the cells form a monolayer across the bottom of a well. However, when cultured and studied in this fashion they rapidly lose their key functions and de-differentiate over the course of only a few days. The ability to culture, characterize and challenge primary cells in a biomimetic 3D environment enables the performance of longer term studies.

Here we present data demonstrating the differences in response between human primary cells cultured in 2D and in the RAFT 3D cell culture system which has the benefits of a collagen hydrogel with tissue-like properties. Camptothecin and pyocyanin were tested for their ability to cause short-term oxidative stress, as well as long-term induction of apoptosis and necrosis. Kinetic live cell imaging was performed using multiple fluorescent non-perturbing probes to monitor the various effects in real time with incubations up to 48 hours which enabled a thorough assessment of the toxic profile. Image overlay allowed for discrete cellular analysis. Variations in cytotoxicity levels were observed after a 24 hour 800 nM camptothecin treatment (75%/2D; 28%/3D). ROS induction was less in 3D than 2D system. Overall, cells exhibited greater viability using the RAFT system, and were less sensitive to toxins than observed in traditional 2D culture for the endpoints which may indicate a more robust cell culture system.

### 307 Validation of a Novel Cell Culture System to Perform 3D In Vitro Cytotoxicity Analyses Using Primary Hepatocytes

T. Moeller1, B. Larson2, G. Cameron3 and P. Banks1.
1BioreclamationIVT, Haldenborde, MD, 2BioTek, Winooski, VT and 3TAP Biosystems, Royston, Hertfordshire, United Kingdom.

More aggressive or invasive prostate cancer cells (PCCs) are often resistant to chemotherapy and have poor prognosis. Differences exist in redox status and mitochondrial metabolism that may help explain this phenomenon. We compared two immortalized human PCC lines, PC-3 cells (more aggressive) and LNCaP cells (less aggressive), with regard to cellular glutathione (GSH) levels and susceptibility to oxidants (tetr-butyl hydroperoxide [tBuH] or methyl vinyl ketone [MVK]) or GSH depleters (diethly maleate [DEM] or diame). We tested the hypothesis that cells resistant to less aggressive PCCs, more aggressive PCCs exhibit higher GSH concentrations and are relatively resistant to cytotoxicity from exposure to various oxidants. PC-3 cells exhibited 4.2-fold higher GSH concentration than LNCaP cells. PC-3 cells only exhibited lower lactate dehydrogenase (LDH) release after toxicant exposures than LNCaP cells at some time points but only LNCaP cells underwent diamide-induced apoptosis. Expression of several proteins involved in stress response and regulation of cell growth and proliferation were measured to determine the possible role of altered levels of certain signaling molecules with differential redox state and susceptibility to toxicants. PC-3 cells exhibited higher levels of Bax and caspase-8 cleavage product and lower levels of Bel-2 than LNCaP cells. PC-3 cells exhibited with higher susceptibility to Fas-induced apoptosis than LNCaP cells exhibited higher expression of FasR than PC-3 cells. Consistent with a compensatory response to lower GSH concentrations and generally greater susceptibility to oxidative stress, LNCaP cells exhibited higher levels of GADD153, p53, Hsp27, Cyclin A, SOD2, Trx2, and mitochondrial GSH transporters than PC-3 cells. Thus, significant differences in redox status and expression of proteins involved in apoptosis and stress response may contribute to PCC aggressiveness.

### 308 Heat Shock Response Antagonism: From Toxicological Liability to Cancer Chemotherapeutic Opportunity

A. L. Davis, C. M. Cabello, S. Qiao, S. Azimian and G. T. Wondrak. Pharmacology and Toxicology, College of Pharmacy and Arizona Cancer Center, University of Arizona, Tucson, AZ.

The cellular heat shock response plays an essential role in cytoprotection that involves maintenance of proteinostasis and suppression of apoptosis. Based on an increased vulnerability of cancer cells to proteotoxic stress, small molecule heat shock response inhibitors are now an emerging class of cancer-directed experimental therapeutics. Guided by a phenotypic screen, we have interrogated a focused compound library for functional heat shock response antagonism targeting a panel of malignant melanoma cell lines (G361, LOX-IMVI, A375). From a collection of pro-oxidants 3,7-diamino-phenothiazinium derivatives [methylene blue (MB), azure A, azure B] we have identified the redox-drug MB, used clinically for the intestinal treatment of methemoglobinemia, as a negative modulator of heat shock response gene expression in human A375 melanoma cells. Stress and toxicity response gene array analysis using the RT2 Profiler™ technology (SuperArray, Frederick, MD; MB: 10 µM, 24 h) revealed that MB-treatment selectively suppressed expression of Hsp70 family members (HSPA1A, HSPA1B) and Hsp22 (HSPB1), a finding confirmed at the protein level. Importantly, MB sensitized melanoma cells to the apoptotic activity of geldanamycin, an Hsp90 antagonist that induces the counter-regulatory upregulation of Hsp70 expression underlying cancer cell resistance to geldanamycin chemotherapy. Similarly, MB-co-treatment sensitized melanoma cells to other apoptogenic chemotherapeutics. Taken together, these data suggest feasibility of repurposing the non-oncological redox drug MB as a proteotoxic heat shock response antagonist for chemotherapeutic intervention. Supported in part by grants from the National Institutes of Health [R01CA122484, R03CA167580, R21CA166926, E0007091, E0066944].

### 309 Apoptosis Modulates Hepatotoxic Effects of 2-Aminoanthracene in Fisher 344 Rat

W. E. Gato1, D. B. Hales2, S. McGee3 and J. C. Means1. 1Department of Chemistry, Georgia Southern University, Statesboro, GA, 2Department of Physiology, Southern Illinois University, Carbondale, IL, and 3Environmental Science & Management, University of California Santa Barbara, Santa Barbara, CA.

The arylamine 2-amino-anthracene (2-AA) is an aromatic hydrocarbon employed in manufacturing of chemicals, dyes, inks, and as curing agents in epoxy resins and polyurethanes. 2-AA has been detected in tobacco smoke and cooked foods. The modulation of the toxic effects of 2-AA on the liver by apoptosis was investigated on twenty four post-weaning 3–4 week old F-344 male rats exposed to 0 mg/kg-diet (control), 50 mg/kg-diet (LD), 75 mg/kg-diet (MD) and 100 mg/kg-diet (HD) 2-AA for 14 (2WK) and 28 days (4WK). Analysis of total mRNA extracts from liver for apoptosis-related gene expression changes in AEN, BAX, CASP3, JUN, MDM2, P53, and GAPDH genes by qRT-PCR was coupled with liver tissue histology (H&E staining), TUNEL (Terminal deoxynucleotidyl transferase DUTP nick end-labeling) assay and Caspase (Caspase Glo assay) activity. Dose-related histological changes in liver cell architecture were observed at the highest doses in both 2WK and 4WK exposures. Dose-related increases in TUNEL positive staining were also observed. Caspase3 assays showed dose-dependent increases (2WK) but suppression in LD and MD (4WK) rat livers and an increase in HD rats. Dose-related increases in expression were observed in all genes measured.

### 310 Glutathione Levels and Susceptibility to Chemically-Induced Injury in Human Prostate Cancer Cells

L. H. Lash, D. A. Pust and A. Jankovich. Pharmacology, Wayne State University School of Medicine, Detroit, MI.

More aggressive or invasive prostate cancer cells (PCCs) are often resistant to chemotherapy and have poor prognosis. Differences exist in redox status and mitochondrial metabolism that may help explain this phenomenon. We compared two immortalized human PCC lines, PC-3 cells (more aggressive) and LNCaP cells (less aggressive), with regard to cellular glutathione (GSH) levels and susceptibility to oxidants (tetr-butyl hydroperoxide [tBuH] or methyl vinyl ketone [MVK]) or GSH depleters (diethyl maleate [DEM] or diame). We tested the hypothesis that cells resistant to less aggressive PCCs, more aggressive PCCs exhibit higher GSH concentrations and are relatively resistant to cytotoxicity from exposure to various oxidants. PC-3 cells exhibited 4.2-fold higher GSH concentration than LNCaP cells. PC-3 cells only exhibited lower lactate dehydrogenase (LDH) release after toxicant exposures than LNCaP cells at some time points but only LNCaP cells underwent diamide-induced apoptosis. Expression of several proteins involved in stress response and regulation of cell growth and proliferation were measured to determine the possible role of altered levels of certain signaling molecules with differential redox state and susceptibility to toxicants. PC-3 cells exhibited higher levels of Bax and caspase-8 cleavage product and lower levels of Bel-2 than LNCaP cells. PC-3 cells exhibited with higher susceptibility to Fas-induced apoptosis than LNCaP cells exhibited higher expression of FasR than PC-3 cells. Consistent with a compensatory response to lower GSH concentrations and generally greater susceptibility to oxidative stress, LNCaP cells exhibited higher levels of GADD153, p53, Hsp27, Cyclin A, SOD2, Trx2, and mitochondrial GSH transporters than PC-3 cells. Thus, significant differences in redox status and expression of proteins involved in apoptosis and stress response may contribute to PCC aggressiveness.

### 311 Coupling of PARP-1 and Store-Operated Calcium Entry Is Independent of PARB Activity in TGHQ-Induced Cell Death

F. M. Ramirez1, 2, S. S. Lau1, 2 and T. J. Monks1, 2. Pharm/Tax College of Pharmacy, U of Arizona, Tucson, AZ and 2SWEHSC, U of Arizona, Tucson, AZ.

Many pathological conditions, including renal disease, are associated with oxidative stress. 2,3,5-tri(Glutathion-yl)hydroquinone (TGHQ), a potent nephrotoxic metabolite of benzene and HQ, generates reactive oxygen species (ROS). ROS generation results in damage to cells, including DNA strand breaks, which activate DNA repair enzymes such as poly(ADP-ribose) polymerase (PARP)-1. Under robust oxidative damage, PARP-1 is hyper-activated, leading to increases in intracellular calcium concentrations (Ca2+) as well as NAD+ and ATP depletion, and ultimately cell death. We are determining the relationship between Ca2+ and PARP-1 during cell death of human renal proximal tubule epithelial cells (HK-2). We have shown that extracellular Ca2+ is responsible for coupling PARP-1 activation to increases in Ca2+ during TGHQ-induced cell death. PARP-1 inhibition attenuates Ca2+ increases induced by TGHQ, and treatment with 2-APB, a store-operated Ca2+ channel (SOC) inhibitor, restored levels of NAD+, with simultaneous de-
creases in PAR protein-ribosylation. Since SOC activation has a direct effect on PARP-1 activity, and PARP-1 inhibition attenuates increases in iCa²⁺, the results show that PARP-1 and SOCs are coupled in TGHQ-induced cell death. We further elucidated the relationship between SOC activation and PARP-1 downstream of PARP-1 activity. Poly(ADP-ribose) glycohydrolase (PARG), which catalyzes the degradation of PARs to yield free ADP-ribose (ADPR), is known to activate SOCs. siRNA knockdown of PARG partially increases PAR ribosylation, but does not restore cell viability in the presence of TGHQ, indicating that free ADPR is not responsible for SOC activation in HK-2 cells. Overall, we show that PARP-1 and Ca²⁺ are coupled through SOC entry, and that the relationship may involve alternative PAR metabolic pathways. We are further investigating the connection between SOCs and PAR metabolism, and other potential mechanism(s) by which PARP-1 and Ca²⁺ interact to contribute to cell death.

**312 Flavonoids Kaempferol but Not Morin Showed Toxic Effects to HepG2 Cell Line**

M. J. Tasso1, A. O. Souza1, L. C. Pereira2, M. F. Bernardes2 and D. J. Dorta1.
1Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto – FECLRP/USP, Ribeirão Preto, Brazil and 2Faculdade de Ciências Farmacêuticas de Ribeirão Preto – FCFRP/USP, Ribeirão Preto, Brazil.

**INTRODUCTION:** Kaempferol and Morin are polyphenolic compounds belonging to a class of chemicals called flavonoids. Both substances have very similar structures, which differ only in the presence of an extra hydroxyl substituent in Morin. Although flavonoids are widely known due to their anti-oxidant and anti-inflammatory properties, toxic effects were already shown in literature. Therefore, this study was aimed to assess the effects of Morin and Kaempferol in HepG2 cells to check for induction of cell death evidences and to verify if the structural difference influences on toxic effects. METHODS: HepG2 cells were incubated at 37°C in an atmosphere containing 5% CO2 and 96% relative humidity for 24 hours before treatment and the flavonoids were tested in concentrations ranging from 1μM to 100μM for 24, 48 and 72 hours. Induction of cell death was evaluated by phosphatidylserine exposure at the outer cell membrane using Annexin V and propidium iodide (PI), followed by the assessment of nuclear fragmentation using Hoechst 33342 fluorescent dye. RESULTS: Kaempferol caused toxic effects in HepG2, since at the highest concentration and all times it increased significantly the phosphatidylserine exposure. Moreover, it showed significant increase in nuclear fragmentation at 50 and 100μM in 24, 48 and 72h. On the other hand, Morin did not show any toxic effects in both experiments at same conditions. CONCLUSIONS: Kaempferol showed a potential cytotoxic effect in HepG2 cells at the highest concentrations tested. The cell death observed may occur by apoptotic pathway, since the increase in nuclear fragmentation and in phosphatidylserine exposure are evidences of this mechanism. However, Morin did not present any cytotoxic effects at same conditions. These results show the importance to do a structure-activity analysis when performing the risk assessment for flavonoids uptake. Acknowledgments: CNPq - Brazil

**312a Diesel Exhaust Particle Exposure Causes Endothelial Cells Apoptosis via Autophagy Pathway**

J. Wang1, C. Tseng1.1, J. Chang1, M. K. Gordon1 and M. Chau1.1, 1Bionce Technology, Chung Yuan Christian University, Chung-Li, Taiwan, 2Biomedical Engineering, Chung Yuan Christian University, Chung-Li, Taiwan, 3Center for Nanotechnology, Chung Yuan Christian University, Chung-Li, Taiwan and 4Joint Program of Toxicology, Rutgers University, Piscataway, NJ.

It is well known that inhaled diesel exhaust particles (DEP) injure human endothelial cells. To elucidate the mechanism, we used an in vitro monolayer HUVEC culture model system. 25000 HUVECs were plated in the well of 24-well dishes overnight. Automobile DEP collected from Japan (courtesy of Dr. Sagai, Tokyo) were sonicated in 0.05% Tween80 with PBS for 1 min, then added immediately at 25 μg/mL and 50 μg/mL medium-diluted DEP solution to the dishes. The Cell Titer 96 Aqueous One Solution Assay (Promega) was applied to detect viable cells after at 1, 2, 4, 8, 16, and 24 h after the treatments. We found the cell viability decreased in both time and dose dependent manner, and only 40% and 20% cell survive respectively at 24 h of 25 and 50 μg/mL DEP. For more detail in sample of 50 μg/mL DEP, TUNEL method was used and demonstrated that those 80% dead cells were killed with apoptosis induction. In order to determine by what mechanism that DEP exposure results in apoptosis, the treated cells were harvested for immunofluorescence microscopy and immunoblotting. Interestingly, autophagy markers LC3-II and Arg1 appeared at 2 h and disappeared at 8 h after exposure to DEP. Their expression both reached the maximal level at 4 h. Furthermore, the up-regulated expression of caspase3, caspase7, caspase9 were confirmed at various time point as well to indicate DEP induce apoptosis in HUVECs. And, ELISA analysis suggested that caspase 3 and caspase 7 expressions increased in a time dependent manner from 8 h to 24 h, while caspase 9 was initiated to be up-regulated from 16 h. In summary, the upregulation of LC3-II and Arg1 unveiled that DEP might induce HUVEC apoptosis via autophagy pathway.

**312b Presence of EndoG in Apoptotic Nuclei during Cisplatin Kidney Injury: A Sign of What?**

A. G. Basnakian1,2, D. D. Zhdanov1, T. Fahmi3, T. Fite1, K. Topiwala4 and S. V. Shah5,6, 1University of Arkansas for Medical Sciences, Little Rock, AR and 2Central Arkansas Veterans Healthcare System, Little Rock, AR.

Endonuclease G (EndoG, EG) is a mitochondrial endonuclease that translocates to nucleus during apoptosis. However, it is unknown whether EG directly causes apoptotic DNA fragmentation and cell death or it is anti-apoptotic. Unlike other apoptotic endonucleases, EG is the only endonuclease found in nucleus during apoptosis, has RNase activity, and induces inactive truncated isoform of another endonuclease, DNase I (DI). We hypothesized that the role of EG in apoptosis depends on the presence of DI in the cell, and used cisplatin kidney injury in vitro and in vivo models to test this. Our pilot observations were that although EG sometimes was present in TUNEL-positive nuclei of cisplatin-treated kidneys, overall it did not coincide with TUNEL. Unlike other endonucleases including DI, EG did not colocalize with DNase activity measured by DNase activity probe in pyknotic nuclei in the cultured kidney tubular epithelial NRK-52E cells. EG overexpression in DI-positive NRK-52E cells showed EG was not cytotoxic but instead protective against cisplatin induced cell death. Further study showed that EG was induced but was not cytotoxic in cisplatin kidney injury in vivo. After injection of cisplatin (20 mg/kg), no protection in EG null mice versus wild-type mice was observed by BUN, SCr or histology. EG induction by cisplatin in WT mice was associated with the decrease of native DI expression and appearance of inactive truncated DI. In conclusion, this study showed that EG acts as a proapoptotic enzyme in the absence of DI and it is anti-apoptotic in the presence of DI in kidney cells and the kidney during cisplatin injury.

**312c Neuroprotective Effects of Natural Compounds against Dopamine Toxicity**

Natural dietary supplements are being hailed as age defying and may, in some cases, present a sustainable medical solution for people around the world. Within the next few decades the aged population in the U.S. will be greater than ever before, increasing the demand for cost-effective medicine for the elderly. One of the major health problems in the elderly are motor deficits, caused, in part, by a loss of dopaminergic neurons. Oxidative stress is known to play a part in this neuronal loss. Resveratrol, a natural compound found in grapes and wild blueberries, has antioxidant, anticancer, and anti-inflammatory properties. Our lab has shown that resveratrol protects dopaminergic-like cells (SH-SY5Y) against oxidative stress produced by exposure to dopamine, as seen by cell viability assays (CellTiter-Glo® and Dead protease fluorescence assay). Interestingly, RES activates the MAP kinases ERK1/2 and ERK5; as seen using western blot analysis. Following inhibition of the ERK1/2 or ERK5 pathways, the neuroprotection afforded by RES is lost. In order to test if apoptotic pathways are also involved in RES-mediated neuroprotection, we examined the expression of Bcl-2, an anti-apoptotic protein, following dopamine exposure. Following dopamine-mediated apoptosis, RES treatment abolished Bcl-2 expression. This suggests that RES can mediate the neuroprotective effects of RES against dopamine exposure.
Oxidative stress plays crucial roles in exerting a variety of damages upon arsenic exposure, and NF-E2-related factor 2 (Nrf2) is a crucial transcriptional regulator protecting cells and tissues from oxidative injury. Here, we tested the antagonistic effects of tert-butylhydroquinone (tBHQ), a well-known synthetic Nrf2 inducer, on arsenic-induced oxidative injuries and apoptosis using cultured human HaCaT cell line. Cells were exposed to sodium arsenite (25 μM) with or without tBHQ (50μM, 12 h) pretreatment for 24 h, and cell proliferation activity, oxidative injury, apoptosis, as well as expression of relevant genes and proteins were examined. Arsenic-induced cytotoxicity, the enhancement of reactive oxygen species generation and lipid peroxidation, and the impairment of anti-oxidative enzymes activity, were all suppressed by tBHQ administration. Arsenic was also found to induce phosphorylation externalization, disrupt the mitochondrial membrane potential (Δψm), release cytochrome c into the cytosol, and trigger the cleavage of caspase-3, typical characteristics of mitochondria-dependent apoptosis. tBHQ co-treatment effectively rescued the cells from arsenic induced apoptosis and related alteration of mitochondria. tBHQ pretreatment resulted in a significant accumulation of nuclear fraction of Nrf2 proteins (155% of control), and Nrf2-regulated downstream genes, heme oxygenase-1 (HO-1) and NADPH:quinone oxidoreductase 1 (NQO1) mRNA expressions were overexpressed. In addition, tBHQ released anti-apoptotic Bcl-2 protein (130% of control), increased Bcl-2:Bax heterodimers and reduced cellular apoptosis. Thus arsenic induces cell apoptosis through the mitochondrial pathway, and the protection of tBHQ appears to include both Nrf2 anti-oxidation and Bcl-2 anti-apoptosis in human keratinocytes.
analysis. Unmetabolized FB1, accumulated in kidney in a dose-related manner at concentrations of up to 10 nmol/g tissue. Its concentrations in liver were 12 to 20-fold lower. In contrast, more HFB1 (1.8 nmol/g) was found in liver than in kidneys (0.3 nmol/g). Low levels of NAFB1 and N-acylated HFB1 species (NAHFB1) were found in both tissues. Metabolites having longer fatty acyl chains predominated in liver whereas those with shorter chains were prevalent in kidney; the different chain lengths likely reflecting differences in tissue-specific ceramide synthase isoforms. Metabolite concentrations decreased in the order: NAHFB1, in liver > NAFB1, in liver > NAFB1, in kidney. Recoveries (% of dose) of total FB1 species from the tissues were < 1%. Recovery of HFB1 species was more variable ranging from about 0.1% in kidney to about 2% in liver. Except for FB1, in kidney, where unmetabolized FB1 was predominant, recoveries (µmol basis) of parent and metabolites from the tissues were similar. The results show that FB1 is metabolized by ceramide synthases in vivo to N-acylated ceramide-like compounds. Additional studies are needed to determine the toxicological significance of the NAHB1 and NAHFB1, metabolites.

Presence of Aflatoxins and Fumonisins in Nixtamalized Masa from Mills in the Metropolitan Area of Monterrey, México

J. M. Villarreal-Guerra1, P. Gonzalez-Barranco2, F. Picon-Rubio3, H. Bernal-Barragan4 and A. G. Marroquin-Cardona1. 1Department of Physiology, Pharmacology and Toxicology, Faculty of Veterinary Medicine, Universidad Autonoma de Nuevo Leon, Escobedo, Nuevo Leon, México, 2Department of Biopharmacy, Faculty of Chemistry Sciences, Universidad Autonoma de Nuevo Leon, San Nicolas de los Garza, Nuevo Leon, Mexico, 3Department of Nutrition and Metabolism, Faculty of Veterinary Medicine, Universidad Autonoma de Nuevo Leon, Escobedo, Nuevo Leon, México, 4Department of Nutrition, Faculty of Agronomy, Universidad Autonoma de Nuevo Leon, Escobedo, Nuevo Leon, México.

Aflatoxins (AFs) and fumonisins (FBs) are toxic metabolites produced by Aspergillus and Fusarium species that frequently contaminate maize, generating a public health risk due to their hepatotoxic and carcinogenic effects. Traditional nixtamalization (treatment of maize with calcium hydroxide) is partially effective in reducing these toxins but under certain circumstances the toxins can prevail in the masa. The aim of this study was to determine the concentration of AFs and FBs in samples obtained from corn mills in the metropolitan area of Monterrey, México. In total 62 samples of masa were dried, ground and sieved before methanolic extraction of mycotoxins. Samples were analyzed by competitive ELISA (AgraQuant®) for detection of total AFs and FBs. In the results, AFs values ranged from 0 to 22.6 µg/kg, while FBs values ranged from 0 to 16.68 mg/kg. Results showed that some samples had AFs values above the permissible limit (12 µg/kg) according to the official regulation in México (NOM-247-SSA1-2008), while other samples had FBs values exceeding the permissible international limits (4 mg/kg), since México does not have specific limits for FBs. Therefore, we concluded that consumption of nixtamalized masa from some of the mills included in this study may represent a risk for human health.

The Effect of Aflatoxin-B1 on Red Drum (Sciaenops ocellatus) and Assessment of Dietary Supplementation of NovaSil for the Prevention of Aflatoxicosis

K. Zychowski1, A. Rodrigues Hoffmann1, H. J. Ly1, C. Pohlenz1, A. Buentello1, 2, A. A. Romoser1, D. Gatlin1 and T. D. Phillips1. 1Schillinger Genetics, East Texas. AFB1-induced histopathological changes in the liver and decreased Proliferating Cell Nuclear Antigen (PCNA) staining. Importantly, NS supplementation improved overall health of AFB1-exposed red drum.

Ginkgo biloba has been used for many thousand years as a traditional herbal remedy and its extract has been consumed for many decades as a dietary supplement. Ginkgo biloba leaf extract is a complex mixture with many constituents, including flavonol glycosides and terpene lactones. The National Toxicology Program 2-year bioassays found that Ginkgo biloba leaf extract targets liver, thyroid gland, and nose of rodents. However, the mechanism of Ginkgo biloba leaf extract-associated carcinogenicity remains unclear. In the current study, the in vitro genotoxicity of Ginkgo biloba leaf extract and its eight constituents were evaluated using the mouse lymphoma assay and the Comet assay, and the underlying mechanisms of Ginkgo biloba leaf extract-associated genotoxicity were explored. Ginkgo biloba leaf extract, quercetin, and kaempferol resulted in a dose-dependent increase in the mutant frequency and DNA double-strand breaks (DSBs). Western blot analysis confirmed that both quercetin and kaempferol activated DNA damage signaling pathway with increased expressions of γ-H2AX and phosphorylated Chk2 and Chk1. In addition, Ginkgo biloba leaf extract produced reactive oxygen species and decreased glutathione levels in L5178Y cells. Loss of heterozygosity analysis indicated that Ginkgo biloba leaf extract, quercetin, and kaempferol treatments resulted in extensive chromosomal damage. These results suggest that Ginkgo biloba leaf extract and its two constituents, quercetin and kaempferol, are mutagenic to the mouse L5178Y cells with induction of DSBs. Quercetin and kaempferol may be responsible for Ginkgo biloba leaf extract-induced genotoxicity. More studies on the mechanism of genotoxicity and carcinogenicity of Ginkgo biloba leaf extract warrant for its risk assessment.
The majority of samples (both foodstuffs and wrappers) analysed proved negative. However, all batches of industrially prepared hamburgers (but not those obtained from a hamburger restaurant) as well as pepper salami significantly induced luciferase activity in the test system, indicating the presence of xenobiotics, with estradiol equivalents of these products ranging from 0.2 to 44 pg/g. All three products contained soy-based ingredients which apparently accounted for, or at least contributed to, their high estrogenic activity, since no signal was observed with extracts of the packaging material, while two different soy sauces tested yielded an intense signal (28 and 394 pg/ml estradiol equivalent). These findings imply that by and large chemicals arising in the processing or packaging of foodstuffs in Finland constitute an insignificant source of xenobiotics to consumers. However, soy-derived ingredients in certain food items might render the entire products highly estrogenic. The estrogenic activity of soy is attributed to isoflavones whose health effects – though widely considered beneficial – are controversial. As hamburgers are a popular type of food among children, our findings are noteworthy and possibly of concern.

### 324 Genotoxicity Testing of Genipin, a Precursor in the Derivation of the Natural Food Colorant Gardenia Blue

Terrorism Risk Assessment (CTRA) Desktop Consequence Calculator, a tool developed by CSAC that incorporates existing models and data inputs from the 2012 Terrorism Risk Assessment (CTRA desktop tool) methodologies used to examine food process systems and provides examples of potential public health consequences that could result from chemical food contamination. The assessments demonstrate the wide range of hazards posed by varying the chemical, varying the contaminated food product, and, in some cases, varying the point of contamination in a food processing system.

### 326 Inactivation of Pathogens on the Surfaces of Sterile Swabs, Fruits, and Vegetables Using Sanitizing Substances Produced by Radiant Catalytic Ionization

Foodborne illness outbreaks linked to fresh products are becoming more frequent and widespread. The United States Department of Agriculture has estimated the costs associated with foodborne illnesses to be between $2.3 billion and $4.6 billion a year. The areas impacted include fruits and vegetables, meats, seafood, poultry, baking, canning, and dairy industries. Reducing pathogens and additional microbially contaminated on food contact surfaces will improve the quality and shelf life of many food products. New sanitizing technologies have emerged in recent years and are being widely used in a multitude of places to better decontaminate contact surfaces. Historically, both ozone-and peroxide-based technologies have been used as disinfectants in numerous applications. Radiant Catalytic Ionization (RCI) technology, particularly ozone, is thought to be safe to humans and the use of ozone is now considered to be an organic form of treatment to disinfect food contact surfaces. RCI technology has been widely accepted within the food processing industry during recent years. Ozone and hydrogen peroxide, generated by RCI, has countless applications for reducing the number of bacteria. This study has focused on the potential use of oxidative gases, including ozone and peroxide, generated by an RCI photocell for the inactivation of Escherichia coli, Listeria innocua, Pseudomonas aeruginosa, Salmonella typhimurium, and Staphylococcus aureus, introduced on the tips of sterile cotton swabs, and a number of fruits and vegetables which include apples, bananas, spinach, strawberries, oranges, and lettuce. Our results indicate a 99.9% killing of bacteria with a 90 minute exposure to RCI, demonstrating that the low level of oxidative gases produced by RCI has the potential to be an effective surface disinfectant tool for use in food processing.

### 327 Toxicological Evaluation of Oleic-Rich Algal Oil

The advancement of algae-based food ingredients is ideal for enriching the nutritional profile and functionality of food products. As a prospective new food ingredient, oleic-rich algal oil has been investigated for its potential to induce gene mutations as well as its toxicological potential in a subchronic study in rats. According to a plate incorporation and pre-incubation test by Salmonella typhimurium strains and an E. coli tester strain at concentrations of 3.1, 100, 316, 1000, 2500 and 5000 μg/plate, no toxic effects, precipitation, or biologically relevant increases in revertant colony numbers of the test item were noted in any of the tester strains used up to the highest dose group evaluated. Therefore, oleic-rich algal oil did not cause gene mutations by base pair changes or frameshifts in the genome of the strains used and was considered to be non-mutagenic in the bacterial reverse mutation assay. In a subchronic study in rats, CD IGS Sprague-Dawley rats consumed 2.5, 5, and 10% test substance in the diet for 90 days and were evaluated. There were no test substance-related changes in viability, behavior, clinical signs, body weight, organ weight, and relative organ weight values between control and treated animals. Decreases in high dose male food consumption throughout the study were not accompanied by decreases in body weight, body weight gain, and food efficiency, and were therefore considered non-adverse and toxicologically insignificant. There were no hematologic, clinical chemistry, or urinalysis, as well as macroscopic or microscopic observations, post-mortem that were attributed to the administration of oleic-rich algal oil. Based upon these toxicological endpoints, it was concluded that the no-observed-adverse-effect-level (NOAEL) for oleic-rich algal oil is 10% in the diet with no toxicity observed, a level calculated to provide a dietary intake of 5200 and 6419 mg/kg/day in males and females, respectively.

### 328 Predicting Public Health Consequences of Toxic Chemical Contamination of Food

J. Moser1,2 and R. Jablonski1.

To assess the risks (likelihood x consequence) associated with chemical contamination within the U.S. food supply system, it is essential to evaluate potential public health consequences resulting from the dissemination of toxic chemicals through food. The Chemical Security Analysis Center (CSAC), a knowledge analysis and management center under the Department of Homeland Security, developed several hazard and risk assessments related to chemical contamination of food. For the hazard assessments, 12 different food scenarios were evaluated. In each scenario, food was contaminated at a particular point in the manufacturing process; a total of 10 chemicals were analyzed. The CARVER plus Shock method was used as the primary tool to assess the hazard within a specific food processing system. For the risk assessments, 103 chemicals were individually evaluated as threats to human health through contamination and ingestion of 11 different foods. The Chemical Terrorism Risk Assessment (CTRA) Desktop Consequence Calculator, a tool developed by CSAC that incorporates existing models and data inputs from the 2012 CTRA into an easy-to-use platform, was used to determine consequences. This presentation compares the hazard assessment (CARVER plus Shock) and risk assessment (CTRA desktop tool) methodologies used to examine food process systems and provides examples of potential public health consequences that could result
TCT Catalase is an enzyme used for the production of gluconates, which are used as dietary supplements. The enzyme is produced from a recombinant strain of *Trichoderma reesei*. A battery of toxicology studies was conducted to investigate its potential to cause adverse effects in humans. All studies were conducted according to OECD Principles of Good Laboratory Practice and in compliance with OECD test guidelines. Catalase (from a different microbial host) was not an eye irritant and not toxic by oral gavage, with an oral LD50 in rats greater than 5000 mg/kg body weight (bw). In an *in vitro* cytogenetic test using human peripheral blood lymphocytes, TCT Catalase did not induce structural or numerical chromosomal aberrations in the presence or absence of metabolic activation (S-9 mix) up to the highest concentration tested (5000 μg total protein (TP)/ml). No mutagenic activity was noted in the bacterial reverse mutation (Ames) assay in the presence or absence of S-9 mix, when tested up to 5000 μg TP/plate. In a subchronic 90-day oral gavage study in CrI:CD(SD) rats, no biological or statistically significant differences were observed on in-life, neurobehavioral, clinical pathology (hematology, coagulation, clinical chemistry, urinalysis), or anatomic pathology (organ weights, histopathology) endpoints. The NOAEL was established as dietary supplements. The enzyme is produced from a recombinant strain of *Sceletium tortuosum* with a long history of traditional use, is marketed under the trade name Zembrin® as an ingredient for use in functional foods and dietary supplements. It is standardized to contain 0.35–0.45% total alkaloids (mesembrenone and mesembrenol as60%, and mesembrine <20%). A 14-day repeated oral toxicity study was conducted at 0, 250, 750, 2500, and 5000 mg/kg bw/d. A 90-day subchronic repeated oral toxicity study was conducted at 0, 100, 300, 450, and 600 mg/kg bw/d. Because *Sceletium tortuosum* has a long history of human use for relaxation, a functional observation battery (FOB), including spontaneous locomotor activity measured using LabMaster ActiMot light-beam frames system was employed. Several parameters such as: locomotion (time resting, moving, and hyperactive in seconds); rearing behavior (time in rearing, number of rearing); spatial parameters; and turning behavior were investigated in the final week of the study. No deaths or treatment-related adverse effects were observed in male or female CrI:W(BR) Wistar rats in the 14- or 90-day studies. In the 14-day study, the MTD and the NOAEL were concluded as 5000 mg/kg bw/d. The NOAEL from the 90-day study was determined to be 600 mg/kg bw/d, the highest dose tested. Toxicological Safety Assessment of a *Sceletium tortuosum* Extract T. Murbach, A. Clewell and J. R. Endres, AIBMR Life Sciences, Inc., Puyallup, WA. A standardized hydroethanolic extract of *Sceletium tortuosum*, a South African plant with a long history of traditional use, is marketed under the trade name Zembrin® as an ingredient for use in functional foods and dietary supplements. It is standardized to contain 0.35–0.45% total alkaloids (mesembrenone and mesembrenol ≥60%, and mesembrine <20%). A 14-day repeated oral toxicity study was conducted at 0, 250, 750, 2500, and 5000 mg/kg bw/d. A 90-day subchronic repeated oral toxicity study was conducted at 0, 100, 300, 450, and 600 mg/kg bw/d. Because *Sceletium tortuosum* has a long history of human use for relaxation, a functional observation battery (FOB), including spontaneous locomotor activity measured using LabMaster ActiMot light-beam frames system was employed. Several parameters such as: locomotion (time resting, moving, and hyperactive in seconds); rearing behavior (time in rearing, number of rearing); spatial parameters; and turning behavior were investigated in the final week of the study. No deaths or treatment-related adverse effects were observed in male or female CrI:W(BR) Wistar rats in the 14- or 90-day studies. In the 14-day study, the MTD and the NOAEL were concluded as 5000 mg/kg bw/d. The NOAEL from the 90-day study was determined to be 600 mg/kg bw/d, the highest dose tested. Oral Toxicity Assessment of siRNAs and Long Double-Stranded RNAs J. S. Petrick, J. H. Sherman, W. F. Hovden and S. L. Lemke, Toxicology, Monsanto Company, Saint Louis, MO. New crop traits harnessing RNA interference are being developed using agricultural biotechnology. For example, when expressed in corn plants, double stranded RNA (dsRNA) targeting corn rootworm vacuolar ATPase (vATPase) provides protection against corn rootworm. Although ingested RNA is not known to be toxic, we conducted oral proof of concept toxicity studies in CD-1 mice with dsRNA targeting the mouse ortholog of vATPase. Mice were gavaged with a 218 bp dsRNA or a pool of four 21-mer small interfering RNAs (siRNAs) in an acute oral toxicity study at 2000 mg/kg and in a 28 day oral toxicity study at 1, 10, and 100 mg/kg. Test substances did not affect in-life or necropsy endpoints in either study (e.g. body weight, food consumption, clinical observations, or gross pathology). There were no treatment-related effects on clinical chemistry, hematology, histopathology, or vATPase gene expression in selected tissues (qPCR) in the 28 day study. The NOAELs for both test materials in the acute and 28-day studies were 2000 mg/kg and 100 mg/kg, respectively, the highest doses tested. The proof of concept toxicity assessment for dietary double stranded RNAs presented herein support the conclusions that ingested RNA is not toxic to mammals at large multiples of anticipated human exposure and that toxicological studies with dietary RNAs will contribute little, if anything, to mammalian/human risk assessment. Nanostructured Synthetic Amorphous Silica—Absence of Disintegration in Intestinal Environment M. Maier1, P. Albers2, R. Retamal Marin3, F. Babick3 and M. Stintz3. 1Inorganic Materials, Evonik Industries AG, Hanau, Germany, 2Aqura GmbH, Hanau, Germany and 3Technical University, Dresden, Germany. Synthetic amorphous silica (SAS) is a nanostructured material formed by flame hydrolysis or precipitation. In commercial SAS products, basic structural elements (fused nanosized primary particles) are submicron aggregates that themselves form micrometer (or even larger) agglomerates. As SAS is employed in processed food, e.g. as a free-flow agent, we aimed to investigate potential structural changes following oral uptake. In a previous study no significant changes in the structure and size distribution of SAS during heating in water (e.g. food processing) and in acid environment (pH of gastric juice) were observed. We now investigated potential structural changes of SAS during the intestinal passage. Intestinal milieu is quite different from gastric conditions with respect to pH as well as the presence of natural solubilizers and residence time is significantly higher. Food grade precipitated and pyrogenic SAS were studied in an in vitro model. FeSIFS is a fed-state simulated intestinal fluid (acetate buffer, pH 5.0) containing the natural solubilizers sodium taurocholate (bile salt) and phosphatidylcholine (lecithine) in physiological amounts. Following suspension in FeSIFS, SAS was slightly agitated for up to 48 hours (37°C). To check for the presence or absence of changes in particle size distribution and potential surface degradation samples were analysed by laser diffraction (volume weighted size distribution) and transmission electron microscopy. Simulated intestinal conditions did not lead to an increase of fine, nanosized SAS particle fractions. There was no indication of chemical reactions or dissolution processes at the surface of SAS particles. In contrast, partial agglomeration of dispersed SAS aggregates was observed shifting the size distribution to its coarse end with large flocculates of several hundreds of micrometers. In conclusion, SAS was shown not to experience additional dispersion or any other type of degradation during the simulated intestinal passage.
In the treatment of prostate disorders, Q, similarly to Tams, induces vasorelaxation, thereby increasing the risk for orthostatic hypotension. This overlapping profile prompted us to investigate the interaction of Q with Tams. Since Q is extensively metabolized, the effects of the metabolites Q-3-glucuronide and 4'O-methyl-Q on Tams effects are also included. We have determined the potentiating effects Q and metabolites on Tams-induced vasorelaxation. This was tested on rat mesenteric arteries constricted by the α1-adrenergic agonist phenylephrine. Tams (0.1 mM) decreased phenylephrine-induced vasoconstriction 16-fold. Q (5, 10 and 20 μM) caused a substantial concentration-dependent (of 5, 7 and 9-fold respectively) decrease of phenylephrine-induced vasoconstriction, while Q-3-glucuronide (10 μM) and 4'O-methyl-Q (10 μM) only slightly decreased this activity (3 and 2-fold). The combination of Tams with Q or Q metabolites proved to be very potent. Q, Q-3-glucuronide and 4'O-methyl-Q synergistically increased the Tams effects to 275, 57 and 169-fold respectively. Our results show that there is a drastic pharmacodynamic interaction between the drug Tams and the supplement Q. Tams effects are synergistically amplified by Q, 4'O-methyl-Q or Q-3-glucuronide. The interaction of Q and Tams with potentially serious consequences draws attention to drug-supplement interactions that have been neglected thus far.

The Unites Arab Emirates is currently evaluating external sources of forage, including perennial ryegrass (Lolium perenne) straw, for its rapidly growing livestock industry. Unfortunately, perennial ryegrass may be infected with the endophyte Neotyphodium lolii which produces lolitre B, a toxic alkaloid responsible for the neurological syndrome ryegrass staggers. Thus, a range-finding study was conducted in 24 female camels fed four doses (0, 1111, 1478 and 2273 ppb) of lolitre B-containing perennial ryegrass straw over 56 days to establish a threshold of toxicity in camels so that perennial ryegrass straw can be safely fed as part of their dietary ration. Morphometric and blood chemistry values were evaluated. Body weight was adversely affected by consumption of lolitre B-camels fed a diet free of lolitre B gained more (7.4%) than the other three groups (-2.5%, 0.5% and -8.8% for 1111 ppb, 1478 ppb and 2273 ppb, respectively (p < 0.001)). Blood urea nitrogen increased significantly in the three treatment groups (p < 0.001), which is indicative of kidney damage. Brain edema, degenerative renal and hepatic lesions as well as Purkinje cell vacuolar degeneration were observed in two necropsied camels receiving the highest dose of lolitre B. Neurological deficits were assessed by videotape and scored using an established scale for ryegrass staggers. Mean date of onset of ataxia was 35.8, 43.7 and 19.8 days (1111, 1478 and 2273 ppb, respectively). AF99 V. aste was also seen in affected camels in which the lower lip was amyotonic and fell ninety degrees perpendicular to the lower jaw, similar to a partial facial nerve paralysis; this has not been reported in other ryegrass toxicosis studies. Based on these observations, we recommend that endophyte-infected perennial ryegrass straw be fed at 500 ppb or lower lolitre B to avoid clinical disease in camels.

Steviol glycoside sweeteners were permitted for use in the United States by the FDA beginning in late 2008. Prior to that, they were only allowed as dietary supplements, and most stevia products before 2008 were not highly purified (≥ 95% steviol glycosides). Steviol glycoside sweeteners are extracted from the plant Stevia rebaudiana (Bertoni), a member of the Asteraceae (Compositae) family. A number of member plants from this family can induce hypersensitivity reactions via multiple routes of exposure: dermal, inhalation, and ingestion. Well-known members of this plant family include the common herbs, widely consumed foods, and the allergens ragweed, goldenrod, and Chrysanthemum. Based on this common taxonomy, food allergy warnings for stevia are given in some popular food information sources. Not surprisingly, many non-scientific media reports and resources allege the potential for stevia allergy. To determine if such allergy warnings are warranted on stevia products, a comprehensive literature search was conducted to identify all available data related to consumption of stevia extracts or highly purified steviol.
glycoside products and allergic responses. Based on the peer-reviewed literature, hypersensitivity to stevia is rare, and the few cases documented in the literature were reported prior to the introduction of high-purity products to the market, which was considered when global regulatory authorities affirmed the safety of steviol glycosides. Additionally, neither stevia manufacturers nor food allergy networks have reported significant numbers of any adverse events related to ingestion of this sweetener. Diligently maintained manufacturer post market surveillance data indicate a normalized (to sales) incidence rate of <1.1 incident/10 million servings. There have been no reports in the scientific literature since 2008 of stevia-related allergy. Therefore, there is little evidence to support warning statements to consumers about allergy to highly purified stevia extracts.

338 A 28-Day Gavage Toxicity Study in Fischer 344 Rats with 3-Methylfurans
S. S. Gill1, M. Kavanagh1, W. Cherry2, M. Barker1, M. Weld2 and G. Cooke1.
1Toxicology Research Division, Health Canada, Ottawa, ON, Canada and 2Chemical Health Hazard Assessment Division, Health Canada, Ottawa, ON, Canada.

Sponsor: R. Meehan.

3-Methylfuran is produced in foods during food processing and preservation techniques that involve heat treatment such as cooking, jarring, canning, and pasteurization. Currently there are no studies available on the toxicity of 3-methylfuran. We conducted a 28-day gavage toxicity study (7 days per week) using doses of 0.0, 0.1, 0.3, 1.5, 3.0, 6.0, 12.0 and 25.0 mg/kg bw/day to in order to determine the dose range needed to establish a No Observed Adverse Effect Level (NOAEL) and to better characterize non-neoplastic effects including those affecting hematology, thyroid, clinical biochemistry, gross morphology and histopathology. Histological changes of the liver were noted in all treated animals and gross changes were noted beginning at 3.0 mg/kg bw/kg. Alterations in the activity of serum enzymes indicative of effects on the liver were observed, including increases in levels of ALT and ALP at the highest dose. There was a significant increase in serum thyroxine (T4) and triiodothyronine (T3) which was not accompanied by histological changes in the thyroid. For the most part, statistically significant changes were seen only at the highest dose for hematology and at the two highest doses for clinical chemistry parameters. In contrast, mild histological lesions in the liver were observed even at the lowest dose of 0.1 mg/kg bw/day.

339 Safety, Efficacy, and Toxicological Evaluation of a Novel, Patented Antidiabetic Extract of Trigonella foenum-graecum Seed Extract (CR00010810)
M. Bagchi1, A. Swaroop2, D. Bagchi2 and P. Kumar3.
1Dr. Herbos LLC, Concord, CA and 2ReD, Cepham Inc., Picataway, NJ.

This study was conducted to examine the safety and efficacy of a novel, patented Trigonella foenum-graecum seed extract (Fenugreek, CR00010810). The project also evaluated the safety of CR00010810 in a variety of toxicological assays including acute oral toxicity studies in male and female Sprague-Dawley rats and Swiss albino mice, as well as repeated dose 28-day oral toxicity study in rats. Four groups of male and female rats and mice (n=5) were orally administered a single dose of either 0, 500, 1000 or 2000 mg/kg body weight. Rats and mice were euthanized and gross necropsy examinations were carried out on the 15th day. No observable toxic effects were observed in rats or mice. In another set of experiment, Sprague-Dawley rats were orally administered either 0, 250, 500 or 1000 mg/kg/day over a period of 28 consecutive days. No toxicological or clinical abnormalities were observed. The anti-diabetic potential of CR00010810 (150 and 450 mg/kg p.o.) was chronically evaluated for 30 days, once daily orally for first 20 days and later administered twice for the last 10 days, in type 2 diabetic rat model (streptozotocin 50 mg/kg i.p.). CR00010810 (450 mg/kg) treatment in streptozotocin-induced diabetic rats exhibited significant hypoglycemic activity (approximately 31.5%) as compared to insulin (48.2% with 1 U/kg i.p.). Further studies in animals and humans are in progress to unveil the broad spectrum safety and anti-diabetic potential of this novel fenugreek extract CR00010810.

340 Effect of Omega-3 Fatty Acid Oxidation Products on the Cellular and Mitochondrial Toxicity of BDE 47
A. Yeh1, S. E. Kruse2, D. J. Marcinek2 and E. P. Gallagher1.
1Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and 2Department of Radiology, University of Washington, Seattle, WA.

High levels of the toxic PBDE flame retardant 2,2’,4,4’-tetrabromodiphenyl ether (BDE 47) detected in fish species such as salmon have raised concern over the safety of salmon consumption. However, salmon are also rich in omega-3 polyunsaturated fatty acids, specifically, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), which are potent antioxidants. In particular, recent studies report the oxidation products of omega-3 fatty acids as critical mediators of the beneficial cellular antioxidant responses associated with dietary intake of omega-3s. In the current study, we used an in vitro approach to test the hypothesis that oxidized omega-3s can ameliorate the cellular and mitochondrial toxicity of BDE 47. HepG2 cells were treated with a mixture of oxidized EPA and DHA (oxEPA/oxDHA) to induce a maximal cellular antioxidant response as evidenced by glutathione (GSH) biosynthesis, followed by exposure to BDE 47. Significant induction of GSH by the oxEPA/oxDHA mixture was associated with a small but significant protective effect against BDE 47-induced loss of cell viability, and with significant protection against loss of mitochondrial membrane potential. Examination of mitochondrial respiration in permeabilized cells revealed that oxEPA/oxDHA pretreatment partially but significantly protected against loss in both State 3 mitochondrial respiration and maximum respiratory capacity (uncoupled respiration). Pretreatment with oxEPA/oxDHA also tended to protect against loss of proton leak respiration (State 4), and of flux capacity through complexes II and IV. Our results support a chemoprotective effect of dietary antioxidants against co-consumed persistent contaminants. This study also provides some biochemical insight into assessing the safety of, and risks associated with, seafood consumption.

341 Safety of Carrageenan in Infant Formula: A 4-Week Toxicity Study in Preweaning Piglets
1TOXpertise, LLC, Princeton, NJ, 2Developmental & Reproductive Toxicology, MPI Research, Mattawan, MI, 3Pathology, MPI Research, Mattawan, MI, 4Abbott Nutrition, Columbus, OH and 5Celtic Colloids, Topsham, ME.

Carrageenan (CGN) is a sulfated galactose polymer extracted from seaweed widely used in the food industry. The potential effects of κ-/CGN (Mw 700 kDa, viscosity 80cps) fed to preweaning Yorkshire crossbred piglets (6/sex/group) 2 days after birth for 28 days were evaluated at concentrations of 0, 300, 1000 & 2250 ppm in infant formula, offered 6x/day, at a volume of 500 mL/kg/day. Clinical observations, body weight & food consumption were recorded daily on each animal. Food efficiency & compound consumption were calculated. Blood was collected for hematology, clinical chemistry & coagulation parameters. Urinalysis was performed via cystocentesis. At scheduled necropsy, piglets were evaluated macroscopically and a complete list of tissues was examined microscopically. There were no deaths from CGN. The CGN formulations were well tolerated by the piglets with clinical findings, body weight & food consumption comparable among all groups. No effects seen on hematology, clinical chemistry & coagulation due to CGN, compared to control animals. Glucosuria was noted in 1 male & 3 female piglets at 2250 ppm on day 29, but blood glucose & renal histopathology were normal. Thus, glucosuria was not considered toxicologically meaningful. No adverse tissue histopathology was noted related to CGN treatment. Toluidine blue staining of gastrointestinal tissues for mast cell assessment showed no differences due to CGN. Assessment of Periodic Acid-Schiff staining of the jejunal goblet cell showed no differences due to CGN. In conclusion, the results of this study verified that dietary exposure to CGN at concentrations of 2250 ppm in infant formula (30-446 mg/kg/day) produced no adverse or treatment-related changes in the growth & development of preweaning piglets or any adverse changes to the parameters evaluated. Funded by FMC Corporation & the International Formula Council.

342 Safety of Carrageenan in Infant Formula: A 4-Week Study of the Potential Immune System Effects in Preweaning Piglets
1TOXpertise, LLC, Princeton, NJ, 2Developmental & Reproductive Toxicology, MPI Research, Mattawan, MI, 3Pathology, MPI Research, Mattawan, MI, 4Abbott Nutrition, Columbus, OH and 5Celtic Colloids, Topsham, ME.

Exposure to κ-/carrageenan (Mw 700 kDa, η 80cps) at concentrations of 0, 100, 300 & 2250 ppm in infant formula was evaluated for potential effects on the immune system in preweaning Yorkshire crossbred piglets, using validated methods
for immunophenotyping, circulating cytokines & immunohistochemistry (ICH) of the stomach, duodenum, jejunum, ileum proximal & distal colon, cecum, rectum. Piglets (6/sex/group) were offered infant formula 6 times/day at a volume of 500 mL/kg/day from 2 days of age for 28 days. Whole blood was collected from animals on days 14 & 19 & evaluated for peripheral blood leukocytes by flow cytometry. All cells types analyzed (lymphocytes, monocytes, B cells, helper T cells, cytotoxic T cells, mature T cells) did not show a biologically significant effect in relative cell percentage or absolute cell counts after carrageenan administration at 2250 ppm. No significant effects across gender or time interval (Day 14 or 19) were observed. Sandwich immunoassays were used for cytokine evaluation. Serum samples were evaluated for IL-6 & IL-8, and plasma samples were evaluated for IL-1p & TNF-α, using commercial, validated ELISA kits. There were no test article effects on levels of any of the cytokines. A validated ICH method was used to evaluate gastrointestinal tissue samples for IL-8 & TNF-α. H&E staining was used to complement the ICH. The results of the ICH evaluation were negative for all treated groups; less than the positive control (Dextran Sodium Sulfate (DSS), 3% w/v). The purpose of this IRB approved study was to validate recent findings in Guatemala showing a significant direct correlation between urinary FB1 and the SaIP/SoIP ratio in blood spots collected from 1240 women in 2011 and 2012 from three separate departments, Chimaltenango (low FB intake), Escuintla (low FB intake) and Jutiapa (high FB intake). Based on a survey of FB in corn conducted in May to October 2012, three different departments were selected for the validation study: Sacatepéquez, Chiquimula and Santa Rosa. The average total FB in the corn from the three departments, respectively, was 1.0 mg/kg (n=48), 4.6 mg/kg (n=53), and 3.8 mg/kg (n=42). Approximately 300 urine and blood spot samples were collected in March and April 2013 from the three departments. Corn samples (n=30) from the same locations and times were collected and analyzed for FB to confirm low and high contamination. The level of FB in corn collected from local markets was significantly higher in Chiquimula and Santa Rosa compared to Sacatepéquez. The urinary FB1, the SaIP/SoIP ratio, and SaIP/mg protein in blood spots were also significantly higher in Chiquimula and Santa Rosa compared to Sacatepéquez. This study confirms the findings of the earlier study. The results are consistent with the hypothesis that FB1 disrupts sphingolipid metabolism in humans consuming large amounts of FB contaminated corn. Supported by NIH grant # 1R4C HD067971-01.

### 343a Evaluation of Concentrations of Nickel, Lead, Cadmium, and Vanadium in Marine Species of the Market “La Nueva Viga.” Using ICP-MS

Toxic metals adversely affect people's health. In very small quantities, many of these metals are necessary to keep good health. However, in larger amounts, they become toxic. The toxicological and environmental studies have focused interest in the determination of toxic metals in foods, particularly fish in the marine environment. In this work cadmium, vanadium, lead, and nickel were analyzed in fish: “mojarra tilapia” and “sierra” sampled in the largest seafood market of Latin America “La Nueva Viga” located in Mexico City. The best sold fish species are the “mojarra tilapia”, “sierra”, shrimp, octopus, crab, sea bass and red snapper. Inductively Coupled Plasma Mass Spectrometry (ICP-MS) was used, because it presents wide spectral coverage, good accuracy and precision, high sensitivity and selectivity. This technique permits the simultaneous detection of elements at low concentration and very small samples. The sample of “mojarra tilapia” and “sierra” was collected in 6 sectors of the market. Samples were dried, grinded and homogenized. The chemical treatment was performed using a Microwave Digestion System prior to the quantification. Analytical parameters were obtained with certified reference material (Dogfish Muscle DORM-2 and Lobster Hepatopancreas TORT-2 (limit of detection, limit of quantification, linear and working range, accuracy and precision). A significant amount of data is necessary for the method development was the selection of the analytic isotope and the internal standards. The mentioned elements were determined finding the following concentrations: “mojarra tilapia” muscle: Ni (0.2-1.2) mg/kg; Pb (0.03-0.12) mg/kg; Cd (0.19-0.22) mg/kg and V (0.043-0.048) mg/kg “sierra” muscle: Ni (0.02-0.05) mg/kg; Pb (0.03-0.16) mg/kg; Cd (0.20-0.22) mg/kg and V (0.010-0.012) mg/kg. The results were compared with national and international norms and all the values were below the maximum allowable limit.
434d β-Alanine: Absorption, Distribution, and Elimination Following Single or Repeated Administration to Rats

A. Augustine1, R. Slatyer1, C. Rosenfeld1, J. Mielke1, B. Franz1, A. Miedema1, B. Fuller1, J. Librizzi1, B. Molitor1, S. Smith1, T. Dubnicka1 and H. Ferguson2.

1Drug Metabolism and Pharmacokinetics, MPI Research, Inc., Mattawan, MI and 2Abbott Nutrition, Inc., Columbus, OH.

β-alanine (BA) is a nutritional supplement used to enhance workout capacity and delay fatigue. To ensure the safety of BA when used as a dietary supplement, a complete understanding of the absorption, distribution and elimination (ADE) of BA and its metabolites is necessary. These studies assess the ADE of (14C)BA and its radiolabeled metabolites following single or daily oral administration of BA. A single, oral dose of 2-[14C]BA was given to groups of adult, male, Sprague-Dawley rats once, or following 28 days of daily oral gavage administration at 1.000 or 2,000 mg BA/kg body weight. No adverse effects of either single or daily administration of BA for 28 days occurred. No quantitative or qualitative differences in the ADE profiles between animals receiving [14C]BA once and animals that received 28 days of BA prior to receiving a single dose of [14C]BA. BA was absorbed into and disappeared rapidly (T1/2 < 4hr) from the plasma. Total radioactivity in the plasma persisted, however (T1/2 > 24 hours). Excretion in urine predominated (~40% of dose), followed by exhalation of [14C]O2 (26.7% of dose); 5.8% of the dose was excreted in the feces. The results of Quantitative Whole Body Autoradiography (QWBA) showed that BA and its radiolabeled metabolites were widely distributed. On average, only 6% of the administered dose remained in the body 168 hours following [14C]BA, uniformly distributed in skeletal muscle. In summary, there were no adverse effects caused by repeated, high-dose administration of BA. Excretion was predominantly in the urine, followed by exhaled [14C]O2, and feces, during the 168 hours following [14C]BA. Daily administration of BA for 28 days had no effect on the ADE of BA and its metabolites. Approximately 6% of the administered dose remained in the residual carcasses, on average, 168 hours following administration of the radiolabeled dose.

434e Oral Repeated 28-Day Study of Moniliformin in Sprague-Dawley According to OECD 407 Rats

K. Peltonen1, M. Jonsson1, M. Jestoii, A. Nathana1, J. Aruso2, U. Kokkonen1, M. Anttila1, P. Koivistolo1 and E. Lilju2.

1Finnish Food Safety Authority, Helsinki, Finland and 2Biochemistry and Food Chemistry, University of Turku, Turku, Finland.

Moniliformin, a Fusarium mycotoxin commonly present in grains in Northern Europe was tested in an oral repeated 28 days study conducted according to OECD 407 guideline. We have shown earlier that a LD50 cut off value of moniliformin is 25 mg/kg bw in Sprague-Dawley rats. In this study five exposed (3, 6, 9, 12 and 15 mg/kg bw) and two satellite groups (12 and 15 mg/kg bw) were exposed 25 mf/kg bw in Sprague-Dawley rats. In this study five exposed (3, 6, 9, 12 and 15 mg/kg bw day) and two satellite groups (12 and 15 mg/kg bw day) were exposed for most oils were 1.5 - 10% (if tested). For some oils, adverse effects were observed at concentrations ranging from 12.5 - 25%. The highest dose used in most of the studies was 10% or 15%. NOAELs for most oils were 1.5 - 10% (if tested). For some oils, adverse effects were observed at the highest doses. In general, lipidosis and toxicity to the liver were observed at concentrations ranging from 12.5 - 25%. Toxicological effects that were oil-specific were identified using concentrations ≥ 5%. The results support use of 5 - 10% as the highest concentration, unless particular oil characteristics prompt concerns that use of such a dose would be expected to cause harm to the animal. Use of higher concentrations may cause nonspecific or secondary effects due to administration of large amounts of oil, which may confound interpretation and have no relevance for humans consuming oils at the levels used in food. The lack of reports of toxicity in humans of oils used in food supports the hypothesis that the maximum doses of oils that have been used historically in 13-week dietary studies in rats are sufficient for risk assessment purposes.

434g Safety Evaluation Methods for Supplemental Nutrients

A. W. Wong1 and J. N. Hathcock2.

1Drug Metabolism and Pharmacokinetics, MPI Research, Inc., Mattawan, MI and 2Abbott Nutrition, Inc., Columbus, OH.

With increasing use of dietary supplements, including those containing nutrients, it is important to determine levels that may be safely consumed. Several regulatory and authoritative bodies have employed the Tolerable Upper Intake Level (UL) method for assessing their safety. For most nutrients, the UL applies to total intake from all sources rather than to supplemental sources. The Council for Responsible Nutrition (CRN) has developed safety evaluation methods to identify an Upper Level for Supplements (ULS). Using these methods, an UL is set if evaluation of the data shows risk. If no risk is identified, a Highest Observed Intake (HOI) can be established as the highest intake as reported within (a) study(ies) of acceptable quality. When appropriate data on supplemental intake are available, the UL may be determined by risk assessment directly (direct safety method). If such data are not available, an indirect/difference method may be used by determining the UL or HOI of a nutrient from all sources, identifying usual intakes from foods, and calculating the UL as a difference.
extensive the dataset, carries a large uncertainty. Application of the CRN methods allows for the derivation of an ULS based on a HOI value for nutrients with no established adverse effects (e.g. vitamin B12), whereas the decision by some authoritative bodies not to set an UL for these nutrients may not adequately communicate the abundance of data available, leading to a perception that there is insufficient evidence to evaluate safety. Additionally, the CRN methods only consider effects that represent a true hazard rather than nuisance effects (e.g. skin flushing associated with niacin). Moreover, these methods conservatively select human No-Observed-Adverse-Effect Levels that do not require adjustment by an uncertainty factor (e.g. vitamin D). The CRN methods are a valuable tool for consumers and their health care providers to make informed decisions about safe and appropriate supplementation levels.

343i Assessing Potential Interactions of “Active” Ingredients in Food
B. S. Lynch and A. Roberts, Cantox Health Sciences International, Mississauga, ON, Canada.

Over the past few decades, many foods have come to contain “active ingredients”, often marketed to perform a functional role in maintenance of health or improvement in athletic and/or cognitive performance. Safety concerns about potential interactions of these active ingredients have been raised, a case in point being that of “energy” or “sport” drinks. Currently there is no consensus on methodology by which biological interactions of ingredients can be assessed. Also, there are generally few studies available specifically designed to assess interactions. We describe a paradigm, using “first principles” of pharmacokinetics, physiology, pharmacology, and toxicology, for assessing interactions of biologically active food ingredients. The method involves assessment of pharmacokinetics and physiological activity, and of the toxicological outcomes, of the ingredients individually, then using this information to predict potential for additive, synergistic, or antagonistic effects at doses encountered in food. As a case study, the potential for adverse effects from the interaction of common “active” ingredients in energy drinks was evaluated.

Caffeine is ubiquitously present in energy drinks. Other ingredients commonly found in these products include: guarana seed extract, d-glucuronolactone, taurine, L-carnitine, inositol, quercetin, and ginseng extract. Typically, caffeine and taurine are present at about 200 and 1000-2000 mg/container, respectively, while the concentrations of the other ingredients generally ranges from 25 to 200 mg/container. Following compilation of the available data for each ingredient, and application of the “first principles” analysis, we found little to no potential for interaction for all but caffeine and taurine. In fact, it is likely that taurine may ameliorate some of the cardiovascular and neurological stimulant properties of caffeine. The results of our analysis are consistent with previously published opinions with respect to the effects of caffeine, taurine and other ingredients present in energy drinks.

343j Assessment of Human Exposures to Fumonisin B1 in Ghana Using LC-MS/MS
K. Rychlík¹, N. J. Mitchell¹, S. Elmore¹, E. A. Romoser¹, P. Eldred¹ and T. D. Phillips¹, *Veterinary Integrative Biociences, College of Veterinary Medicine and Biomedical Sciences, Texas A&M University, College Station, TX and School of Public Health, University of Alabama at Birmingham, Birmingham, AL.

Humans can be exposed to fumonisin B1 (FB1) through ingestion of contaminated grain products. FB1 has been shown to co-occur with other mycotoxins including aflatoxin, and may act as a pro-carcinogen. Evaluating toxin exposures through the use of biological markers in vulnerable populations is essential for risk determination and the development of food safety strategies. An ultra-performance liquid chromatography/electrospray ionization tandem mass spectrometry method (UPLC/ESI-MS/MS) has been developed to detect FB1 in human urine following purification and concentration with a fumonistest immunoaffinity column. Cleanup conditions were optimized to obtain maximum analyte recovery and sensitivity. Validation was performed in the range of 2-200 µg/L based on expected urinary concentrations. LOD for the method was equal to 0.01 µg/L with an LOQ of 0.1 µg/L. A mean apparent recovery of 71.5% with an inter-day precision of 24.69% relative standard deviation (RSD) was achieved. In this study, 40 urine samples were collected from three Regions in Ghana (i.e., Central, Ashanti, and Greater Accra), and evaluated for the presence of FB1. Our results indicated that 16 out of 40 (40%) of the samples were positive for FB1 (37.5% in the Central, 40% in the Ashanti, and 50% in the Greater Accra Regions). These samples were previously shown to be positive for aflatoxin M1, indicating that Ghanaians exposed to aflatoxins may be co-exposed to fumonisins and that mitigation strategies for multiple mycotoxins are needed in high-risk populations (Research supported by NIH1R01MD005819-01).

344 Chronic Intrathecal Infusion/Sampling via a Surgically Implanted Access Port with Functional Observation Battery Evaluation in Cynomolgus Monkeys
R. Taveré¹, S. Authier¹, M. Meghazzi¹, S. Groom¹ and R. Forster², *GTxToxLAB North America, Laval, QC, Canada and GTxToxLAB France, Evreux, France.

Intrathecal administration (IT) and sampling continues to be critical in non-clinical pharmaceutical development for drugs that must be delivered across the blood-brain barrier or to allow sampling of cerebral spinal fluid (CSF) to investigate pharmacokinetics. In alignment with the 3Rs (reduction, replacement, refinement) we have refined a method to allow long term intrathecal administration of candidate drugs and/or sampling of CSF. In addition, a modified function observation battery (FOB) often conducted as part of the ICH S7A safety pharmacology core battery, was developed for the evaluation of neurological changes in non-human primates. A cerebrospinal fluid catheter was inserted into the intrathecal space in the vertebral lamina (L3) and connected to a vascular access port. Implanted animals were first used for the evaluation of the cerebrospinal pharmacokinetics of a pharmaceutical, with CSF sampling of 10 timepoints over a period of 36 hours. Following the end of the first phase the animals were fitted with a jacket and tether system to evaluate the feasibility of continuous infusion for 28 days with PBS. Following the 28 day period, the animals were assessed using a FOB evaluation and euthanized for histopathological evaluation. No neurological abnormalities were observed and minimum to mild catheter-associated chronic granulomatous inflammation was associated with the catheter in the subarachnoid space at the injection/sampling site, next to the spinal cord and spinal nerve roots. Similar moderate catheter-associated chronic granulomatous inflammation was also noted along the catheter track beside the vertebral body and dorsal spinal process below the lumbar muscles. In conclusion, the port/catheters were patent for the duration of the experiments (over 100 days in total), greater than the duration of a chronic study. Therefore the improved method was deemed to be appropriate for long term toxicological, neurological and pharmacokinetic evaluations in Cynomolgus monkeys.

345 Successful Conduct of Continuous Intravenous Infusion Combined with Intrathecal Implantation and Administration in the Juvenile Monkey

Early childhood onset of neurological diseases present several challenges and often these diseases represent rare, unmet medical needs. Potential drug candidates may need to cross the blood-brain barrier to reach their target, which may or may not be feasible via systemic administration depending on the nature of the compound. To mimic the clinical scenario as closely as possible, intravenous (IV) infusion and/or cerebrospinal administration in juvenile animals would be indicated. Undertaking such surgical procedures and achieving a viable model in juvenile animals also presents significant challenges. Herein, we show that concomitant surgical implantation of a femoral IV catheter and an intrathecal (IT) catheter at the lumbar level (comparable to clinical site of injection) in juvenile cynomolgus monkeys (18-23 months old) can be successfully achieved. The IT catheter was implanted via a microlaminectomy procedure of the L5 vertebra followed by a durotomy and catheter insertion into the IT space. A subcutaneous pocket was created in the lumbar region, cranial to the catheter site, and the access port was secured to the muscle and the catheter connected to the port. For the IV cannulation, the femoral vein was isolated and the catheter was inserted; the tip of the catheter was placed in the vena cava. The catheter was secured in place with appropriate suture material and brought subcutaneously to an exteriorization point on the animal’s back. Post surgical recovery was completed over a 7-day period. Animals were administered saline by continuous IV infusion and by IT injection every other day over 14 days. Endpoints evaluated included body weights, clinical observations, hematology, coagulation, clinical biochemistry, neurological examinations, gross observations at necropsy as well as histopathology. The results obtained are comparable to historical data obtained in animals of 2 to 5 years undergoing similar experimental procedures and as such feasibility of continuous IV infusion combined with IT implantation at the lumbar level for injection was confirmed.
The objective of this study was to establish and validate a functional observational battery (FOB) at the Center for Drug Safety Evaluation & Research (CDSER) that provides a basic neurological and behavioral assessment in group housed Cynomolgus Monkey. Four female cynomolgus monkeys were assigned to this study and were given vehicle, chlorpromazine, (s)MK-801 or caffeine in 4 separated days. A FOB was performed and recorded by two independent observers for each animal at designated time points in order to minimize the subjective biases. The administration of 5 mg/kg chlorpromazine resulted in sedative effect between 0.5 and 3 hrs and decreased body temperature at 1 hr post dose. The dose of (s)MK-801 (0.1, 0.5, 1.25 and 2.5 mg/kg) resulted in suppressed behavior (low arousal, infrequent vocalization, hypoactive), autonomic responses (salivation, decreased respiration and rectal temperature) and sensorimotor/neuromuscular alterations (un-coordinated, lack of auditory response, tremor/convulsion) at all doses, and unconscious/pupil dilation at high doses (1.25 and 2.5 mg/kg). Caffeine resulted in stimulant behavioral (high arousal, hyperactivity and intermittent circling behavior) at dose of 30 mg/kg and one of two monkeys at dose of 45 mg/kg resulted in stimulant behavioral (high arousal, hyperactivity and intermittent circling behavior) at dose of 45 mg/kg (between 0.5 and 4.5 hr post dose). At higher doses (one at 45 mg/kg and one at 60 mg/kg), caffeine resulted in decreased arousal and hypoactive between 0.5 and 3 hrs post dose. Autonomic alteration was evidenced by vomiting/retching seen in 45 and 60 mg/kg monkeys between 0.5 and 3 hrs post dose. In conclusion, the observations recorded in this study were consistent with expected pharmacological effects of the neurosedative or neurostimulant reference substances. A FOB in group housed cynomolgus monkeys has been successfully established at CDSER for safety pharmacology and/or toxicology studies to support regulatory submission.

A Validation Safety Pharmacology Study of the Central Nervous System, Employing a Functional Observational Battery (FOB) in Female Cynomolgus Monkey

L. Hu1, W. Zheng1, B. Platzeck1,2, R. A. Bialecki1,2, Y. Chen1,3, H. Yu1 and J. The purpose of the current investigation is to examine available mechanistic data with n-butanol and explore potential mechanisms that might lead to the observed neurotoxic effects. Acute mechanistic studies with n-butanol have suggested a link between the observed neurotoxic effects and alterations in neuronal receptors (e.g. ion channels, G-protein coupled receptors), transport systems, and direct interaction with phospholipids and cellular adhesion molecules. These findings from the mechanistic data suggest that there may be some similarities with n-butyrate to other known neurotoxins such as butyl acetate, a metabolic precursor to n-butanol, have reported no neurobehavioral changes with repeated exposure in rodent studies. However, significant decreases in absolute brain weight in male rats have been observed following n-butyrate exposure.

Potential Mechanisms Leading to Neurotoxicity following N-Butanol Exposure

A. S. Bale, National Center for Environmental Assessment, US EPA, Washington, DC.

There is growing interest with respect to potential widespread human exposure of n-butanol toxicity due to consideration of usage as a fuel additive. However, limited evidence of toxicities, including neurotoxicity, following exposure to n-butanal is available. Neurotoxicity effects resulting from either an acute or subchronic exposure to n-butanol primarily consist of disruption in motor movement and coordination in experimental animal studies conducted to date. In humans, one study reported that exposure to n-butanol exacerbated hearing impairment in workers chronically exposed to high noise conditions. Studies with n-butyrate, a metabolic precursor to n-butanol, have reported no neurobehavioral changes with repeated exposure in rodent studies. However, significant decreases in absolute brain weight in male rats have been observed following n-butyrate exposure.

Potential Mechanisms Leading to Neurotoxicity following N-Butanol Exposure

A. S. Bale, National Center for Environmental Assessment, US EPA, Washington, DC.
were exposed to 10mg/kg DNB, i.p., and mitochondria (mt) isolated from cortex and brainstem by differential centrifugation. Mitochondrial proteins were separated by SDS-PAGE and analyzed by LC-MS/MS to identify protein modifications. Database searches were performed using the Mascot search engine and NCBI & UniProt databases. Results were displayed in ScaffoldTM software and the Normalized Spectral Abundance Factor (NSAF) and %Oxidation were calculated. Proteins were selected for pathway analysis in the Database for Annotation, Visualization and Integrated Discovery (DAVID) based on <0.25 or >4.0-fold changed by NSAF or %Oxidation. Brains from 1mo control rats had significantly higher levels of native proteins in several key metabolic pathways, whereas brains from older control animals showed lower levels of native protein. While cortical %Oxidation was not affected by age, specific brainstem mt-proteins were more prone to oxidation, i.e., the number of oxidized brainstem mt-proteins increased with age. Pathway analysis revealed that DNB caused age-related oxidation specific for protein and nucleotide binding (catalyt transmembrane transporters, nucleotide-oxide-triphosphates, and phosphates, (p<0.05)). These data suggest that oxidation of the brain mitochondrial proteome is region, age and pathway specific and that brainstem mitochondria are more susceptible to oxidative xenobiotic injury as a function of age than their cortical counterparts. This work was supported by NIH 2R01 ES08846 (MAP) and NIH 2T32 ES007062 (LLK).

### 351 Dioxin-Like and Non-Dioxin-Like Polychlorinated Biphenyls (PCBs) Modulate Basal and Activity-Dependent Dendritic Arborization in Primary Neuronal Cell Cultures

C. Barnhart, W. Feng, Y. Dong, L. N. Pessah and P. Lein, Molecular Biosciences, University of California, Davis, Davis, CA.

PCBs are ubiquitous environmental contaminants that have been linked to cognitive and behavioral deficits in children and experimental animals. We previously demonstrated that exposure to the non-dioxin-like (NDL) PCB congener 95 increases dendritic arborization of primary hippocampal neurons in vitro via activation of the ryosyndrome receptor (RyR) calcium channel. However, whether other PCBs similarly trigger dendritic growth via RyR-dependent mechanisms is unknown. To address this question, we measured the effects of NDL PCB congeners 95 and 52 and dioxin-like (DL) PCB congener 77 on RyR activation and on dendritic arbor complexity. Radioilgand-receptor binding analysis with trinitated ryosyn-dine (3H-Ry) showed that PCBs 95 and 52 increased specific receptor occupancy, indicating RyR sensitization; however, the concentration-effect relationships differed. In contrast, PCB 77 did not affect 3H-Ry binding. To determine whether RyR sensitization predicted effects on dendritic growth patterns, primary cultures of perinatal rat hippocampal neurons were exposed to varying concentrations of each congener for 48 h, and the number of dendritic termini was quantified as a measure of dendritic arbor complexity. Each congener enhanced dendritic growth, but exhibited a unique concentration-effect relationship that did not correlate with potency of RyR activation. PCB exposure reduced arborel complexity in neurons treated with bicusculin, a GABA receptor antagonist that stimulates dendritic arborization, leading to an antagonistic interaction between PCBs and activity on dendritic growth. These data demonstrate that dendritic arborization may be a convergent cellular outcome in PCB developmental neurotoxicity, but that NDL and DL PCBs may stimulate dendritic growth via RyR-dependent and/or -independent pathways. This work was supported by NIH (grants R01 ES014901, R01 ES017425, T32 ES007059), the ARCS Foundation, and the Superfund Research Program (P42 ES04699).

### 352 Perfluorobutrate (PFBa) Produces Dose-, Time-, and Sex-Dependent Pupal Light Reflex (PLR) Deficits and Retinal Degeneration

D. A. Fog1, J. A. Hart2, T. N. John1, D. I. Ehresmann1, S. Chaney1, R. Hamilton1, S. Chang1 and J. L. Butenhoff1, 1Univ Houston, Houston, TX, 2Emory University, Atlanta, GA.

During toxicological evaluation of PFBa, we saw a delayed direct PLR in Sprague-Dawley male, but not female, rats exposed to 30 mg/kg PFBa by oral gavage for 90 days. No other signs of neurotoxicity were seen (Reprod Toxicol 2012). To characterize this unusual deficit, retinas from males and females were stained and examined. To determine time course and dose-dependence, the PLR was assessed prior to and weekly during a 28 day exposure of male rats to 0, 30 and 150 mg/kg PFBa (n=18-40/group) followed by retinal histology and immunocytochemistry (n=6-10/group). Staining of the 90 day PFBa retinas with the fluorescent nuclear dye DAPI revealed significant decreases in outer (ONL), inner (INL), ganglion cell layer (GCL) and nuclear detectable (TR) thicknesses for males, but not females, relative to controls. PLR studies in dark-adapted 0, 30 and 150 PFBa groups showed significant dose- and time-dependent delays beginning 1 week after exposure. DAPI staining revealed significant dose-dependent decreases in ONL, INL, GCL and TR thickness. In the 150 PFBa group compared to controls, single- and double label confocal studies demonstrated a loss of bipolar cells and retinal ganglion cells (RGCs), with no increase in GFAP immunoreactivity (no reactive gliosis). Consistent with the loss of photoreceptors and inner retinal cells, mitochondrial and structural retinotoxic effects in male, but not female, rats: consistent with the shorter PFBA half-life in the latter. Although the molecular mechanism is unknown, we suggest that the synaptic connections and somas of the intrinsically photosensitive RGCs mediating the PLR were lost. Supported by 3M and NIH grants EY07024 and EY07551.

### 353 The Toxicity of Low Doses of Ultrafine Diesel Exhaust Particles on Bovine Brain Microvascular Endothelial Cells

Y. Kim1, Y. Choi1, S. Eom1, S. E. Ali1, S. Lantz2, W. Towner1, M. T. Kleinman1 and H. Kim1, 1Dept of Preventive Medicine, College of Medicine, Chungbuk National University, Cheongju, Republic of Korea, 2Neurochemistry Laboratory, National Center of Toxicological Research/NIH, Jefferson, AR and 3Department of Medicine, University of California at Irvine, Irvine, CA.

Diesel exhaust particles (DEPs), originated from combustion of diesel fuel, are one of major pollutant in urban area. DEPs are composed of various sized of particles, the most of them are ultrafine particles, chemicals, and gases. DEPs are known as an important risk factor for various health problems including brain diseases. However, we have limited evidence for the toxicity of low doses of ultrafine DEPs on brain. This study was performed to evaluate the neurotoxicity of low doses of ultrafine DEPs with bovine brain microvascular endothelial cells (bBMEC) as a blood-brain barrier (BBB) model. Various concentrations of DEPS (from 1.28 ng/ml to 20 ng/ml) were exposed to bBMEC for 24 h in vitro. After exposure, we evaluated cytotoxicity with lactate dehydrogenase (LDH) activity, reactive oxygen species (ROS) generation with DCFH-DA method, total antioxidant capacity (TAC) with bathocuproinedisulfonic acid disodium salt, and permeability by measuring the flux of fluorescein. As results, low doses of DEPs decreased cell viability and induced oxidative stress by increasing ROS generation and decreasing TAC with dose-dependent manner. Additionally, BBB permeability was shown to increase by DEPs exposure. This study showed that exposure to low doses of ultrafine DEPs might disrupt BBB function accompanied with oxidative stress generation. This suggests a possibility that exposure of DEPs, even if the dose is extremely low, may induce adverse effects on CNS by altering the integrity of BBB.

### 354 Role of Oxidative Potential versus Nicotine in Tobacco Smoke-Induced BBB Toxicity: Genomic and Proteomic Assessment of BBB Endothelial Dysfunction

P. Naik1, N. M. Fofaria2 and L. Cucullo1, 1Pharmaceutical Sciences, Texas Tech University Health Sciences Center, Amarillo, TX and 2Biomedical Sciences, Texas Tech University Health Sciences Center, Amarillo, TX.

Until recently toxicological studies on tobacco smoke (TS) have preferentially focused on lung and cardiovascular physiology leaving out the blood-brain barrier (BBB) and the cerebrovascular system. Previous studies from our group have shown that BBB impairment by TS is mediated through induction of vascular adhesion molecules, pro-inflammatory cytokines and matrix metalloproteinases from activated leukocyte and endothelial cells (EC). These TS-dependent inflammatory stimuli are suppressed by antioxidants. Thus, we hypothesized that TS-induced oxidative stress (including nitric oxide release) is a major determinant for BBB toxicity of cigarette products. For this purpose, we assessed the impact of soluble cigarette smoke extract (CSE) on gene and protein expression levels in BBB EC. Herein we report the specific impact of nicotine (100ng/ml) versus CSE from full flavor (FF) and ultralow nicotine (ULN) cigarettes. Initial profiling showed that levels of reactive oxygen (ROS) and nitrogen species (RNS) were significantly higher in ULN product compared to the FF and nicotine alone thus indicating a higher oxidative potential. Down regulation of BBB endothelial tight junction (TJ) proteins such as ZO-1 was observed in both ULN and FF cigarettes but not in nicotine-exposed EC. In addition, the membrane expression of VE-cadherin was up-regulated; perhaps a safe fail (compensatory) mechanism to inhibit leukocyte transmigration across the BBB. Nrf2- a transcription factor involved in anti-oxidant response signaling was also increased in CSE-exposed endothelial cells substantiating the role of the ROS generation in BBB toxicity. In summary, our results suggest that BBB toxicity of tobacco products correlates to their relative oxidative capacity which also implies that labeling low-nicotine product as light or less harmful in misleading.

535 Neurotoxic Effects of the Global Smokeless Tobacco Product, Gutkha

D. E. Lauterstein1, C. Hoffman1, A. Hawkins2, C. Klein1, M. Rice3 and T. T. Zheng1,2

1Environmental Medicine, NYU, Tuxedo, NY and 2Neurosurgery, NYU, New York City, NY.

Gutkha, a smokeless tobacco (ST) product manufactured in India and readily available in the U.S. (used extensively by South Asian immigrant communities), is composed of powdered tobaccos, areca nut, and a variety of spices. To assess the neuropharmacological effects of subacute gutkha usage, adult male mice were exposed via daily “painting” of the oral mucosa with either water (control), gutkha, or nicotine for 7 d. Serum cotinine levels for all groups were analyzed upon sacrifice within 1 hr post-exposure; gutkha and nicotine alone had comparable cotinine levels ranging between 18-50 ng/mL and 20-60 ng/mL respectively. Evaluation of methylation status of genes in the frontal cortex demonstrated that gutkha treatment increased methylation state of genes known to be associated with specific mental disorders (e.g. Bdnf, Atp1a, and Comt1). In follow-up experiments, gutkha’s effects on local dopamine (DA) regulation in the striatum, important for executive function and reward-related events, were evaluated using ex vivo voltammetry. Brain slices were exposed ex vivo to varying concentrations of nicotine or gutkha and the lowest concentration causing nicotinic acetylcholine receptor (nAChR) desensitization. These studies demonstrated that a >10-fold higher concentration of gutkha (concentration determined by nicotine content in gutkha mixture) than nicotine was needed to cause nAChR desensitization (p<0.05). The results suggest that: (1) effects of gutkha on certain brain parameters may be due to gutkha-associated toxins other than nicotine; (2) gutkha causes changes in the epigenome that could be associated with development of certain mental disorders; and, (3) higher doses of gutkha may need to be consumed in order to desensitize nAChRs associated with nicotine dependence. Thus, gutkha, and possibly other ST products, poses a public health threat that requires further investigation and ultimately enhanced regulation. Supported by Memorial Sloan Kettering Cancer Center and NYU NIEHS Center of Excellence Grant No. ES000260.

536 Assessment of the Neurotoxic Potential of 50 Hz Extremely Low-Frequency Electromagnetic Fields in Naïve and Chemically-Stressed PC12 Cells

M. de Groot, M. Kock and B. H. Westerink, Toxicology Division, Institute for Risk Assessment Sciences, Utrecht, Utrecht, Netherlands.

The increasing exposure to extremely low frequency electromagnetic fields (ELF-EMFs, 50 Hz), generated by power lines and electric appliances, is associated with childhood leukemia. This raised public and scientific concern about (other potential adverse) health effects of ELF-EMFs. The central nervous system is expected to be particularly vulnerable to ELF-EMFs as its function strongly depends on electrical excitability and ion channel activity. Moreover, potential neurotoxic effects more likely occur in developing or aged/stressed neuronal cells.

We therefore investigated effects of ELF-EMFs on stressed/aging neuronal cells as these have higher levels of iron and reactive oxygen species (ROS) and are thus more sensitive to environmental insults. We exposed naïve and chemically-pre-treated pheochromocytoma (PC12) cells acutely (30 min) and chronically (48 h) to 50 Hz ELF-EMFs (0.1 – 1000 μT) and measured changes in Ca2+-homeostasis using Fura-2 single cell fluorescent microscopy. Additionally, effects on ROS production and cell viability were assessed using H2-DCFDA and a combined Alamar Blue/Fura-2 single cell fluorescent microscopy. However, both acute and chronic exposure of the different PC12 models to 50 Hz ELF-EMFs up to 1000 μT, i.e. 10,000 times above background exposure, failed to affect basal or K+-evoked [Ca2+]i cell viability and ROS production. This suggests that 50 Hz ELF-EMFs do not induce neurotoxic effects in vitro. Moreover, stressed neuronal cells do not appear more vulnerable to ELF-EMFs. Our future experiments in vitro for developmental neurotoxicity aim to elucidate the toxic potential of ELF-EMFs to developing neuronal cells.

537 Bisphenol A and 4-Methyl-2, 4-bis(4-hydroxyphenyl)pent-1-ene Induces Neuronal Cell Apoptosis via Akt/Endoplasmic Reticulum Stress-Regulated Signaling Pathway

C. Huang1, C. Su2, T. Liu3, Y. Chung1, C. Wu3, C. Yen2, S. Liu2 and Y. Chen1,2

1School of Chinese Medicine, China Medical University, Taichung, Taiwan, 3Department of Otorhinolaryngology, Changhua Christian Hospital, Changhua City, Taiwan, 4Department of Physiology and Graduate Institute of Basic Medical Science, China Medical University, Taichung, Taiwan, 5Department of Occupational Safety and Health, Chang Shan Medical University, Taichung, Taiwan, 6Department of Public Health, China Medical University, Taichung, Taiwan and 7Institute of Toxicology, National Taiwan University, Taipei, Taiwan.

Objectives: Bisphenol A (BPA) and 4-methyl-2,4-bis(4-hydroxyphenyl)pent-1-ene (MBP), an active metabolite of BPA, are an endocrine disrupting chemicals (EDCs) or environmental estrogenic property which can disrupt the hormones produced or secreted in mammalian. Several studies have been reported BPA and MBP can cause severely toxicological effects, including neurological dysfunction. However, effects and action mechanisms of BPA and MBP-induced neurotoxicity remained unclear.

Results: BPA significantly decreased cell viability (the LD50 was determined to be approximately 75 μM) and induced the increase in sub-G1 hypodiploid population, annexin V-FITC binding, and the protein expressions of caspase-3/-7 in Neuro-2a cells, indicating that BPA could induce neuronal cell apoptosis. Exposure of Neuro-2a cells to 75 μM BPA also could trigger ER-stress as indicated by several key markers (GRP-78, GRP-94, CHOP, and XBP-1) and caspase-12 cleavage. Moreover, treatment of Neuro-2a cells with MBP more markedly reduced the number of viable cells (the LD50 was determined to be approximately 10 μM), which was associated with inducing apoptotic events and the expression of ER stress-related key molecules and decreased the phosphorylation of Akt. Transfection with specific si-RNA (GRP-94, CHOP, and XBP-1) and over-expression of constitutive activation of Akt (i.e. Akt), respectively, effectively attenuated MBP-induced neuronal cells apoptosis.

Conclusions: These results indicate that Akt/endoplasmic reticulum (ER) stress-regulated apoptotic pathway plays the crucial role in BPA and MBP-induced neuronal cell death.

538 Quinone-Induced Protein Handling Changes: Implications for Major Protein Handling Systems in Quinone-Mediated Toxicity

R. Xiong, D. Siegel and D. Rees, Department of Pharmaceutical Sciences, Skaggs School of Pharmacy and Pharmaceutical Sciences, Anschutz Medical Campus, University of Colorado, Aurora, CO.

Para-quinones such as 1,4-benzoquinone (BQ) and menadione (MD) and ortho-quinones including the oxidation products of catecholamines, are derived from the metabolism of xenobiotics as well as endogenous molecules. Both BQ and MD have been shown to perturb protein-handling systems and we have demonstrated that the dopamine-derived quinone aminochrome (AC) could inhibit pro tease activity. Since the potential hazardous effects of quinones on protein handling systems, including the 20/26S proteasome, the ER stress/unfolded protein response (UPR), autophagy, heat shock proteins (Hsps) and aggresome formation have not been investigated in detail, we conducted this study to systematically examine quinone-induced protein handling changes. In addition, the potential importance of NAD(P)H:quinone oxidoreductase 1 (NQO1) in modulating protein handling changes and toxicity was investigated using stable transfection to generate an isogenic NQO1-overexpressing neuronal cell line. Our data showed that both BQ and AC could inhibit proteasomal activity and activate the ER stress response in rat dopaminergic N27 cells as indicated by increased phosphorylation of eIF2α. While menadione had no significant effect on any protein handling systems, AC was able to stimulate autophagic flux and induce formation of aggresomes as determined by increased LC3 I/II turnover and the formation of ubiquitin positive inclusion bodies. By modulating quinone-induced ER stress responses, NQO1 protected against BQ toxicity but potentiated AC and MD toxicity. This suggests that NQO1-mediated reduction to unstable hydroquinones and subsequent redox cycling was important for the activation of the ER stress response and toxicity of AC and MD in N27 cells. In summary, our data demonstrates that quinone-specific changes in protein handling are evident in N27 cells and the induction of the ER stress response is associated with quinone-mediated toxicity (supported by R01ES018943).
Scavenging Seizure-Induced Reactive Oxygen Species with a Catalytic Antioxidant Attenuates Oxidative Stress and Neuroinflammation in the Pilocarpine Model of Nerve Agent Toxicity

P. Bhuyan1, L. Liang1, S. D. Rowley2, J. N. Pearson2, A. White3, B. L. Davis1, and M. N. Patel1, 1Department of Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO. 2Neuroscience Training Program, University of Colorado Denver, Aurora, CO. 3Department of Pediatrics, University of Colorado Denver, Aurora, CO and 4Department of Medicine, National Jewish Health, Denver, CO.

Seizure activity is a critical injury response following exposure to nerve agents. Reactive oxygen species (ROS) have been identified as key mediators of seizure-induced neuronal damage, along with aberrant inflammation. One potential avenue of controlling pro-inflammatory responses is by scavenging seizure-induced ROS and thereby improving the redox balance. Adult male rats were subjected to pilocarpine-induced status epilepticus (SE) and proinflammatory cytokine production was assessed in the hippocampus and pitiform cortex which revealed acute increases in their levels. To determine the role of ROS in SE-induced cytokine production, a separate cohort of rats were treated with AEOL10150 [Mn(III) tetrakis(N,N-diethylimidizolium-2-yl)porphyrin], a catalytic antioxidant with high superoxide dismutase and catalase activities and sacrificed after 24h. Pilocarpine-induced SE significantly increased 3-Nitrotyrosine/Tyrosine (3NT/Ty) ratio, decreased glutathione redox status (GSH/GSSG), decreased mitochondrial respiration and increased proinflammatory cytokine production, which were significantly attenuated by AEOL10150. Treatment with AEOL10150 also decreased microgliosis and neuronal death, without altering pilocarpine-induced SE. These results demonstrate that scavenging ROS can decrease indices of seizure-induced neuroinflammation and oxidative stress and highlight the importance of redox mechanisms in controlling inflammation in nerve agent-induced toxicity.

Combined Therapy with Allopregnanolone and Diazepam Mitigates TETS-Triggered Hyperexcitability of Neuronal Networks In Vitro and Rescues Mice from TETS-Induced Seizures and Death

D. Krupa1, Z. Cao1, S. Huilzer2, B. Inceoglu2, S. Viro3, J. N. Pesah1 and P. Lenn1, 1VM Molecular Bioscience, UC-Davis, Davis, CA and 2Estonology, UC-Davis, Davis, CA.

Tetramethylenedisulfotetramine (TETS) is a potent convulsant GABA A receptor antagonist considered to be a chemical threat agent. Mice that receive a lethal dose of TETS (0.15 mg/kg, i.p.) can be rescued by the GABA A receptor positive allosteric modifier diazepam (DZP) when administered at a high dose (5 mg/kg, i.p.) immediately after the second clinical seizure (~20 min after TETS injection). However, at this dose, DZP significantly reduces blood pressure and mobility but does not suppress TETS-induced neuroinflammation in the brain. To identify alternative medical countermeasures, we used a primary culture cell model to screen GABAA receptor agonists, singly or in combination. Acute exposure of cultured mouse hippocampal neurons to TETS reversibly alters the pattern of spontaneous Ca2+ oscillations and increases discharge frequency and synchronicity as determined by Fluo-4 fluorescence and extracellular microelectrode array recording. Low concentrations (0.1 μM) of DZP and allopregnanolone (Allop) that are minimally effective when added singly to cultures, show synergy in suppressing TETS-induced alterations of Ca2+ dynamics and electrical discharges when added in combination 20 min after cultures are exposed to TETS. As predicted by the in vitro experiments, doses of DZP (0.05 mg/kg) and Allop (0.03 mg/kg) that are minimally effective when administered singly, increase survival to nearly 100% and reduce the total number of seizures when given in combination immediately after the second clinical seizure. In contrast to high dose DZP, this combinatorial therapy has no effect on blood pressure or mobility, and mitigates TETS-induced activation of microglia but not astrocytes. These studies indicate that in vitro studies can be used to predict effective drug combinations for post-exposure prevention of TETS-induced death. This work is supported by NINDS CounterACT Program grant U54 NS079202.
participant with an age of 65 years and older into T-pos (IgG ≥ 1:100) and non-infected individuals (T-neg; IgG < 1:100). Their cognitive status was evaluated by standardized quantitative tests of memory-based and non-memory-based cognitive functions. The depressive state and the quality of life were assessed by questionnaires. Infected individuals reported different aspects of these functions. In contrast, executive functions were not affected. In particular, lower performance in T-pos seniors was found in a short-term verbal memory test, both regarding immediate recall (P=0.022) and delayed recognition (P=0.037) and in recall from long-term memory assessed by the word fluency tests (P=0.029). Moreover, the rate of correct identified target symbols in a 2-back task was decreased (P=0.048), indicating a reduced working memory capacity. Decreased memory functions in T-pos seniors were accompanied by a decreased self-reported quality of life. The observed association is relevant for public health considering the high prevalence of toxoplasmosis. The relatively large effects on some of the here reported memory functions correspond to the mean decrease usually observed between year 60 and 70.

Changes in gene and protein expression of liver ABC transporters have been previously described during acute APAP intoxication. However, the effect of hepatoxic doses of APAP on brain ABC transporters has never been studied. The aim of this study was to evaluate the effect of APAP on brain ABC transporter expression and the role of the translation factor eIF2α in Nrf2 activation.

For this purpose, male C57BL/6 mice received APAP (400mg/kg) or vehicle. 24h later, brains were removed and protein expression of Mrp1-Mrp5, Bsep and P-gp was determined by Western blotting from total brain homogenates. mRNA expression for these ABC transporters was also assayed by q-RT PCR between 6 and 24 h after APAP. The results show that APAP treatment significantly increases the expression of brain P-gp (159%), Mrp2 (293%) and Mrp4 (38%) proteins relative to controls, with no changes in Bsep, Mrp1 and Mrp5 detected. Mrp3 protein was not detectable in either group. The increased protein expression for P-gp, Mrp2 and Mrp4 correlated with changes in mRNA expression. In agreement with protein content, mRNA expression for Bsep, Mrp1, Mrp3 and Mrp5 did not change with APAP treatment. Indicative of Nrf2 activation, mRNA and protein expression of NAD(P)H:quinone oxidoreductase 1 increased significantly in brain tissue with APAP treatment. Furthermore, nuclear content of Nrf2 protein was found to increase by 50% at 12 h after APAP. In conclusion, acute APAP intoxication induces protein expression of several brain ABC transporters through a transcriptional mechanism. This study also suggests that these changes may be due to in situ Nrf2 activation by APAP. The functional consequences of these changes in brain ABC transporters by APAP deserve further attention.

Mesencephalic dopaminergic neurons are heavily involved in the development and maintenance of drug dependence. Therefore, the morphological changes in dopaminergic neurons of the substantia nigra (SN) and ventral tegmental area (VTA) in morphine dependent rats were investigated. Models of morphine dependence were established in rats, and paraffin-embedded sections, immunohistochemistry and immunofluorescence were used to observe the changes in expression of tyrosine hydroxylase (THI) protein, a specific marker of dopaminergic nerve cells. Fluoro-Jade B staining was used to detect degeneration and necrosis, and terminal deoxynucleotidyl transferase-mediated dUTP nick-end-labeling (TUNEL) detected apoptosis of mesencephalic dopaminergic nerve cells. The number of TH positive cells significantly decreased in rats that were morphine dependent for a longer period of time. With prolonged morphine exposure, SN and VTA dopaminergic nerve cells showed degeneration and necrosis, while apoptotic cells were not observed. The number of SN and VTA dopaminergic nerve cells decreased with increasing periods of morphine dependence, which was most likely due to degeneration and necrosis of nerve cells induced by morphine toxicity.
differentiation. We manipulated mES cells in culture to differentiate in 3 stages: cell transformation to embryoid bodies (EBs); EB differentiation to neural progenitor cells (NPC); and, mES cell differentiation to neural/glial cells. Cell types are confirmed by monitoring expression of Oe4, nestin, mtap-2, and GAP43, as cell-specific markers for stem cells, NPC, neurons, and astrocytes, respectively, using RT-PCR and flow cytometry analysis. Similarly, opioid receptor gene expression for mu (μ), kappa (κ) and delta (δ) receptors, was confirmed in each cell type. Our results demonstrate that 100 μM morphine sulfate (MS) for 24-hrs does not alter cell viability or cell cycle kinetics in mES cells. In addition, MS does not alter μ-opioid receptor gene expression nor receptor protein expression after 24-hrs exposure. However, MS causes internalization of μ-receptors in a concentration-dependent manner, and down regulation of κ-receptor gene expression in stem cells. Chronic exposure of stem cells during transformation to EBs and NPC results in down regulation of both μ-receptor gene expression and NPC-specific marker expression of nestin, respectively. Overall, these results indicate that acute MS exposure does not alter self-renewal of mES cells; however, chronic treatment inhibits cell differentiation to NPC cells. Consequently, the project focuses on the significance of the relationship between MS administration in early and late stage differentiation, and opioid receptor expression and receptor activity. Understanding this mechanism has particular clinical applications for the prevention or treatment of fetal and childhood narcotic addictions.

369 Effect of Prenatal Methadone on Reinstated Behavioral Sensitization Induced by Methamphetamine in Adolescent Rats

L. Tian1, C. Wong1,2,3, Y. Lee1, Y. Chiang4, L. Fan1 and L. Hu1,2,3,4, 1School of Medicine, Fu Jen Catholic University, New Taipei City, Taiwan, 2Department of Anesthesiology, Cathay General Hospital, Taipei, Taiwan, 3Graduate Institute of Clinical Medical Science, China Medical University Hospital, Taichung, Taiwan, 4Graduate Institute of Medical Science, National Cheng Kung University, Tainan, Taiwan.

The present study was to investigate the effect of prenatal exposure to methadone on methamphetamine (METH)-induced behavioral sensitization as an indicator of drug addiction in late life. Pregnant rats received saline or methadone (7 mg/kg, s.c.) twice daily from E3 to E20. To induce behavioral sensitization, offspring (5 weeks old) were treated with METH (1 mg/kg, i.p.) or saline once daily for 5 consecutive days. Ninety-six hours (day 9) after the 5th treatment with METH or saline, animals received a single dose of METH (1 mg/kg, i.p.) or saline to induce the reinstated behavioral sensitization. Prenatal methadone treatment enhanced the level of development of locomotor behavioral sensitization to METH administration in adolescent rats. Prenatal methadone treatment also enhanced the reinstated locomotor behavioral sensitization in adolescent rats after the administration had ceased for 96 hours. These results indicate that prenatal methadone exposure produces a persistent lesion in the dopaminergic system, as indicated by enhanced METH-induced locomotor behavioral sensitization (before drug abstinence) and reinstated locomotor behavioral sensitization (after short term drug abstinence) in adolescent rats. These findings show that prenatal methadone exposure may enhance susceptibility to the development of drug addiction in later life. This could provide a reference for drug usage such as METH in their offspring of pregnant woman who are treating with methadone.

370 Inhibition of the Vesicular Monoamine Transporter 2 Alters the Acute and Long-Term Effects of 3,4-(2)-Methylenedioxymethamphetamine

J. E. Lizarraga, A. M. Phan, S. S. Lau and T. J. Monks, Pharmacology/Toxicology, University of Arizona-College of Pharmacy, Tucson, AZ.

3,4-(2)-Methylenedioxymethamphetamine (MDMA, Ecstasy) exerts a biphasic pharmacological response on the brain resulting in contrasting acute and long-term effects. During the acute phase, MDMA causes major monoamine release into the striatum of SD rats. As expected, MDMA significantly increased DA and 5-HT release in the caudate putamen. Ro 4-1284 pretreatment had little effect on MDMA-mediated increases in dialysate monoamine concentrations. However, increases in dialysate concentrations of DA and 5-HT metabolites (DOPAC and 5-HIAA, respectively) were indicative of increased monoamine turnover. Immunohistochemistry revealed that Ro 4-1284 prevents striatal depletion of the 5-HT reuptake transporter in MDMA-treated rats, consistent with findings that inhibition of VMAT2 protects against long-term MDMA serotonergic neurotoxicity. In conclusion, we have demonstrated that VMAT2 inhibition by Ro 4-1284 has significant effects on the acute and long-term effects of MDMA. Further studies are required to decipher the mechanisms by which Ro 4-1284 protects against MDMA neurotoxicity. (DA023525, P30ES006694, & T32ES007091).

371 Enhanced Vesicular Function and Reduced Neurotoxicity in Mice Overexpressing the Vesicular Monoamine Transporter

G. W. Miller, K. Lohy, A. L. Bernstein, K. Stout, A. R. Dunn and A. Salahpour, Environmental Health, Emory University, Atlanta, GA.

The vesicular monoamine transporter 2 (VMAT2) packages monoamine neurotransmitters into vesicles for rapid release at the synapse. In addition to its role in neurotransmission, VMAT2 also sequesters toxins away from their sites of action in the cell. Our laboratory has previously characterized mice with reduced vesicular capacity, which results in progressive degeneration of dopamine and noradrenaline neurons and motor and non-motor deficits (J. Neurosci., 2007; J. Neurosci., 2009; Neuropharmacology, 2013). However, it was unknown if an increase in VMAT2 level would result in increased vesicular function in an animal model. We created a BAC transgenic VMAT2 overexpressing (VMAT2-HI) mouse line to determine the effects of increased vesicular monoamine filling on associated neurochemical, behavioral, and toxicological outcomes. The increased vesicular filling in the VMAT2-HI mice results in an enhanced vesicular storage capacity for dopamine as shown by increased vesicular uptake and increased vesicle size. This corresponds to a 21% increase in striatal dopaminergic content, suggesting a sustained enhancement of the dopaminergic system in the VMAT2-HI mice. This increased dopamine storage also results in an 80% increase in synaptic dopamine release as measured by fast-scan cyclic voltammetry. Further, VMAT2-HI mice show behavioral changes, including increased locomotor activity and an enhanced response to amphetamine. VMAT2-HI mice also show improved outcomes on measures of anxiety and depressive-like behaviors, including a 42% reduction in marble burying and a 22% decrease in immobility time on the forced swim test. Finally, since VMAT2 level is a neuroprotective mechanism in monoaminergic systems, we tested the vulnerability to the parkinsonism-inducing neurotoxin MPTP and found that the VMAT2-HI mice had reduced dopaminergic toxicity. These data suggest that monoamine vesicular capacity can be increased and this increased capacity corresponds to reduced toxicity.

372 Diverse Models of Neurotoxicity Link Induction of Astroglial Activation to Activation of STAT3

K. A. Kelly, D. B. Miller and J. P. O’Callaghan, CDC-NIOSH, Morgantown, WV.

Dr. Paul Greengard received the 2000 Nobel Prize in Physiology or Medicine for identifying the dopamine- and cAMP-regulated neuronal phosphoprotein (DARPP-32) signaling pathways in medium spiny striatal neurons. Identification of multiple phospho-sites on DARPP-32 revealed upstream effectors regulating the activation of this specific neuronal cell type. We adopted the same approach to map signaling pathways upstream of the key astrocyte damage marker, glial fibrillary acidic protein (GFAP). In a 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) model of dopaminergic neurotoxicity, we demonstrated the development of neuroinflammation (upregulation of proinflammatory cytokines/chemokines) and activation of the janus kinase and signal transducer and activator of transcription (JAK2-STAT3) pathway preceding the up-regulation of GFAP in astrocytes in the brain. Here, we show that multiple mechanistically distinct models of neurotoxicity (MPTP, amphetamine (AMP), methamphetamine (METH), 3,4-methylenedioxymethamphetamine (MDA), kainic acid (KA) and trimethyltin (TMT)) engender the same neuroinflammatory response and STAT3 activation in target brain regions of the respective neurotoxins. Pharmacological antagonism of neurotoxic effects of MPTP, METH and KA with nomifensine, ethanol and diazepam, respectively, blocked the neuroinflammation, phosphorylation of STAT3 and GFAP induction, indicating neuronal damage as a component of the initiation of neuroinflammation. Deletion of astrocyte STAT3 in conditional knockout mice prevented the induction of GFAP in MPTP-treated mice. Double immunostaining of GFAP and STAT3 showed...
enhanced nuclear staining localized to astrocytes in association with the induction of astrogliosis. These findings strongly implicate the STAT3 pathway in astrocytes as a key signaling pathway for astrogliosis.

373 BAC-TRAP Technology in Neurotoxicology: The ALDH1L1 BAC-TRAP Mouse As a Tool to Assess Astrocyte Specific Responses to Neurotoxic Injury

L. P. O'Callaghan, K. A. Kelly and D. B. Miller, CDC-NIOSH, Morgantown, WV.

A central problem in neurotoxicology is detecting the selective and unpredictable damage to specific cells produced by toxic agents and mixtures. Evaluating astrogliosis overcomes this problem because reactive astrocytes show the location of toxicant-induced damage occurring anywhere in the CNS. Enhanced expression of GFAP is a hallmark of reactive astrocytes; however, few other astrogliosis biomarkers are known. Thus, determining the specific in vivo transcriptional profile of astrocytes under control and reactive conditions will allow for the identification of additional astrogliosis biomarkers. Heintz and Greengard (2008) introduced BAC-TRAP (translating ribosome affinity purification) technology as an approach for identification of cell-type-specific responses in vivo. Here, we implemented this approach for the assessment of mRNA translation specific to astrocytes responding to damage caused by known neurotoxins. ALDH1L1 is an enzyme thought to serve a housekeeping function in astrocytes. Using hippocampal and striatal damage due to TMT and MPTP, respectively, we evaluated the localization and response of ALDH1L1 compared to astrogliosis seen by GFAP immunohistochemistry and ELISA. Staining of ALDH1L1 revealed localization to astrocytes after TMT and MPTP, while immunoblots of ALDH1L1 revealed basal expression of this protein but little enhanced expression after MPTP and TMT, confirming to be an astrocyte “housekeeping” gene/protein. We then used the ALDH1L1 BAC-TRAP mouse to evaluate astrogliotic-specific mRNA with expression analyses by gene array in control conditions. Tissue was subjected to TRAP utilizing an eGFP antibody that only binds to actively translating RNA in astrocytes. This revealed numerous genes in “resting” astrocytes, including genes previously localized to astrocytes (e.g., GFAP), as well as novel genes to this cell type (e.g., PHOX2A). MPTP expression data are reported in accompanying poster. The ALDH1L1 BAC-TRAP mouse represents a promising tool to investigate astrogliotic responses to neurotoxic injury.

374 BAC-TRAP Technology in Neurotoxicology: Assessing the Astrocyte Response to MPTP-Induced Damage in the ALDH1L1 BAC-TRAP Mouse

D. B. Miller, K. A. Kelly and L. P. O'Callaghan, CDC-NIOSH, Morgantown, WV.

A central problem in neurotoxicology is detecting the selective and unpredictable damage to specific cells produced by toxic agents and mixtures. Evaluating astrogliosis overcomes this problem because reactive astrocytes show the location of toxicant-induced damage occurring anywhere in the CNS. Enhanced expression of GFAP is a hallmark of reactive astrocytes; however, few other astrogliosis biomarkers are known. Heintz & Greengard (2008) introduced BAC-TRAP (translating ribosome affinity purification) technology that allows the characterization of the actively translating RNA in astrocytes. Using hippocampal and striatal damage due to TMT and MPTP, respectively, we evaluated the localization and response of ALDH1L1 compared to astrogliosis seen by GFAP immunohistochemistry and ELISA. Staining of ALDH1L1 revealed localization to astrocytes after TMT and MPTP, while immunoblots of ALDH1L1 revealed basal expression of this protein but little enhanced expression after MPTP and TMT, confirming to be an astrocyte “housekeeping” gene/protein. Thus, ALDH1L1 BAC-TRAP mice can be used to characterize the transcriptome of astrocytes under various conditions. To begin to characterize additional biomarkers of astrogliosis occurring in response to neurotoxic damage ALDH1L1 BAC-TRAP mice were given a single 12.5 mg/kg s.c. dose of MPTP, a well characterized dopaminergic neurotoxicant that induces significant astrogliosis. Striatal tissue was obtained at 12, 24, and 48 hrs following a single s.c. dosage of saline or 12.5 mg/kg MPTP. Striatal tissue was subjected to TRAP utilizing an eGFP antibody that only binds to actively translating RNA in astrocytes. Changes in the actively translating RNA induced by MPTP damage were determined by microarray (illumina MouseWG-8 v2 Expression BeadChip) and the dataset interrogated using Ingenuity Pathway Analysis (IPA). MPTP induced robust transcriptome changes in genes previously identified as astrocyte specific (e.g., 405, 399, 804 fold increases in TIMP1 at 12, 24, 48 hrs, respectively) as well as others not previously considered astrocyte-specific (e.g., 219, 203, 3,69 fold increases in PHOX2A at 12, 24, 48 hrs). Our data indicate the BAC-TRAP technology can be used to identify additional biomarkers of astrogliosis and will aid in characterizing various astrocyte phenotypes.

375 Human iPSC Neurons: In Vitro Models to Predict Clinical CNS Toxicity

C. A. Snyder, K. Staflin and D. L. Misner, Safety Assessment, Genentech, South San Francisco, CA.

A major cause of drug attrition from clinical trials is neurotoxicity, a problem stemming from the lack of a relevant model to predict human CNS safety. Current neurotoxicity assessment depends on in vivo animal models, which are time-consuming and expensive. In vitro models consist of immortalized cell lines and primary rodent cultures, which are often a poor representation of human physiology. There is need for high throughput, human-based assays that can narrow down drug candidate panels for in vivo animal studies, and augment those studies with human data before initiation of clinical trials. We chose to establish such assays with human induced pluripotent stem cells (iPSCs) that have been differentiated into mature neurons. These iPSC neurons offer a renewable source of mature cells, relevant to human drug safety, and free from ethical concerns. CNS toxicity results from disruption of complex neural networks, which is why our test panel addresses neuronal activity, in addition to neurite outgrowth, cytotoxicity and mitochondrial stress. Few studies tackle neuronal activity in a high throughput system, and fewer still integrate changes in activity with other functional toxicological endpoints. Our novel platform will combine a semi-high throughput multi-electrode array (MEA) with high throughput neurotoxicity assays for potential screening of drug candidates. By using a panel of test compounds known to cause CNS toxicity in vivo we put forward a panel of in vitro human physiological-based assays to evaluate the translatableity of drug safety.

376 Live Cell-Based Assay Using GFP+ Human Stem Cell-Derived Neurons

Adverse outcome pathways (AOP) are conceptual frameworks that portray existing knowledge concerning the link between a molecular initiating event and an adverse outcome. High throughput screening (HTS) and high content screening (HCS) approaches seek to gain a greater perspective of the AOP, leading to more efficient and reliable identification of adverse outcomes of compounds and chemicals. However, HCS assays often utilize primary or stem cell sources which are not amenable to large scale screening and can require extensive cell culture, fixation and permeation, and immunocytochemistry prior to imaging. Thus, major costs are associated with 96-well based high content neurotoxic screening. In addition, preserving or fixative steps can alter cell architecture and a new plate of cells is required for each time point, thus introducing variability to data. This new human cell-based assay provides a scalable solution to the previously labor intensive, single-end-point, and hence limited nature of neurotox assays, while preserving the breadth and quality of data. The assay utilizes clonal, embryonic stem cell derived, human neural cells that have been genetically modified with a non-viral vector encoding a Green Fluorescent Protein (GFP) reporter gene driven by a ubiquitous promoter. Previously, hN2TM human neuronal cells faithfully reproduced early brain development, providing a cell model > 95% positive for neuronal markers while demonstrating higher sensitivity to neuronal toxins than mouse cortical neurons, and our new GFP+ neurons are equally sensitive. Additionally, previous studies using rodent primary cells examined mixed and unknown ratios of neuronal cells, often at various stages of proliferation and differentiation. These new GFP+ neurons are differentiated from a clonal GFP+ neural progenitor population, thus removing variability from cultures while maintaining an adherent monolayer amenable to high content imaging. By eliminating the need for fixing and staining cells, these GFP+ human neurons provide a scalable means to analyze neurite outgrowth in live cells spanning the course of hours to days following exposure to test compounds.

377 A Functional Phenotypic Screen for Synapse Formation in Human iPS-Derived Neurons

There is need for high throughput, human-based assays that can narrow down drug candidate panels for in vivo animal studies, and augment those studies with human data before initiation of clinical trials. We chose to establish such assays with human induced pluripotent stem cells (iPSCs) that have been differentiated into mature neurons. Therefore, we used antibodies to measure expression levels of the pre- and post-synaptic proteins, Synapsin I and post-synaptic protein 95 (PSD95), respectively. Furthermore, using advanced image analysis algorithms we masked neurite regions demarked by enhanced nuclear staining localized to astrocytes in association with the induction of astrogliosis. These findings strongly implicate the STAT3 pathway in astrocytes as a key signaling pathway for astrogliosis.

SOT 2014 Annual Meeting 95
expression of TuJ1 (beta-III tubulin) and measured colocalized signals for the pre- and post-synaptic markers only in these functionally-relevant regions. Additional information that may be related to the mechanism of action for chemicals that showed an effect in the assay included the amount of neurite outgrowth (TuJ1) and alterations in nuclear texture (Hoechst 33342). Our high content screening (HCS) approach enabled us to screen a library of FDA-approved drugs (the NCC2 library) as well as other agents such as forskolin, estrogen, and tamoxifen known to modulate neuronal function. Using this approach we have developed a robust platform for large-scale screening of chemicals that affect synapse formation, the basic unit of neuronal function in humans.

378 eCiphrNeuro: A High-Throughput Assay to Detect Neurotoxic Compounds in Early Drug Discovery

Seizuregenic neurotoxicity produces significant drug attrition during drug discovery. Currently available in vitro assays cannot predict this toxicity due to the failure of general cytotoxicity assays to predict subthalamic target specific electrophysiological liabilities. Ion channel and receptor activity assays can be used to predict some seizure potential, but these only focus on specifically measured targets for prediction and may miss a response which relies on a combination of endpoints. Most evaluation of seizure inducing compounds occurs later in preclinical development in vivo studies which have much higher costs. Therefore, the development of a high-throughput in vitro assay to screen compounds for seizuregenic potential would lead to evaluating compounds earlier at lower cost and greater reliability. Here we demonstrate the use of a 48-well microelectrode array (MEA) to screen for seizuregenic compounds using rat cortical neurons. Spikes were measured and the results were computed for mean firing rate, synchrony, and spike train organization (inter-spike and burst statistics) using custom Matlab scripts and NeuroExplorer. All of the seizuregenic compounds, including GABA-A antagonists, showed significant changes in MFR, synchronization, and spike train and burst organization, while all of the negative controls were ineffective. Glutamate, the excitatory neurotransmitter, showed a robust increase in activity. Neuroinhibitory molecules such as Domoic Acid, a neurotoxin, GABA (GABA agonist), Tetrodotoxin (sodium channel blocker) and TEA (potassium channel blocker) were also tested and found to block activity. These results illustrate the power of a high-throughput rat cortical neuron MEA assay for predicting compound induced neural toxicity.

378a Low Frequency Activity of Cortical Networks Is Differentially Altered by Bicuculline and Carbaryl

D. Hall1, C. M. Mack2, D. W. Herr2 and T. L. Shafer1. 1ISTD, US EPA, RTP, NC and 2TAD, US EPA, RTP, NC.

Thousands of chemicals need to be characterized for their neurotoxicity potential. Neurons grown on microelectrode arrays (MEAs) are an in vitro model used to screen chemicals for functional effects on neuronal networks. Typically, after removal of low frequency components, effects on high frequency events (neuronal action potentials, or “spikes”) are used to differentiate chemical effects. However, such approaches discard information and low frequency activity has yet to be examined for its utility in screening chemicals. In this pilot study, spontaneous network activity in primary cultures of rat cortex was collected in MEAs and differential expression of Tuj1 (beta-III tubulin) and measured colocalized signals for the pre- and post-synaptic markers only in these functionally-relevant regions. Additional information that may be related to the mechanism of action for chemicals that showed an effect in the assay included the amount of neurite outgrowth (TuJ1) and alterations in nuclear texture (Hoechst 33342). Our high content screening (HCS) approach enabled us to screen a library of FDA-approved drugs (the NCC2 library) as well as other agents such as forskolin, estrogen, and tamoxifen known to modulate neuronal function. Using this approach we have developed a robust platform for large-scale screening of chemicals that affect synapse formation, the basic unit of neuronal function in humans.

378b Evaluation of the Neuroactivity of ToxCast Compounds Using Multiwell Microelectrode Array Recordings in Primary Cortical Neurons

P. A. Valdivia1, M. T. Martin2, W. LeFevre2, D. Hall1, J. Ross2, K. Houck2 and T. L. Shafer1. 1Axion Biosystems, Atlanta, GA, 2NCC, US EPA, RTP, NC and 3ISTD, US EPA, RTP, NC.

Assessment of spontaneous activity in neuronal cultures using multi-well microelectrode arrays (MEA) systems is a rapid, efficient and sensitive method to detect neuroactivity of drugs, chemicals, and particles. Effects of 68 ToxCast compounds (biased for neuroactive compounds) on neuronal activity using 48 well MEA plates were examined previously. In this experiment, effects of 20 additional ToxCast compounds, with a bias towards those inactive in ToxCast ion channel assays, were examined. Five additional compounds, known to be without effect on neuronal function in MEAs (negatives) were included. Further, these experiments refined data analysis approaches by considering recording stability post-hoc and establishing criteria for data inclusion. On day in vitro 14, 1 hr of baseline activity was recorded prior to exposing the cortical networks to 40 μM of each compound for 1 hr; the percent change in mean firing rate (MFR) was determined in the absence and presence of each chemical. Post-hoc analysis determined that the first 20 min of baseline recording was a period of activity stabilization and thus was omitted from analysis. A hit detection threshold of a 39.1% change in weighted (wMFR) was determined based on 2 standard deviations beyond the mean response to DMSO treatment; none of the 5 known negatives altered wMFR beyond this threshold. However, of the 20 ToxCast chemicals, 12 altered wMFR beyond the hit threshold. Hits included tetraethin and fenitin, 4/9 conazoles, piperonyl butoxide, vinclozolin, lactofen, prochloraz, butyl benzyl phthalate and genistein. None of the 25 chemicals were cytotoxic. Concentration-response assessments were concordant with the single point screen result for 7/8 chemicals. These results indicate that spontaneous activity of cortical neurons measured with MEAs may be sensitive to chemicals with actions on endpoints other than ion channels. This abstract was supported by CRADA #644-11 with Axion Biosystems and does not reflect EPA Policy.

378c Effects of Organophosphorus Flame Retardants on Spontaneous Activity in Neuronal Networks Grown on Microelectrode Arrays

T. L. Shafer1, K. A. Wallace1, W. Mundy1 and M. Rehl1. 1Integrated Systems Toxicology, U.S. Environmental Protection Agency, Research Triangle Park, NC and 2NIEHS, Research Triangle Park, NC.

Organophosphorus compounds are increasingly used as alternatives to brominated flame retardants (BFRs) and thus are commonly found in house air and dust. However, there is limited information on their potential health effects. Assessment of spontaneous neural network activity using microelectrode arrays has been shown to be a sensitive method to screen chemicals for potential neuroactivity/toxicity. Therefore, this study compared the effects of nine organophosphorus flame retardants (OPFs) with the BFR tetrabromobisphenol A to determine their ability to alter network function in primary cultures of rat cortical neurons grown on 48 well microelectrode array (MEA) plates. On day 13 or 14 in vitro, 1 hr of baseline activity was recorded prior to exposure to flame retardants (0.1 to 30 μM). Changes in spontaneous mean firing rate (MFR) relative to the vehicle control were assessed 1 hr after exposure. The BFR tetrabromobisphenol A and the OPF tris (2-chloroethyl) phosphate did not alter the spontaneous activity at any concentration tested. The remaining 8 OPFs decreased spontaneous activity in a concentration-dependent manner, with EC50 values ranging from 6.6 to 18.6 μM in the following order: 3-butylyphenyl diethyl phosphate ≥ tricresyl phosphate ≥ 2-ethylhexyl diphenyl phosphate ≥ isopropylated phenyl phosphate ≥ isodecyl diphenyl phosphate ≥ ortho-tricresyl phosphate ≥ triphenyl phosphate ≥ tris (1,3-dichloroisopropyl) phosphate. None of the flame retardants decreased the viability of cortical cells at any concentration tested. This data indicates that some OPFs have the ability to alter the spontaneous activity in neuronal networks in vitro at micromolar concentrations. This abstract does not necessarily reflect U.S. EPA policy.

378d Neurotoxic Effects of Tri-Ortho-Cresyl Phosphate In Vitro

V. Hausherr1, N. Schöbel1,2 and C. van Thrill1. 1Neurotoxicology and Neuroonervation, IFADO - Leibniz Research Centre for Working Environment and Human Factors, Dortmund, NRW, Germany and 2Animal Physiology, Ruhr-University Bochum, Bochum, NRW, Germany.

Tri-ortho-cresyl phosphate (TOCP) provokes organophosphate-induced delayed neuropathy (OPIDN) in the peripheral nervous systems of humans and sensitive animals. On the cellular level axon swelling and disturbance of axonal transport

SOT 2014 ANNUAL MEETING
are the initial events of OPIDN. Low-dose effects of TOCP on central nervous system (CNS) functions on a cellular level have only been rarely studied yet. In the present study, we investigated neurotoxic effects of TOCP on neurons of mice cerebral cortices in vitro. We evaluated cell viability, neurite outgrowth, and the functionality of neurochemical processes. A 24 h exposure of mouse primary cortical neurons (pCNs) to TOCP yielded dose-dependent cytotoxic effects. 89 µM TOCP were associated with significant reduction of about 50 % in cell viability. In addition, TOCP impaired neurite outgrowth and caused degeneration of neurite networks with a lowest effective dose of 1 µM. Using fluorescence-based life-cell imaging techniques we showed that TOCP-induced alterations in cellular ion currents were associated with altered excitatory neurotransmitter glutamate. Glutamate-evoked signals in pCNs were significantly decreased after 24 h exposure to TOCP 100 nM. Both, the percentage of glutamate-responsive neurons and the mean response amplitudes were decreased. In addition to these results, we observed a direct inhibition of glutamate receptor-mediated responses by TOCP. In detail, the simultaneous application of TOCP (100 µM) together with the glutamate stimulation resulted in a block of glutamate-induced responses by 70 %. In summary, we showed here low and lowest-dose effects of TOCP on functional parameters of CNS neurons. Further research aims at investigating the mode of action of TOCP on glutamate receptors and the identification of receptor subtypes that might be affected. Possibly, the effects described here are associated with some neurobehavioral symptoms related to the acrylotic syndrome.

**378e** Rat Brain Neurolemma Microtransplanted into Xenopus Oocytes Is a Useful Tool to Examine the Effects of Environmental Toxins on Endogenous Voltage-Sensitive Ion Channels

S. B. Smyrning1, E. Murenzi1, T. G. Ozimira2, L. P. Sheets4, D. Minnema3, M. Brooks5, D. W. Gammon7 and J. M. Clark8, 3.

Microtransplantation of mammalian neurolemma is a tool to study the structure and function of transmitter receptors and ion channels associated with the central nervous system. Microtransplanted neurolemma can originate from a variety of sources, possess ion channels and receptors in their native configuration and lipid matrix, and are applicable to examine diseases associated with different channelopathies. This functional system makes neurolemma-injected Xenopus oocytes a viable method for detailed investigations of toxins on ion channel function. Our preliminary results indicate that Xenopus oocytes, injected with rat brain neurolemma are capable of reconstituting native ion currents into their plasma membrane. Expressed ion currents were sensitive to tetrodotoxin, t-conotoxin MVIIIC, and TEA; indicating the presence multiple voltage-gated ion channels (voltage-gated sodium channel, calcium channel and potassium channel, respectively). Furthermore, neurolemma-injected oocytes, exposed to increasing concentrations of permethrin, exhibited a concentration-dependent increase in TTX-sensitive current. Once completely characterized, this procedure will also be amenable to the study of the developmental and reproductive toxicity of various drugs and other environmental contaminants and for the study of additional agents causing acute, chronic, and developmental neurotoxicity in mammalian neuronal tissues, including those from knockout mice and humans.

**378f** Noninvasive Magnetic Resonance Imaging Marker of White Matter Neurotoxicity Caused by Hexachlorophene in the Rat Brain

S. Lischken1, J. Ramu1, S. Sarfar2, M. G. Paule3, L. Schmed1 and J. P. Hampt1, 1Division of Neurotoxicology, NCTR/FDA, Jefferson, AR and 2Office of Testing and Research, CDER/FDA, White Oak, MD.

Neurotoxicity assessment in drug development is accomplished using microscopic analysis, which may require different types of histological staining depending upon the type of damage to be assessed. Histopathology studies can be time consuming and easily miss lesions if the wrong stain or locus for tissue sample is selected. In this study we used magnetic resonance imaging (MRI) to detect presumably neurotoxic changes in the rat brain caused by hexachlorophene (HC). Adult male Sprague-Dawley rats (N = 7, 347 ± 20 g) were given either HC (30 mg/kg, N = 5) or pure vehicle (corn oil, 1 ml/kg, N = 2) orally once a day for 5 consecutive days. Animals were imaged using MRI T2 mapping before the treatment and at 4 and 6 days after the start of the treatment. At the time of imaging, animals were anesthetized with isoflurane and positioned inside a 7 tesla MRI scanner. T2 relaxation mapping of the whole brain was performed at a resolution of 0.2 x 0.2 x 1.0 mm per pixel. All rats were perfusion-fixed at the end of the observation and their brains underwent histopathological assessment using aminocumarin silver (classic neurotoxicity) and black gold (white matter damage) stains. MRI revealed significant increases in T2 values in all HC-treated animals in areas which correspond closely to white matter. Histological sections stained with aminocumarin silver did not show any damage in HC-treated rats and were classified as 'normal' by a neuropathologist. However, black gold-stained sections revealed the vast damage to white matter, which was seen in the non-invasive MRI scans. Controls treated with corn oil did not exhibit any changes in MRI scans or histology. These data suggest that MRI can be used to detect neurotoxic changes of the brain and could be used to guide not only the loci for histopathology sectioning but also the type of stain used for histopathological studies. (Supported by NCTR and CDER, FDA, #E0741801).

**378g** Mitochondrial Bioenergetics in Young, Adult, Middle-Age, and Senescent Brown Norway Rats

J. D. Pandy1, A. Sebastian1, L. E. Rowland3, R. C. MacPhail1, P. G. Sullivan1 and P. S. Kodavanti1, 1Neurotoxicology Branch, US EPA, Research Triangle Park, NC, 2Dept of Anatomy and Neurobiology, University of Kentucky, Lexington, KY and 3Genetic and Cellular Toxicology Branch, US EPA, Research Triangle Park, NC.

Mitochondrial and central regulators of energy homeostasis and may play a pivotal role in mechanisms of cellular senescence and age-related neurodegenerative and metabolic disorders. However, mitochondrial bioenergetic parameters have not been systematically evaluated under identical physiological conditions within multiple organ samples in diverse age-groups. In the present study, we used the Seahorse Extracellular Flux Analyzer (SeaKem Bioscience XF-24) to measure four different life-tasks [i.e., 1 Month-Young (Y), 4 Month-Adult (A), 12 Month-Middle-Aged (M) and 24 Month-Old-Aged (O)] of Brown Norway rats (n=5 animals/group). Mitochondrial (15-40 µg/ml) bioenergetic parameters were evaluated together from five brain regions [brain stem (BS), frontal cortex (FC), cerebellum (CER), striatum (STR), hippocampus (HIP)] and three peripheral organs [heart (HRT), liver (LVR), lung (LNG)]. In general, all the regions of the brain followed identical patterns where the maximal respiratory capacities (State V and State V叔) were reduced with age (Y>A>M-O). The State III respiration in BS, CER and HIP demonstrated a similar pattern like State V (Y>A>M-O); whereas the FC and STR displayed highest State III rates in adult group (A>Y>O). The proton leak (State IV) remained unaffected in peripheral organs. In cerebral cortex, the State V and State III rates were highest in younger animals followed by gradual decline with aging as evident in both HRT (Y>A> O>M) and LNG (Y>A> O>M). In LVR, the NADH-linked bioenergetics remained unchanged whereas the FADH-linked maximal respiratory (State V叔) rates increased gradually as a function of age (Y>A>M-O). In summary, the comparative data analysis of this study gives valuable insight into the metabolic status of various organs that could potentially lead to age-associated changes in neurodegenerative or metabolic disorders. Additionally, the observed changes in mitochondrial bioenergetics will serve as a basic platform to elucidate chemically-induced life-stage susceptibility mechanisms important in community health-related research. (This abstract does not necessarily reflect USEPA policy).

**378h** Optineurin Expression in Dopaminergic Neurons and Response to Parkinson’s Disease Relevant Insults

J. Wise1, Z. S. Apin1, M. A. Tambe1, J. Rochet1 and J. R. Cannon1, 1Biology and Biomedical Science, Salve Regina University, Newport, RI, 2Laboratory of Neurochemistry and Neurotherapeutics, University of Massachusetts, Amherst, MA, 3Department of Molecular and Cellular Biology, University of Massachusetts, Amherst, MA, 4Bayer CropScience, Research Triangle Park, NC, 5Syngenta Crop Protection, Greensboro, NC, 6Ag-chem Consulting, Gilfion, VA, 7EMC, Ewing, NJ and 8Vet Brain Matter Neurotoxicity Caused by Hexachlorophene in the Rat

Optineurin (OPTN) is a protein that was first identified in 1998 as a genetic factor in normal tension glaucoma. Since then, multiple functional roles have been identified for OPTN, including roles in vesicle trafficking, Golgi organization, induction of macroautophagy and cell cycle. Recent data has also shown that OPTN aggregates in sensitive neurons in several neurodegenerative diseases, including Parkinson’s disease (PD). The characteristic pathology of PD includes the aggregation of α-synuclein into Lewy bodies and the progressive loss of DA neurons in the substantia nigra. Macroautophagy is a primary route for degradation of α-synuclein but is dysregulated in PD. Currently, data on potential roles for OPTN in the pathogenesis of PD is very limited. Given OPTN’s roles in many cellular pathways implicated in PD pathogenesis, we wished to characterize basal brain expression and response to dopaminergic (DA) neurotoxins. Here, for the first time, we show immunohistochemical evidence that OPTN is enriched in the pars compacta region of the substantia nigra of untreated rats, in cells with a morphology characteristic of dopaminergic neurons. In primary rat mesencephalic cultures containing dopaminergic and nondopaminergic neurons, OPTN was primarily localized in DA neurons. We also demonstrate increased OPTN expression in DA neurons after methamphetamine exposure, compared to control, assessed by quantitative immunofluorescence. These data demonstrate that OPTN has high expression in
future directions of research, prioritizing a multidisciplinary approach. Dietary factors, obesity, and dysregulation in puberty onset have been reported. The study of these factors is crucial for understanding the determinants of pubertal timing. It has been demonstrated in animal and human studies that a highly heterogeneous group of exogenous substances interfering with the hypothalamic-pituitary-gonadal axis can alter pubertal timing. This phenomenon has been observed in various populations around the world and is known as the “pubertal transition.”

Pubertal timing significantly varies among individuals, and recent studies have demonstrated a progressive decrease in age of onset of puberty in children around the world. This is generally accepted to be due to a complex interaction between genetic, neuroendocrine, and environmental factors, acting in concert with one another in each individual. Determining the underlying mechanisms has been demonstrated in animal and human studies, and understanding these mechanisms can lead to the identification of new biomarkers for the early detection of pubertal disorders.

The purpose of this informational session is to broaden the dialog around the necessary steps for translating DIDI biomarkers for use in drug discovery and development, as well as highlighting ongoing research related to the discovery and validation of DIDI biomarkers across species. Traditional parameters used to detect DIDI include serum creatinine (sCr) and blood urea nitrogen (BUN). In all species, sCr and BUN lack sensitivity and/or specificity in detecting early stages of renal tissue injury identified by routine histopathology. The Critical Path Institute’s Predictive Safety Testing Consortium, the Foundation for the National Institutes of Health, the International Life Sciences Institute-Health and Environmental Sciences Institute (ILSI-HESI), and the European Union Innovative Medicines Initiative (IMI) Safer and Faster Evidence-Based Translation program are in the process of identifying and validating novel biomarkers of kidney injury and dysfunction.

Eight novel urinary protein kidney biomarkers have already been qualified for specific “context of use” in rat preclinical safety studies. Ongoing qualification of additional biomarkers in rats will be discussed. The potential utilities for the qualified rat renal biomarkers in canines and nonhuman primate preclinical toxicology studies will be reviewed. Paramount is the need for qualified renal biomarkers that allow for the monitoring of DIDI in the clinical setting. Efforts have been focused on bridging the gap between biomarkers being qualified in rats to nonrodent species and humans. During this informational session, selected data and other relevant information will be presented that underpins our overall translational strategy for the qualification of biomarkers in rodents leading to the qualification of safety biomarkers for use in the clinical trials.
383 Effects of Nitrated Fatty Acids on Phthalate-Induced Inflammation in Neonatal Neutrophils

M. Mohammed1, F. E. Archer1, S. Gowda1, J. Akbukhrah1, I. Malik1, D. L. Laskin2, B. Weinberger1 and A. M. Vetrano1.

Rationale: Hospitalized infants are exposed to numerous devices that contain the plasticizer di-(2-ethylhexyl)phthalate (DEHP). Metabolites of DEHP, including mono-(2-ethylhexyl) phthalate (MEHP), are markedly elevated in the urine of premature infants and have the ability to alter neutrophil function. MEHP binds PPAR-γ, a nuclear transcription factor that mediates the resolution of inflammation, and is a process that is developmentally impaired in neonatal neutrophils. Nitroalkene derivatives of fatty acids (NO-FA), such as linoleic acid (LA, LNO), and oleic acid (OA, OA-NO3), are formed naturally in the body and are potent PPAR-γ ligands. We hypothesized that NO-FA would suppress the effects of MEHP by competitively binding to PPAR-γ. Methods: Neutrophils from umbilical cord and adult peripheral blood were isolated by density centrifugation and treated with LA, OA, LNO3, OA-NO3 (1μM) or medium control, in the presence or absence of MEHP (100-500 μM). H2O2 production was measured by Amplex Red assay. Cytokines were measured by cytomtric bead array analysis, and gene expression was measured by qPCR.

Results: MEHP induces dose dependent increases in H2O2 production and Cox-2 expression in neonatal neutrophils. Both OA-NO3 and LNO3 inhibit MEHP-induced hydrogen peroxide production and cyclooxygenase-2 (Cox-2) expression in neonatal neutrophils. While OA and LA did not inhibit hydrogen peroxide production, they were effective inhibitors of Cox-2 expression. OAN3 inhibited both basal and MEHP-stimulated IL-1β production.

Conclusions: These data demonstrate that nitrated lipids are capable of down-regulating MEHP-induced effects on neonatal neutrophil activity. Nitrated fatty acids are generated physiologically from dietary lipids. Our findings suggest that specific dietary alterations may help reduce the burden of inflammatory diseases in hospitalized neonates.

385 3, 3-Diindolylmethane (DIM) Ameliorates SEB-Induced Acute Lung Injury: A Role for microRNA

D. M. Elliott, P. S. Nagarkatti and M. Nagarkatti.

Pathology, Microbiology and Immunology, University of South Carolina School of Medicine, Columbia, SC.

Acute lung injury (ALI) and acute respiratory distress syndrome (ARDS) are characterized by pulmonary infiltration, hypoxemia, and edema. Among other etiologies, inhalation of toxic substances can lead to this serious condition. Staphylococcal enterotoxin B (SEB), a CDC select agent and public health threat during nosocomial infections, can be used to model ALI. Current clinical therapies for ALI and ARDS remain unreliable and mortality rates are still high. 3,3-diindolylmethane (DIM), a dietary compound found in cruciferous vegetables, has been recently shown to have anti-inflammatory properties and provides a potential therapeutic for ALI. We studied the mechanism underlying the ameliorative effects of DIM on SEB-induced ALI. Mice were exposed to SEB [50 mg; intranasal] and administered DIM [100 mg/kg] via oral gavage. Forty-eight hours after SEB exposure, serum, lung tissue and lung infiltrating mononuclear cells were collected. DIM treatment led to a decrease in lymphocytic infiltration, specifically CD4+, CD8+ and αβ+ T cells. DIM also led to a reduction of vascular leakage in lungs. Isolated mononuclear cells were subjected to high throughput microarray analysis to ascertain global microRNA expression levels. SEB led to dramatic microRNA dysregulation; in particular, modulating miRNAs such as miR-34a, -13a [decreased] and miR-21, -222 [increased], which were reversed in DIM treated mice. These microRNA have various gene targets dispersed throughout the apoptotic and cell cycle pathways, including SIRT1 and Bcl-2, as well as p27kip1, PUMA, CCND1, and CDK6, respectively. Moreover, DIM [10, 25, 50 μM] induced apoptosis in splenocytes and CD3+ T cells treated in vitro with SEB in a dose-dependent manner. Together, these studies demonstrate that DIM treatment may suppress SEB-mediated ALI by induction of apoptosis in T cells via alteration in expression of miRNA.

384 Lipidomic Changes in the Pancreas and Plasma of Hepatic Alcohol Dehydrogenase-Deficient Deer Mice after Long-Term Ethanol Feeding

H. Fernando, K. K. Bhopale, G. A. Ansari and B. S. Kaphalia.

Pathology, The University of Texas Medical Branch, Galveston, TX.

Alcoholic pancreatitis (AP) is a major disease causing significant morbidity and mortality among chronic alcohol abusers. Disregulation of lipid metabolism is one factor that is involved in the early stage of AP can lead to inflammation and fibrosis and may be pancreatic cancer in some cases. However, the mechanism of AP is not well understood due to the lack of a suitable animal model. Earlier, we reported pancreatic injury and a significant endogenous formation of fatty acid ethyl esters (FAEEs) in the pancreas in hepatic alcohol dehydrogenase (ADH)-deficient (ADH-) deer mice fed 3.5 % ethanol daily for 2 months. Therefore, we evaluated the lipidomic changes and FAEE levels in the lipids extracted from the pancreas and plasma of ADH- deer mice fed ethanol for 3 or 6 months using 800 MHz proton (1H)-NMR spectroscopy and GC-MS. NMR data was analyzed by hierarchical clustering and principal component analysis. Pancreatic and plasma total lipid levels increased in mice fed ethanol daily for 3 months, but decreased for those fed daily for 6 months. Decreases were found for phosphatidycholine (PC) related protons in plasma of mice fed ethanol for 3 or 6 months while this change was significant only at 3 months in the pancreas. However, peaks corresponding to the protons of the dialylic group were increased in the pancreatic lipids as compared to a decrease at 3 months and an increase at 6 months in the plasma. The increased signals of FAEEs in the pancreas were confirmed by GC-MS analysis. Our findings suggest that metabolism of ethanol under hepatic ADH deficiency (a metabolic condition found during chronic alcohol abuse) generates FAEEs and decreases PC resulting in mild fatty deposition in the pancreas and its progression to pancreatitis with increasing the duration of ethanol feeding.

In response to excessive nucleotide-binding oligomerization domain–containing protein 2 (Nod2) stimulation caused by mucosal bacterial components, gut epithelia need to activate regulatory machinery to maintain epithelial homeostasis. Activating transcription factor 3 (ATF3) is a representative regulator in the negative feedback loop that modulates TLR-associated inflammatory responses. In the current study, the regulatory effects of ribosomal stress-induced ATF3 on Nod2-stimulated pro-inflammatory signals were assessed. Ribosomal inactivation caused persistent ATF3 expression that in turn suppressed pro-inflammatory chemokine production facilitated by Nod2. Decreased chemokine production was due to attenuation of Nod2-activated NF-κB and early growth response protein 1 (EGR-1) signals by ATF3. However, the underlying molecular mechanisms involve two convergent regulatory pathways. Although ATF3 induced by ribosomal inactivation regulated Nod2-induced EGR-1 expression epigenetically through the recruitment of histone deacetylase 1, NF-κB regulation was associated with posttranscriptional regulation by ATF3 rather than epigenetic modification. ATF3 induced by ribosomal inactivation led to the destabilization of p65 mRNA caused by nuclear entrapment of transcript-stabilizing human Ag R protein via direct interaction with ATF3. These findings demonstrate that ribosomal stress-induced ATF3 is a critical regulator in the convergent pathways between EGR-1 and NF-κB, which contributes to the suppression of Nod2-activated pro-inflammatory gene expression. (This work was carried out with the support of “Cooperative Research Program for Agriculture Science & Technology Development (Project No. PJ008405032012)” Rural Development Administration, Republic of Korea.)
Role of TRIF and MAP Kinases in TLR3 & 4-Mediated Regulation of Drug Metabolizing Enzymes and Transporters

P. Shah, R. Ghose, T. Guo and O. Omolsabi. Pharmaceutical and Pharmacological Sciences, University of Houston, Houston, TX.

Purpose: The expression and activity of hepatic drug metabolizing enzymes and transporters (DMET) is altered on activation of an inflammatory response by bacterial or viral components. Inflammation in the liver is mediated primarily by the Toll-like receptors (TLR). TLR3 and TLR4 mediate responses by viral and gram -ve bacterial components respectively, through adaptor molecules Toll/interleukin (IL)-1 receptor (TIR) domain containing adaptor protein and TIR domain containing adaptor inducing interferon (IFN)-β (TRIF). We have shown TLRs regulate gene expression of DMET however, the mechanism by which TLR signaling regulates these genes is not known. We hypothesize that TRIF and MAP kinases (MAPK) play a role in down-regulation of DMET through TRIF and TLR4.

Methods: Male, TRIF+/+ or TRIF−/− mice (6-8 weeks) were treated with saline, Poly I:C (5mg/kg) or LPS (2mg/kg) for 8 and 16h respectively. Liver tissues were harvested and stored at -80°. To assess the roles of MAPK, primary hepatocytes were isolated from C57BL/6 mice and treated with and without the following inhibitors: JNK (SP600125, 10µM), ERK (PD98059, 20µM) and p38 (SB203580, 25µM) for 30 min followed by treatment with Poly I:C (50µg/ml) or LPS (1µg/ml). RNA was extracted from livers/cells and gene expression was analyzed by qPCR analysis.

Results: In TRIF+/- mice, Poly I:C treatment led to down-regulation of Cyp3a11, Cyp2a4, Cyp1a2, Cyp2e1, Ugt1a1, Mrp2 genes where as LPS treatment led to down-regulation of Cyp3a11, Cyp2a4, Ugt1a1 and Mrp2 genes. Surprisingly, this down-regulation was not attenuated in TRIF−/− mice. In hepatocytes, Poly I:C and LPS down-regulated the gene expression of DMET in the absence of inhibitors. While JNK inhibitor completely attenuated the down-regulation, p38 and ERK inhibitors did not affect down-regulation of DMET through TLR3 or TLR4.

Conclusion: These results show that down-regulation of DMET through TLR3 & 4 is dependent on JNK where as it is independent of the adaptor protein TRIF.

Regulation of Drug Metabolizing Enzymes and Transporters

Coculture of Hepatocytes and Kupffer Cells As an In Vitro Model of Inflammation and Liver Hepatotoxicity

K. Rose, N. S. Holman, M. E. Anderson and E. LeChuy. The Hammer Institutes for Health Sciences, Research Triangle Park, NC.

Immune-mediated chemical-induced hepatotoxicity, i.e. indirect hepatocellular toxicity resulting from immune cells activating liver inflammatory responses, is often overlooked as a potential mode of action due to unavailability of appropriate in vitro models. We have established an in vitro rat co-culture model using Kupffer cells (KC) and hepatocytes (HC) to study how inflammation impacts chemically induced effects on liver. Optimal cell culture conditions have been identified to maintain HC, KC, and KC/HC co-cultures for 48 hours with varying doses of chemicals +/- LPS, representing diversity in the cytokine profiles that may be reflective of compound-specific mode of action in vivo.

Intratracheal Bleomycin (ITB) induces pulmonary injury, inflammation, resolution and subsequent fibrosis. We hypothesize that recruited cells are critical for the inflammatory process, while resolution is dependent upon resident cells. To study the cell populations involved in ITB we used green fluorescent protein (GFP) chimeric mice. Recipient bone marrow was ablated with X-ray radiation and subsequently replaced with GFP+ bone marrow cells. Following 6 weeks of recovery, mice were either intratracheally instilled with saline or 3units/kg bleomycin. Mice were sacrificed at (inflammation phase) or 14 days post ITB. Bone marrow cells and BAL cells were collected and analyzed by flow cytometry. The mean bone marrow replacement was 85% ± 5% GFP+. While resident alveolar macrophages were GFP-, 8 days post injury, GFP- populations were similar between groups in number and appear as mature macrophages (F4/80+ CD11c+). The recruited populations, GFP+, are also primarily F4/80+ CD11c+. In saline treated mice the GFP+ cells are unactivated (CD11b(low)Ly6C−). In ITB treated mice these cells are activated (CD11b(high)Ly6C+). At 15 days there is minimal change in either resident or recruited cell populations with respect to 8 days for saline treated mice. However, in ITB treated mice GFP+ F4/80+ CD11c+ cells are reduced in number, while GFP+F4/80+ CD11c− Ly6C+ are increased in relative quantity. In addition, a novel population of F4/80+ CD11c− is seen in both recruited and resident cells. Recruited but not resident F4/80+ CD11c− cells are activated as they are Ly6C+. We propose that the GFP+ F4/80+ CD11c− cells are resident macrophages that are mediating the resolution process. These studies show that only recruited cells display an acute activation profile in response to ITB at either 8 or 15 days. However, resident cells do differentiate their phenotype by 15 days post ITB, possibly as a mechanism to mediate resolution. Supported by NIH grants F31GM108463, HL086621, TESS05022

Inhalation Exposure to the Tobacco Smoke Component Acrolein Enhances Allergic Responses to Ovalbumin

E. O’Brian1, P. Spiess1, A. Habibovic2, M. Hristova2, R. A. Bauer2, M. J. Randall1, M. E. Poynter2 and A. van der Vliet1. 1Pathology, University of Vermont, Burlington, VT and 2Medicine, University of Vermont, Burlington, VT.

Acrolein, an α,β-unsaturated aldehyde generated in part through cooking oils and smoking tobacco, is a highly reactive electrophilic respiratory irritant implicated in asthma pathogenesis. However, few studies have directly investigated the influence of acrolein exposure on allergic sensitization and pulmonary inflammation. This study uses a murine inhalation model to examine whether inhaled acrolein alone or in combination with inhaled ovalbumin (OVA) enhances allergic sensitization to subsequent OVA challenge. Adult male C57BL/6 mice were sensitized to inhaled OVA (1%, 30 min/day, 4 days/week) and/or inhaled acrolein (5 ppm, 4 h/day, 4 days/week) over 2 weeks before challenge with aerosolized OVA (1%, 30 min/day) over three days. Sera, bronchoalveolar lavage (BAL) fluids, and lung tissues were collected after OVA challenge to assess pulmonary inflammation and allergic sensitization. Serum anti-OVA IgG1 levels were increased 4-fold in animals sensitized to both OVA and acrolein, compared to animals sensitized to OVA alone or acrolein alone. In addition, differential cell counts revealed an increase in BAL neutrophils among animals sensitized to OVA and acrolein. Acrolein sensitization was also observed to increase lung mRNA levels of Il13 and Il1a. Interestingly, exposure to both OVA and acrolein did not influence Il13 and Il1a mRNA levels, though it did significantly increase Ccl20 mRNA levels. This study suggests that prolonged inhalation can enhance allergic sensitization and lead to worsened airway inflammation.

Effects of Current Tobacco Exposure on T Cell Immune Responses

U. C. Nygaard3, 2, K. M. Hew1, S. Mackey3, L. Jack4, G. E. Swan4, R. Krasnow4, S. Runyon1, H. T. Maecker3, C. L. Dekker3 and K. Nadeau1. 1Dept of Pediatric Allergy and Immunology, Stanford University, Stanford, CA, 2Div. of Environmental Medicine, Norwegian Institute of Public Health, Oslo, Norway, 3Stanford University, Stanford, CA and 4Center for Health Sciences, SRI International, Menlo Park, CA.

Epidemiological studies have shown that smokers suffer from more frequent infections and infectious complications. The scope of the present study was to test the hypothesis that tobacco smoke exposure (TSE) modulates T cell function, thereby leading to impairment of cellular and humoral responses to the influenza vaccine. Monozygotic twins (MZT) ages 3 to 55 yrs were studied. Each participant’s PBMC immune profile was determined 7 days after flu immunization by measuring expression of 37 different cell surface markers using CyTOF analyses and 51 different serum proteins using Luminesix technology. Influenza vaccine responses were quantified by hemagglutination inhibition (HAI) 28 days after immunization. Associations between TSE and a selection of T cell subsets, some related serum cytokines and vaccine responses were investigated by comparing twins discordant for TSE (i.e. ever smoked vs. never smoked) and concordant for TSE (i.e. both ever smoked or both never smoked).
The percentage of T cells, CD4+, CD8+ and regulatory T cells (p<0.001), as well as serum levels of IFNγ, IL-5 and TNFα (p<0.05), were significantly lower in ever smoking individuals compared to their non-smoking twins (n=16 pairs). If restricted to only current smokers (n=12), stronger significances were seen (p≤0.0002). No differences were seen between TSE concordant twins. Preliminary results indicate no significant differences (p>0.94, n=4 pairs) in vaccine responses between smoking and non-smoking twins, but a larger number of current smokers is needed to draw conclusions.

Overall, our preliminary data suggest that current tobacco smoke exposure may affect T cell immune responses and related cytokines, which may have implications for the development of immune diseases and infection resistance.

**392 Exposure to Sidestream Tobacco Smoke Induces Airway Hyperresponsiveness and Inflammation in Early Postnatal Mice**

There are abundant epidemiological studies linking early environmental tobacco smoke (ETS) exposure with childhood asthma. The present study was designed to determine changes on airway responsiveness and innervation after ETS exposure during early postnatal period. The postnatal day (PD) 2 mice were exposed to either ETS or filtered air (FA) for 10 consecutive days. Lung function, substance P (SP) airway innervation, and nerve growth factor (NGF) and cytokines in bronchoalveolar lavage (BAL) fluid were measured 1, 3 and 7 days after last ETS exposure. 1 day after the last ETS exposure, airway responsiveness and SP innervation in airway smooth muscle were significantly increased, as well as altered airway inflammation, which include significant elevated levels of IL-1β, IL-4, IL-6, IL-10, TNFα and INFγ in BAL compared with FA exposure. Interestingly, 3 days after ETS exposure, airway hyperresponsiveness and SP innervation in airway smooth muscle remained elevated, parallel with high levels of IL-1and NGF. These results indicated that the change in SP airway inflammation play an important roles in airway inflammation and hyperresponsiveness induced by ETS exposure during early in life.

**393 Comparison of Proinflammatory Cytokine (IL-6 and IL-8) Release from Two Types of Cells Exposed to Mainstream Cigarette Smoke Total Particulate Matter**

X. Li, P. Shang, F. Xie, H. Liu and J. Xie. *Key Laboratory of Tobacco Chemistry, Zhengzhou Tobacco Research Institute of CNTC, Zhengzhou, Henan, China.* Sponsor: R. Meng.

Mainstream cigarette smoke is a complex aerosol consisting of thousands of chemical compounds and oxidants, which can cause cellular oxidative injury and inflammation involved in the development and progression of human respiratory diseases such as chronic obstructive pulmonary disease (COPD). Many cell lines are available to be used as the *in vitro* models for investigating the mechanisms of cigarette smoke-induced diseases. Different types of cells can respond to cigarette smoke-induced toxicity differently. AS49 cells (human adenocarcinoma cells) and BEAS-2B cells (human bronchial epithelial cells) widely used in many laboratories are representative two types of cells. The purpose of this study was to compare the difference in proinflammatory cytokine release from two types of cells in response to cigarette smoke total particulate matter (TPM). Cells were exposed to TPM for 24 h. The neutral red uptake (NRU) assay was employed to assess the cytotoxicity of cigarette smoke, and the levels of proinflammatory cytokine (IL-6 and IL-8) were measured by ELISA. The results showed that BEAS-2B cells were more sensitive to smoke-induced cytotoxicity than AS49 cells. TPM of mainstream cigarette smoke caused dose-dependently increase of cytokine IL-6 and IL-8 release from BEAS-2B cells. While the induction of IL-6 and IL-8 release from AS49 cells was not impacted after TPM exposure, and in contrary, the release of IL-6 and IL-8 decreased with the concentration of TPM solutions increased, compared to control cells. These results indicate that the inflammatory response to cigarette smoke can be different depending on the characteristic of cells, and non-tumor cells might be an appropriate model for investigating the smoke-induced inflammatory mechanisms.

**394 The Effects of Ozone Exposure on Inflammasome Activation and Heart Failure during CVB3 Myocarditis**

M. M. Aladdin, A. Bucek and D. Fairweather. *Environmental Health Science, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Ozone (O3) is a common secondary air pollutant that contributes to increased morbidity and mortality. Studies have shown a positive correlation between O3 exposure and emergency department visits for the exacerbation of pulmonary conditions. Ozone is also linked to cardiovascular conditions such as cardiac ischemia and heart attacks. In this study, we explored the effects of O3 on heart failure (HF) during coxsackievirus B3 (CVB3) myocarditis. Myocarditis is an autoimmune disease that is characterized by inflammation of the myocardium with or without cardiomyocyte damage. Viral infections, such as CVB3, are the most common cause of myocarditis in the US. Myocarditis is a very important public health issue as it goes largely undiagnosed, and can progress to other conditions like HF and dilated cardiomyopathy (DCM). The Fairweather lab found marked sex differences in the incidence and severity of disease; and has established that testosterone increases myocarditis and DCM in mice with CVB3 myocarditis by increasing IL-1β and the inflammasome. Air pollution can exacerbate the underlying inflammation in myocardium and drive HF. O3 has been shown to increase this pathway in the lung.

We hypothesized that O3 exposure during CVB3 myocarditis activates the inflammasome via TLR4 and increases IL-1β, which may drive HF in males. We explored this hypothesis by injecting 8-10 week old BALB/c mice with CVB3 or PBS intraperitoneally at day 0, and then exposing them to either room air (RA) or ozone (O3) at 0.3 ppm, continuously for 48 hours at days 8 and 9. Mice were subsequently sacrificed at day 10. The interaction of CVB3 and O3 increased protein expression of IL-1β. Furthermore, pressure-volume loop data showed that simultaneous exposures to O3 and CVB3 increased the risk for HF in mice. To our knowledge, this is the first study to explore the interaction between CVB3 infection and O3 exposure in HF. Through this study we can provide a mechanistic explanation for how air pollution increases the risk for cardiovascular events.

**395 Role of Spleen Monocytes (Mo) in Ozone-Induced Lung Inflammation and Injury**

M. Francis, M. Mandal, H. Choi, J. D. Laskin and D. L. Laskin. *Rutgers University, Piscataway, Nj.*

Ozone is a ubiquitous air pollutant known to damage the lung. Activated macrophages (MP) have been implicated in ozone toxicity; however, the origin and phenotype of these cells is unknown. Evidence suggests that the spleen functions as an extramedullary source of inflammatory monocytes (Mo). In these studies we used spleenectomized (SPX) mice to assess the contribution of spleen Mo to the pulmonary inflammatory response to inhaled ozone. Lung, spleen, and bone marrow were collected 24-72 h after exposure of mice to ozone (0.8 ppm, 3 h) or air and analyzed by flow cytometry. Ozone caused increases in bronchoalveolar lavage (BAL) protein and MP, markers of lung injury and inflammation. Resident alveolar MP from control animals expressed F4/80 and Cd11c+, but not Cd11b+. Following ozone exposure, increases in immature Cd11b+F4/80+ and mature Cd11b+F4/80+ MP were observed in the lung. Subpopulations of these cells were identified that expressed high and low levels of the proinflammasome Mo/MP marker, Ly6C+. Both immature Cd11b+F4/80-Ly6Chi and mature Cd11b+F4/80+Ly6Chi proinflammatory MP increased in the lung after ozone, reaching a maximum at 48 h. This correlated with a decrease in Cd11b+Ly6Chi Mo in the spleen. Conversely, Cd11b+F4/80-Ly6Chi proinflammatory Mo increased in the bone marrow. Splenectomy resulted in a decrease in the total number of inflammatory cells in the lung after ozone, and reduced tissue injury. Flow cytometric analyses revealed a reduction in immature (Cd11b+F4/80-Ly6Chi) and mature (Cd11b+F4/80+Ly6Chi) proinflammatory MP in lungs of SPX mice, but increases in mature Cd11b+F4/80+Ly6Chi anti-inflammatory MP. Cd11b+F4/80-Ly6Chi immature proinflammatory Mo in bone marrow of ozone-treated SPX mice were also decreased relative to sham control. These data suggest that the spleen is a source of proinflammatory/cytotoxic MP that contributes to ozone-induced lung injury. Moreover, in the absence of this splenic reservoir, there is a compensatory increase in inflammatory cells generated in the bone marrow. Supported by NIH ES004738, CA132624, AR055073, ES007148 and ES005022.
Subsequent Ozone Exposures In Vitro Result in Attenuation of Inflammatory Response
E. C. Bowers1, 2, S. D. McCullah3, L. A. Dailey4 and D. Draz-Sanchez4. 1UNC Chapel Hill, Chapel Hill, NC and 2United States Environmental Protection Agency, Clinical Research Branch, Chapel Hill, NC.

Approximately 133 million residents of the United States live in areas where ozone levels exceed the National Ambient Air Quality Standards. Some of these regions may experience such exceedances on a daily basis. While the health effects of acute ozone exposure are well documented, the effects of chronic exposures are less understood. Given that many people are exposed to harmful levels of ozone on a chronic basis, it is important to characterize the physiological effects of subsequent, daily exposures. Controlled human exposure studies have shown that response to ozone varies between acute and chronic exposure conditions. If only exposed to ozone for one to two days, subjects present with increased airway inflammation and decreased lung function. However, additional exposures up to six days result in the attenuation of these effects. We were interested in investigating the mechanism underlyng this phenomenon using an in vitro model. To accomplish this we used primary human bronchial epithelial cells from healthy volunteers grown in air-liquid interface culture and exposed them to 0.3 ppm ozone or clean air for two hours per day for seven consecutive days. Because inflammatory state varied between chronic and acute exposures, we chose to measure the expression of IL-8, IL-6, and IL1-β, as these are key mediators of inflammation. The expression of these genes peaked following a single day of ozone exposure. During subsequent days of exposure the ozone-mediated induction of pro-inflammatory mediators declined and eventually approached baseline levels. Thus daily ozone exposure in vitro produces a similar suppression of the pro-inflammatory response as observed in clinical studies. Using this model, we plan on identifying the central mechanisms responsible for this effect, which may include altered signaling pathways and epigenetic modifications. Understanding the health consequences of this effect may help identify and treat vulnerable populations.

Development of an In Vitro Functional Assay for Human Macrophages
A. Hudson, C. Bono, J. Whiteneout and S. Casinghino, Pfizer, Inc., Groton, CT.

Macrophages play a critical role in the defense against pathogens. Drugs being developed to treat inflammatory diseases often target macrophages, which are potent producers of cytokines and other inflammatory mediators. These drugs have the potential to compromise host resistance by inhibiting other macrophage functions (e.g. oxidative burst and phagocytosis) besides cytokine production. The objective of these studies was to develop an in vitro method to measure oxidative burst and phagocytosis in human monocyte-derived macrophages. CD14 positive monocytes were isolated from whole blood using magnetic beads and then stimulated with granulocyte macrophage colony stimulating factor to generate macrophages, and cultured for various incubation periods (from 2-9 days). The macrophage phenotype was verified using the CD206 and -HLA-DR antigens. The expression of microbeigen species (ROS) generation and phagocytosis were measured using FcOxyburst and pHrodo® Bioparticles, respectively. Assay conditions (4 days of culture and 50,000 cells per assay tube) and length of pre-incubation time with inhibitors were optimized for maximal viability and function of the macrophages. Typical assay results show that more than 50% of the CD206-expressing macrophages are phagocytic and more than 90% produce ROS. Cytochalasin D and N-acetyl cysteine were used to inhibit phagocytosis and ROS generation, respectively. Results showed that macrophage immune functions could be measured and inhibited in this assay. These data suggest that the macrophage function assay can be used as a tool for determining the potential of drug candidates to inhibit phagocytosis and oxidative burst.

Evaluation of Sex Sensitivity in Local Lymph Node Assay Using Acetophen and α-Hexylcinnamaldehyde
V. R. Dalal1, V. J. Piccirillo1, M. V. Patel1, R. Chhimwal2, N. Patel2, S. Jaiswal2, B. Prajapati2, D. R. Boverhof3, M. R. Woolhiser3 and V. Balakrishnan1. 1VIP Consulting, Inc, Ashburn, VA, 2Toxicology, Jai Research Foundation, Vadodara, Gujarat, India, 3TERC, The Dow Chemical Company, Midland, MI and 4Department of Zoology, Faculty of Science, The M.S. University of Baroda, Vadodara, Gujarat, India.

The current OECD Test Guideline for the conduct of the Local Lymph Node Assay (LLNA) recommends the use of only female mice for the assessment of skin sensitization potential for a given chemical. The NIH publication No. 99-4494 recommends that only female CBA mice be used, as they reportedly develop a greater tendency to fight and to be involved in ‘social ranking’ behavior when group housed. However, there are several advantages to consider with the inclusion of male mice in LLNA testing including a more refined and responsible use of animals. Therefore, to begin to systematically assess the appropriateness of using male mice in the LLNA a comparative guideline study was conducted with individual housing of mice using the sensitizer, Butachlor 50% EW (BU50) and α-hexylcinnamaldehyde (HCA) respectively. The study compared 5 male and 5 female CBAJ mice/group, at three BU50 concentrations [10%, 25%, 50% (w/v)] and a single HCA concentration [25%] using 1% lotic as the vehicle. Stimulation indices (SI) for the three BU50 treatment groups were 1.16, 1.58 and 1.59 for male and 0.39, 1.55 and 1.56 for females, respectively and SI for the HCA treated group were 4.31 for male and 5.44 for females. The results revealed no significant difference between samples means or variability between the sexes and the SI values observed for both male and female mice of positive control were within the range of historical control data for female mice. These data provide initial support for the use of male mice in the LLNA and will be followed by further experimentation.

Impact of Collection Site and Method on Blood Lymphocyte Subsets in Sprague-Dawley Rats

Immunotoxicology studies in rats often include peripheral blood collection from multiple anatomical sites, and can vary due to non-terminal or terminal collection. Differences in lymphocyte subset counts based on collection site in humans and mice have been recently reported. In order to better control for potential cell count differences between multiple anatomical blood sampling sites in rat research studies, lymphocyte cell counts were performed for samples from the lateral tail or saphenous veins (non-terminal) or inferior vena cava (terminal) of Sprague Dawley rats. Non-terminal samples were collected without anesthesia, and terminal samples were collected after CO2 overdose. Additional lateral tail vein samples were drawn after animals were heated to dilate the vein, for comparison to samples from non-heated animals. T, B, and natural killer (NK) cell subsets were evaluated using a flow cytometer.

In two separate studies, it was found that NK cell percentage and counts were increased, while T cell counts and percentages were decreased in inferior vena cava terminal samples compared to non-terminal samples. Cytotoxic and helper T cell counts were concomitantly lower in inferior vena cava samples relative to...
non-terminal samples. B cell and total CD45+ lymphocyte counts were not impacted by collection site. Pre-heating animals to dilate the lateral tail vein did not impact lymphocyte subset counts.

These results highlight the importance of understanding the possible impact of non-terminal and terminal blood collection, or collection from peripheral and central anatomic sites, on study design and data interpretation.

**401 The Guinea Pig Systemic Anaphylaxis Model Revisited**

J. Descotes1, M. Duclos2, V. Haag and R. Fontes2. 1Poison Center, Lyon, France and 2ToxLab, Evreux, France.

The guinea pig systemic anaphylaxis model was introduced decades ago to evaluate the sensitizing potential of pharmaceuticals and chemicals. After years of use, it was nearly abandoned, but is attracting renewed interest for the evaluation of pharmaceutical macromolecules or medical devices. As standardization of this model has been meager, the aim of this study was to analyze data obtained with the positive reference compound ovalbumin (OVA) using various experimental modalities. A total of 14 studies including 285 male Dunkin-Hartley guinea pigs were selected. Groups of 5 animals received 1, 2, 3 or 6 sensitizing injections of 0.2, 2 or 20 μg OVA by the intraperitoneal (0.5 ml), subcutaneous (0.1 ml) or intradermal route (0.1 ml). Few animals received aluminum hydroxide with the first sensitizing injection. The delay between the injections was 7 days, except in some animals (2 injections, 14 days apart). After a rest period of 7 or 14 days, the animals were challenged with 0.2 or 20 μg OVA (0.1 ml) via the penile vein (or the ear vein in rare animals). Controls received injections of saline using the same route, volume and injection schedule. Sensitization was evaluated from signs of anaphylaxis observed during a one-hour follow-up. The retrospective analysis of the results shows that the optimal sensitizing dose of OVA was 2 μg. Inconsistent results were obtained with 0.2 μg. Results were similar with the subcutaneous and the intradermal route, but were more variable with the intraperitoneal route. Similar clinical signs were observed after 2, 3 or 6 sensitizing doses with the same challenging dose, but were less consistent after 1 sensitizing dose. The optimal challenging dose of OVA was 20 μg and no overt differences were seen in animals given aluminum hydroxide. The conclusion of this retrospective analysis is that an optimal study plan consists of 2 sensitizing subcutaneous injections of 2 μg OVA with a 7-day interval followed by a challenging intravenous injection of 20 μg OVA after a 14-day rest period.

---

**402 Transferability and Reproducibility of the Myeloid U937 Skin Sensitization (MUSST) Test for Skin Sensitization Testing**

Skin sensitization is a disturbed immunological process in which a sensitizer is a substance that triggers an immunological cellular response. Initially, the substance penetrates the epidermis prior to the formation of a stable conjugate with skin proteins. This stable conjugate is then processed by the epidermal dendritic cells, which subsequently mature and migrate out of the skin to the local lymph nodes. The MUSST test method is modeling the dendritic cell activation upon exposure to sensitizers by means of measuring phenotypical changes in the U937 human myeloid cells. Like the dendritic cells, upon contact with sensitizers, U937 cells induce CD86 expression as they are activated. Cell viability is assessed using propidium iodide exclusion. Both parameters are measured by flow cytometry. The prediction model is defined by a stimulation index above 150 with a dose response relationship and at least 2 concordant experiments, for identifying a substance as Sensitizer S/Non-Sensitizer NS.

The aim of this study is to demonstrate the transferability and reproducibility of the MUSST in 4 laboratories and define its predictivity.

The main determinant of the test method reliability assessment was the concordance of classification. S/NS. The intra-laboratory reproducibility (WLR) study was assessed with 21 chemicals tested in 3 independent experiments within L’Oréal. Similar prediction was obtained resulting in a WLR of 95%. Eleven out of the 14 substances were consistently classified (S/NS) by the 4 laboratories resulting in an inter-lab reproducibility (BLR) of 79%. The BLR for the pair-wise comparisons was comprised between 86-93%.

To determine the predictive capacity of the MUSST, a set of 123 substances has been evaluated. The predictive capacity of the MUSST is 86.2% with a sensitivity of 86.1% and a specificity of 86.4%.

The MUSST is an efficient transferable and reproducible assay for the skin sensitization hazard characterization, promising as a tool to be integrated within a battery of assays to perform a skin sensitization risk assessment.

---

**403 Time Course Difference in Sensitivity and Sensitivity of Immunotoxicity of Cyclophosphamide in Female Swiss Albino Mice**

P. Mehta1, D. Gohel1, V. J. Piccirillo2, M. V. Patel1, S. Jadhav1, K. Shah1 and M. Pandya1. 1Toxology, Jai Research Foundation, Vadodara, Gujarat, India and 2VIP Consulting, Inc, Ashburn, VA.

The study was conducted to evaluate the time course difference in sensitivity and sensitivity of in-house bred female Swiss Albino mice to the immunosuppressive effect of Cyclophosphamide Monohydrate (CPM). The mice were treated with CPM by intraperitoneal administration for 4 consecutive days at dose levels of 5, 25 and 50 mg/kg body weight/day, dissolved in Phosphate Buffer Saline (PBS). Concurrent control group animals were dosed with vehicle (PBS) alone. On the first day of treatment, all animals were treated with SRBCs (Innovative Research, USA) in normal saline (8 x 107 RBCs) at fixed dose volume of 0.2 ml/animal intravenously. Eight animals from each group sacrificed on day 5 and four animals per group were sacrificed on day 15. Significant reductions in anti-SRBCs IgM antibody level, WBC count, neutrophil count and absolute and relative weight of spleen and thymus were observed in animals sacrificed on day 5 from groups treated with 25 and 50 mg of CPM/kg body weight whereas significant changes were not observed in animals treated with 5 mg/kg b. wt. dose. Animals sacrificed on day 15 showed no significant immunotoxic changes when compared to control group suggesting recovery. The effects observed in the 25 and 50 mg/kg dosed animals sacrificed on day 5 were consistent with immunotoxic effect of CPM seen in previous immunotoxicity studies in mice. Based on these results, it can be concluded that the time course for treatment and sacrifice of Swiss albino mice in immunotoxicity studies is critical and also demonstrates that in house Swiss Albino mice give responses similar to other recommended strains (e.g. B6C3F1 hybrid mouse).

**404 Quantitation of Leukocyte Subsets and Leukocyte Activation in Canine Blood Using a 7-Colour Flow Cytometry Assay**

A. J. Beavis, M. S. Perpetua, S. Harvey and G. Bannish. Biomarkers, Bionanalysis, and Clinical Sciences, Huntington Life Sciences, East Millstone, NJ.

We developed and validated a 7-colour flow cytometry assay to identify lymphocytes, monocytes, granulocytes, T cells, T cell subsets, B cells and HLA-D expression in canine whole blood. Six commercial antibody conjugates recognizing canine leucocyte antigens were used: CD3FITC, CD21PE, HLA-DP/EC5, CD4ECD7, CD8AFE674 and CD14AF647, in combination with the DNA-binding dye DAPI and the LiveDead viability dye. Whole blood (EDTA, 100 μl) was incubated with lysing buffer, washed and labeled with the viability dye. Cells were stained with CD3/CD21/CD4/CD8,CD14 and HLA or control, washed, fixed and incubated in DAPI. Counting beads were added and samples analysed on the flow cytometer. Data for frequency (%), absolute number (cells/μl) and HLA-D mean fluorescence intensity (MFI) were reported. Viable leucocytes were identified with DAPI and LiveDead stain. Monocytes were gated as the CD3-CD64-+ cluster from a plot of CD3/CD14 versus CD3. Lymphocytes were identified by light scatter and Boolean Logic to exclude monocytes. The T and B cells were identified by expression of CD3 and CD21 respectively and T cell subsets by expression of CD4 and CD8 antigens. Granulocytes were identified from a plot of side scatter (SSC) and CD4 with the granulocyte cluster expressing the CD4+ phenotype and a granulocyte subpopulation with CD4- phenotype. In naïve animals, differential MHC class II expression was observed on lymphocytes but not on granulocytes. Intra-assay precision of ≥ 20 % CV was demonstrated for all major cell types for frequency, absolute values and MFI. Whole blood was stable up to 24 h post-collection and stained samples stable up to 24 h when stored refrigerated. This assay was validated with acceptable precision, stability and robustness and is applicable for assessing the impact of test articles on leucocytes and leucocyte activation in canine peripheral blood.

---

**405 Comparison of the Lymphocyte Subpopulations from Peripheral Blood of CD1, CBA/J and Swiss Albino Female Mice following Administration of Cyclophosphamide Monohydrate**

D. Ujwane1, M. V. Patel1, V. J. Piccirillo2, K. Hadiya1, M. Shinde1, M. Poushiya1, D. Gohel1 and J. Mistry1. 1Department of Toxicology, Jai Research Foundation, Vadodara, Gujarat, India and 2VIP Consulting, Inc, Ashburn, VA.

The prevalent guidelines (OCSPP, 870.7800) for determination of immunotoxic potential recommend use of CD1 mice. Considering the diversity of strains existent with different toxicology labs, a comparative study of immunosuppressive activity induced by cyclophosphamide monohydrate (CPM) was evaluated in CD1, CBA/J and Swiss albino female mice.
The immunotoxicity of a compound is ideally determined by assessing all three components of an immunotoxicity evaluation. Future studies will include development of an assay to measure CTL function by direct assessment of antigen-specific target cell killing by non-human primate CD8+ T cells.

**Quantitative Immunophenotypic Analysis of Rat Thymocytes**

Quantitative immunophenotypic analysis of rat thymocytes is often required for the evaluation of test article effects; changes of thymocyte subsets reveal the test article effects and the severity of the effects. In this study, two methods for assessment of absolute thymocyte numbers were evaluated. Thymuses were harvested and weighed from 15 male and 15 female rats at 12 to 13 weeks of age. Single cell suspension was prepared and thymocytes enumerated for FACs analyses. Thereafter, two ways of absolute cell number evaluation were compared: cell number per thymus and cell number normalized by thymus weight. Cell number per thymus was positively correlated to thymus weight; heavier thymuses yielded more cells, thus male rats had more thymocytes per thymus compared to female rats (Mean±SD: 1136.7±296.4 million cells/thymus and 990.3±218.1 million cells/thymus for male and female rats, respectively). These variations (CV=25%) indicate that cell number per thymus is not a valid basis for calculation of absolute numbers for thymocyte subsets. However, when thymocyte numbers were normalized by thymus weight, results were more comparable among all rats (CV=14%) and between sexes (Mean±SD: 2714.1±359.8 million cells/g and 2712.0±421.5 million cells/g for male and female rats, respectively). Based on the weight normalized thymocyte number, absolute number could be calculated for thymocyte subsets: CD3- cells, CD3-CD4+CD8- cells, CD3-CD4-CD8+ cells, CD3-CD4+CD8+ cell, CD3+ cells, CD3+CD4+CD8- cell, CD3+CD4+CD8+ cells, and CD3+CD4+CD8+ cells. In conclusion, weight normalized thymocyte numbers are a valid basis for calculation of absolute numbers of thymocyte subsets. These absolute numbers can be used for statistical analyses to assess the effects of test articles on the thymus. Furthermore, because the variation of weight normalized thymocyte numbers is small between male and female rats, the two sexes can be combined for statistical analyses when animal numbers/sex/group are inadequate.

**Application of the KeratinoSens™ Assay for Assessing the Skin Sensitization Potential of Crop Protection Active Ingredients and Formulations**

B. S. Settiwarı, S. C. Gehen, R. Acosta Amado, N. Visconti, A. Natsch, E. W. Carney and D. R. Boverhoff, 1The Dow Chemical Company, Midland, MI, 2Dove AgroSciences LLC, Indianapolis, IN and 3Givaudan Schweiz AG, Dübendorf, Switzerland.

Recent regulations have advocated for the development of non-animal approaches that can reliably predict the skin sensitization potential of low molecular weight chemicals. The KeratinoSensTM assay has emerged as one of the most promising in vitro assays for predicting skin sensitization of single chemicals, however its performance with formulations and mixtures has not been previously addressed and is a significant need. To assess this potential application, the KeratinoSensTM assay was conducted for 8 crop protection active ingredients including 3 sensitizers (acetochlor, metyldinocap, triclopyr butoxyethyl ester), 5 non-sensitizers (aminopyralid, clopyralid, florasulam, methoxyfenozide, oxyfluorfen) and 10 correspond-
For immunotoxicology testing, there is a big demand to replace animal testing by in vitro experiments. Whole genome miRNA expression analysis on cells exposed to test chemicals in vitro promises to be a valuable option for this aim. The immunological response involves many different cell types. It is therefore likely that multiple immune cell types have to be included to enable adequate evaluation of immunotoxic hazard.

In this study, the value of the mouse thymoma EL-4 cell line as an in vitro screening model for immunotoxicity was assessed using two immunotoxic model compounds, the mycotoxin deoxynivalenol (DON) and the organotin compound tributyltin oxide (TBTO). EL-4 cells were exposed to 0.25, 0.5 and 1 mM DON for 3, 6 or 11 h or to 0.5 and 1 mM TBTO for 3 or 6 h. Biological interpretation of the microarray data revealed that part of the previously detected modes of action of TBTO and DON in the Jurkat T cell line were not observed in the EL-4 cell line. TBTO induced genes involved in calcium signalling and ER stress but did not induce genes involved in T cell activation and apoptosis. DON induced RNA related processes and ribosome biogenesis. Furthermore, DON downregulated ER stress, T cell activation and apoptosis which is opposite to the mechanism of DON observed in the mouse thymus in vivo and in Jurkat T cells in vitro. Apparently, EL-4 cells lack factors that are important to link ribotoxic stress to ER stress and cannot elicit a T cell activation response. Based on the results obtained for TBTO and DON, it can be concluded that the EL-4 cell line has no added value for immunotoxicogenomics based screening.

The Comparative Toxicogenomics Database (CTD; http://ctdbase.org) is a free resource that forms hypothesis development about environmental effects on human health. CTD content consists of manually curated chemical-gene-disease interactions, which are integrated with functional information, canonical pathways, and novel tools to infer relationships between chemical exposures and biological events. Here, we highlight new analysis and data visualization features of CTD, including the ability to generate novel pathways associated with chemicals and diseases. We also report results from a pilot project in which we expanded our curations to include relationships between chemicals and non-disease phenotypes (e.g., cell proliferation, adipogenesis). The goal of this project was to determine if including chemical-phenotype data in CTD could advance: a) understanding of environmental disease progression, b) identification of exposure biomarkers, and c) the capacity to conduct and interpret studies across species and experimental systems. We integrated chemical-phenotype and disease data from this pilot project and performed a two-dimensional hierarchical clustering that revealed 18 disease clusters with distinct phenotype profiles. Our results suggest the potential for this strategy to generate meaningful links between chemicals, early cellular phenotypes and diseases. We continue to expand the depth and functionality of CTD to meet the evolving needs of the environmental health research community.

Drug-induced liver injury (DILI) is one of the leading causes of drug development failures and drug withdrawals. DILIsym® is being developed to identify and mitigate DILI risk through in silico analysis of compounds. The DILIsym® representation of the innate immune response was initially based on acetaminophen (APAP) data. Carbon tetrachloride (CCl4), a compound with hepatoxic similarities to APAP, was simulated for further evaluation of the innate immune response to liver injury. DILIsym® simulation results for CCl4 pharmacokinetics were consistent with published PK data. CCl4 is generally thought to induce hepatotoxicity via a free radical metabolite which drives lipid peroxidation. However, when CCl4 was simulated via DILIsym®, free radical generation and lipid peroxidation to levels consistent with the public literature were insufficient to drive hepatotoxicity. Analysis demonstrated that saturation of the metabolic pathway generating the free radical limited the extent of lipid peroxidation and thus the extent of cell death. In comparison, the APAP metabolic pathway had a greater dynamic range, resulting in higher levels of lipid peroxidation and cell death. Papers were identified in which lipid peroxidation independent mechanisms of cell death were suggested, including lipid peroxidation independent mitochondrial toxicity. The CCl4 representation was modified to induce mitochondrial electron transport chain (ETC) inhibition. Concurrent induction of lipid peroxidation and ETC inhibition mechanisms permitted reconciliation of simulated hepatotoxicity with published data. For exam-
ple, >3x ALT elevations were simulated at doses >50 mg/kg, with the highest ALT elevations (>1000 U/L) at doses >100 mg/kg in mice. Simulated CC14 was then used to evaluate and further refine the innate immune response. In summary, quantitative analysis of CC14 in DILysm® not only permitted evaluation of the innate immune response, but also suggested a limitation in the putative primary mechanism of hepatotoxicity.

**413 Organotypic Tissue Cultures As Models to Study the Impact of Cigarette Smoke on Human Upper and Lower Respiratory Tract**

M. Talikka1, R. M. Kostadinova-Angelova1, Y. Xiang1, D. Kuehn1, S. Majed3, C. Mathis1, S. Frentzel1, N. Ivanov2, F. Martin1, A. Hare1, J. Hoeng2 and M. Peitsch1. 

Cigarette smoke (CS) is etiologically linked to fatal respiratory diseases. To enable the development of modified risk tobacco products (MRTPs) to reduce the risk of smoking-related diseases, there is a need to understand the mechanisms whereby CS causes damage. As an alternative to animal experimentation, the principles of 3 R’s, necessitate the establishment of reliable in vitro models, which may also provide a better predictability of exposure response, when derived from human cells. Among the in vitro models, the three-dimensional organotypic pseudo-stratified culture systems better mimic the morphological, physiological, and molecular attributes of human respiratory tract than primary or immortalized cells cultured as a submerged monolayer. The bronchus and lung parenchyma are the primary sites that manifest smoking-related diseases, however, nasal epithelium has been proposed as a surrogate tissue to study smoking effects on the respiratory tract. We are evaluating the utility of organotypic culture systems derived from upper and lower respiratory tract in the assessment of exposure response to CS and prototypic MRTPs. Repeated whole CS exposure showed that both bronchial and nasal organotypic cultures tolerated in a similar manner the two CS concentrations (10% and 16%), measured by tissue integrity (trans epidermal electric resistance) and cellular toxicity (lactate dehydrogenase) assays. By combining the transcriptomic data with computable biological network models, we further showed that several biological processes, including those related to cellular stress response and proliferation, were perturbed in both nasal and bronchial tissues in response to smoke exposure. In summary, the study gives valuable insight into the effect of repeated whole CS exposure on organotypic models derived from both the upper and lower respiratory tract.

**414 Integration of the Hepatic and Urinary Metabolome with Hepatic Differential Gene Expression in C57BL/6 Mice following Repeated TCDD Dosing**

**415 Cigarette Smoke-Induced Perturbations of Molecular Pathways in Human Organotypic Cultures of Buccal and Gingival Mucosa**

M. Cabanski1, C. Mathis1, R. M. Kostadinova-Angelova1, S. Wagner1, S. Frentzel1, D. Kuehn1, S. Majed3, M. Geeters2, F. Talamo1, E. Guedj1, Y. Xiang1, F. Martin1, W. Kuchle1, A. Hare1, J. Hoeng2 and M. Peitsch1. 

1Philip Morris International, Neuchatel, Switzerland and 2Sphero Consulting, Rockville, MD.

Smoker’s oral mucosa is subject to cigarette smoke (CS)-induced cytopathological, genomic, and transcriptional changes that could potentially lead to the development of mouth disease. To characterize CS effects, we used two human organotypic in vitro models of the buccal and gingival epithelia (MatTek®). Both in vitro models were exposed at the air-liquid interface to fresh, diluted CS (one reference cigarette smoke, 3R4F at a time, with Health Canada smoking regimen and nicotine doses of 0.279mg/ml or 0.575mg/ml) on 4 occasions with 1h intervals between exposures where the tissues were kept in the incubator under appropriate culture conditions. Systems biology endpoints (gene and miRNA expression) were determined at time 0 following the 4th exposure and 4h, 24h, 48h after exposure to investigate time- and dose-dependent CS effect on both tissues. Other endpoints (e.g. cytotoxicity, pro-inflammatory marker release, cytochrome P450 (CYP) activity, histology) were also measured for some time points. The release of pro-inflammatory markers such as VEGF and MMP-1 was up-regulated in both CS-exposed buccal and gingival tissues 24h after exposure. However, only gingival tissues showed a significant up-regulation of CYP1A1/CYP1B1 activity 48h after exposure. By using computational approaches and capturing systems biology endpoints, various perturbations of biological processes (e.g. inflammation, proliferation, cellular stress) triggered by repeated CS exposure were observed in both buccal and gingival in vitro models.

We describe here for the first time the impact of CS exposure on human buccal and gingival organotypic models using various approaches: a combining systems biology, biological network models, computational methods and standard endpoints.

**416 Tobacco-Specific Gene Profiles in Korean Male Smokers**

H. Na and M. Yang. 

Research Center for Cell Fate Control, College of Pharmacy, Sookmyung Women’s University, Seoul, Republic of Korea.

Tobacco smoking-related cancers can be protectable with well controlled cancer prevention strategies. Particularly, the prevalence of male smoking in Korea belongs to the world’s highest levels. Therefore, we performed microarray to find our Korean-specific genetic factors associated with tobacco smoking among age- and sex-matched healthy male smokers and non-smokers (age=38.9±3.7, N=12) with Illumina human HT-12 platform with 47,231 transcript probes. Subjects were evenly divided into tobacco-high and low exposed groups, according to levels of urinary cotinine, a major metabolite of nicotine, which was measured with HPLC-UVD. We also performed qRT-PCR to confirm microarray results, and found that we could express the expression patterns of blood to those of buccal cells. Finally, we performed gene network analyses using DAVID Bioinformatics and KEGG pathways to integrate tobacco smoking-responses. As results, smoking-upregulated genes were 16 genes including ARPC3, CXCR4, ACTG1, and CYP1B1 (p<0.01 and >1.5-fold change). On the other hand, smoking-downregulated genes were 22 genes including DEFA4, VAV3, and FCGR3A. The expression levels of FCGR3A in blood were correlated with those in buccal cells (r2=0.85, p<0.001). After network analyses, we found that Korean male smokers differentially expressed immune responsive pathways such as Fcy-receptor mediated phagocytosis and leukocyte transendothelial migration, compared to non-smokers. In conclusion, our findings provide new insights in understanding of ethnic specific toxic mechanisms and health endpoints of tobacco smoking.
drial ATP, cytosolic GSH depletion, LDH release, and oxidative stress at 1-10mM. APAP induced toxicity was minimal at 4h, moderate at 8h, and substantial after 24h of exposure, suggestive of early, middle, and late stage of injury. A LC/MS/MS based proteomic analysis was performed to investigate alterations of molecular signature in the liver model. Differential expression proteomic signatures were identified by linear model with Empirical Bayes Method (FDR-adjusted p < 0.05). Total of 306, 323, and 485 proteins were found to be differentially expressed at 4h, 8h, and 24h, respectively. Pathway analysis demonstrated that the proteome of the APAP liver toxicity model was enriched in ribosomal proteins, mitochondria content, and stress response proteins. Among the proteins that differentially expressed, 26, 21, and 26 proteins were exclusively altered at 4h, 8h, or 24h by lethal dose acetaminophen (10mM), with potential utility as stage specific markers of APAP toxicity. In addition, two specific proteins were dose-dependently induced or suppressed at 24h, suggesting their potential utility as biomarkers to assess the severity of liver injury. Efforts are underway to validate these proteins in rodent and human from samples. Validation of these biomarkers will aid in shaping clinical intervention in APAP overdose.

418 Use of Mummichog to Map the Exosome: Associating Environmental Chemicals with Perturbed Metabolic Pathways

S. Li, J. Reechta, K. Uppalb and D. P. Jonesc. aDept Medicine, Emory University, Atlanta, GA and bStegh School of Pharmacy and Pharmaceutical Sciences, University of Colorado, Aurora, CO.

High-resolution metabolomics (HRM) using liquid chromatography and high-resolution mass spectrometry has routinely captured >20,000 chemicals in biologic samples. In this study, 3170 compounds were identified and the majority appears to represent low-abundance metabolites and environmental chemicals, which have not been fully characterized. How to interpret such data in the appropriate biological context remains a great challenge, and the identification of chemicals is often the rate-limiting step. This is especially problematic for the >10,000 chemicals used in commerce, where systematic analytic methods for biomonitoring are not available and potential biologic impacts of environmental products have not been fully explored. We have recently described a set of computational algorithms that directly predict pathway and network activities from high-resolution metabolomics, by leveraging the collective power in genome scale metabolic models. This approach greatly speeds up the analysis of metabolomics data, since metabolite identification can be deferred to a posterior confirmation step. In a case study using in vitro models of Parkinson disease, we extended these algorithms to integrate metabolomics and transcriptomics. Our results revealed that a metabolic network of oxidative phosphorylation and carnitine shuttle is dysregulated by the herbicide paraquat. The transcriptomics. Our results revealed that a metabolic network of oxidative phosphorylation and carnitine shuttle is dysregulated by the herbicide paraquat. The.

418a Computational Embryology and Predictive Toxicology of Hypospadias

Hypospadias, one of the most common birth defects in human male infants, is a condition in which the urethral opening is misplaced along ventral aspect of the penis. We developed an Adverse Outcome Pathway (AOP) framework and computer simulation that describes the pathogenesis of hypospadias. We first utilized semi-automated literature mining to identify 511 PubMed hypospadias articles based on MeSH annotations with 'chemicals' and 'proteins'. This information was used to develop an AOP framework linking potential molecular initiating events, altered cellular behaviors, tissue morphogenesis, and abnormal organogenesis. We selected vinclozolin (hypospadias in rats at 96 mg/kg/day in ToxRefDB, AC50 = 0.307 μM for inhibition of the human androgen receptor binding in ToxCast) as a reference for proof-of-concept. A multicellular computer simulation model capable of rendering key events in GT development was built in CellDesigner for simulation using a cellular agent-based model (CompuCell3D.org) by incorporating key signals (e.g., SHH, FGF10, EphB2, and androgen) and cellular behaviors (e.g., selective adhesion, motility) to control urethral tubulogenesis. Overall, the AOP approach and computer simulation: 1) provide a platform for integrating available biological information to predictively model the complex pathogenesis of hypospadias; 2) enable the generation of new research hypotheses; and, 3) contribute to better mechanistic understanding of this adverse developmental outcome. (This work is approved by EPA but does not necessarily reflect official Agency policy).

418b Using High-Content Screening Data from ToxCast to Analyze Cell State Dynamics

We developed a novel approach for analyzing chemical-induced dynamic cell ‘state’ changes using in vitro data. The ToxCast project conducted a high content screening study in which HepG2 cells were treated with 10 concentrations (ranging from 0.4 to 200 μM) of 976 diverse chemicals, and 10 cellular end points were measured after 1, 24 and 72 h of exposure. After analyzing the concentration response data we found 669 chemicals significantly changed one or more end points including: mitochondrial functions (435), cell cycle (412), cytoskeletal stability (332), JNK (253), p53 (253), and cell number (510). In order to capture the overall response to each chemical at a single time point, we constructed a bioactivity vector based on the magnitude and the direction of the change in each end point. The bioactivity vectors for all chemicals were analyzed using the Euclidean distance metric. K-means and cluster quality analysis to identify 15 clusters. We assumed that these clusters capture a range phenotypic ‘states’ of the HepG2 system as it responds to different perturbations ranging from normality to adversity (defined by significant cell loss). By translating bioactivity vectors to cellular states, the temporal effects of each chemical can be described as a sequence of states, called a trajectory. A trajectory describes the dynamic sequence of changes in the HepG2 system as it adapts to chemical exposure. Chemicals with similar mechanisms such as, mitochondrial disruptors, cytoskeletal disruptors and stress kinase activators, produced similar trajectories. On the other hand, structurally similar chemicals, such as thiazolidinediones, produced different trajectories that were consistent with their known toxicity. By analyzing trajectories, it is possible to characterize chemicals that cause adaptive changes that lead to recovery, or those that lead to adversity. Further work is necessary to evaluate the relevance of this work to in vivo outcomes. This abstract does not reflect EPA Policy.

418c Using Targeted Proteomics and Next-Generation Sequencing Approaches to Identify New Plasma Biomarkers and Assess Systematic Drug-Induced Adverse Effects

Adverse effects caused by therapeutic drugs are a serious and costly health concern. Despite the body’s systemic responses to changes in the chemical environment, the liver is often the focus of damage and it is usually the focus of studies of toxic effects due to its active roles in the metabolism of xenobiots. Applying sensitive and high throughput proteomics and transcriptomics technologies including Selected Reaction Monitoring (SRM) and next generation sequencing (NGS) on body fluid samples open a window to identify new biomarkers and assess adverse effects at systems level. To explore this, we utilized SRM and NGS technologies to quantify and profile circulating protein and cell-free RNA in plasma using a well-characterized acetaminophen (APAP) overdose mouse model. As a proof principle study, we initially focused on the levels of 85 liver-enriched proteins. Among them, 52 showed concentration changes in plasma after APAP overdose. Some of the proteins showed better performance than the existing blood markers for detecting and monitoring acute drug-induced injury. From NGS profiling of circulating RNA, the levels of a number of transcripts, both protein-coding and noncoding RNAs, showed changes in plasma. The results are in agreement with our previous report on the association of blood miR-122 levels with liver injury. Detailed analysis revealed the changes of circulating RNA reflected not only the liver injury induced by APAP overdose, but also damage in tissues other than the liver. Besides endogenous RNAs, we also identified a significant amount of exogenous RNAs (exRNAs). The changes in exRNAs also reflect alteration of dieting behavior after APAP overdose. Besides the identification of new blood biomarker candidates, this study illustrates the possibility of using SRM and NGS to assess global effects of therapeutics. This could lead to a new approach for a more comprehensive assessment of the efficacy and safety of therapeutics.
Converging scientific opinion from both the regulatory and scientific community recognize the importance of developing a new mechanism driven toxicity assessment paradigm. We use functional profiling in yeast, Saccharomyces cerevisiae, to identify the fundamental adverse outcome pathways involved in cellular toxicity. The ~4500 viable deletion barcoded strains are pooled, grown for multiple generations in the presence of a toxicant, and sensitivity/resistance of each strain to the toxicant is individually quantified. We screened a diverse variety of industrial chemicals at multiple doses and determined the functional importance of each gene for optimal growth in the presence of each chemical. We used high-resolution profiling dataset for diverse toxicants and the network inference ARACNE algorithm to infer a network representing toxicity related functional linkages between non-essential genes in S. cerevisiae. We identified key network modules enriched in different functional properties impaired upon toxicant exposure which we hypothesize represent common cellular responses to adverse outcomes hubs. We subsequently identified adverse outcome hubs associated with each individual toxicant. Additional dose response analysis enabled us to identify candidate adverse outcome pathways linking early cellular response through to adverse outcomes for each toxicant. We suggest that this functional approach in yeast and development of functional networks provides a unique insight into both the shared and unique molecular responses to toxicant exposure.

Potential use of ToxCast assays for assessing drug-induced liver injury in humans

M. Lee1, J. Zhang1, Y. An2, C. Chang1 and W. Tong1. National Center for Toxicological Research, Jefferson, AR and 1Hanyang University, Gyeonggi-Do, Republic of Korea.

Predicting a drug’s potential to cause drug-induced liver injury (DILI) is still a major challenge with the animal models. A paradigm shift from in vivo animal testing to in vitro systems has been proposed, but met with challenges. The EPA has assayed many chemicals with an array of mechanisms-based in vitro systems, providing an opportunity to develop in vitro prediction system for DILI. We developed a robust quantification of dose response for the ToxCast assay data coupling with the DILI annotation by the FDA’s Liver Toxicity Knowledge Base (LTKB) to investigate the potential use of the ToxCast data to predict DILI in humans. Specifically, the LTKB developed 287 benchmark drugs and some of which were assayed by ToxCast, which was used in this study. Area under the dose-response curve, with the median value from each concentration, was calculated for each drug/assay combination and the assay potential for predicting DILI was evaluated by area under Receiver Operating Characteristic (AUROC). With the criteria of AUROC > 0.6 and p-value < 0.05, 42 endpoints out of 451 assayed by ToxCast were identified with the prediction potential. Some of these endpoints associated with key mode of actions underlying DILI mechanisms including mitochondria damage, oxidative stress, PPAR and NURR pathways. The findings are encouraging and indicate the potential utility of the ToxCast system for DILI assessment in humans. The future study will be focused on applying the identified assays to rank and prioritize the ToxCast chemicals according to the DILI potential and improving mechanistic understanding on DILI.

Development of a Novel Method for Deriving Thresholds of Toxicological Concern (TTCs) for Vaccine Constituents

J. White1, 2, C. Weresinski1, M. Green1, G. T. Johnson1, J. D. McAulay2 and R. D. Hubbard1. 1Division of Vaccine and Related Products Applications, and Drug Administration, Rockville, MD and 2Environmental and Occupational Health, University of South Florida, Tampa, FL.

Safety assessment of impurities, residual materials and contaminants in vaccines is an important risk assessment process for evaluating public health risks associated with new and existing vaccines. Defining thresholds of toxicological concern (TTCs) is a concept that can be applied for screening vaccine constituents and evaluating the toxicity of specific vaccine constituents with little or no toxicity data. TTCs are mathematically modeled and extrapolated levels, below which adverse human health effects are not expected to occur. Probist and lowest-toxic-dose (TDLo) data were obtained from INCHEM, RepDose, RTECS and TOXNET. ToxTree software using three different algorithms (The Cramer Extended, the In Vivo Rodent Micronucleus Assay algorithm, and the Benigni-Bossa rule base for carcinogenicity by IJS) was assigned to assign the chemical test set (n = 197) into structural families based on structural alerts (SA). This resulted in six potential methods for elucidating TTCs: In Vivo Rodent Micronucleus Assay/ probit, Benigni-Bossa/ probit, Cramer Extended/ probit, In Vivo Rodent Micronucleus Assay / TDLo, Benigni-Bossa/ TDLo, and the Cramer Extended/ TDLo. These were subjected to 10-fold cross validation in a Preliminary algorithm (SOT), resulting in two TTC methods for further consideration: Benigni-Bossa/ probit and the Cramer Extended/ probit. The Benigni-Bossa/ probit method outperformed the Cramer Extended/ probit method in terms of specificity (87.2 vs. 48.1%), accuracy (65.2 vs. 52.9%), positive predictivity (66.6 vs. 50%), negative predictivity (64.8 vs. 56%), positive operating characteristics (ROC+) (2 vs. 1) and ROC- (1.84 vs. 1.3). Our results indicated that the Benigni-Bossa/ probit was the most appropriate method. These comments are an informal communication and represent our own best judgment. These comments do not bind or obligate FDA.

Comparison of Cramer Class Prediction between Toxtree, OECD QSAR Toolbox, and Expert Judgment—Strategies for Refinement

S. Bhatia1, J. Shen1, L. Kromidas1, 2T. W. Schultz1, 3R. Ford1, D. Roberts1 and A. Apil1. 1RIFM, Woodcliff Lake, NJ, 2University of Tennessee, Knoxville, TN and 3Liverpool John Moores, Liverpool, United Kingdom.

The Threshold of Toxicological Concern (TTC) approach is used to predict the toxicity of compounds with low oral exposure. The Cramer classification decision tree is used extensively for TTC estimation. Assigning an accurate Cramer class to a material is a crucial step to preserve the integrity of the risk assessment. The Cramer class of over 1000 fragrance materials across diverse chemical classes were determined by using the OECD QSAR Toolbox (TB), Toxtree and expert judgment. Concordance between Cramer class predictions by Toxtree, predictions by OECD Toxubs and expert judgment are presented. The overall concordance between expert judgment and Toxtree was 76%, Toxtree (with extensions) 72%, TB (with extensions) 65%, TB 72%. The concordances between predictions and expert judgment for different chemical classes were also analyzed. The concordance between Toxtree (with extensions) and expert judgment for esters, alcohol, ketones and aldehyde chemical classes was 77%, 58%, 54% and 81% respectively. The concordance between TB and expert judgment for esters, alcohol, ketones and aldehyde classes was 70%, 61%, 51% and 61% respectively. The concordance between Toxtree (with extensions) and expert judgment for esters, alcohol, ketones and aldehyde classes was 82%, 50%, 54% and 91% respectively. More detailed evaluation of chemical categories (subgroups) suggested that the lowest concordance between expert judgment and in silico tools (Toxtree and TB) to be among Heterocycles/Oxygen Containing/Furan/Monocyclic/Saturated (<30%), Alcohol/Aryl alkyl (<55%) and Ketone/Cyclic/Monocyclic/Saturated (<55%). Strategies and guidance on determining the Cramer class for various chemical classes are discussed. The suitability of software for specific chemical classes and possible re-coding of rules are presented.

xMSanalyzer and xMSannotator: R Packages for Systematic Study of the Exposome

K. Uppal1 1and D. P. Jones1. 1Emory University, Atlanta, GA and 2Georgia Institute of Technology, Atlanta, GA.

Improved analytical technologies and better data extraction algorithms for high-resolution mass spectrometry have enhanced the coverage of chemical detection for metabolic profiling and environmental biomonitoring, including detection of low abundance environmental chemicals and their metabolites. Our recently published software, xMSanalyzer (Uppal et al. 2013), includes utilities that allow quantitatively reliable measurement of metabolites detected in individual biological samples. A number of databases and online tools are available to perform mass spectrum searches, but most of the web-based tools allow query of only few hundred mass-to-charge values in a single search. No convenient interface exists to query including data sources to be searched within ChemSpider and can be used in combination with existing R packages for processing environmental metabolomics data. Our results demonstrate that together, xMSanalyzer and xMSannotator allow reliable detection of environmental chemicals in individual biological samples and facilitate the ability to gauge the physiological relevance of the environmental chemicals and their metabolites.
The exposome is the array of environmental influences and cumulative biological responses throughout an individual’s lifespan, including exposures from the environment, diet, behavior, and endogenous processes. To operationalize exposome research, an “open” database structure is needed in which data from newly acquired samples can be added to existing data in a sufficiently rigorous manner to allow time-dependent studies of an individual over years to decades. Liquid chromatography-high-resolution mass spectrometry with triplicate analysis, improved data extraction and automated 24/7 operation now provides capability to measure >100,000 ions, representing >20,000 chemicals, in a few microliters of biological samples. The number of ions and presence of many unidentified low-abundance chemicals (m/z range 85-2000) makes commonly used analytic procedures, such as MS/MS with calibration against authentic standards, impractical for routine measurement. Consequently, we have devised and begun to test standard operating procedures for exposome research. Analysis of samples in triplicate facilitated detection of chemicals present at low abundance and present in only a small percentage of individuals. Inclusion of a mixture of stable isotopic standards in each sample provided authentication of instrument calibration and consistency of response; single internal standards were insufficient for this goal. The standard also allowed direct determination of consistency of elution characteristics. With daily Quality Control (QC) using apLCMS with xMSAnalyzer (Uppal et al BMC Bioinformatics 2013) and routine replacement of columns and instrument cleaning after 25 days of continuous operation, the results are sufficiently robust to warrant evaluation as a routine pipeline for combination of data in a cumulative exposome research database.

**423 Exposure Data and the Comparative Toxicogenomics Database (CTD)**

C. J. Grodin1, A. P. Davis and C. J. Mattingly. Biology, North Carolina State University, Raleigh, NC.

Exposure science studies and characterizes the interactions between environmental stressors and human or ecological receptors. This research plays a critical role in the translation of toxicity data to prioritize research, assess human health risks, and inform public health decisions. To facilitate the characterization of stressor-receptor interactions (including identification of connections between real-world exposures, chemicals, genes and proteins, diseases, and molecular pathways), we initiated a project to curate and integrate chemical exposure data into the publicly available Comparative Toxicogenomics Database (CTD; http://ctdbase.org). CTD is a manually curated database containing over 21 million toxicogenomic relationships for chemical-gene-disease interactions. Gene Ontology (GO) annotations, and molecular pathways that are integrated with analysis tools to promote understanding of the molecular mechanisms underlying environmental diseases. In our exposure curation paradigm, the peer-reviewed literature is manually curated using several controlled vocabularies and free text to capture details in more than 50 data fields characterizing the four major exposure concepts defined by the Exposure Ontology (ExO): Stressor, Receptor, Event, and Outcome. To date, over 600 articles have been curated, resulting in more than 21,000 exposure statements for 550 unique chemicals, 95 distinct receptor populations from 70 countries, 1,545 diseases, and 70 phenotypic outcomes. Integrating this information with core CTD data will allow exposure science data to be queried, retrieved, and contextualized within CTD’s broader biological framework. This integrated platform will help promote mechanistic understanding of environmental influences on human health.

**424 LocaTox: An Interactive Tool Linking Known Environmental Contaminants, Associated Chemical-Human Gene Interactions, and Birth Defect Statistics in Specific Locales**

K. Aquino, K. Hald, M. Reyna, M. Zamora and D. Johnson, Nutritional Sciences & Toxicology, UC Berkeley, Berkeley, CA.

Several areas in the US have higher incidences of birth defects than the national average, yet do not display clusters of a single type of congenital abnormality where an association with a specific chemical contamination can be made. To aid in current research to quantify specific chemicals and birth defects, we hope to develop an interactive tool, LocaTox, where an extensive array of data can be integrated on specific locales including topography, local infrastructure, specific industries and levels of air, water, and ground pollution. These environmental factors are then associated with specific birth defect statistics and are paired with chemical-gene and gene-birth defect interactions. A user can actively explore potential connections as an opening to developing research questions. As a prototype, we selected Fresno County California where statistics show a higher rate of birth defect-related infant deaths compared to the cumulative rate in California and where the causes of many birth defects remain unknown. In this study we identified some of the most prominent environmental pollutants in Fresno and their associations, if any, with a wide array of birth defects. Resources used included DART, CTD, ChemIDPlus, t3db, Scorecard and websites such as Pesticide Action Network (PAN) and several US EPA resources. Chemicals prominent in Fresno County previously associated with birth defects were identified and specific chemical-disease-gene relationships were identified. One valuable result from the searching capability is the possibility of linking several exposures rather than individual chemical to various birth defects which possibly expands the overall environmental risk assessment. The content-design of the tool can be adapted for any specific locale of interest.

**425 iLINCS—A Web-Based Portal for Integrative Analysis of Multidimensional Data**

J. F. Reichard1, M. Medvedovic2, S. Sivagase1, J. Chen1, M. Phatak2 and W. Niu3. Toxicology Excellence for Risk Assessment, Cincinnati, OH and Environmental Health, University of Cincinnati, Cincinnati, OH.

New technologies and systems approaches are being applied to identify biological signatures that are common across chemicals sharing similar modes of action or predict adverse outcome exposures. However application of systems data for risk assessment requires integration of multidimensional endpoints (readouts) acquired from multiple “omic”, network and biochemical platforms. The effective application of these distinct readouts to risk assessment requires advances in biostatistics, bioinformatics, and computational methods. The NIH Library of Integrated Network-based Cellular Signatures (LINCS) program aims to create a network-based understanding of biology by cataloging changes in gene expression and other cellular processes (http://www.lincsproject.org/). Previously, we demonstrated that integration of transcriptomic and transcription factor RNA-binding profiles significantly improves detection of otherwise obscured chemical signatures. Here, we introduce the web-based iLINCS [Integration of Interactive LINCS Gene Expression Portal; a computational biology tool integrating various types of systems biology readouts (http://eh3.uc.edu/GenomicsPorts/viewLincs.jsp)]. Currently, these readouts include publicly accessible data from Broad Institute (LINK signatures, Connectivity Map signatures), ENCODE transcription factor binding signatures, and disease-related signatures (NCBI GEO GDS collection). The objective is to leverage publicly available libraries of the signatures, meta-signatures and regulatory network signatures to evaluate and identify chemical-related network signatures shared or common to diseases, chemical exposures and transcription factor pathways. The iLINCS web-based portal enables the identification of functional connections between chemicals, genes and diseases. Integrative analysis based on multidimensional data will vastly improve in vitro prediction of apical toxicological outcomes for chemicals lacking in vivo toxicological data. Supported by: U01HL111638.

**426 Harnessing the Wealth of Pharmaceutical Preclinical Toxicity Data—The eTOX Database (eTOX Part I)**

T. Steger-Hartmann1, E. Pognan2 and K. Briggs1. Investigational Toxicology, Bayer HealthCare, Berlin, Germany. 2Discovery Investigative Safety, Novartis, Basel, Switzerland and 3Lhasa Ltd., Leeds, United Kingdom.

Most preclinical data acquired during drug development are not available in the public domain due to attrition of projects or IP issues. Lack of data accessibility was identified by the European Federation of Pharmaceutical Industries and Associations (EFPIA) as an obstacle to read-across approaches, development of new in silico tools and data mining for biomarkers.

In the framework of the European Innovative Medicines Initiative, 13 pharmaceutical companies and 12 public partners initiated the eTOX project to collect un-published preclinical safety data and build a database covering multiple endpoints. The participating EFPIA companies identified archived reports on systemic tox studies (paper or pdf) and manually extracted them. In parallel a trusted organisation (“honest broker” - Lhasa Ltd., Leeds) set up the database. The data sets were sent to the honest broker and incorporated into the database after quality check. Due to data heterogeneity a major effort was undertaken for data harmonization and ontology work (see abstract eTOX Part II).

The steadily growing database currently contains 2127 reports (status: Aug 2013) of systemic toxicity studies with more than 800 different chemical structures. The database was populated with virtually all endpoints investigated in systemic toxicity
studies according to guidelines, i.e. clinical observations, clinical chemistry, hematology, macroscopic findings and histopathology. The majority of datasets pertain to rats (72%), followed by dogs, primates and mice. Reported findings are strictly attributed to treatment-related or non-treatment based on the original report. Liver was the most frequently (30 % of the findings) affected organ, followed by spleen (19 %), kidney (17 %) and thymus (16 %). The eTOX database should become one of the largest and most granular preclinical databases for pharmaceuticals. It will facilitate comparison of early candidates ("read-across") and pave the way for the development of new in silico tools (see abstract eTOX Part III).

427 eTOX Ontologies: Enhancing Standards for Better Knowledge Management of Animal Study Data (eTOX–Part II)

Switzerland, 1GlaxoSmithKline, Ware, United Kingdom, 2Pfizer, Groton, CT, 3Sanofi, Paris, France, 4Novartis, Basel, Switzerland, 5GlaxoSmithKline, Ware, United Kingdom, 6Pfizer, Groton, CT.

The eTOX consortium has collected data from more than 5,000 toxicology reports from 13 companies in order to enable data mining and structure-based prediction. Data from these reports were manually extracted and verbatim findings were stored as "is". In order to make that collection of diverse data and terminologies useful, relevant code lists had to be identified and the 1.5 million extracted finding verbatim terms mapped to the appropriate locations. Developments delivered by eTOX include OntoBrowser, an open source tool dedicated to the mapping of verbatim term to preferred terms and maintenance of created ontologies. On top of existing code lists from SEND, a complete ontology was also developed, which included dependencies of terms in order to facilitate endpoint definition and database queries. The most challenging ontology was derived from standard pathology texts, includes the evolving INHAND terms and describes the microscopic anatomic pathology findings. All these ontologies will be shared in the public domain in order to increase interoperability of data in the preclinical safety world.

428 New Frontiers in the In Silico Prediction of In Vivo Drug Toxicity: The IMI eTOX Project (eTOX Part III)

The IMI eTOX project [1] is a European-wide R&D initiative that, for the first time, is collecting and integrating information from in vivo preclinical toxicity reports buried in the archives of the pharmaceutical companies. The resulting repository, complemented with information obtained from public sources, is being exploited using methods as read-across and a fully integrated in silico prediction system.

The project, started in 2010, begins to yield valuable outcomes. So far the 13 participating pharmaceutical companies have already donated more than 5,000 toxicology reports (see eTOX Part I), the consortium has developed ad hoc ontologies to facilitate data integration (see eTOX Part II) and nearly a hundred models have been developed and implemented. With respect to methodological outcomes, the project has developed an integrated prediction system using an original archi-tecture based on independent virtual machines developed by academic partners and interconnected using web services. This solution allows efficient academic-industry collaboration and a safe deployment of the software within the pharmaceutical companies. Predictive models are being developed using a new integrated modeling framework that facilitates their development and maintenance and incorporates functionalities such as structure normalization or assessment of the predictions applicability domain. The predictive models already developed address most of the endpoints classically studied in toxicology. Moreover, since the project is specifically aimed to the prediction of in vivo and organ level toxicological endpoints, some of these models implementing multilevel and multiscale approaches [2].

1. Integrating bioinformatics and chemoinformatics approaches for the development of expert systems allowing the in silico prediction of toxicities (eTOX). IMI-JU project 115002. http://www.etoxproject.eu

429 An Ensemble Model of In Silico Tools to Improve Toxicity Prediction
P. Pradeep1, R. J. Povinelli1, R. Brown2, S. White3, A. Korolev4 and S. J. Merrill1, 2, 3, 4.

1Department of Math, Statistics and Computer Science, Marquette University, Milwaukee, WI and 2Center for Devices and Radiological Health, US FDA, Silver-Spring, MD.

Quantitative structure activity relationship(QSAR) are theoretical models that relate a quantitative measure of chemical structure to a physical property, or a biological effect. Such models are of particular interest in regulatory settings for toxicity (adverse affect) profiling of drugs or compounds that may be released from medical devices. Free/proprietary in silico tools are gaining wider acceptance as a faster alternative to otherwise time-consuming clinical and animal testing methods. However, different in silico tools often make contrasting predictions for a given chemical and also vary in the accuracy of prediction across different chemical datasets. The objective of this study is to apply the ensemble learning approach in machine learning paradigm for combining predictions from different models, based on the understanding that consensus predictions are better than an individual prediction. We have developed a novel hybrid QSAR model based on a decision tree framework using Bayesian classification. We compare the predictive performance of in-silico tools (Toxtree, Lazar, OECD Toolbox and Danish QSAR) and the ensemble model for carcinogenicity prediction for a dataset of 332 compounds), medical device leachables (84 compounds) and the gold carcinogenic potency database (480 compounds). The results show that the ensemble model has improved overall performance (Accuracy: 83.81%, 88.10% and 81.04%) and highest inter-rater agreement, (kappa (κ): 0.6322, 0.759 and 0.6164). The study suggests that the ensemble model significantly improves the quality of predictions from a regulatory standpoint.

430 DIAMONDS: Data Infrastructure for Applying Models ON Design and Safety

Innovations in many industrial sectors involve the development of new chemical entities with improved properties. Regulatory frameworks in place may differ per industrial sector, but all have the avoidance of harmful effects to exposed humans as major objective. Safe limit values are often driven by complex endpoints like repeated dose toxicity, carcinogenicity, or reproductive toxicity. Until recently, these limits could only be established by animal studies on a compound by compound basis. Today, developments in toxicological sciences, systems biology and computational chemistry, provide opportunities to predict toxicological profiles of chemicals with highly reduced in vivo testing. At TNO, we are developing 'DIAMONDS', a data infrastructure with statistical and computational tools that achieves and visualizes exactly this goal: the efficient prediction of complex toxicological hazards of new molecules. The applied methodology, detailed in this poster, relies on the combined knowledge of known toxicologically characterized toxicants. By extracting the determinants of a specific toxicological outcome, the toxicological profile of a novel compound can be predicted and its probability specified. In addition, DIAMONDS encompasses the use of (in vitro) screening models for 'biological verification', as structural similarity does not guarantee similar toxicological profiles, and to use that screening model outcome for prediction of the potential toxicity of novel molecules. Our visualization tool allows a rapid interpretation of toxicity prediction probability on the basis of all available data. We have applied this tool on TG GATEs, and ToxCast/ToxRef databases and found associations between structural properties, Omics pathway signatures and toxicity/pathology profiles. We found a strong diversity in predictive performance depending on the chosen endpoint. ToxCast assay data did not provide additional predictive value compared to structural fingerprint-based data (Grants NIGIL-NTC, Celtic-LRI-AIMT-2&3, ZonMW-ASAT).
**431** Collaborative Interoperability between Public Projects to Support Replacement of *In Vitro* Repeated Dose Toxicity Testing

**432** Hazard Evaluation Support System Database (HESS DB) for Repeated-Dose Toxicity of Chemical Substances: A Multifunctional Tool for Hazard Assessment and Predictive Toxicology  
T. Yamada¹, T. Abe¹, R. Hasegawa¹, Y. Sakuratani¹, J. Yamada¹, T. Yamashita³, K. Yoshibari², Y. Yamazoe³, A. Hirose⁴ and M. Hayashi⁴.  
¹National Institute of Technology and Evaluation, Tokyo, Japan, ²Fujitsu Limited, Chiba, Japan, ³Tohoku University, Sendai, Japan, ⁴National Institute of Health Sciences, Tokyo, Japan and ⁵BioSafety Research Center, Iwata, Japan.

Repeated-dose toxicity (RDT) is one of the key regulatory endpoints in the hazard assessment of chemical substances. We have recently released Hazard Evaluation Support System (HESS) and the attached database (HESS DB). HESS is compatible with OECD QSAR Toolbox and has a supportive function to group structural analogs with toxicity data. HESS DB contains test data of RDT studies for currently about 600 industrial chemicals, most of which were conducted in accordance with GLP principles. The DB also includes reference information on ADME and toxicity mechanism for some of those chemicals. Here we demonstrate that HESS DB is very useful for hazard assessment and predictive toxicology. HESS DB has full data set at all tested doses. That allows us to calculate benchmark dose (BMD) and find a parameter useful for hazard assessment. Moreover, chemicals causing similar toxicity can be efficiently searched with the DB, facilitating to find marketed toxic chemicals and new structural alerts whose mechanistic information is limited. These are new targets of toxicological research. Finally, HESS DB provides information on predictable or measurable key events identified on adverse outcome pathways. The combination use with HESS supports to perform category approach or integrated testing strategy to predict the primary toxicity of untested chemicals in a transparent and interpretable manner. Both HESS DB and HESS are downloadable from the website of NITE at no charge (http://www.safe.nite.go.jp/english/kasinn/qsar/ress-e.html).

**433** A Web Application for Estimating Provisional Health Guidance Values of Diverse Environmental Chemicals Using Reliable QSAR Models  
A. Prussia, N. M. Khalil and E. Demchuk. Division of Toxicology and Human Health Sciences, Agency for Toxic Substances and Disease Registry, Chamblee, GA. Sponsor: A. Prussia.

ATSDR is congressionally mandated to develop health guidance values, defined as minimal risk levels (MRLs), to be used for assessing the risk of exposure to hazardous environmental chemicals. Epidemiological data and/or toxicity data from animal studies are the preferred sources of information for developing MRLs. However, such in vivo data exist for only a few hundred chemicals compared to the many thousands present in the environment. Through quantitative structure-activity relationship (QSAR) models for predicting these properties exist in the literature, the models generally lack defined measures of reliability and are difficult to apply to current chemicals of interest. To address these issues, a web application was developed for prediction of rat chronic oral toxicity endpoints known as lowest-observed-adverse-effect-levels (LOAELs). The user need only supply a CAS number for an organic compound of interest, which is interpreted and applied to Q SAR models developed from 159 environmental chemicals with experimental LOAELs. The general reliability of these models is confirmed through application of an external test set (Q2 = 0.53); the specific reliability for the chemical of interest is determined through a distance metric to the models’ descriptor space. In the future, web-based use of further validated QSAR models may provide quick and reliable toxicity predictions to guide Agency decisions on risk assessment, provisional exposure levels and investigational prioritizations.

**434** Toxicophores: Identification, Validation, and Application  
B. M. Pailey, C. M. Zwickel and T. K. Baker. Investigative Toxicology, El Lilly, Indianapolis, IN.

Growing pressure to move away from animal testing, forge a need for more predictive *in vitro* and computational tools. Cheminformatics is an attractive approach as it is inexpensive and enables early safety assessment. Our goal was to identify toxicophores, substructures with an increased potential for specific toxicological outcomes within a defined chemical and/or biological context. Over 1000 internal compounds with 4 to 14 day rat and dog histopathology data from toxicology studies were included. The compounds comprise diverse pharmacological (NHRs, kinases, GPCRs, ion channels), physicochemical and toxicological properties. Leadscope® was utilized to identify substructures of compounds within the dataset with statistical significance at any of 50 toxicological end points we considered. These “substructure correlates” were evaluated, prioritized and validated against an external test (Pharmacopendium®) and an internal test set. *In vivo* and *in vitro* ADMET data paired with structural, pharmacological and other data were used to determine the context in which each toxicophore has an increased likelihood of an adverse event in rat or dog 4 to 14 day tox studies. Eight toxicophores for 3 target organ toxicities have been identified to date. Current chemistry containing these substructures are evaluated visually and screened through the relevant *in vitro* surrogate assays to assess relevance and to determine potential for preclinical toxicity risks. Despite the high predictive power of QSAR models, complex molecular descriptors typically do not provide information on what to modify to mitigate risk. The toxicophore approach is a combined knowledge- and judgment-based method with lower applicability compared to QSAR; however, for compounds containing these toxicophores, it can provide strong chemically and biologically relevant hypotheses to interrogate risk. Our data demonstrate an inexpensive, ethical and informative approach to identify molecules with potential preclinical *in vivo* toxicity risks.

**435** Mechanistic Modeling of Acute Oral Toxicity for Rat  
S. Ringeissen¹, A. Detroyer², R. R. Note³, N. Nedelcheva², N. Dimitrova², S. Dimitrov² and O. Mekenyan². ¹Advanced Research, L’Oréal R&D, Aulnay-sous-Bois, France and ²LMC-OASIS, Bourgas, Bulgaria. Sponsor: D. Bury.

Our aim is to develop a structure-activity model for acute oral toxicity (AOT) of chemicals to rats. The presented AOT model is based upon a category approach: chemicals are grouped in the same category based on their common interaction mechanism and toxicological mode of action. The formed categories include two types of toxicity: basic and excess. Basic toxicity results from the chemical affecting the most basic function of the cells. Most of the chemicals in this category are non-reactive chemicals acting by narcissism mechanism, which alter reversibly the physiological properties of cell membranes. Chemicals having reactive groups could also reveal basic toxicity because of their limited bioavailability. Excess toxicity is a result of destroying some critical processes for the cells or the whole organism.
Chemicals of this category have highly reactive groups acting by specific interaction mechanisms, which result in an enhanced toxicity compared to the basic toxicity. Two types of excess toxicity were defined: bioavailability dependent and invariant excess toxicity. Bioavailability dependent excess toxicity of chemicals is conditioned by two factors: bioavailability and reactivity. The solubility and partitioning parameters are considered to be adequate descriptors for bioavailability of toxicants. After reaching a certain threshold of water solubility the reactivity factor is starting to play role increasing acute toxicity. The toxic potency of chemicals revealing invariant excess toxicity does not depend on their bioavailability and they possess a constant toxicity within a certain studied range of solubility or partitioning parameters. The current version of TIMES-AOT model contains 2500 training chemicals. Some data were provided with thanks to the Dow Chemical Company. Based on the structure analysis, mechanisms of interaction and toxicological modes of action, 64 AOT categories were already determined. For each of them, local models for predicting AOT were derived.

436 Computational Analysis of the Combined Therapeutic Effects of Traditional Chinese Medicines and Western Therapeutics in Breast Cancer
A. Chu, M. Lin, D. Loomba, J. Ma and D. Johnson, Nutritional Sciences & Toxicology, UC Berkeley, Berkeley, CA.

Allleviating the side effects of chemotherapy drugs with herbal remedies is increasing in popularity. In this research, we used a computational systems pharmacology/toxicology approach to study Taxol and Traditional Chinese Medicine (TCM) recipes used in conjunction to treat and alleviate side effects in breast cancer treatment regimens. Phytochemicals from TCM recipes were determined from the TCM Database®Taiwan and the mechanism of action, potential molecular targets, metabolic pathways, herb-herb and herb-drug interactions, and potential toxicity of individual phytochemicals were elucidated using several resources including the Comparative Toxogenomics Database (CTD), DrugBank, ToxNet, Toxin and Toxin Target Database (t3db), Side Effect Resource (SIDER), Search Tool for Interactions of Chemicals (STITCH), and Pathwaycommons. Phytochemical findings were integrated into Taxol/breast cancer pathways to elucidate potential synergistic and inhibitory effects. This study provides insight on the potential benefits – and some potential negative effects – of commonly used TCMs and Taxol in the treatment of breast cancer. Relevant findings include the induction of gshelin by atracyclins, inhibition of VEGF and cMyc by baicalin and baicalein, and inhibition of cyclin D by tashinones. This research supports the continued search for isolated phytochemicals (and structural analogues) from TCM recipes for use in breast cancer treatments.

437 Computational Analysis of Potential Interactions from the Combined Use of Western Therapeutics and Traditional Chinese Medicines in Postmenopausal Osteoporosis
R. Chang and D. Johnson, Nutritional Sciences & Toxicology, UC Berkeley, Berkeley, CA.

Osteoporosis is a disease that significantly decreases bone mineral density and increases the risk for fractures. Boniva® and BoneVigor® are two medications used to treat osteoporosis in postmenopausal women. Boniva® contains ibandronate sodium (IS), while BoneVigor® is a Traditional Chinese Medicine (TCM) that contains the herb Psoralea corylifolia. Bakuchiol (Bk) is one of the 35 active phytochemicals found in the herb. Many osteoporotic patients choose to use a combination of these therapies, which presents a more significant focus for chemical toxicity testing, examination of protein acetylation, may constitute a stratified cellular defense program, allowing cells to handle threshold stresses are unable to activate the transcriptional program, whereas supra-threshold stresses can transcriptionally induce stress genes, with concomitant alterations of expression of genes regulating cell metabolism, proliferation and apoptosis. These transcriptional alterations may be associated with adverse cellular outcomes. Posttranslational and transcriptional control pathways, acting in concert, may constitute a stratified cellular defense program, allowing cells to handle stressors of wide-ranging intensity coherently. As cell-based in vitro assays become a more significant focus for chemical toxicity testing, examination of protein activity changes in the absence of transcriptional changes deserves more attention. Biomarker monitoring for safety assessment at low stress levels may also need a shift in focus to posttranslational pathways.

438 Network Motif Basis of Threshold Responses
O. Zhang1, S. Bhattacharya2, R. B. Conolly2, H. J. Clewell1, N. E. Kaminski3 and M. E. Andersen1. 1Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Durham, NC. 2Integrated Systems Toxicology Division, NIEHS, USEPA, Durham, NC, and Department of Pharmacology & Toxicology, Michigan State University, East Lansing, MI.

There has been a long-running debate over whether or not environmental toxicants exhibit thresholds for adverse health effects. The difficulty in answering the question stems from two fundamental challenges: (i) statistical analysis by itself cannot prove the existence of a threshold; and (ii) there has been little progress in developing a more mechanistic understanding of how threshold phenomena might arise in biological systems. We believe that mechanistic evidence for the existence of thresholds has to come from studying the underlying biological networks as nonlinear dynamical systems. We computationally analyzed the abilities of several intracellular biochemical network motifs to generate threshold responses. These motifs include proportional and integral feedback control, incoherent feedforward control, saddle-node, pitchfork, and transcritical bifurcations, and ultrasensitivity. For each motif, we present mathematical models to illustrate the kinetic basis for threshold responses. We conclude that integral feedback, feedforward and transcritical bifurcations can generate well-defined thresholds below which the response does not deviate from non-stressed control. Other motifs, such as proportional feedback and ultrasensitivity, can give rise to “threshold-like” responses where the low-dose region rises slowly staying close to the baseline. Feedforward control can also produce nonmonotonic/hormetic responses. In conclusion, threshold behaviors may be understood at the level of network motifs, the study of which is necessary for the emerging, toxicity pathway-based approach for chemical safety assessment. This is an abstract or a proposed presentation and does not necessarily reflect USEPA policy. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

439 Post-Translational Control of Adaptive Cellular Stress Responses and Its Implications in Toxicity Testing and Risk Assessment
M. E. Andersen1, O. Zhang, S. Bhattacharya1 and J. Di, Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Durham, NC.

Transcriptional induction of stress genes constitutes a major cellular defense program against a variety of stresses arising from exposures to environmental toxicants. Besides these transcriptional programs, which are slow to activate, fast-acting, posttranslational control mechanisms are also at work in the face of cellular stresses. Through computational systems biology pathway models, we are examining processes that would lead to a dose-dependent transition from posttranslational control to transcriptional control with increasing stress levels. These models indicate that posttranslational control serves at least two functional purposes: (1) it handles small and/or transient stress in a timely manner and alleviates the initial impact of persistent stress; and (2) it stabilizes the transcriptional network, which by itself is prone to oscillation due to its delayed negative feedback nature. Posttranslational control, in a feedback or feedforward manner, can underpin perfect adaptation and thus produce thresholds in the responses against external perturbations. Subthreshold stresses are unable to activate the transcriptional program, whereas supra-threshold stresses can transcriptionally induce stress genes, with concomitant alterations of expression of genes regulating cell metabolism, proliferation and apoptosis. These transcriptional alterations may be associated with adverse cellular outcomes. Posttranslational and transcriptional control pathways, acting in concert, may constitute a stratified cellular defense program, allowing cells to handle stresses of wide-ranging intensity coherently. As cell-based in vitro assays become a more significant focus for chemical toxicity testing, examination of protein activity changes in the absence of transcriptional changes deserves more attention. Biomarker monitoring for safety assessment at low stress levels may also need a shift in focus to posttranslational pathways.

440 Computational High-Throughput Quantitative Analysis of Dose-Dependent Histological Features
B. Nault1, D. Colby4, J. R. Harkema3 and T. R. Zacharewski1-5. 1Department of Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI. 2Department of Pathobiology & Diagnostic Investigation, MSU, East Lansing, MI. 3Center for Integrative Toxicology, MSU, East Lansing, MI and 4Institute for Cyber-Enabled Research, MSU, East Lansing, MI.

Manual quantitation of stained features can be onerous and subjective, yet valuable when integrated with complementary molecular responses. Alternatively, computational approaches such as image segmentation can be used to quantify features.
We have developed a high throughput Matlab®-based tool that runs within the MSU High Performance Computing Center to quantify the level of vacuolization (Oil Red O), immune cell infiltration (H&E or F4/80), and fibrosis (picrosirius red). To test the tool, volume density (Vv) was manually estimated by point counting on representative H&E slides from 2,723 Oil Red O stained hepatic sections from mice orally gavaged with 9 doses (0 to 30 µg/kg) of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) every 4 days for 28 days. Significant correlations were calculated between the manual and computational Vv, demonstrating the reliability and accuracy of the tool to identify and quantify histopathological features. Furthermore, unlike manual approaches, the tool was also used to simultaneously quantify vacuole number and size revealing both an increase in number of vacuoles at 30 µg/kg TCDD as well as a dose-dependent increase in size, consistent with a change from micro- to macro-vesicular steatosis noted following visual assessment. Dose-response modeling of Oil Red O stained features estimated ED₂₀, BMD, and BMDL values of 10, 0.26, and 0.12 µg/kg TCDD, respectively, using manual counting and 27, 1.40, and 1.01 µg/kg TCDD, respectively, using our computational tool. In summary, high throughput image segmentation dramatically reduced analysis time to ~1h, facilitated large-scale assessment of histopathological features, and is a viable alternative that is consistent with results from the ≥ 60h manual assessment. Funded by SRP P42ES049111.

440a Deriving Points of Departure and Performance Baselines for Predictive Modeling of Systemic Toxicity Using ToxRefDB
K. W. McLaurin¹, L. Truong¹, G. Ouedraogo², S. Loisel-Joubert¹ and M. T. Martin¹
¹NCCTFORD, US EPA, Raleigh, NC and ²L’Oreal, Paris, France.

A primary goal of computational toxicology is to generate predictive models of toxicity. An elusive target of alternative test methods and models has been the accurate prediction of systemic toxicity points of departure (PoD). We aim not only to provide a large and valuable resource of PoD, but also to scope the problem by generating floor and ceiling baseline uncertainty bounds for which to judge future models. EPA’s ToxRefDB, originally populated with pesticide registration data, has grown to incorporate guideline-like studies from the pharmaceutical industry, National Toxicology Program, and publicly available research literature. Over 6000 high quality animal studies on 1071 chemicals were captured using standardized study design, treatment and effect vocabulary. Systemic lowest and no effect levels (LEL/TEL) were obtained from each study across a diverse set of study types including systematic review (SAC), subchronic (CHR), and short-term (ST) studies as well as systemic adult effects observed in developmental (DEV) and reproductive (MGR) studies. Species and study type adjusted chemical-level NEL were derived demonstrating a floor baseline of roughly 5 orders of magnitude uncertainty (OMU; 95% CI) based on the default distribution of NEL. Using SUB to predict CHR rat and mouse to predict rat CHRISTEL, baseline ceilings were established as 3 and 3.5 OMU, respectively. Further classification of study types based on exposure duration (short = SAC, DEV; medium = SUB; long = CHR), established a ceiling baseline for short vs medium, and long vs medium to be 3.3 and 3.9 OMU, respectively. Thusly, the goal of any predictive model of systemic toxicity is to be able to identify the approximate 5 OMU and approach 3-3.5 OMU, but cannot be expected to exceed the inherent uncertainty in toxicological testing and evaluation. This abstract does not necessarily reflect US EPA policy.

440b Dynamic Interaction between Human Serum Albumin and PFOS: A Theoretical Study
A. Zhang, H. Cao and J. Fu, Research Center for Eco-Environmental Sciences, CAS, Beijing, China. Sponsor: B. Zhao

Numerous studies have focused on whether or not PFOS may displace fatty acids bound to human serum albumin (HSA) since the famous persistent organic pollutant exhibited a long half-life of elimination in human serum, approximately 5-4 years. However, there are insufficient information on both PFOS binding sites with HSA and the potential biological function induced by the PFOS-HSA interaction. Recent study of PFOS-HSA complex structure at extremely high PFOS concentration revealed two PFOS binding sites in HSA which overlapped with fatty acid binding sites FA3/4 and FA6, respectively. Unfortunately, such still can not elucidate which site acts as the preferable binding cavity at rational human exposure concentration. Therefore, molecular simulation was adopted to answer the question in the present study. The allosteric modulation associated with PFOS-PFOS interaction of 2 binding sites of HSA, FA3/4 and FA6, was analyzed using molecular dynamics simulations and binding free energy calculations. FA6 site was firstly recognized by PFOS binding to HSA although PFOS exhibit higher binding affinity with FA3/4 site. Single binding PFOS at FA6 site can generate allosteric modulation of subdomain 3A through increasing cavity volume of FA3/4 site. Key residues R410 and Y411 locating at entrance of FA3/4 site controlled the allosteric effect and the binding procedure of second PFOS molecule in FA3/4 site subsequent to the first PFOS in FA6. Besides, FA6 may act as only binding site for PFOS at environmental exposure dose, while both crystallographic structures of ligands-HSA complex and binding free energies analysis excluded the possibility that PFOS binding HSA at FA6 site would significantly affect blood delivery of fatty acids in normal physiological conditions. Nevertheless, PFOS binding at FA6 site can still lead to the potential disturbance in natural transport function of HSA due to conformation alterations induced in other subdomains.

440c Utilization of Gene Expression Marker Data to Computationally Generate Nested Networks Underlying Embryonic Stem Cell Differentiation

Predictive tools which model the differentiation of stem cells under a variety of stresses are an area of current research interest. The biological stem cell differentiation network delineates which cell differentiates into which cell. However, the underlying rules which determine where cells differentiate are not fully understood. We suggest there exists a nested regulatory network that governs, controls, and modifies the probabilities of lineage specification. Pluripotent J1 mouse embryonic stem cells (mESCs) were maintained on a mouse embryonic feeder (MEF) cell layer supplemented with LIF. mESC differentiation was initiated on culture day zero using an adherent cell model. MEF-depleted pluripotent mESCs were seeded onto 96-well gelatin-coated plates in the presence of fetal bovine serum without LIF. Cultures were maintained through day nine (cardiomyocyte formation). On days zero through nine, RNA was isolated from the cell population and analyzed using the MouseRef-8 v2.0 Expression BeadChip (illumina). To detect the regulatory network, genes were selected as biomarkers of specific cell types (pluripotent, ectoderm, primitive streak, mesoderm, and endoderm cells). A novel model was used to calculate plausible daily cell counts for each cell type using biomarker expression data, supplemented with cell number counts on each culture day, and computationally generated daily counts for each cell type were used to generate possible nested regulatory networks. Networks were generated using a Bayesian optimization approach over a stochastic model describing differentiation and proliferation. We will demonstrate the model in controlled and perturbed systems of differentiation. The methodology is scalable to larger systems and modular so that improvements to any feature may be applied independently. This abstract does not necessarily reflect EPA policy.

440d Development of Quantitative Adverse Outcome Pathways Using Health-Protective Assumptions to Fill Data Gaps
R. B. Conolly¹, W. Cheng¹, D. L. Villeneuve² and G. T. Ankley², ¹US EPA, Research Triangle Park, NC and ²US EPA, Duluth, MN.

In an adverse outcome pathway (AOP), the target site dose participates in a molecular initiating event (MIE), which in turn triggers a sequence of key events leading to an adverse outcome (AO). Quantitative AOPs (QAOPs) are needed if AOP characterization is to address risk as well as hazard. A QAOP is based on data gaps, and as its mature form, has the ability to predict the dose response and time course (DRTC) behaviors linking toxicant dosimetry, the MIE, and the key events with each other and with the AO. Identification of data gaps during QAOP development is common and, typically, some of the gaps cannot be filled given constraints of time and resources. In such situations, alternative assumptions can be identified about how the missing data would affect DRTC behaviors and the more risk-conservative assumptions incorporated until the missing data become available. We are developing a QAOP for fetal minnows. The MIA is inhibition of CYP19A, which converts testosterone to estradiol (E2). Depression of plasma E2, upregulation of CYP19A mRNA, and reduced levels of the glycoprotein egg yolk precursor vitellogenin (VTG) are key events. Depression of VTG is associated with decreased fecundity, the AO. Available data include time-course studies with 3 doses of the CYP19A inhibitor fadrozole, plasma E2 and VTG levels, ovarian CYP19A mRNA levels, and fecundity. In this presentation we show how quantitative dose-response relationships between key events, such as expression of CYP19A mRNA as a function of decreased plasma E2 levels, while constrained by data, can be described by alternative functions with different low dose behaviors. These alternatives assumptions provide different DRTC behaviors for the overall relationship between the MIA and the AO and can be selected to bias the QAOP to provide risk conservative predictions. This is an abstract or a proposed presentation and does not necessarily reflect EPA policy. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.
The aromatase inhibitor fadrozole inhibits CYP19A, a key enzyme that converts testosterone to estradiol (E2). In fish, E2 levels control synthesis of the glycolipoprotein vitellogenin (VTG), an egg yolk precursor protein essential to oocyte development and larval survival. Fathead minnows were exposed to various concentrations of fadrozole continuously for 8 days and then held in control water for an additional 20 days. Plasma E2 and plasma VTG concentrations were reduced during exposure. While E2 concentrations recovered to control levels post-exposure, VTG concentrations did not fully recover, even after 20 days of deputation. We developed alternative hypotheses to explain the effect of fadrozole on VTG levels. First, it is possible that hepatic production of VTG returned to normal as the E2 concentration recovered. However, plasma VTG could remain depressed for an extended period while oocyte VTG is being replenished. A second hypothesis is that the plasma VTG concentration is not simply proportional to the level of E2 but rather, involves a more complicated biological circuit with alternative setpoints, or attractors, to which it would move after the initial perturbation by fadrozole (i.e., allostasis). Computational modeling cannot by itself identify the actual biological structure of this circuit but it can identify candidate structures that could be investigated in the laboratory. We modeled a candidate circuit that reproduces the VTG data. Our approach is intended to identify the underlying biological explanation for the dynamics of VTG perturbations by fadrozole. This work illustrates the application of computational modeling to evaluate alternative hypotheses and to thereby identify the most appropriate hypothesis for follow-up experimental work. This is an abstract or a proposed presentation and does not necessarily reflect EPA policy. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

A deterministic biologically based dose response (BBDR) model was developed for the hypothalamic-pituitary-thyroid (HPT) axis to evaluate the effects of iodide intake and perchlorate exposure in the near-term pregnant woman and fetus. The goal of the current study is to extend the model to a probabilistic framework evaluating the response of pregnant population to thyroid disturbances. Maternal thyroid hormones play a crucial role in the fetal neurodevelopment. Perturbation of serum levels of maternal free thyroxine (fT4) following inhibition of thyroperoxidase (TPO) activity by JZL 184. The modeling also was able to predict reduced 2-AG levels mediated metabolism of AA and 2-AG (via neuronal CB1 activation). Our model had a high AC50 (66.5 nM) for cannabidiol (CBD) and its subsequent influence on maternal fT4 levels. Traditional toxicology tests required by US regulatory agencies are expensive and time consuming especially in light of the many chemicals that require such testing. An alternative vertebrate model for developmental toxicity is the zebrafish embryo (Danio rerio). In this study, 309 environmental chemicals were screened, mainly pesticides and antimicrobials from the ToxCastTM Phase I chemical library. Embryos were immersed in media containing chemical concentrations from 0.001 to 80 μM and the half-maximal activity concentration (AC50) for toxicity (lethality, non hatching, or dysmorphology) determined. To extrapolate to mammalian toxicity, the demonstrated relationship between lipophilicity (LogP) and bioconcentration was used to estimate a body burden associated with developmental toxicity (EC50). Toxicity potency rankings derived from AC50 and EC50 calculations for most toxic chemicals with a mean AC50 of 4.01 μM. To further assess extrapolation to mammalian systems, oral equivalent doses from regulatory toxicological studies were used to correlate in vitro concentrations with potential in vivo effects. The ability of the zebrafish developmental screen to predict mammalian toxicity was then assessed by examining the correlation between chemical potencies based on EC50, chemical class, and known toxicity, non hatching, or dysmorphology. The ability of the zebrafish developmental screen to predict mammalian toxicity was then assessed by examining the correlation between chemical potencies based on EC50, chemical class, and known toxicity, non hatching, or dysmorphology. research effort which is the goal of International transporter consortium (ITC). In this study, based on public sources, we developed a panel of CASE Ultra modules for 14 human drug transporters expressed in intestine, liver, kidney and brain (MDR1, MRPI-5, BCRP, ASBT, NTCP, BSEP, OATP2B1, OCT1, MCT1, PEPT1). These modules provide evidence of active transport or its inhibition and are based on datasets that range in size from 34 molecules (BCRP substrates) to 1,585 chemicals (MDR1 inhibitors). Performance of the modules was evaluated by 10% bootstrapping and 10-fold external cross-validation. All modules achieve good sensitivity (60-100%), specificity (60-100%), balanced accuracy (70-100%), as well as positive (60-100%) and negative (60-100%) prediction rates. The panel of transporter modules was then applied to 1,543 FDA approved drugs. Only 20% of the drugs were predicted to have no active transport, while over half were predicted as substrates of two or more transporters. The developed panel of modules can be used for assessing transporter interactions at early stages of drug development or chemical hazard evaluation.

**440j** Computational Modeling of OATP1B1 Inhibitors

OATP1B1 (organic anion transporting polypeptide 1B1) is a member of the solute carrier family of transporters. It is expressed predominantly in the liver where it occupies the basolateral side of hepatocyte cell membranes and transfers molecules from the blood into the liver. OATP1B1 substrates include natural products such as bile salts as well as pharmaceuticals such as statins and sartans. OATP1B1 is inhibited by several compounds including cyclosporine A and rifampicin. Drug-drug interactions can occur when an inhibitor of the transporter is coadministered with a substrate drug. For example, when orally administered pravastatin is taken with cyclosporine A, the area under the curve of pravastatin increases almost 900%, potentially leading to toxicological effects. The first International Transporter Consortium report identified OATP1B1 as one of the seven most important transporters in drug disposition. A data set of 336 compounds was compiled from recent publications. The data consisted of single-concentration, percent inhibition data with either estradiol-$\beta$17-glucuronide or estrone-$\beta$-sulfate as the substrate. These values were first converted to IC50 values and then to inhibition constants (Ki) using the Cheng-Prusoff equation. Compounds with Ki values less than 20 mM were classified as inhibitors. The overall data set contained 74% noninhibitors and 26% inhibitors, so the population was skewed towards noninhibitors. An artificial neural network classification ensemble (ANNce) model was trained on 80% of the compounds with the remaining 20% set aside as an external test set. The best model consisted of seven descriptors and six hidden neurons. The model includes lipophilic, atomic charge, and sigma Fukui index descriptors. It has high specificity (90%), sensitivity (89%), and overall concordance (90%) when applied to the external test set. The model was used to predict OATP1B1 inhibition of a subset of about 2,300 compounds from the World Drug Index (WDI). The model predicted 26.5% of the compounds to be OATP1B1 inhibitors with less than 1.5% of the molecules outside the model’s applicability domain.

**440l Global Phosphoproteome Dynamics of Zebrafish (Danio rerio) Embryos**

O. Kwon1, S. Kim2, J. Sim1, M. Song1, K. Yun1, J. Kim2, T. Jeong3 and S. Lee1.1 College of Pharmacy, Kyungpook National University, Daegu, Republic of Korea, 2 Mass Spectrometry Research Center, Korea Basic Science Institute, Ochang, Republic of Korea and 3 College of Pharmacy, Yeungnam University, Gyeongsan, Republic of Korea.

The zebrafish (*D. rerio*) is a popular animal model in studies of vertebrate development and organogenesis. Recent research has shown a similarity of about 70% between the human and zebrafish genomes and of 84% of human disease-causing gene. In particular, zebrafish embryos show a number of desirable features, such as, transparency, a large size, and rapid embryogenesis. Protein phosphorylation is a well-known post-translational modification (PTM), and performs various biological functions. Recent mass spectrometry (MS) developments have been used to study global phosphorylation using MS-based proteomics coupled TiO2 phosphate enrichment. In the present study, we identified 3,500 non-redundant phosphorylation sites on 2,166 phosphopeptides and 1,564 quantified phosphopeptides in zebrafish embryos. The distribution of Ser/Thr/Tyr phosphorylation sites in zebrafish embryos was found to be 88.9%, 10.2%, and 0.9%, respectively. Using Motif-X analysis, a potential kinase motif was predicted for 80% of the identified phosphorylation sites, motif related to MAPK has been found the most frequently appearing. In particular, we found that the pSF motif of 35 phosphorylation sites has not been previously reported in vertebrates. In addition, we created 6 of phosphopeptides cluster pattern during developmental stages in zebrafish embryos. Throughout these results, we reported the largest data set for phosphoprotein in zebrafish embryos and the pSF motif at the first time in vertebrate found. Finally, our zebrafish results can be used the further studies of phosphorylation site or dynamic phosphopeptides in zebrafish embryos.

**440k Interpretable QSAR of Skin Sensitization for Screening Cosmetics and Environmental Chemicals**

R. D. Saiakhov, S. Chakravarti and A. Sedykh. *MultiCASE Inc, Beachwood, OH.*

Computational models of skin sensitization provide important alternative to animal testing of chemicals. However, many of reported models have limited applicability due to small training sets, insufficient validation, and unclear interpretation of results. To address this, we have compiled from scientific literature a harmonized dataset of 374 small molecules with categorical data from local lymph node assay (LLNA). We used CASE Ultra expert system (v.1.4.7.0) to derive two types of models. Model 1 defined strong and extreme sensitizers as active group (73 cmpds), moderate sensitizers as marginally active (103 cmpds), and treated weak and non-sensitizers as inactive (198 cmpds). Model 2 defined strong, extreme, and moderate sensitizers as active (173 cmpds), weak sensitizers as marginal (108 cmpds), and non-sensitizers as inactive (93 cmpds). External cross-validation (10-fold) for Model 1 yielded sensitivity of 50% and specificity of 90%, while for Model 2 - sensitivity of 80%, and specificity of 52%. The developed models have distinct advantages (lower false positives vs. lower false negatives) and can be used jointly for early prioritization of skin care products, topical drugs and environmental chemicals. Major chemical features found by these models to be associated with sensitization were various aromatic, phenolic and ketone groups. Exemplary screening with these models 298 skin application drugs from DrugBank and Drugs@FDA databases suggested that 15 to 30% of them may have some skin sensitizing effect.

**441 Genotoxic Compound Profiling Using MILLIPLEX® MAP DNA Damage/Genotoxicity 7 Plex Panel**

J. Hwang1, N. Scotti2, T. Warrmke1, R. Maheshwari1 and R. Wiese1. 1 R&D Immunooassay, EMD Millipore Corp., St. Charles, MO and 2 Biomedical Engineering, Washington University, St. Louis, MO.

A cell’s response to DNA damage involves many complex pathways and mechanisms, collectively called the DNA damage response. Once initiated, these pathways ultimately lead to the repair of the damage or the initiation of apoptosis. The DNA damage response plays a crucial role in maintaining the function, genomic stability, and viability of the cell and organism at large. Dysfunctions in the response are implicated in many disease states including cancer, premature aging, and neurodegenerative disease. We have developed a Luminex® bead based multiplex immunoassay that allows for the simultaneous detection of multiple DNA damage proteins in a single well, including phosphorylated Chk1, Chk2, H2AX, and p53, and total protein levels of ATR, MDM2, and p21. Using the DNA Damage/Genotoxicity 7 Plex panel, we analyzed the levels of phosphorylated and total proteins in HEPG2 and HEK293 cells treated with genotoxic compounds (ethynitrosourea, methyl methansulfonate, cisplatin, p-chloroaniline, etoposide, hydroquinone, sodium arsenite, paclitaxel and chloramphenicol) and non-genotoxic carcinogens (ethylnitrosourea, methyl methansulfonate, cisplatin, p-chloroaniline, etoposide, hydroquinone, sodium arsenite, paclitaxel and chloramphenicol) and non-genotoxic carcinogens (D-limonene and diethanolamine). Genotoxic compounds, but not non-genotoxic carcinogens, resulted in changes in DNA damage response in a dose and time dependent manner. However, the profile of the genotoxic compounds showed differential regulation of the seven analytes in the DNA Damage/Genotoxicity panel, which implies different modes of action. Cell toxicity was also confirmed using the Human Kidney Toxicity Panel 2 on HEK293 cells. These studies demonstrate the validity of using the DNA Damage/Genotoxicity 7 Plex panel in screening genotoxic compounds.

Ochratoxin A (OTA) is a carcinogen targeting proximal tubules at the renal outer medulla (ROM) in rodents. We previously reported that OTA increased mutant frequencies of the red/gam gene (Spi), suggesting deletion mutations. In the present study, Spi assays and mutation spectrum analyses of the Spi mutants were performed using additional samples collected in our previous study. Spi assay results were similar to those in our previous study, revealing large (over 1 kb) deletion mutations in the red/gam gene. To clarify the molecular progression from DNA damage to gene mutations, in vivo comet assays and analysis of DNA damage/repair-related mRNA and/or protein expression was performed using the ROM of gpt delta rats treated with OTA at 70, 210, or 630 µg/kg/day for 4 weeks. Western blotting and immunohistochemical staining demonstrated that OTA increased γ-H2AX expression specifically at the carcinogenic target site. In view of the results of comet assays, we suspected that OTA was capable of inducing double-strand breaks (DSBs) at the target sites. mRNA and/or protein expression levels of homologous recombination repair (HR)-related genes (Rad51, Rad18, and Brip1), but not nonhomologous end joining-related genes, were increased in response to OTA in a dose-dependent manner. Moreover, dramatic increases in the expression of genes involved in G2/M arrest (Chk1 and Wee1) and S/G2 phase (Cen2a and Cdk1) were observed, suggesting that DSBs induced by OTA were repaired predominantly by HR, possibly due to OTA-specific cell cycle regulation, consequently producing large deletion mutations at the carcinogenic target site.

**Identification of Genotoxic Compounds Using Isogenic DNA Repair Deficient DT40 Cell Lines in a Quantitative High-Throughput Screening (qHTS) Platform**

K. Nishihara1, J. Zhao2, R. Huang1, K. L. Witt1, R. R. Tice2, S. Takeda1 and M. Saito3.

DNA repair pathways play a critical role in cellular homeostasis by repairing DNA damage induced by endogenous processes and xenobiotics. Isogenic chicken DT40 cell lines deficient in different DNA repair pathways can be used to identify genotoxic compounds and aid in characterizing the nature of the induced DNA damage. As part of the U.S. Tox21 program, we previously optimized several DT40 isogenic clones for qHTS in a 1536-well format and confirmed the utility of this screening system, which is based on measuring differential cytotoxicity in wild type and DNA repair deficient cell lines following exposure to chemicals. In this study, we screened the Tox21 10K compound library against two isogenic DNA repair deficient DT40 cell lines (ku70/ rad54 and rev3) and one wild-type cell line using a cell viability assay based on measuring ATP levels. Ku70 and rad54 are associated with DNA double-strand break repair, and rev3 is associated with translesion DNA synthesis pathways. From the primary screening, we identified several well-known genotoxic compounds (e.g., melphalan, aclotiam) that induced significantly greater cytotoxicity in the rev3 deficient cell line compared to the wild type cell line. Moreover, several previously unknown compounds were identified as potential direct-acting genotoxic chemicals in our assay. Our results demonstrate the utility of this approach for evaluating the genotoxic activity of chemical compounds using 1536-well based qHTS and for acquiring detailed information on the type(s) of DNA damage induced by these compounds. Supported by NIEHS Interagency Agreement Y3-ES-7020-01.

**A 6-Week Inhalation Protocol to Measure Cigarette Smoke-Induced Damage in the Rat Lung by Ex Vivo Comet and Histopathological Analysis**

Guidelines for the provision of genotoxicity data in mammalian cells have been re-defined such that an ex vivo study is preferable to a second in vitro mammalian study. We have explored the potential of the Comet assay to monitor DNA damage in rat lung alveolar type II epithelial cells (AECII) isolated from rats exposed to cigarette smoke (CS) via inhalation for 6 weeks. Concurrent histopathology was undertaken to monitor characteristic lesion formation following CS exposure. Female and male rats were exposed to sham air or 0.6 mg/L 3RF4 reference CS for 1 h or 2 h a day for 6 weeks. Lungs were collected, the left lobe processed for histopathology and AECII isolated from the right lobe. Histopathological evaluation demonstrated that goblet cells in the main bronchus, plus unpigmented macrophages and pigmented macrophages in the alveolar lumina were statistically significantly increased in CS exposed rats when compared to sham air. Values obtained (mean severity scores ± SEM) were 0.45±0.16, 1.47±0.30 and 1.38±0.26 for goblet cells, 0.45±0.15, 1.85±0.18 and 2.42±0.19 for unpigmented macrophages and 0.00, 0.45±0.14 and 1.11±0.17 for pigmented macrophages following exposure to sham air, 1.3RF4 CS or 2h 3RF4 CS respectively. The level of DNA damage in isolated AECII was statistically significantly increased in CS exposed rats when compared to sham air. Values obtained (mean % tail DNA ± SD) were 3.19±7.29, 13.43±14.54 and 13.83±16.20 for the Alkaline Comet assay and 18.58±15.52, 37.75±16.17 and 39.84±17.36 for Modified Alkaline Comet following exposure to sham air, 1h 3RF4 CS or 2h 3RF4 CS respectively. In conclusion, we have developed a 6 week inhalation protocol with an ex vivo endpoint. This protocol may have potential use to monitor characteristic lesion formation alongside DNA damage induced by CS.

**Integration of Pig-a Mutation and Micronucleated Reticulocyte Frequencies in a 28-Day Repeat Dose Study**

Genotoxicity of N-ethyl-N-nitrosourea (ENU) was evaluated for Pig-a gene mutation and micronucleated reticulocyte (MN-RET) endpoints in rat peripheral blood using high throughput flow cytometry-based methods. Male Sprague Dawley rats (7-8 weeks age, 6 animals/group/dose) were treated via oral gavage for 28-consecutive days with several doses of ENU (0.625, 2.5, or 10 mg/kg/day) or the vehicle (Phosphate Buffered Saline, pH 6.0). Blood samples were collected from the tail vein on days 0, 15, 29 and 46 for measuring Pig-a gene mutation frequencies in total red blood cells (RBCs) and reticulocytes (RETs) using MutaFlow-PLUS kit reagents. On day 4 and day 29 of the study, blood samples were processed for measurement of MN-RET frequencies with MicroFlow-PLUS kit reagents. Mutant RBCs and RETs exhibited significant dose and time-dependent increases on days 15, 29 and 46 at all the dose levels tested except at the lowest dose (0.625 mg/kg) on day 15. This 0.625 mg/kg dose induced a small but significant increase only in mutant RETs frequencies at this early time point, whereas both mutant RBCs and mutant RETs were elevated on days 29 and 46. With regard to MN-RET frequencies, a significant increase was found on day 4 and day 29 at the highest dose level (10 mg/kg). The mid dose (2.5 mg/kg) was significantly elevated on day 29. In conclusion, the lowest dose of ENU tested in this study (0.625 mg/kg) was observed to cause marked increases in Pig-a mutation despite the fact that it is lower than the threshold dose of 0.88 mg/kg estimated by Dobo and colleagues who also studied the Pig-a endpoint (Mutat. Res., 725:13-21). This increased sensitivity may be attributable to our use of immunomagnetic column separation step that allowed scoring of many times more cells per sample. In addition, the results validated the simultaneous scoring of two genotoxicity endpoints as well as provided a statistical robustness to the data collected. This approach of analyzing more than one endpoint in a single study results in reducing the number of animals used and proves highly cost-effective.

**In Vivo Genotoxicity of 1, 4-Dioxane in Rats**

Medicinal Safety Research Laboratories, Daichi Sanyo Co., Ltd., Tokyo, Japan.

1,4-Dioxane is used widely as a solvent in the manufacture of chemicals, and as a laboratory reagent. 1,4-Dioxane induces liver adenomas and carcinomas in mice and rats, and is categorized by IARC Group 2B chemicals. 1,4-Dioxane has been reported to be non-genotoxic in in vitro studies, e.g. Ames, mouse lymphoma TK, chromosomal aberration, in vitro micronucleus and sister-chromatid exchange assays. In the in vivo studies, positive results were obtained in bone marrow micronu-
clesus assay in C57BL6 and CD-1 mice, and liver micronucleus assay with or without partial hepatectomy (PH) in CD-1 mice. However, negative results were also observed in many in vivo genotoxicity studies; e.g., drosophila sex-linked recessive lethal, rat liver DNA alkali elution, rat liver DNA repair, bone marrow (BALB/c mice) and peripheral blood (CD-1 mice) micronucleus assay. Therefore, there is no clear conclusion for its in vivo genotoxicity in rodents. In the present study, we investigated the ability of 1,4-dioxane to induce micronuclei in rat bone marrow and liver. In the liver micronucleus assay, we performed the juvenile animal method and two PH methods (dosing before PH or after PH). We also evaluated the mutagenicity of 1,4-dioxane by Pig-a gene mutation assay using rat peripheral blood. As a result, all methods of liver micronucleus assay detected micronucleus induction by 1,4-dioxane. In the sensitivity to liver micronuclear induction by 1,4-dioxane, the dosing before the PH method, a suitable method for structural chromosome aberration inducer, is the highest among the three methods. This finding is consistent with a report that 1,4-dioxane induces chromosome breakage in the liver. Negative results were observed in the bone marrow micronucleus and Pig-a gene mutation assays. These results suggested that 1,4-dioxane is genotoxic in the liver but not in the bone marrow of rats. The fact that genotoxicity of 1,4-dioxane in the liver was detected in rats as well as mice supports the usefulness of the rat liver micronucleus assay because the rat is more common species in toxicology research and requires easier operation in PH.

**447 Combination of Multitissue Micronucleus Assay and Gene Mutation Assay: Simultaneous Detection of Multitissue Micronucleus Inducibility and Gene Mutation in Gpt Delta Transgenic Rats**

Recently, the combination or integration assay attracts attention because the readout in the number of experimental animals is required from the viewpoint of the animal welfare. If the evaluation of multi-tissue gene mutation assay using transgenic rat is combined to the results of micronucleus assay which shows different genotoxicity endpoints, it is expected that more information will be obtained from the same animals.

The gpt delta male rats were orally administered with 1, 2-dimethylhydrazine dihydrochloride (DMH) at day 1 and N-nitroso-N-methylurea (MN) at day 3 and 4. DMH and MN are known to induce micronuclei in the glandular stomach and colon, respectively. The colon, glandular stomach, peripheral blood and liver were removed from the animals euthanized on one day after the final administration. The gpt assay and Spi-assay were conducted using these tissues. The micronucleus assay was conducted using the colon, glandular stomach and peripheral blood.

In the results, statistically significant increases in the frequency of micronucleated cells in the colon, glandular stomach and peripheral blood were observed in the DMH and MNU-treated groups compared with the negative control. In the gpt assay, mutant frequencies in all assayed organs were also significantly increased. In the Spi-assay, mutant frequency in the liver only was significantly increased.

These results suggest that the multi-tissue gene mutation assay using transgenic rat can be combined to the micronucleus assay in gastrointestinal tract.

**448 Toxicity of Chemical Dispersants, Oil, and Chemically Dispersed Oil in Sperm Whale Skin Cells**

C. Wise, 1, 2, J. Wise, 1, 2, S. Wise, 1, 2, 3 and J. P. Wise, 1, 2, 3, 1Wise Laboratory of Environmental and Genetic Toxicology, Portland, ME, 2Maine Center for Toxicology and Environmental Health, Portland, ME and Department of Applied Medical Science, University of Southern Maine, Portland, ME.

Two major oil crises in United States history, the 1989 Exxon-Valdez oil spill in Alaska and the 2010 Deepwater Horizon Oil Rig explosion in the Gulf of Mexico, drew attention to the need for toxicological experiments on oil, chemical dispersants and, importantly, chemically dispersed oil. We are still learning the effects these spills had on wildlife. However, little data is known about the toxicity of these substances in marine mammals. The objective of this study is to determine the toxicity of the two dispersants (Corexit 9500 and 9527), Alaskan and Gulf oil, as well as chemically dispersed oil. Corexit 9500 and 9527 are both cytotoxic to sperm whale skin fibroblasts. Corexit 9527 is less cytotoxic than 9500. S9 mediated metabolism did not alter cytotoxicity of either dispersant. Both dispersants are genotoxic to sperm whale skin fibroblasts; S9 mediated metabolism increased Corexit 9527 genotoxicity. Oil experiments were performed using the water accommodated fraction of oil (WAF). The Alaskan WAF is not cytotoxic to sperm whale skin cells. Chemically dispersed Alaskan oil (CEWAF) is more cytotoxic and genotoxic than the WAF. S9 mediated metabolism increased genotoxicity caused by CEWAF and WAF.

**449 In Vitro Cytotoxicity and Genotoxicity Testing Using upcyte® Hepatocytes**

We have developed a novel technique which causes primary human hepatocytes to proliferate whilst retaining an adult phenotype including functional phase 1 and 2 metabolism. In this study we evaluated the resulting “upcyte® hepatocytes” for their potential use in cyto- and genotoxicity testing.

For the establishment of an upcyte® hepatocytes based genotoxicity test we adapted the conditions of the frequently used micronucleus test. Conditions for upcyte® hepatocytes from a single donor (Donor 740) showed that a treatment duration of 96 h, without a recovery period was optimal for detecting both directly acting and metabolically activated genotoxins, whilst true negative and “misleading” positive compounds were correctly identified as negative. The micronucleus rate (%MN) in upcyte® hepatocytes treated with DMSO, cyclophosphamide and MMC was essentially unaffected by the growth stage (between a population doubling of 18 and 59). In conclusion, these data support the use of upcyte® hepatocytes in the MN test, since they were able to correctly identify known direct and metabolically activated genotoxicants, while misleading positives and true negative compounds resulted in negative outcomes.

The cytotoxicity of 31 compounds was measured using upcyte® hepatocytes derived from four donors to include effects due to donor variation. The compounds were classified as either severely, moderately or non-hepatotoxic. There was a very good intra- and inter-experimental reproducibility of the measurements. The cytoxicity of the majority of compounds was donor-dependent. The predictive capacity of the assay was generally good such that known non-hepatotoxicants were clearly negative and compounds that were associated with hepatotoxicity caused damage to the upcyte® hepatocytes.

In conclusion, these studies show that use of upcyte® hepatocytes which combine proliferation with long-term stable expression of adult hepatic phenotype enables the development of new in vitro liver cell models for metabolic drug and toxicity analysis.

**450 The Liver Micronucleus Test Integrated into 5-Day Repeated-Dose Toxicity Study in Mice Would Be Useful to Detect the Genotoxicity of Hepatocarcinogens**

The liver micronuclear test has the potential to detect liver carcinogens due to the accumulation of micronuclear by repeated dosing and could be expected to be integrated into repeated-dose toxicity study. In this study, to assess the possibility of its integration into 5-day repeated-dose toxicity study in mice, genotoxic hepatocarcinogens: diethylhydrazine (DEN), 2,4-diaminotoluene (2,4-DAT), 2,4-dinitrotoluene (2,4-DNT) and 2-acetylaminofluorene (2-AAF), non-genotoxic hepatocarcinogen; clofibrate, and non-carcinogen; 2,6-diaminotoluene (2,6-DAT), were administered orally to male ICR mice once daily for 5 consecutive days. Hepatocytosis were collected 24 h after the final administration, and the frequencies of micronucleated hepatocytes (MNHEPs) were examined. Significant increases in MNHEPs were observed in DEN- and 2,4-DAT-treatment groups, but not in 2,4-DNT-, 2-AAF-, 2,6-DAT- and clofibrate-treatment groups. 2-AAF might not induce MNHEPs because of its mitosis inhibitory effect on parenchymal hepatocytes. The result of 2,4-DNT is reasonable because it is a hepatocarcinogen in rats, but not in mice. In conclusion, the liver micronucleus test integrated into 5-day repeated-dose toxicity study in mice would be useful to detect the genotoxicity of hepatocarcinogens with consideration on results of general toxicity studies.

**451 Evaluation of Reactive Textile Dyes with Organs-Specific Genotoxicity Using In Vitro Flow Cytometry-Based Micronucleus Assay**

D. M. Leme, 1 A. Sehr, 2 T. Grummt and D. P. Oliveira, 1FCFRP-USP, Ribeirão Preto, São Paulo, Brazil and 2Univembcbuentes, Bad Ems, Germany.

Introduction: The textile industry extensively uses synthetic chemicals as dyes. There are several studies reporting the deleterious effects (e.g. DNA damage) of dyes to humans. Humans can be exposed to toxic dyes either through ingestion of contaminated waters or dermal contact with colored garments. Thus, genotoxicity assessments of these chemicals using organ-specific cell lines can be relevant to estimate their hazard. Objective: Cyto- and Genotoxicity of the textile dyes Reactive Green 19 (RG19), Reactive Black 12 (RB12), Reactive Black 19 (RB19), Reactive Black 5 (RB5), Reactive Red 120 (RR120) and Reactive Orange 16 (RO16) were assessed using in vitro MicroFlow® kit (Litron Laboratories Ltd.)
with immortalized human keratocytes (HaCaT) and human hepatoma cells (HepaRG TM, Biopredict International, Rennes, France, purchased at Fisher Scientific). Methodology: HaCaT and HepaRG TM at 1×105 and 2×105 cells/mL, respectively, were exposed in a 96-well format to six concentrations of the test dyes (at 31.25 to 1000 μg/mL), PBS 20% v/v (solvent control), Mitomycin c at 2.5 to 10 μg/mL and Vinblastine at 12.5-50 μg/mL (positive controls) for 48 and 24 h, respectively. 2-fold over concurrent solvent control mean (EMA-fold: cytotoxicity, MN-fold: genotoxicity) were used to define the positive results. Results and Discussion: A dose-dependent cytotoxicity was observed using HaCaT cells for all tested dyes, unlike in the experiments carried out with HepaRG TM, where cytotoxic effects were detected only for RB19 and RO16 at the highest concentration (1000 μg/mL). Genotoxicity was not observed for any of the tested dye under both experimental conditions (HaCaT and HepaRG TM). Conclusion: Based on our findings, HaCaT cells showed to be more sensitive to detect the cytotoxic effects of textile dyes than HepaRG TM. The reactive dyes studied herein can be considered not hazardous to human skin in respect to the criticality of in vitro testing of these target tissue (epidermis and liver). Financial Support: FAPESP (Process No. 2010/14941-3)

**452 Kinetics and Dose-Response Assessments of Cisplatin-Induced Genotoxicity in Sprague-Dawley Rats**

S. Derringer1, S. Phoneothawth1, S. Aylavicius1, D. K. Toros1, C. Labash1, J. Costrom1, J. Metensess1, S. Bryce1, J. Bernis2 and J. T. MacGregor2. Litton Laboratories, Rochester, NY and 2Toxicology Consulting Services, Arnold, MD.

Cisplatin and other platinum-type drugs exhibit tremendous efficacy in treating some types of malignancies, for example testicular cancer. However, secondary malignant hematopoietic disorders, with some estimates suggesting rates as high as one in three. We set out to determine whether a rat model and two blood-based endpoints could be used effectively to study the genotoxicity of cisplatin at low, tumorigenic dose levels. Male Sprague Dawley rats, age 7 weeks, were administered cisplatin via ip injection at 0, 0.05, 0.1, 0.2 and 0.4 mg/kg/day for 28 consecutive days. Allometric scaling suggests that the highest dose level corresponds to a human equivalent of 2.4 mg/m²—well below typical therapeutic levels of 20 mg/m² iv (once/day for 5 days/cycle). Two endpoints of genotoxicity were studied: micronucleated reticulocytes served as an indicator of chromosomal damage and were measured on days 4 and 29, and Pig-a mutant phenotype cells were scored in blood samples collected on days 15, 29, 56 and 84. Even the earliest time points evaluated showed dose-related increases for both endpoints, long before tumors or blood samples collected on days 15, 29, 56 and 84. Even the earliest time points evaluated showed dose-related increases for both endpoints, long before tumors or mortality information for assessing whether suspected leukemogenic agents such as cisplatin contribute to the risk of secondary malignancies through a genotoxic mode of action. Furthermore, given the pharmaceutical industry’s desire to combine platinum drugs with novel anti-neoplastic agents, we speculate that this rodent model may prove useful for studying adjuvants’ effects on platinum drug-induced DNA damage, and by extension the tumorigenicity of combination therapies.

**453 Development of a Flow Cytometric Assay for Measuring In Vivo Mutation in an Autosomal Gene**

J. A. Bhai1,3, V. N. Dobrovolsky2 and R. H. Heilich1. 1Division of Genetic and Molecular Toxicology, National Center for Toxicological Research, Jeffersonville, AR and 2Genetic Toxicology, Covance Laboratories Inc, Greenfield, IN.

The product of the X-linked Pig-a gene is essential for the synthesis of glycosyl phosphatidyl inositol (GPI) anchors that link specific proteins to the cell surface. Although an assay that detects in vivo mutation in the Pig-a gene (the Pig-a assay) has generated considerable interest in the regulatory community, the Pig-a assay is not expected to detect an important class of mutation, i.e., loss of heterozygosity (LOH). LOH mutations can most readily be detected using a heterozygous autosomal reporter gene, as is the case with the heterozygous Tk gene employed in the mouse lymphoma assay. In this study, we investigated the feasibility of a flow cytometric Pig-a-like assay using an autosomal gene that codes for a GPI-anchored surface marker protein, CD24. CD24+/− mice were generated by breeding CD24 knockout (KO) males to wild-type females. A labeling strategy was devised to differentiate between Pig-a and CD24 mutant RBCs. Leukodepleted blood was labeled with a PE-conjugated anti-mouse CD24 antibody and FLAER (AlexaFluor®488-conjugated nontoxic variant of procarboxylase), which binds to GPI anchors. A pilot study was performed by treating groups of five 6-8-week-old male CD24+/− mice with single doses of 0 or 140 mg/kg ENU by oral gavage; blood was collected on Days -1, 15 and 29, labeled, and processed by flow cytometry to quantify fluorescently labeled and unlabeled erythocytes. Significant increases in the frequency of FLAER-negative (presumably Pig-a mutant) and CD24-negative (presumably Pig-a and CD24 mutant) erythrocytes were observed in ENU-treated animals, with CD24-negative erythrocyte frequencies being somewhat higher. Additional studies using agents that induce high frequencies of LOH-type mutations (e.g., ionizing radiation) should be conducted in order to confirm that the CD24-negative phenotype is detecting a greater number of mutations than Pig-a-negative phenotype.

**454 Evaluation of Thioacetamide Genotoxicity in Rat Liver and Stomach As Measured by the In Vivo Alkaline Comet Assay**

R. Nef1 and C. Beever1. 1Covance Laboratories Ltd, Harrogate, North Yorkshire, United Kingdom and 2Covance Laboratories Inc, Greenfield, IN. Sponsor: J. Bhai1.

Thioacetamide is a known hepatotoxic agent and dietary administration caused hepatocellular carcinoma in mice and rats and tumors of the bile duct in rats. It is negative in Ames and in vitro chromosome aberration tests, however, there are conflicting reports regarding its genotoxicity in vivo. It induced micronuclei in the bone marrow of two strains of mice, albeit mostly at lethal dose levels, but similar effects were not seen in rats. No micronuclei were induced in the liver or peripheral blood of thioacetamide treated rats. In the Comet assay, thioacetamide was positive in stomach, colon and urinary bladder, but not in bone marrow or liver of mice treated by intraperitoneal injection. We examined thioacetamide activity (up to a maximum tolerated dose) in a rat alkaline comet assay and measured DNA migration in liver and stomach after 3 exposures (21-24 hours apart), sampling 3 hours after the final administration. Thioacetamide caused an increase in DNA migration in the stomach of rats treated at 38 and 75 mg/kg/day as well as an increase in hedgehogs, a Comet morphology indicative of highly fragmented DNA that is excluded from Comet analysis. Thioacetamide did not cause any increase in DNA migration in the liver, despite evidence of marked hepatotoxicity. These findings confirm that toxicity does not always confound assessment of genotoxicity-related DNA migration in the Comet assay.

**455 Evaluation of the DNA Adductome Approach to Assess the DNA Reactivity of Chemicals in Rat Liver**

The usefulness of DNA adductome approach, a comprehensive measurement of DNA adducts using highperformance liquid chromatography equipped with tandem mass spectrometry (LC–MS/MS), was evaluated to assess the DNA-damaging capability of chemicals in vivo. Male Sprague-Dawley rats were treated with compounds from three categories: (1) genotoxic carcinogens causing DNA alkylation, dimethylnitrosamine (DMN) and methylmethanethiosulfonate (MNT); (2) genotoxic carcinogens producing DNA bulky adducts, 2-acetylaminofluorene (2-AAF), 2,4-Diaminotoluene (2,4-DAT), 7,12-di-methylbenz[a]anthracene (DMBA) and 4-Nitroquinoline 1-oxide (4NQO); and (3) non-genotoxic carcinogen, Di(2-ethylhexyl)phthalate (DEHP), DNA extracted from liver samples were enzymatically hydrolyzed to deoxyribonucleoside by micrococcal nuclease/bovine spleen phosphodiesterase or P1 nuclease method, and subsequently applied to the LC/ESI-MS/MS analysis. The methods was designated to detect the neutral loss of deoxyribose from positively ionized deoxynucleoside adducts by monitoring the DNA samples transmitting their [M+H]+-[M+H+116]+ transitions. The transitions were monitored over the m/z range of 250-702. All genotoxic carcinogens produced various DNA adduct peaks in the liver. Some of DNA adduct peaks had the m/z values corresponded to compound-derived adducts (methyl-dG for DMN and MNT, aminofluorene-dG for 2-AAF, DMBA-diol-epoxide-dG for DMBA, 4-aminoquinoline 1-oxide-dG for 4NQO). On the contrary, no DNA adduct peak was detected in liver of DEHP treated rats. These results indicate that this DNA adductome approach would be useful to identify the DNA reactivity of compounds, and to support the understanding of their mechanism of action.
tion assessment: 1) to dose for 28 days plus 3 days expression period and sample both developing germ cells from the seminiferous tubules and mature sperm from the cauda epididymis/vas deferens or 2) to dose for 28 days and sample only mature sperm a minimum of 7 weeks (mice) or 10 weeks (rat) after last treatment. Option 1 has significant advantages in terms of logistics, duration and cost of the study. Even more importantly where somatic tissues are investigated alongside germ cells, Option 1 is more ethically justified as it would use up to half the number of animals as Option 2. However, it has been questioned whether all stages of germ cell development are adequately covered by the 28 plus 5 day study design to ensure accurate detection of germ cell mutagens. We treated male MutaMice with saline or the potent mutagen ethyl nitrosourea (ENU). Animals were treated orally by gavage for 28 consecutive days at 10 mg/kg/day. On Day 31, animals were necropsied and developing germ cells from the seminiferous tubules and mature sperm from the cauda epididymis/vas deferens were isolated. Both cell types were examined for mutation in the neutral lacZ transgene using positive selection methods. Clear increases in in vitro mutagenesis were detected in developing germ cells, however, weaker, equivocal increases were detected in the mature sperm, supporting the idea that a 28 plus 3 day study design is not optimal for robust detection of germ cell mutagens.

**457 Genotoxic Effects on HepG2 Cells Induced by Brominated Flame Retardant (BDE-47)**

A. O. Souza1, M. J. Tasso1, L. C. Pereira2, D. P. Oliveira1 and D. J. Dorta1, 2.
1Quimica, FCFLCR-UPF, Ribeirão Preto, SP, Brazil and 2Analises Clinicas, Toxicológicas e Bromatológicas, FCFRP, Ribeirão Preto, SP, Brazil.

INTRODUCTION: BDE-47, a brominated flame retardant, shows evidences of potential toxicity to the organisms and the environment. The levels of BDE-47 on biotics and abiotics systems are increasing and its high bioaccumulation has leading to growing concerns about its presence in the environment and the consequences to the human health, such as its genotoxic potential. BDEs genotoxic potentials had been shown for some cell lines, but there is no information to the liver cells, which are one of the main targets of BDEs. Therefore, the full evaluation about the risks of BDE use are still necessary to better understand their toxicity to the human health. OBJECTIVE: The aim of the work was to investigate the genotoxic effects of the BDE-47 on human hepatoma cells (HepG2). METHODOLOGY: Briefly, cells were incubated at 37°C, in an atmosphere containing 5% CO2 and 95% relative humidity and treated with concentrations ranging from 0.1 to 25 μM for 4 hours. After the exposure period, the HepG2 cell were fixed with agaropectin and transferred to slides. The cell on the slides were lysed for 2 hours and submitted to electrophoresis (300 mA and 25 V for 20 min). Then, the cells were stained with propidium iodide solution (10 μg/ml) and examined using fluorescence microscopy. RESULTS: Our results showed the capacity of BDE-47 to cause DNA damage at doses starting at 10 μM (p<0.05) while at lower concentration there isn’t difference between treatments and negative control (without BDE-47). CONCLUSIONS: According to these results, BDE-47 showed the ability to cause DNA damage of HepG2 cells after the high concentration exposure. These conclusions contribute with evidences to the genotoxic potential of BDE-47, which high bioaccumulation potential can easily lead to a high concentration into the DNA damage of HepG2 cells after the high concentration exposure. These conclusions reinforce the importance of using different assays for toxicological analyzes and suggest that BDE-153 induces genotoxic effects that can lead the cell to death by apoptosis.

**458 BDE-153 is Genotoxic to HepG2 Cells and Lead to Apoptotic Cell Death**

L. C. Pereira1, A. O. Souza1, M. F. Bernardes1, M. J. Tasso1, D. P. Oliveira1 and D. J. Dorta1, 2. 1Quimica, FCFLR-UPF, Ribeirão Preto, SP, Brazil and 2FCFRP, Ribeirão Preto, SP, Brazil.

INTRODUCTION: Polybrominated diphenyl ethers have been used in diverse products and are ubiquitous contaminants in sediments and biota. They are also found in human tissues, food and wildlife. There is a lot of information about the presence of brominated flame retardants in the environment, however little is known about their mechanisms of inducing toxicity. The use of different assays as well as monitor different endpoints is important to evaluate the hazard potential of chemicals OBJECTIVE: The aim of this work was to investigate the mechanisms by which BDE-153 (penta-BDE) can induce toxicity to HepG2 cells in concentrations ranging from 0.1 to 25 μM. METHODS: Briefly, the affects of BDE-153 in HepG2 cells were evaluated by different endpoints. First, we assessed the exposure of phosphatidylserine on the outer cell membrane after 24 and 48 hours of exposure to BDE-153. After that, we assessed nuclear fragmentation using the fluorescent dye Hoechst 33342, and finally, we evaluated the genotoxic potential of the compound through the comet assay. RESULTS: We observed that in concentrations of 5 μM and higher BDE-153 was able to induce apoptotic cell death since it was observed exposure of phosphatidylserine in the outer cell membrane and nuclear fragmentation of HepG2 cells after 24 h of exposure to the compound. In addition BDE-153 is able to induce primary DNA damage observed by comet assay at the same concentrations but much earlier, with only 4 hours of cell exposure to the compound. CONCLUSIONS: The results reinforce the importance of using different assays for toxicological analyzes and suggest that BDE-153 induces genotoxic effects that can lead the cell to death by apoptosis. Supported by: FAPESP - Proc. 2012/13133-0

**459 Validation of an Expert Rule-Based System to Support the ICH M7 Guideline on Drug Impurities**

G. J. Myant, K. P. Cross and D. Bower. ReD, Leadscope, Columbus, OH. Sponsor: R. Bent

The ICH M7 guideline on drug impurities states that two distinct in silico methodologies can be used to qualify certain drug impurities as not mutagenic. This poster outlines a new expert rule-based system to predict the results of a bacterial mutagenesis assay. In the development of this system, an internal library of mutagenicity structural alerts was identified from the literature. This process included consolidating the same or similar alerts cited in multiple publications. Information on plausible mechanisms was collected alongside the structural definitions. Factors that deactivate the alerts were also identified from the literature and through an analysis of the corresponding data using the Leadscope data mining software. Over 200 distinct alerts were identified and these alerts were further validated against a database of over 7,000 chemicals with known bacterial mutagenesis results. Only validated alerts with a sufficiently strong association with positive expert-reviewed calls from Salmonella and E. coli strains were included. A prediction of the bacterial mutagenic assay can be made using these validated alerts; however, this is only possible where the compound is within the applicability domain of the alert system. In addition, a confidence score based on information collected for each alert is provided alongside the positive or negative call. This poster outlines the expert system along with the results of validating the system, both as a standalone system as well as in combination with a statistical-based approach. The system was tested using a set of 3,734 compounds with concordance of 79.4% and coverage of 99.8%.

**460 An In Vitro Mutagenicity Test of Hydroquinone Using the lacZ Transgenic Mouse**

A. Ono1, M. Honma2, S. Masumori2, M. Matsumoto1, M. Hirata-Koizumi1 and A. Hirose1.
1Division of Risk Assessment, National Institute of Health Sciences, Tokyo, Japan and 2Division of Genetics and Mutagenesis, National Institute of Health Sciences, Tokyo, Japan and 3Genotoxicology Laboratory, Biosafety Research Center, Shizuoka, Japan.

Hydroquinone (HQ) is used as an antioxidant in rubber industry and as a developing agent in photography. HQ is also used as a skin-lightening agent, and some cosmetics with an excess of content over 10% are marketed in Japan. Health risks in general population may be of concern due to highly absorbed HQ via dermal exposure. Carcinogenicity of HQ was suggested from previous studies in which HQ induced hepato cellular adenomas and forestomach hyperplasias in mice and renal cell adenomas in male rats. In genotoxicity tests, positive results in chromosomal aberration tests and micronuclei tests both in vivo and in vitro were reported, whereas most reported tests in Ames tests were negative except in a few studies. In this study, the lacZ transgenic mouse (MutaTM Mouse) model was used to clarify whether mutagenic mechanisms are involved in HQ-induced carcinogenesis in according to the OECD guideline 488. Male MutaTM mice were subjected to repeated oral administration of HQ at dosages of 0, 50, 100, or 200 mg/kg/day for 28 days. High dose was set based on the result of the NTP fourteen day gavage study using B6C3F1 mice in which HQ related death was observed in males receiving 250 mg/kg/day. Body weight was not affected by HQ administration up to 200 mg/kg/day. Mutant frequency in the liver and stomach of HQ treated mice were not significantly different from the negative control. N-Ethyl-N-nitrosourea, used as a positive control, induced mutation at a frequency 2-fold higher in the liver and 11-fold higher in the stomach than in their respective negative control organs. These results suggest that the mutagenic mechanism is not responsible for carcinogenesis of HQ.

461 Oligoquat M Does Not Induce Mutagenesis and Chromosome Aberration in the V79 and CHL Cell Lines
Z. Lu1, 2, J. Liang1 and M. Wang1, 1The Institute of Toxicological and Functional Evaluation, Jiangsu Provincial Center for Disease Control and Prevention, Nanjing, China and 2Basic Medical Sciences, University of Arizona Medical College-Phoenix, Phoenix, AZ. Sponsor: S. Qiu.

Oligoquat M is a novel cationic moisturizing polymer derived from sugar cane with the active ingredient being stearyl dihydroxypropyldimonium oligosaccharides. Oligoquat M is used as a personal hygiene product and therefore warrants a detailed assessment of its safety, including mutagenesis potential. In this study, the toxicity of the Oligoquat M to the Chinese hamster lung cells (V79 and CHL) was tested in the presence and absence of the metabolic system (S9), and the V79 HGPRT gene mutation and the CHL chromosome aberration induced by Oligoquat M were tested. We found that the half of the growth inhibitory concentration (IC50) was 209μg/mL to the CHL cell. The number of resulting mutant clones from V79 cells treated by the dose levels of 75, 150 and 300μg/mL were similar to those of the negative control (P<0.05); in contrast, the cell mutation frequency (MF) of positive control was 49.4/10E6 and 63.0/10E6 for EMS and MCA, respectively, which was greater than 3 times of the negative control group (4.4/10E6 and 3.51/10E6 with or without S9, respectively). In the dose level of 50, 100 and 200μg/mL, the incidence of the chromosome aberration of CHL cells were less than 4% in the presence and absence of S9, and showed no clear dose-response relationships. We can conclude that Oligoquat M has no significant mutagenic and chromosome aberration effects in V79 and CHL cells under this laboratory conditions.

KEYWORDS: Oligoquat M; HGPRT locus; Gene mutation; Chromosome aberration

462 Assessment of Genotoxicity and Antigenotoxicity of Ethanolic Extract of Spondias mombin L. (Anacardiaceae) Leaves in In Vitro and In Vivo Models
O. E. Oladewin1, J. E. Mata2, A. O. Adeogun1 and O. S. Olowuyi3, 1Department of Veterinary Physiology, Biochemistry and Pharmacology, University of Ibadan, Ibadan, Oyo, Nigeria, 2Department of Basic Medical Sciences, College of Osteopathic Medicine of the Pacific, Western University of Health Science, Lebanon, OR and 3Department of Zoology, University of Ibadan, Ibadan, Oyo, Nigeria.

Spondias mombin, a medicinal plant found in Nigeria contains high amounts of phenolic compounds with antioxidant activity. The ethanolic extract of the leaves was evaluated for its safety and beneficial effects using genotoxicity and toxicity tests. None of the plant fractions had detectable mutagenic activity. The S. mombin fractions were not only non-mutagenic in Salmonella typhimurium strains TA98 in the presence and absence of metabolic activation, but also exhibited antimutagenic activities against 2 – amino – 3 methyl – 3H – Imidazo[4, 5 – F] quinoline (IQ) – induced mutagenesis. Phytotoxic analysis revealed that S. mombin revealed the presence of alkaloids, tannins, saponins, phlobatannins, flavonoids and anthraquinones. The administration of S. mombin at concentration of up to 8,000 mg/kg body weight did not induce acute toxicity in rats. A bone marrow micronucleus test was performed to detect clastogenicity and anticlastogenicity. The extract in the dose of 2,000 mg/kg did not cause micronucleus formation in the bone marrow of rats. Furthermore, in rats administered 50–100 mg/kg of the extract, no anticlastogenic effect against sodium arsenite induced micronucleus formation was observed. These studies provide data concerning the safety and antimutagenic potency of an ethanolic extract of Spondias mombin leaves.

463 Detection of Sulfur Mustard-Induced DNA Adducts in Human Skin Cells with Laser Scanning Microscopy
K. Kehe1, S. Miiller2, D. Steinruck2 and H. Thiermann2, 1E - Research and Development, Biontechwer Institute Academy, Munich, Germany and 2Biontechwer Institute of Pharmacology and Toxicology, Munich, Germany.

Introduction: Sulfur mustard (SM) and 2-chloroethyl ethyl sulfide (CEES) are bi- and monofunctional DNA alkylating agents, respectively. SM is an old chemical warfare agent causing blisters (vesicant). Both chemicals react with N7 guanine. SM will form 7-Hydroxyethylthioethylguanine for SM. A specific monoclonal antibody (2F8) exists which detects SM at N7 position. Aim: The 2F8 antibody was used to develop a microscopique technique for detection of SM exposure in human keratinocytes (HaCaT cells). Methods: HaCaT cells were cultured on cover slips and exposed with different concentrations of SM (30 min). After exposure, cells were fixed and treated with Proteinase K. Subsequently, the preparation was treated with the monoclonal 2F8-antibody against the N7- guanine monoadduct. Next, the antibody molecules attached to the DNA damage were made visualized by binding to a goat-anti-mouse antibody that contains covalently a fluoresceum group emitting red light to bind to them. The preparation was also treated with DAPI to counterstain cell nuclei. By means of laser scanning microscopy, red fluorescence was quantified. Results: DNA adducts were concentration dependent detected after SM exposure below 30 μM which is the vesicant threshold. Conclusion: The presented technique is potentially able to detect and quantify SM exposure in HaCaT cells in vitro. The technique may be useful to confirm SM exposure in blister roofs of intoxicated patients.
Introduction: LLL-3, an anthracene derived compound, has been shown to be a promising therapeutic agent in the treatment of some kinds of cancer such as chronic myeloid leukemia. This compound is derived from the commercial product STA21 and acts by inhibiting the STAT3, which has been associated with the induction of proliferation and survival of cancer cells. Although LLL-3 has presented good properties to be a potential therapeutic agent in the treatment of some types of cancer, there is no data in the literature about the toxic properties of this compound.

Objective: To investigate the genotoxic and cytotoxic activities of the LLL3 by Micronucleus (MN) and WST assays, using mouse macrophage cell line RAW 264.7.

Results and Discussion: LLL-3 did not induce genotoxicity in RAW 264.7 cells, moreover, it was noted that apoptosis or necrosis cell death in these cells, although the mitotic index decreased after exposure in the same tested conditions, which may suggest some cytostatic effect, since this compound acts by inhibiting the STAT3. Besides, the cell viability evaluated by WST assay was not affected by LLL-3. One LLL-3 did not show mutagenic activity as most of other drugs used in cancer treatment, the results increase the chance of using this drug in cancer therapy.

Conclusion: LLL-3 should be of interest to further explore the possibility of using it as a potential agent for human cancer treatment.

Estragole and safrole, naturally-occurring constituents of various herbs and spices, are rodent liver carcinogens. To further understand the mechanisms underlying their carcinogenicity, genotoxicity was measured in rats using Comet, 32P-postlabeling DNA adduct and micronucleus assays, combined with histopathological analysis. Oxidative damage was measured using human 8-oxoguanine-DNA-N-glycosylase (hOGG1) and Endonuclease III (EndoIII)-modified Comet assays. Groups of 5 seven-week old male F344 rats were administered corn oil or with various doses of estragole or safrole in corn oil by oral gavage at 0, 24, and 45 hr and were sacrificed at 48 hr. Estragole induced a dose-dependent increases in DNA strand breaks, DNA adducts, and oxidative DNA damage in the liver, the cancer target organ. DNA strand breaks were not detected in kidney, stomach or bone marrow, non-target tissues for cancer. Peripheral blood micronuclei were observed at the highest dose in estragole treated animals. Safrole also induced dose-dependent increases in DNA strand breaks and oxidative DNA damage in the liver. No DNA damage was detected in kidney, stomach or bone marrow nor was micronuclei elevated in peripheral blood in safrole treated animals. Evidence of inflammation, single-cell necrosis, and cell proliferation were found in estragole but not safrole-treated rat livers. Taken together, these results imply mixed genotoxic mechanisms. The direct genotoxic effects, indicated by DNA strand breaks and DNA adducts, are associated with the generation of initiated cells; while an indirect genotoxic effect, involving oxidative stress, accompanied by inflammation and cell proliferation, could be associated with tumor development.

Evaluation of Mutagenicity of Vinyl Acetate and Acetaldehyde in Gpr Delta Mouse Lung Fibroblast Cell Line, GDL-1

Vinyl acetate monomer (VAM) induces nasal tumors in rats and oropharyngeal tumors in rats and mice. VAM is weakly genotoxic in vitro and non-genotoxic in vivo. A critical key event in VAM’s rodent carcinogenicity is its carboxylated metabolite, vinyl acetate. The mutagenicity of VAM and AA was evaluated in a newly established gpr delta mouse lung fibroblast cell line (GDL1) harboring two reporter genes, gpt and red/gam (Spy) employing either horse serum (HS) or fetal bovine serum (FBS) since HS was shown to rapidly metabolize VAM to AA. GDL1 cells were exposed to VAM and AA at concentrations ranging from 0.5 mM to 10 mM for 24 hr. Cells were washed and further cultured for 6 days for mutation fixation. Cytotoxicity was measured by relative cell count and ethynylisouriboside and mitomycin C were used as positive controls. VAM was also tested for micronuclei (MN) induction in GDL cells. VAM and AA were not mutagenic at the Spy locus which detects large deletion mutations in GDL cells. In contrast, VAM induced a dose-dependent increase in the MN frequency which was higher in the HS than in FBS. Apparent increases in the MN frequency which were higher in the HS than in FBS. Apparent increases in the MN frequency which were higher in the HS than in FBS. Apparent increases in the MN frequency which were higher in the HS than in FBS.
467c Effects of Ethyl Methanesulfonate on DNA Damage of Uterine Mucosa in Rats

It is known that the DNA damage in the multiple organs can be detected by the in vivo comet assay. However, this assay that uses the uterus as a target organ is hardly known. The in vivo comet assay was examined by using ethyl methanesulfonate (EMS) whether there was a difference in DNA damage in the uterine mucosa when dosed in each stage of the estrous cycle. EMS was administered orally to female rats at a single daily dose of 200 or 300 mg/kg for 2 days. The 10 weeks old female rat when the estrous cycle was steady was used. At 3 hours after the final dosing, the uterus was removed, and specimens were prepared. The % tail DNA, an indicator of DNA damage, was determined. As a result, DNA damage was observed dose-related in the EMS dosing group compared with the negative control (distilled water) group. The influence by the difference at the estrous cycle was not admitted in the negative control group and EMS dosing group.

467d In Vitro Toxicity Testing of 2, 4, 6-Trinitrotoluene (TNT) Contaminated Soil
L. K. Markell1, M. P. Mawn2, C. E. Pooler1, A. Myhre1, P. Bloxham1, A. Faranda1, E. M. Donner1, X. Han1 and T. S. Bingman1,1 DuPont Haskell Laboratories, Newark, DE, 2DuPont Corporate Center for Analytical Sciences, Newark, DE, 3URS Corporation, Louisville, KY and 4DuPont Corporate Remediation Group, Wilmington, DE.

Remediation of 2,4,6-trinitrotoluene (TNT) contaminated soil at explosive manufacturing sites may use approaches for monitoring the remediation progress. Previous studies have identified TNT as a mutagen and extracts from TNT contaminated soil may show mutagenicity in a number of in vitro assays. The purpose of this study was to demonstrate proof-of-concept for in vitro mutagenicity testing of contaminated soil, which may be used to validate the effect of future remediation processes. Here, we use an extraction procedure based on the EPA 8330B method, which includes the use of a ring and puck mill to homogenize the soil, incremental sampling and subsampling and LC/UV analysis. Acetonitrile extracts from soil contaminated with TNT and soil determined to be free of TNT, as well as a TNT standard were tested in a Reverse Bacterial Mutation (Ames) assay. Salmonella typhimurium strain TA98, TA100, TA1535, and TA1537 and the Escherichia coli WP2uvrA strain with and without Aroclor 1254 induced rat liver S9 metabolic activation were used. Results from soil extracts absent of TNT yielded no mutagenicity. As expected, treatment with the TNT standard yielded a positive response with 4 strains (TA98, TA100, TA1537, WP2uvrA) and a dose response trend with TA1535. A similar mutagenicity profile was observed with extracts from soil contaminated with TNT, indicating that the extraction procedure and Ames assay are appropriate methods. The addition of the S9 fraction reduced the number of bacterial revertants, demonstrating that metabolic activation is a key determinant of TNT. Yet, it is possible that other unidentified contaminants in the soil may be contributing to the Ames results. This study verifies the methodology used for in vitro mutagenicity testing of soil contaminated with TNT and demonstrates a simple and inexpensive technique by which effective hazard reduction may be demonstrated following remediation.

467e Evaluation of Genotoxicity of 6-Diazo-5-Oxo-L-Norleucine (DON)
R. Kulka1, E. W. Dakoulas1, K. E. Miller2 and P. S. Terse3, 1BioReliance, Rockville, MD, 2Kemmx Corporation, Sapulpa, OK and 3National Center for Advancing Translational Sciences, NIH, Bethesda, MD.

6-Diazo-5-oxo-L-norleucine (DON), a glutamine antagonist, was isolated originally from Streptomyces in a sample of Peruvian soil and was demonstrated to exhibit analgesic and anticancer properties. The current study was performed to characterize its in vitro and in vivo genotoxic potential. DON was tested in the Bacterial Reverse Mutation Assay (Ames test) for its mutagenic potential using Salmonella typhimurium tester strains TA98, TA100, TA1535 and TA1537 and Escherichia coli tester strain WP2uvrA with and without S9 and also with reductive S9. DON was tested for the chromosome aberrations in Chinese Hamster Ovary (CHO) cells with or without S9 to evaluate the clastogenic potential of the test article. DON was also evaluated for its clastogenic activity and/or disruption of the mitotic apparatus by detecting micronuclei in polychromatophilic erythrocyte (PCE) cells in mouse bone marrow.

In the mutagenicity assay using the plate incorporation method with and without S9 and using the preincubation method with uninduced hamster liver S9, no positive mutagenic responses were observed. In the in vitro chromosome aberration assay, dose dependent statistically positive increase in structural aberrations was observed at and 20 hours using DON with S9 and also at 4 hour exposure with S9. In the in vivo micronucleus assay, bone marrow was collected from the male mice dosed intravenously with 100, 10, 1 and 0.1 mg/kg at 24 and 48 hour post dose. Three animals dosed with 500 mg/kg were also analyzed 24 hours post injection for micronuclei induction. A statistically positive response for micronuclei formation was observed at 100 mg/kg at 24 and 48 hour post exposure. Thus, DON appears to be negative in the Ames test but positive in the in vitro chromosome aberration assay and in the in vivo micronucleus assay. In conclusion, the results indicate DON is a potential genotoxic compound with a plausible epigenetic mechanism of action. (Supported by NCI-SAIC Contract No. HHSN26120080001E and NIAMS under BiDGS Program).

467f Ames Bacterial Mutation Test—Comparative Sensitivity of Standard and Micro Formats
R. Proudflock, K. Evans and I. Bundell, Moltox, Molecular Toxicology Inc., Boone, NC.

The Ames test is the most widely used genotoxicity assay and is a regulatory requirement for almost all new chemicals that enter the environment. Because of its importance as an early predictor of carcinogenicity, a screening version using modifications to reduce compound requirement is often employed at an early stage of compound development. The 24-well plate micro screen (μAmes) employs virtually the same methods as the standard test but uses 95% less compound while reducing labor costs significantly. Since the methodology is so similar to the standard Ames test it should, theoretically, be highly predictive of the eventual full-scale GLP assay and allow extrapolation from one version to the other. One important question that remains largely unanswered for this and other screening versions of the test is ‘How do the two methods compare in terms of sensitivity?’ We have determined the lower limit of sensitivity of the two formats using a wide range of 40 mutagens with different physical and chemical characteristics to provide an objective and quantitative answer to this question. The 40 compounds included those recommended as standard positive controls by OECD, compounds in the NTP database and diagnostic mutagens recommended by Ames and others.

The reduced culture volume in the μAmes theoretically reduces the sensitivity of the method; this is compensated for by increasing the number of replicate control plates, resulting in improved reliability and reduced variability of the estimate of the background mutation rate. The μAmes test gives almost identical results to the standard assay while using 5 to 10 times less test material. In summary, the μAmes appears highly predictive of the standard Ames, at least for potent mutagens, while being less labor-intensive and using much less material. We are extending this validation of the μAmes using compounds which are only weakly active in the Ames test to elucidate possible limitations of the screening method.

467g Development of a High-Throughput Homogenous Assay to Detect DNA Double-Strand Breaks
B. Goodwin1, T. Khuc1, R. Huang1, K. L. Witt2, R. R. Tice1 and M. Xia1, 1Division of Preclinical Innovation, NCATS, Rockville, MD and 2Division of the National Toxicology Program, NIEHS, Research Triangle Park, NC.

Identification of compounds with the potential to induce DNA damage is an important component of the chemical safety evaluation process. The most deleterious DNA lesions are DNA double strand breaks (DSBs), which, if unrepaired, can lead to cell death or mutations leading to cancer. Following DSBs, the histone H2A variant, H2AX, is rapidly phosphorylated at serine-139 by ataxia telangietasia mutated (ATM) kinases and accumulates in foci at the sites of damage in the nucleus. A homogenous assay was developed in a high throughput screening format for detecting phosphorylated H2AX (γH2AX) using homogeneous time resolved FRET (HTRF) technology. To optimize the assay condition, the best pair of antibodies for detecting γH2AX-responsive DNA damage was identified after testing multiple antibodies labeled with donor and acceptor fluor. Following treatment with compounds for one hour, the cells are lysed, and an anti-γH2AX antibody labeled with the donor fluor, Europium cryptate, and an anti-H2AX antibody labeled with the acceptor fluor, d2, are combined and added to the cell lysate. In the presence of phosphorylated H2AX, the donor fluor transfers energy to the acceptor fluor, which emits at 665 nm. Signal is detected as the ratio of 665 nm/615 nm on an Envision plate reader. Using camptothecin, this assay was optimized in CHO-K1 and HepG2 cells, with good performance (e.g., signal to background of 3.5 fold, coefficients of variation of <5%, Z’ factor of 0.7). This assay was further validated by screening the 1280 compounds in the Library of Pharmacologically Active Compounds in both cell lines; the resulting hit rate was 2.0% for CHO-K1.
and 0.6% for HepG2. All known genotoxicants including etoposide, mitomycin C, and gemcitabine the library were active in CHO-K1 cells. Therefore, this assay has been selected for screening the Tox21 10K compound library using CHO-K1 cells as part of Tox21 screening program.

467h Cytotoxicity and Genotoxicity Assays for Assessing the Toxicity of the Reactive Black 5 Dye

G. A. Oliveira¹, E. S. Paula², D. M. Leme³, A. Sehr², T. Grumme¹ and D. P. Oliveira¹
¹Faculdade de Farmácia, Universidade Federal de Goiás - FF/ UFG, Goiânia, Goiás, Brazil, ²Departamento de Análises Clínicas, Toxicológicas e Bromatológicas, Universidade de São Paulo - FCFRP/UFP, Ribeirão Preto, São Paulo, Brazil and ³Umweltbundesamt, Bad Elster, Germany.

Introduction: The textile industry plays a key role among the main economic activities of Brazil. However, during textile processing, inefficiencies in dyeing result in large amounts of dyes that are directly discharged into water bodies, contaminating the environment and endangering human health. The amount of dye that is lost during the dyeing processes depends on the class of dye used, which may vary from 2% to 50% for basic and reactive dyes, respectively. Reactive Black 5 (RB5) is an azo compound, commonly used in textile industry. Cytotoxicity and genotoxicity assays are crucial tools for predicting both human and environmental health risks. Objective: Evaluate the cytotoxicity and genotoxicity of the RB5 dye. Methodology: Cultures of HepG2 cells were exposed to RB5 dye at concentrations ranging from 1.5 to 500 µg/mL and cytotoxicity was evaluated after 4, 24 and 48 hours using the MTT test. Analysis of micronucleus (MN) in HepG2 cells was performed by flow cytometry-based in vitro MN assay (In Vitro MicroFlow® Kit) and 2-fold over control solvent control mean were used to define the positive results. Results: RB5 dye showed cytotoxic effect in a dose- and time-dependent manner (p<0.05) and a significant increase of MN frequencies was produced by the dye at 50 and 100 µg/mL. Discussion: Overall, our data indicate that RB5 dye is cytotoxic and genotoxic to human hepatocarcinoma cell line. Conclusion: The use of these bioassays showed to be an efficient approach for the initial screening of different dyes and dye containing effluents, in order to establish toxicological information about textile dyes, avoiding damages on humans and to the aquatic environment.

The determination of adverse cardiovascular events in non-clinical studies is a pivotal requirement in drug development. Compound attrition due to adverse cardiovascular side effects occurs rarely in phase I clinical trials, but the frequency increases in phase II and III, suggesting that measurement of cardiovascular endpoints and decision making in non-clinical studies requires improvement. In this project, we compared different technologies (Physiotel digital and JET-BP) and dosing regimens (Latin square cross-over and parallel design) for cardiovascular assessment using a positive control, etilefrine (a sympathomimetic that directly stimulates adrenergic receptors to induce hypertension). In the first model, etilefrine was administered orally (0, 2, 5 and 10 mg/kg) in a Latin square design to 4 male animals pre-implanted with an L21 full implant and systemic blood pressure measured using Physiotel™ digital system. A slight (2 mg/kg) to marked (5 and 10 mg/kg) increase in mean, systolic, diastolic blood pressure and pulse pressure for up to 2 hours (2 mg/kg) or 5 (5 and 10 mg/kg) hours post dose was measured. In our second model, etilefrine was administered at 0, 1, or 10 mg/kg on 3 occasions (days 1, 8, and 15) to 12 female animals (4/group) and blood pressure measured using JET-BP technology. Systolic blood pressure was slightly increased at 1 mg/kg and markedly increased at 10 mg/kg. The magnitude of change for systolic pressure was higher using Physiotel digital and the Latin square design with a maximal increase of 10 (2 mg/kg), 20 (5 mg/kg), and 40 (10 mg/kg) mmHg and 10 (1 mg/kg) and 25 (10 mg/kg) mmHg using JET-BP and a parallel design. These data indicate that these technologies and study deigns allow good sensitivity for the detection of CV effects.

469 Tethered Subcutaneous Infusion in Telemetry-Instrumented Nonhuman Primates for Cardiovascular Assessment of Short-Half-Life Compounds

Nonclinical Safety Assessment, Covance Laboratories Inc, Madison, WI.

Assessing potential cardiovascular (CV) effects of a compound in experimental pharmacology and toxicology studies is critical to understanding the compounds safety profile in humans. Frequently, the half-life of a compound is such that Tmax occurs shortly after administration; therefore, potential test article related CV findings can be masked by “background noise” associated with animal response to human presence in the animal room for dose administration. For this study we developed a novel approach to subcutaneous infusion in which the telemetry-instrumented cynomolgus monkeys were surgically implanted with subcutaneous catheters in the dorsal region to facilitate remote dose administration. Animals were fitted with an infusion jacket and tether system post surgery and connected to an external syringe infusion pump. Catheter patency was maintained through continuous infusion of 0.9% sodium chloride at a rate of 0.3 mL/hr. During dose administration, two infusion pumps were used per animal. Both pumps were programmed for delayed start, with one pump programmed to deliver the control or test article (known to cause immediate CV effects) over approximately 1 minute and the second pump programmed to deliver a flush to clear the remaining control or test article from the infusion apparatus post-dose administration. Animals exhibited minimal signs of discomfort during dose administration. Statistical analysis of cardiovascular data (hemodynamics) indicated a significant, dose dependent response to compound administration within 5 minutes of the start of infusion. Given the impact of human presence during and after room entry (background noise), using standard subcutaneous dosing procedures would have masked CV responses, and made it difficult to accurately describe the profile and time course of action of the test article. This novel approach to dose administration appears to be a viable option when short half-life and/or human presence-related artifact are considerations for study design.

470 Utilisation of JET-BP (Jacketed External Telemetry with Blood Pressure) for Collection of Cardiovascular Data in the Minipig Administration of a Positive Control

JET-BP (DSI) enables continuous collection of cardiovascular data from toxicology study animals for extended periods of time without the need for animal restraint, therefore resulting in the capability to acquire not only an increased quantity of data, but increased quality. The mini-pig, whilst commonly utilised in dermatological-related evaluations, is an increasingly popular laboratory species due to its anatomical and physiological similarities to humans. Male mini-pigs (purpose bred Gottingen ApS mini-pigs obtained from Ellegaard Gottingen, Denmark) surgically implanted with calibrated sensors (DSI C10 series) for arterial blood pressure (ABP) in conjunction with electrocardiographic (ECG) measurements using jacketed external telemetry (JET) were orally administered Moxifloxacin (fluoroquinolone antibiotic). Data were acquired pre-dose and for up to 24 hours post-dose. Administration of Moxifloxacin at 30, 100 and 300 mg/kg elicited a dose related increase in QTcF of up to 10-20% (300 mg/kg), compared to control (0.5% methacellulose) treated animals. The increase was evident within the first 2 hours following dose administration and was maintained throughout the majority of the post-dose data collection period. Whilst the intended cardiovascular effect was evident following Moxifloxacin administration, the data highlighted the challenges that are associated with the twice daily feeding required for mini-pigs. Significant changes in cardiovascular parameters are evident around the time of day of the second daily feed (approximately 6 hours post-dose) and although consistent with the effects in the control treated group could potentially be an issue depending on the profile of the compound.

In conclusion, JET-BP is an acceptable method of cardiovascular data collection in mini-pigs. Special considerations, unique to the general care of mini-pigs must be taken into consideration during study design, in relation to the profile of the compound to be administered, in order to avoid mis-interpretation of the data-set.
Non-invasive telemetry monitoring is widely used to investigate potential ECG effects in toxicology studies. Data quality is one of the most critical success factors when using non-invasive ECG monitoring technologies. Beagle dogs (n=4), Göttingen minipigs (n=4) and cynomolgus monkeys (n=4) were fitted with jackets and undershirts and leads from a telemetry transmitter with three bipolar channels were applied using cutaneous adhesive patches. All animals were instrumented to record three Einthoven standard ECG derivations (Lead II, V4 and Lead III) throughout the acclimation period and for 24 hours prior to and after dosing with sotalol (PO, 15 mg/kg). Lead II was used for ECG interval analysis while all derivations were used for interpretation when suspected arrhythmias were present. The period of ECG monitoring prior to dosing was used to establish parameters for individual QTc calculations as previously described (Spence et al., Toxicol Sci, 1998, 45(2), 247-58). Evaluation of ECG data revealed that acclimation to experimental procedures varied between animals from 12hrs to 2 days as evidenced by the presence of normal stable circadian cycle for heart rate and values in the normal range of HR and QT in both species. These results suggest that IRI at the point can be applied using cutaneous adhesive patches. All animals were instrumented to acquire via a JET system from conscious cynomolgus monkeys and beagle dogs and ECG parameters (PR and QT intervals, QRS duration) and heart rate (HR) were recorded and analyzed by a JET system (Ponemah Physiological Platform, Data Science, Inc.). The overall and individual reference intervals (IRI) were calculated. The ECGs showed wide individual and time variability and clear circadian rhythms of HR and QT in both species. These results suggest that IRI at the point can be used for evaluation of drug effects on ECG parameters in small-scale design studies, especially preliminary TOX studies. To evaluate the validity of IRI, data on sotalol-induced QT interval prolongation (at 3 and 10 mg/kg, po) in monkeys was analyzed using the IRI. Sotalol at 10 mg/kg statistically significantly prolonged QT interval when compared with the control. Sotalol at 3 mg/kg prolonged QT interval beyond the IRI at some time points after dosing, where there was no statistically significant difference from the control. IRI analysis is considered helpful for detecting possible adverse effects on cardiovascular systems in TOX studies, especially preliminary study. A combination of statistical comparison between groups (standard method) and IRI analysis enhances the ability to predict toxicity of drug in TOX studies.

Electrocardiography is now one of the standard investigations performed in preclinical toxicity studies. One of the key parameters is the QT interval, as certain types of drugs have the capacity to delay cardiac repolarization, an effect seen in the electrocardiogram traces as a prolongation of the QT interval. Even when this effect is part of the therapeutic mechanism of an anti-arhythmic drug, excessive QT interval prolongation is also undesirable as this can provoke new arrhythmias (torsades de pointes) and sudden death. The detection of drug induced QT interval changes is sometimes masked by concurrent heart rate changes and therefore it is normalized by means of various formulae (such as Bazett, Frederica, Van der Waters and Linear regression analysis) into a heart rate independent corrected value known as the QTc interval. The purpose of this publication is to compare the hemodynamic and electrocardiographic parameters from naive telemetry-instrumented beagle dogs (Canis familiaris) from two suppliers one in the USA and the other in China. The control cardiovascular data for the USA animal were obtained from published data (Soloviev MV, et. al., 2006). The mean systolic and diastolic pressures for Chinese dogs were 125/69 mmHg and 134/72 mmHg for male and female animals respectively, compared with 142.5 and 84.7 mmHg. The mean heart rate were slightly higher in the Chinese Beagle (126 bpm and 112 bpm for males and females respectively) when compared to the published data for the USA animal of 97.6 bpm. The QT and QTc intervals for the Chinese beagle were, 198 ms and 241 ms for males and, 209 ms and 246 ms for females respectively, compared with the published values of 217 ms and 245 ms, respectively. In conclusion the the cardiovascular parameters collected from beagles sourced in China were essentially similar to those reported for USA sourced animals.

Non-invasive (Jacketed) ECG Monitoring with Telemetry in Beagle Dogs, Göttingen Minipigs, and Cynomolgus Monkeys: Benefits from Multiple Derivations

Evaluation of ECG and Hemodynamic Changes in Nonhuman Primates Given Four Reference Compounds in Pen or Individual Housing

L. Kreckler, J. Grosh, J. Schneider and M. Foley. Nonclinical Safety Assessment, Covance Inc, Madison, WI.

An evaluation of the effect of a compound on the cardiovascular (CV) system is a critical part of safety assessment and can be achieved in general toxicology studies using jacketed external telemetry (JET) with an implanted telemetry blood pressure (BP) transmitter. We assessed CV changes using JET-BP in nonhuman primates (NHPs) in response to administration of four different reference compounds under two different housing conditions, pen and individual housing. Thirty-six male NHPs group-housed in pen-style cages (three animals/pen) were dosed with etilefrine (sympathomimetic; 1 or 10 mg/kg), hydralazine (vasodilator; 1 or 10 mg/kg), sotalol (nonspecific β-blocker; 3 or 30 mg/kg), or moxifloxacin (antibiotic known to prolong QT; 10, 50, or 175 mg/kg). Following the last dose, animals were transferred to individual housing, allowed to acclimate, and the same dosing regimen was repeated except that hydralazine was given at 10 or 30 mg/kg. Continuous JET-BP measurements were recorded for at least 90 minutes prior to dosing through 20 hours postdose. Electrocardiographic (ECG) parameters of PR, QT, and rate-corrected QT interval and hemodynamic parameters of systolic, diastolic, and mean arterial pressure; heart rate; and arterial pulse pressure were determined. Etilerine at 10 mg/kg increased systolic and pulse pressure at a similar magnitude in both housing conditions. Hydralazine did not decrease BP at 10 mg/kg (pen and individual housing) or 30 mg/kg (individual only). Sotalol and moxifloxacin significantly prolonged QT with no change in BP, and changes were of similar magnitude under both housing conditions. Finally, hemodynamic parameters of control animals when housed in pen or individual housing were compared. Systolic, diastolic, and mean arterial pressure and heart rate were slightly lower when animals were housed in pens than when housed individually. In summary, ECG and BP changes caused by four different reference compounds were detectable using JET-BP technology in NHPs under two different housing conditions.

Potential Advantages for Combining Gender for the Assessment of Cardiovascular Effects: A Case Study with Three Positive Control Articles

L. K. Kremer1, H. Chen2, A. J. Bills3, N. Hanke1, M. Foley1 and M. Osinski1,2.
1Covance Laboratories Inc., Madison, WI and 2Covance Laboratories Inc., Chantilly, VA.

Nonclinical safety studies are increasingly incorporating cardiac safety endpoints into toxicology studies, either as a supplement or replacement for traditional stand-alone safety pharmacology studies. One liability to this approach is the reduction in sensitivity to detect test article-related changes due to the study design (e.g. cross-
over versus parallel), room environment, telemetry technology, etc. One potential strategy to boost statistical power is to increase group size by combining CV data across gender.

Methods: Thirty-six male and female beagle dogs (n=6/group) were outfitted with jacketed external telemetry and an implanted miniature blood pressure transmitter (JET-BP) and administered control (RO water, all days) or etilefrine (1.10 mg/kg, day 1), sotalol (3.30 mg/kg, day 8), and hydralazine (1.10 mg/kg, day 15). Telemetry data were collected pre-dose and up to 20 hours post-dose. Test article exposure for each positive control article was confirmed at 7 hours post-dose.

Results: Prior to combining the CV data across sex, it was confirmed that the test article exposure and pharmacodynamic responses (e.g. changes in ECG or hemodynamic data) were consistent across males and females. Exposure levels were dose-dependent and were within 41% (etilefrine), 6% (sotalol), or 14% (hydralazine) when comparing males and females. When genders were combined, additional statistically-significant changes were noted as compared to when genders were analyzed separately. Increased sensitivity which produces electrocardiogram (ECG)-like waveforms. All ion channels that contribute to the cardiac action potential are therefore incorporated into this ECG-like recording. Importantly, the xCELLigence RTCA Cardio system can indirectly monitor cardiomyocyte contraction and cellular viability in real-time using impedance-based measurements. As a corollary, while not detected on MEA, compounds that affect long-term cell viability (such as doxorubicin), or contractility (such as blebbistatin) in the absence of electrophysiological effects, can be accurately detected. The combination of these two synergistic platforms provides for a thorough and cost-effective pre-clinical assessment of cardiac risk. Our data compare the effects of multiple compounds from different drug classes across both platforms, and highlight the utility of each platform.

Discussion: This case study demonstrates the potential advantages of combining CV data across gender when the test article exposure and pharmacodynamics were consistent.
480 Metallothionein As a Compensatory Component Prevents Intermittent Hypoxia-Induced Cardiomyopathy in Mice
Obstructive sleep apnea (OSA) causes chronic intermittent hypoxia (IH) to induce cardiovascular disease, which may be related to oxidative damage. Metallothionein (MT) is a potent and highly inducible antioxidant protein that is expressed in the heart. The present study was to test the hypotheses that MT as a potent antioxidant protects the heart from OSA-derived IH-induced cardiomyopathy. Mice were exposed to IH for 3 days to 8 weeks, which is consists of alternating cycles of 20.9% O2/8% O2 FIO2 (30 episodes per h) with 20 seconds at the nadir FIO2 for 12 h a day during daylight. IH significantly increased the ratio of heart weight to tibia length at 4 weeks with a decrease in cardiac function from 4 to 8 weeks, shown by decreased left ventricular ejection fraction (EF) and fractional shortening (FS). Cardiac oxidative damage and fibrosis were observed after 4 and 8 weeks of IH exposures. Endogenous MT expression was up-regulated in response to 3-day IH, but significantly decreased at 4 and 8 weeks of IH. In support of MT as a major compensatory component, mice with cardiac overexpression of MT gene and mice with global MT gene deletion were completely resistant and highly sensitive, respectively, to chronic IH-induced cardiac effects. These findings show that chronic IH induces cardiomyopathy characterized by oxidative stress and cardiac damage. The antioxidant MT protects the heart from such pathological changes.

481 Lack of Recovery from Lead-Acetate-Induced Cardiotoxicity in Wistar Rats

Lead poisoning continues to be a serious health problem and more significantly so in developing countries with ineffective waste disposal systems. Recent efforts at solving lead poisoning issues have seen entire towns being re-settled from lead-contaminated areas. This study was designed to investigate whether withdrawal of lead exposure results in a resolution of toxic effects of lead to cardiac tissues. Adult male Wistar rats were exposed orally to lead acetate at doses of 0.25, 0.5 and 1.0mg/ml for 6-week duration, after which one-half was sacrificed and the remaining left for a further 6 weeks without lead treatment. Exposure of rats to lead acetate produced significant decline (p<0.05) in the activities of antioxidant parameters, including Glutathione peroxidase (GPx), Glutathione S-transferase (GST), Catalase (CAT), Superoxide dismutase (SOD) and Reduced glutathione (GSH), while Malondialdehyde (MDA) concentration was significantly elevated. Animals from the withdrawal period exhibited similar pattern of alterations, with significant (p<0.05) reduction in GSH, GPx and SOD and significant elevation in MDA and H2O2 concentrations respectively. However, GST activity was elevated, while CAT activity remained unaltered in the recovery period. The results of this study showed that cardiotoxicity induced by injection of oxidative stress and reduction in antioxidant parameters in this study failed to resolve upon withdrawal of lead exposure in male rats during the period of study.

482 Methyl Honokiol Prevention of High-Fat Diet-Induced Cardiac Hypertrophy and Dysfunction Is Associated with Attenuating Lipid Accumulation and Insulin Resistance
Z. Zhang1, 2, S. Zhou1, 2, X. Yan1, Y. Tan1, K. Kim3, K. Kim1, Y. Zheng2, L. Cai1 and Y. Kim3. 1KCHRI at the Department of Pediatrics, University of Louisville, Louisville, KY, 2The First Hospital of Jilin University, Changchun, Jilin, China and 3Bioland Nature, Science & Life, Shanghai, China.
Obesity is associated with inflammation, oxidative stress, apopotic cell death, cardiac hypertrophy and cardiac dysfunction. Magnolia as a herbal material obtained from Magnolia officinalis has been found to play an important role in anti-inflammation, anti-oxidative stress and anti-apoptosis. This study was designed to investigate the effect of methyl honokiol (MH, an activity standard of Magnolia) on obesity-associated insulin resistance, lipid accumulation and inflammation in the heart. C57BL/6 mice were fed with a low-(10 Kcal% fat) or high-(60 Kcal% fat) fat diet (LFD and HFD, respectively) for 24 weeks to induce obesity and insulin resistance. HFD-fed mice were given a gavage of vehicle, 0.5 or 1 mg/kg body weight of MH daily. Treatment with 0.5 mg/kg MH significantly ameliorated insulin resistance and slightly decreased HFD-caused body weight gain. Both 0.5 and 1 mg/kg MH treatments significantly attenuated HFD-induced cardiac hypertrophy and dysfunction, cardiac lipid accumulation (reflected by increasing Oil Red O and diastolic diameter, fatty acid content to triglyceride ratio), and cardiac inflammation (evidenced by down-regulating TNF-α and PAI-1 expression). Treatment with 0.5 and 1 mg/kg of MH also ameliorated HFD-induced cardiac insulin resistance, shown by up-regulating Akt and Akt2 phosphorylation and hexokinase II expression. This study demonstrates that MH treatment can attenuate HFD-associated cardiac damage through the prevention of HFD-induced cardiac lipid accumulation, inflammation and insulin resistance.

483 Metallothionein Preservation of Cardiac Akt2 Function and Insulin Signaling by Down-Regulating TRB3 Prevents Diabetic Cardiomyopathy
Y. Tan1, 2, X. Yan1, 2, S. Zhou1, 2, C. Zhang1, 2, Y. Li1, Y. Li1 and L. Cai1, 2. 1KCHRI, Departments of Pediatrics, Biochemistry and Surgery Oncology, University of Louisville, Louisville, KY and 2Chinese-American Research Institute for Diabetic Complications, Wenzhou Medical University, Wenzhou, Zhejiang, China.
Cardiac insulin resistance is a key pathogenic factor for diabetic cardiomyopathy, but its mechanism remains largely unclear. Here we demonstrated that diabetes significantly inhibited cardiac Akt phosphorylation (p<0.05), Akt2 expression and phosphorylation was decreased and insulin-induced cardiac Akt2 and GSK-3β phosphorylation and GS dephosphorylation were also significantly attenuated in WT, but not MT-TG diabetic mice. Deletion of Akt2 gene either in vitro H9c2 cells or in vivo significantly improved glucose metabolic signaling. In addition, diabetes significantly increased cardiac Akt2 negative regulator (TRB3) expression only in WT mice, suggesting the possible contribution of MT inhibition of diabetic up-regulation of TRB3 to Akt2 function preservation. Cardiac H9c2 cells with and without forced MT-overexpression (MT-H9c2) were treated with tert-butyryl hydroperoxide (tBHP), which significantly reduced Akt2 phosphorylation in both basal and insulin-stimulating conditions only in H9c2 cells. Silencing TRB3 expression with SiRNA completely prevented (tBHP’s) inhibition of stimulated Akt2 phosphorylation in H9c2 cells, while overexpression of TRB3 in MT-H9c2 cells completely abolished MT inhibition of stimulated Akt2 phosphorylation. Forced-overexpression of TRB3 by adenovirus-mediated gene delivery in MT-TG hearts also abolished MT’s preservation of cardiac insulin signaling and prevention of diabetic cardiomyopathy. These results suggest that diabetes-attenuated cardiac Akt2 function via up-regulating TRB3 plays a critical role in diabetic inhibition of insulin signaling in the heart. MT preservation of cardiac Akt2-mediated insulin signaling by inhibition of TRB3 prevents diabetic cardiomyopathy.

484 Intratracheal Exposure to PVP-Coated Nanosilver Expands Cardiac IR Injury in Male Sprague-Dawley Rats Seven Days After Exposure
N. A. Holland1, D. P. Becak1, R. M. Lus1, S. C. Summer1, T. Fennell1 and C. J. Wingard1. 1Physiology, East Carolina University, Greenville, NC and 2RTI International, Research Triangle Park, NC.
The potential uses of engineered nanomaterials have expanded in biomedical technology and consumer manufacturing. Our lab has demonstrated expansion of myocardial infarction in male Sprague-Dawley (SD) rats 24 hours after intratracheal (IT) instillation of nanosilver (AgNP). We hypothesized that pulmonary exposure to AgNP induces a persistent increase in circulating proinflammitory cytokines which results in expansion of cardiac ischemia-reperfusion (IR) injury. To test this hypothesis, we exposed male SD rats to an instillation of 200 μg of AgNP. We found that intratracheal (IT) instillation of PVP-coated AgNP expanded cardiac IR injury compared to AgNP alone. Significant differences were demonstrated between 110 nm AgNP and large PVP. Based on these
Multiwalled carbon nanotubes (MWCNTs) are being increasingly designed for industrial/biomedical applications raising concerns on their safety, especially during unique life-stages such as pregnancy. We hypothesized: pulmonary MWCNT exposure during pregnancy will increase vasoconstrictor responses in uterine and placenta derived blood vessels by increasing rho-kinase (ROCK) signaling. We exposed gestational day 17-19 pregnant and non-pregnant female Sprague Dawley rats to 100ng/kg of MWCNT’s suspended in 10% Intrasurf surfactant by intratracheal instillation. Vasoactive responses of uterine, mesenteric, aortic and umbilical vessels were studied 24h post-exposure by wire myography. Maximum stress generation in the uterine artery following MWCNT exposure was increased during pregnancy in response to phenylephrine by 2.6 mN/mm2 (+37%) and to angiotensin II by 4.9 mN/mm2 (+118%), as compared to naïve response. Following MWCNT exposure serotonin induced -4 mN/mm2 increase in stress generation of the mesenteric artery from both pregnant and non-pregnant rats as compared to vehicle response. Wire myographic studies in the presence of a ROCK inhibitor did not reveal significant changes. RhoA and ROCK mRNA/protein expression in rat aortic endothelial cells were unaltered with in vitro exposure to MWCNT’s, suggesting absent/minimal contribution of ROCK to the enhanced contractions following MWCNT exposure. The reactivity of the umbilical vein was not changed; however, mean fetal weight gain was reduced by 7% with MWCNT exposure. These results suggest a higher susceptibility of the uterine vasculature to MWCNT induced vasoconstriction predisposing reduced fetal blood supply/growth during pregnancy. This work is supported in part by NIEHS U19ES019525, RO1ESS016246, AHA Mid-Atlantic Affiliate Predoctoral Fellowship and East Carolina University.

Applications of nano-cerium dioxide (CeO2) are potentially endless, but its biologic interactions must first be understood. We have reported that pulmonary CeO2 exposure results in endothelium-dependent and -independent arteriolar dysfunction. Based on these observations, we predict that this dysfunction is mechanistically linked to impaired nitric oxide (NO) signaling. Rats were intratracheally instilled (65 μg) or intravenously injected (IV,100 μg) with CeO2 suspended in saline (5%) serum. Mesenteric arterioles were examined post 24 hrs via intravital microscopy or isolated vessels. Arterial reactivity was evaluated by using acetylcholine (ACh, 10^-10^ M), and spermere NONOate (10^-10^ M). The role of NO synthase and cyclooxygenase reactivity was tested in the presence of Nω-Nitro-L-arginine methyl ester hydrochloride (L-NMMA) and/or indomethacin (INDO) (respectively). Soluble guanyl cyclase activator (YC-1) and cyclic guanosine monophosphate mimetic (8-Bromo-cGMP) assessed smooth muscle activation. Electron spin resonance and a free radical analyzer assessed the ability of NO to react with CeO2 and the level of tissue free radicals. At the time of writing, results were similar in both models and exposure routes. Control animals responded normally to increasing concentrations of ACh (80±4%) and this dilation was impaired in the presence of L-NMMA (34±4%) or INDO (45±11%). Pulmonary CeO2 exposure significantly impaired this dilation (30±4%). INDO treatment did not alter this impairment (44±10%) but there was a partial restoration in function during L-NMMA treatment (51±11%). Smooth muscle activation was intact following both exposure routes. CeO2 is capable of reacting with NO and there appears to be minimal changes in free radicals. These results are consistent with the notion that CeO2 exposure impairs endothelial function at least in part via a NO dependent mechanism. RO1-E5015022(TRN), NSF IGERT(VCM), F32-ES023435(PAS)
duction events required for normal heart development via activation of G protein-
toined estrogen receptor 1 (GPER). Potential targets include, GATA4, ERK, PKA and Nfat. GATA4 regulates the expression of Hand2 and Lrcc10, which are involved in heart cell differentiation and development. This transcription factor can be activated by several kinases, such as ERK and PKA, both of which are down-steam targets of the estrogen signaling pathway. GATA4 has also been proposed to interact with Nfat, whose activation is regulated by calcium influx. We hypothe-
size that exposure to E2 would alter the expression of important heart determinant
genes such as Hand2 and Lrcc10, as well as calcium homeostasis in zebrafish. To
explore potential molecular mechanisms of cardiac dysfunction, expression of genes
involved in signal transduction and calcium homeostasis were examined in zebrafish
embryos following exposure to E2. Embryos were exposed to 20μM and 5 μM of
E2 at 2 hpf and RNA was extracted at 28hpf. Preliminary qPCR results suggest that
E2 exposure during early embryogenesis causes a decrease in the expression of
Lrcc10 and Hand2. Additional studies will not only measure the expression of other
genes related to GPER activation by estrogen, but also measure calcium influx to better understand how endocrine disruptors alters cardiac development.

492 Diesel Exhaust Causes Stress-Induced Cardiac Conduction
Instability in Hypertensive Rats As Demonstrated by a Novel
Measure of Refractoriness
M. S. Hazar1, J. Lancaster2, J. Storobin3, A. K. Farrai4 and W. Cascio5
1Environmental Public Health Division, Environmental Protection Agency, Research
Triangle Park, NC and 2University of North Carolina at Greensboro, Greensboro,
NC.
Loss of cardiac refractoriness, which prevents early stimulation in the heart,
increases the risk of arrhythmogenesis. Although the heart has a large reserve of
refractoriness (RoR), disease can cause impairment, particularly when under stress or
toxic insult, and thus conduction instability and mechanical dysfunction. RoR is an
assessment of the heart’s minimum level of refractoriness as compared with the crit-
ical level associated with conduction instability. We previously showed that diesel
exhaust (DE) causes cardiac electrical disturbances in rats during exercise-like stress.
To further assess the subtle impacts of DE on the intrinsic conduction properties
of the heart, we used the Chemnyak-Scarbin-Cohen (CSC) model to calculate RoR
and thereby analytically determine conduction stability during dobutamine (DOB)
challenge, which mimics exercise by increasing heart rate and contractility (i.e.,
pacing). We hypothesized that spontaneously hypertensive (SH) rats would have a
greater decrease in RoR than Wistar-Kyoto (WKY) rats during pacing, and that
DE would exacerbate the response. WKY and SH rats exposed to 150μg/m3 of DE
were challenged with increasing doses of DOB. The CSC model was customized for
each rat; QT and RR intervals taken from the electrocardiogram after a given
dose of DOB were used to determine action potential duration and diastolic inter-
val. These values were then analyzed to calculate model conductance parameters and
determine RoR. Air-exposed WKY and SH rats did not have any decrease in RoR,
whereas DE-exposed WKY and SH rats did have a decrease in RoR during pacing.
However, DE caused a significant decrease during pacing in both strains. SH rats had an eight times steeper decrease in RoR when compared with WKY suggesting greater risk. These data indicate that after exposure to DE, risk of cardiac instability increases with increasing stress, particularly with underly-
ning cardiovascular disease. (This abstract does not reflect EPA policy)

493 Prevention of Angiotensin II-Induced Cardiomyopathy by
Sulforaphane-Activated Nrf2 Partially via AKT/GSK-3β/Fyn
Pathway
Y. Xin1, X. Jiang2, Y. Bai2 and L. Cai2
1University of Louisville, Louisville, Ky and 2The First Hospital of Jilin University, Changchun, Jilin Province, China.
Angiotensin II (Ang II) is an important causative of diabetic cardiomyopathy. Sulforaphane (SFN) is an anti-oxidative supplement through activation of AKT/GSK-3β
way. The present study examined whether SFN could protect from Ang II-induced
cardiomyopathy and the underlying mechanism. FVB mice were given subcutane-
ous injection of Ang II (0.5 mg/kg) for 2 months with or without SFN treatment
(0.5 mg/kg) for 3 months and then kept until 6 months. At 3 and 6 months, blood
pressure and cardiac function were assessed. SFN significantly prevented Ang II-
induced high blood pressure at 6 months and cardiac dysfunction at both 3 and 6
months. Ang II caused remarkable pathological changes, including myocardial
hypertrophy and collagen accumulation, along with increases in cardiac oxidative
damage (3-NT and 4-HNE), inflammation (TNF-α and PAI-1), and fibrotic re-
duction (TGF-β1 and CTGF). Those damages were almost completely prevented
by 3-month SFN treatment that up-regulated Nrf2 function, reflected by increased
Nrf2 phosphorylation and downstream antioxidants. To define the direct role of
SFN-activated Nrf2 in preventing Ang II-induced cardiomyopathy, in vitro H9c2
cells were treated with Ang II in the absence or presence of Nrf2 siRNA to silence
Nrf2 expression. SFN significantly up-regulated Nrf2 and also prevented Ang II-
induced CTGF and PAI-1 expression, which were completely abolished by Nrf2
silence. Furthermore, cardiac-overexpressing Nrf2 gene (Nrf2-TG) and wild-type
(WT) mice were treated with Ang II (0.5 mg/kg) for 2 months. Ang II-induced
cardiomyopathy was seen in WT mice, but not in Nrf2-TG mice. To dissect the
mechanism for SFN activation of Nrf2, H9c2 cells were given SFN (10 μM) simul-
taneously with and without Akt inhibitor (LY294002, 10 μM), SFN’s activation of
Nrf2 was partially inhibited by Akt inhibition that also induced GSK-3β activation

490 Investigating Proepicardial, Epicardial, and Myocardial Cells
As Targets of TCD Cardioxicity in Zebrafish Embryos
M. S. Yue1, S. J. Pavlik2, M. Kim3, P. J. Holtser4, R. E. Petersen2 and W. Heidenmann1
1Molecular and Environmental Toxicology, University of Wisconsin Madison, Madison, WI and 2School of Pharmacy, University of Wisconsin Madison, Madison, WI.
Exposure to the ubiquitous environmental contaminant 2,3,7,8-tetrachlorodiben-
dioxin-pyridin (TCD) causes severe cardiovascular toxicity via activation of the
AHR pathway. These effects are likely due to the anti-angiogenic and pro-apoptotic
properties of TCD. The epicardium is the outer layer of the heart, and is important for heart develop-
ment and regeneration. In the zebrafish heart the epicardium is derived from the
proepicardium (PE), which forms adjacent to the heart and begins to migrate to the
myocardium at 70 hours post fertilization (hpf). Recent work has shown that expos-
ure to TCD inhibits PE formation, epicardial progenitor cell migration, and the
spread of epicardial cells across the myocardium. We hypothesize that the myocar-
dium is a target site of TCD that contributes to inhibition of PE migration and
epicardial spread in TCD-exposed hearts. To investigate this, we have activated
AHR2 expression exclusively in myocardial cells using constitutively activated
AHR2 (caAHR2) linked to the cardiac myosin light chain 2 (cmi2) promoter.
Here we show that caAHR2 in myocardial cells does not inhibit development of the
PE, however, the PE or PE cells fail to migrate onto the myocardium. This may
explain the lack of epicardium formation in these caAHR2 embryos. Additionally,
using scanning electron micrography (SEM), we show that TCD-exposed hearts have a smooth myocardial surface topography, which contrasts significantly from
the rough and pockmarked surface of controls. To further examine the role of the
myocardial cells on epicardium formation, we are developing an epicardial migra-
tion assay to assess the ability of untreated epicardial cells to spread onto the myo-
cardium of TCD-treated hearts in vitro, and to test whether caAHR2 myocardial
cells are receptive to migrating epicardial cells. (Supported by NIH ES012716 and
5T32ES007015-35)

491 Comparison of Exposure Route on Cardiorespiratory Effects
following Acute Benzo[a]pyrene in Adult Zebrafish (Danio
rerio)
L. P. Weber1,2 and C. J. Gerger2
1Veterinary Biomedical Sciences, University of Saskatchewan, Saskatoon, SK, Canada and 2Toxicology Graduate Program, University of Saskatchewan, Saskatoon, SK, Canada.
Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous environmental contami-
ants. PAH exposure causes developmental toxicity in multiple fish species, but acute adult fish toxicity is thought to be minimal. However, there is some
indication of sublethal PAH effects. We hypothesize that acute PAH exposure in adult
fish will cause cardiorespiratory impairment that will not differ with exposure route. In order to investigate this hypothesis, adult zebrafish (Danio rerio) were in-
jected (i.p.) twice with increasing concentrations of the prototypical PAH, benzo[a]
pyrene (BaP; 0.1, 10, and 1000 μg/kg) or exposed aquously (static, renewal at 24
hr; 16.2 and 162
μg/kg) or exposed aquously (static, renewal at 24
hr; 16.2 and 162
μM) simul-
taneously with and without Akt inhibitor (LY294002, 10 μM), SFN’s activation of
Nrf2 was partially inhibited by Akt inhibition that also induced GSK-3β activation
and thereby analytically determine conduction stability during dobutamine (DOB)
challenge, which mimics exercise by increasing heart rate and contractility (i.e.,
pacing). We hypothesized that spontaneously hypertensive (SH) rats would have a
greater decrease in RoR than Wistar-Kyoto (WKY) rats during pacing, and that
DE would exacerbate the response. WKY and SH rats exposed to 150μg/m3 of DE
were challenged with increasing doses of DOB. The CSC model was customized for
each rat; QT and RR intervals taken from the electrocardiogram after a given
dose of DOB were used to determine action potential duration and diastolic inter-
val. These values were then analyzed to calculate model conductance parameters and
determine RoR. Air-exposed WKY and SH rats did not have any decrease in RoR,
whereas DE-exposed WKY and SH rats did have a decrease in RoR during pacing.
However, DE caused a significant decrease during pacing in both strains. SH rats had an eight times steeper decrease in RoR when compared with WKY suggesting greater risk. These data indicate that after exposure to DE, risk of cardiac instability increases with increasing stress, particularly with underly-
ning cardiovascular disease. (This abstract does not reflect EPA policy)
and Fyn nuclear accumulation. These results suggest that Ang II-induced cardiomyopathy can be prevented by SFN via Akt/GSK-3β/Fyn-mediated activation of Nrf2 antioxidant pathway.

**(+-) Usnic Acid-Induced Myocardial Toxicity in Rats**

(-) Usnic acid (UA) has been known to be a strong uncoupler, and mitochondrial and endoplasmic reticulum (ER)-related stresses are suggested to be involved in the mechanism of hepatotoxicity. However, it has not been clarified whether UA causes toxicity in other mitochondria-rich organs. We confirmed whether UA induced cardiotoxicity and its mechanism. In the preliminary study of oral administration at 100 mg/kg/day of UA for 14 days in rats, cytoplasmic rarefaction of myocardium and swollen mitochondria were observed. Immunohistochemically, increased intensity of prohibitin, a marker for mitochondrial involvement, was demonstrated. Toxicogenicomic analysis indicated oxidative stress, ER stress, and amino acid limitation as a possible cardiotoxicity mechanism of UA. In the present study, rats were orally given 100 mg/kg/day of UA for 1, 4, 7 and 14 days, and were sacrificed on the next day of final dosing. The day of first dosing was defined Day 1. The gene expression analysis of the heart by real-time RT-PCR for representative oxidative stress (Nqo1 and Txnrd1), ER stress (Gp96, Trike3 and Olig3), and amino acid limitation-related genes (Mthfd2, Asn and Athf5) were performed in combined with histopathological examination. No changes were detected on Day 2, while up-regulation or up-regulating tendency were shown in Nqo1 and Mthfd2 on Day 5, and in Nqo1, Txnrd1, Trike3, Mthfd2, Asn and Athf5 on Day 8. Up-regulation of Mthfd2, Asn and Athf5 were sustained on Day 15. Ultrastructurally, swollen mitochondria were seen only on Day 15. In conclusion, it was manifested that amino-acid limitation and oxidative stress preceded the morphological change of mitochondria were seen only on Day 15. In conclusion, it was manifested that amino-acid limitation and oxidative stress preceded the morphological change of mitochondria were seen only on Day 15. In conclusion, it was manifested that amino-acid limitation and oxidative stress preceded the morphological change of mitochondria were seen only on Day 15.
inhalation abuse that result in sudden death due to DFE. Many human DFE abuse cases have been studied but the exact cause and the mechanism behind their death is still unknown.

To investigate arrhythmogenic effect Sprague dawley rats (n=8) were exposed to 30 sec of 20 L/min DFE. Arrhythmogenic effects were evaluated by electrocardiographic monitoring (ECG test). These effects were quantified after multiple DFE doses. In addition, severity of those arrhythmias was evaluated. Furthermore, using the same procedure for DFE administration, electrolyte and some enzyme levels were evaluated. Following DFE administration blood was collected by cardiac puncture. Sodium, potassium, calcium and magnesium levels were measured, and Lactate dehydrogenase (LDH) and Creatine Kinase (CK) levels represented cardiac markers.

Electrocardiographic monitoring showed that DFE resulted in graded severity of arrhythmias from minor skipped beat to serious ventricular fibrillation. Electrolyte levels showed a change in plasma potassium and magnesium level while sodium and calcium levels did not change. In addition, LDH and CK levels in DFE administered rats were higher as compared to control rats. Further organ bath experiments will be performed to determine the possible mechanism. These results suggest DFE show cardiotoxic effects in form of arrhythmias and in addition, there were altered plasma potassium and magnesium levels followed by higher LDH and CK levels.

**500 Species Difference in Isoproterenol-Induced Cardiotoxicity between Sprague-Dawley Rats and Duncan Hartley Guinea Pigs**

In the clinical setting, serum levels of cardiac troponin I and cardiac troponin T are widely used in the detection of acute myocardial infarction and other cardiac conditions. These along with other cardiac specific biomarkers such as fatty acid-binding proteins have been previously measured in several experimental models utilizing rats, mice, dogs and non-human primates. The objective of the present study was to compare isoproterenol-induced cardiotoxicity in rats and guinea pigs using the meso scale discovery (MSD) rat muscle injury panel along with histopathology. Male guinea pigs and rats were injected subcutaneously either with saline at 1 ml/kg or single dose of isoproterenol at 4 mg/kg. Four and 24 hours post injection, blood samples were collected for troponin levels and at 24 h heart and skeletal muscle were harvested for histopathological examination. Isoproterenol injection in rats induced a significant increase in the cardiac troponin I levels, fatty acid binding protein and myosin light chain at 4 h and correlated to ventricular damage on histopathology. Surprisingly, there was a significant increase in the skeletal muscle troponin levels at four hours. Selectivity of cardiac vs. skeletal troponin detection was confirmed using heart and skeletal muscle homogenate as well as with purified proteins. However, the same dose of isoproterenol did not induce any change in cardiac troponin I levels or histopathological lesions in guinea pigs. In summary, our data suggests a species difference in the cardiac injury to isoproterenol.

**502 Fenofibrate Reduces Cardiac Fibrosis Due to the Reduction of the DNA Binding Activity of the Hypoxia-Inducible Factor-1/Aryl Hydrocarbon Receptor Nuclear Translocator Complex**

S. Ichihara1, Y. Suzuki1, S. Tada-Oikawa1 and G. Ichihara2. Mie University, Tsu, Japan and Nagoya University Graduate School of Medicine, Nagoya, Japan.

Background: The aryl hydrocarbon receptor (AHR) is a transcription factor that binds to DNA as a heterodimer with the AHR nuclear translocator (ARNT) after binding with ligands such as polycyclic and halogenated aromatic hydrocarbons found in tobacco smoke and the environment. We investigated the roles of AHR-ARNT signaling on the development of left ventricular hypertrophy and cardiac fibrosis by angiotensin II (Ang II) infusion in mice lacking the AHR gene (AHR-/-). Moreover, we accessed the hypothesis that peroxisome proliferator-activated receptor-t activator, fenofibrate reduces cardiac fibrosis through the ARNT signaling. Methods and Results: Male AHR-/- and age-matched wild type (WT) mice were observed in females but not males treated with DAPM. This elevated 5-HT was also significantly correlated with peak pressure gradient, an indirect measure of pulmonary arterial pressure. DAPM-treated females also exhibited increased levels of the serotonin transport protein 5-HTT, or SERT, in their pulmonary arteries. 5-HT is known to induce HPVSMC proliferation and its role in PAH has been established. In culture, DAPM stimulated female human pulmonary artery endothelial cells (HPAEC) to release 5-HT. No such response was seen in male cell isolates. Additionally, human pulmonary artery smooth muscle cells (HPAVSMC) were stimulated to take up 5-HT, and to proliferate, when treated with DAPM. In our attempts to determine the mechanism(s) by which DAPM elicits these effects, we have observed DAPM-induced activation of the DNA binding target of the aryl hydrocarbon receptor (AhR) - the xenobiotic response element (XRE). Ongoing studies are seeking to address the extent at which the AhR mediates the observed DAPM-induced effects in vitro and in vivo.

**501 DAPM-Induced Alterations in Serotoninergic Signaling May Be Aryl Hydrocarbon Receptor-Mediated in a Novel Model for Female-Specific Pulmonary Arterial Hypertension**

M. A. Carroll Turpin, V. Y. Hebert, T. Choritub and T. R. Dugas. Pharmacology, Toxicology and Neuroscience, LSUHSC-Shreveport, Shreveport, LA.

Pulmonary Arterial Hypertension (PAH) is a cardiovascular disorder characterized by elevated pulmonary artery pressure as a result of arterial wall thickening. Though relatively rare, it is inevitably fatal. The few available therapies only slow progression – there is no cure. Patients are 4–5 times more likely to be women than men. Our purpose was to develop a relevant animal model of PAH in order to identify sex differences that contribute to disease progression, and in doing so, identify potential new treatment strategies. 4,4’-Methylenedianiline (DAPM) is an aromatic amine used industrially in the synthesis of polyurethanes. Chronic, intermittent treatment of rats with DAPM results in medial hyperplasia of pulmonary arterioles, exclusively in females, coupled with increases in pulmonary arterial pressures. After 12 wk, significant increases in plasma levels of serotonin (5-HT) were observed in female but not male rats treated with DAPM. This elevated 5-HT was also significantly correlated with peak pressure gradient, an indirect measure of pulmonary arterial pressure. DAPM-treated females also exhibited increased levels of the serotonin transport protein 5-HTT, or SERT, in their pulmonary arteries. 5-HT is known to induce HPVSMC proliferation and its role in PAH has been established. In culture, DAPM stimulated female human pulmonary artery endothelial cells (HPAEC) to release 5-HT. No such response was seen in male cell isolates. Additionally, human pulmonary artery smooth muscle cells (HPAVSMC) were stimulated to take up 5-HT, and to proliferate, when treated with DAPM. In our attempts to determine the mechanism(s) by which DAPM elicits these effects, we have observed DAPM-induced activation of the DNA binding target of the aryl hydrocarbon receptor (AhR) - the xenobiotic response element (XRE). Ongoing studies are seeking to address the extent at which the AhR mediates the observed DAPM-induced effects in vitro and in vivo.
According to the ICHS7A guidelines, new chemical entities (NCE) must be evaluated for potentially undesired effects on the cardiovascular (CV), respiratory, and central nervous systems. Additionally, the ICHS7B guidelines were established to assess the potential of NCE to affect the ventricular repolarization and proarrhythmic risk. Advancements in telemetry technology allow for the concomitant capture of CV, ECG, and respiratory endpoints in conscious, freely moving animals. Such collection paradigms allow researchers to evaluate the relationship between the CV and respiratory systems concurrently, thus providing a more robust risk assessment in a single study, whilst using fewer animals and less test compound.

The objective of the presented investigation was to evaluate the potential acute effects of CBL0137 on respiratory, CV, and ECG following nasogastric administration in telemetry-implanted cynomolgus monkeys. Cardiovascular and ECG data were acquired from implanted telemetry devices, while concurrent respiratory data was acquired via a jacketed system in conjunction with respiratory inductance plethysmography (RIP).

Acute nasogastric administration of CBL0137 to radiotelemetry-implanted male cynomolgus monkeys at 10 and 30 mg/kg resulted in lower arterial blood pressure (systolic, diastolic, and mean arterial pressure) and lower body temperature; and at 30 mg/kg resulted in test article-related prolongation of the heart rate corrected QT (Bazett) intervals. CBL0137 administration at all dose levels had no affect on heart rate, pulse pressure, PR, QRS, and RR interval, ECG waveforms, or respiratory function (respiratory frequency, tidal volume, or minute volume). It is concluded that preclinical safety pharmacology results do not preclude the FIH (First-in-Human) study of CBL0137.

**504 Inhibition of Gene Expression of Carnitine Palmitoyltransferase I and Heart Fatty Acid Binding Protein in Cyclophosphamide and Ifosfamide-Induced Acute Cardiomyopathic Rat Models**

It is well documented that high therapeutic doses of cyclophosphamide (CP) and ifosfamide (IFO) are associated with acute and lethal cardiotoxicity. Therefore, this study has been initiated to investigate whether CP and IFO therapy alters the expression of the key genes engaged in long-chain fatty acids (LCFA) oxidation outside rat heart mitochondria, and if so, whether these alterations should be viewed as a mechanism during CP and IFO-induced cardiotoxicity. To achieve the ultimate goals of this study, a total of 60 adult male Wistar albino rats were assigned to one of six treatment groups namely, control, L-carnitine, CP, IFO, CP plus L-carnitine and IFO plus L-carnitine. Treatment with CP and IFO significantly decreased expression of heart fatty acid binding protein (H-FABP) and CPT I genes in cardiac tissues. Moreover, CP but not IFO significantly increased Acetyl-CoA Carboxylase (ACC) mRNA expression. Conversely, IFO but not CP significantly decreased mRNA expression of Malonyl-CoA Decarboxylase (MCD), Both CP and IFO significantly increased serum lactate dehydrogenase (LDH), creatine kinase isoenzyme MB (CK-MB), and malonyl-CoA content in cardiac tissues. Interestingly, carnitine supplementation completely reversed all the biochemical and gene expression changes induced by CP and IFO to the control values, except CPT I mRNA and protein expression remained inhibited by IFO. Data from the current study suggest that: (1) CP and IFO therapy are associated with the inhibition of the expression of H-FABP and CPT I genes in cardiac tissues with the consequent inhibition of mitochondrial transport and oxidation of LCFA. (2) The progressive increase in cardio toxicity enzymatic indices and the decrease in H-FABP and CPT I expression may point to the possible contribution of these genes in CP and IFO-induced cardiotoxicity. (3) L-carnitine prevents CP and IFO-induced cardiotoxicity by modulating the expression of genes involved in LCFA oxidation.

**504b Cardiac Myocyte-Specific AhR Activation Phenocopies Embryonic Dioin Exposure in Zebrafish**

K. A. Lanham, J. S. Plavicki, R. E. Peterson and W. Heideman. School of Pharmacy, UW Madison, Madison, WI.

Exposure of zebrafish embryos to 2,3,7,8-tetrachlorodibenzop-p-dioxin (TCDD) activates the zebrafish aryl hydrocarbon receptor 2 (Ah2r) to produce developmental and cardiovascular toxicity. It has been hypothesized that cardiovascular collapse following exposure to TCDD is the cause of early life stage mortality in fish and other species; however, since TCDD acts systemically it is difficult to determine its influence on any one tissue or system. We have constructed a constitutively active AHR (caAhR) that is functional in zebrafish and expressed it tissue specifically to test whether AHR activation in the myocardium reproduces cardiovascular endpoints of TCDD toxicity. We show that AHR activation within the myocardium reproduces most, if not all, of the cardiovascular defects seen following TCDD exposure; in addition to other endpoints outside of the cardiovascular system. This work identifies a single cellular site of TCDD action, the myocardial cell, that can sufficiently account for the cardiovascular collapse and mortality observed following early life stage exposure to TCDD.

**504c Cardiovascular Effects of Diesel Exhaust Exposure**

M. Berg1, L. Harrell2, D. R. Cawthon2, K. C. Scribner2, P. T. Good2 and T. Hesterberg3. 1Toxicology, Center for Toxicology and Environmental Health, LLC, Kemah, TX, 2Toxicology, Center for Toxicology and Environmental Health, LLC, Little Rock, TX and 3Toxicology, Center for Toxicology and Environmental Health, LLC, Denver, CO.

Emissions from diesel engines are a highly variable and complex mixture of particulate and gas-phase compounds derived from the incomplete combustion of fuels, fuel-additives, and lubricating components. While recent scientific evaluations of Traditional Diesel Exhaust (Pre-1988; TDE) continue to show adverse cardiovascular effects at elevated exposures, it is hypothesized that New Technology Diesel Exhaust (Post-2007; NTDE) will not produce such impacts. To evaluate potential cardiovascular endpoints, we reviewed the recent scientific literature, restricting our analyses to publications with well-defined exposures, limited confounders, and occurring through the inhalational route. While controlled human-exposure studies using TDE or TDE-like exhaust examined a variety hemodynamic, inflammatory, thrombogenic, and atherogenic responses; the most consistently observed effect was a marginal, albeit transient, alteration in cardiovascular vasomotor response (e.g. attenuation of vasodilation) in acute, elevated (≈300 μg/m3 DPM) exposures.
These effects appeared reduced or absent in the limited number of studies which evaluated exposure to NTDE or NTDE-like exhausts. Recent animal studies provide mechanistic insight into these cardiovascular endpoints via knockout (Apoe−/−) or spontaneously-hypersensitive animals – models representing sensitive human receptors. The use of these animal models to predict potential TDE health effects to occupationally-exposed individuals is problematic because the DE concentrations used in the animal and human studies were 1-2 orders of magnitude higher than above-ground occupational exposures. While further research on NTDE is needed, an individualistic evaluation of both forms of diesel exhaust is of significant regulatory importance because it provides additional data from which to evaluate whether or not current emission standards are effective in preventing human disease.

**505 Identification of Inhibitors of Cytochrome P450 (CYP) 1B1**

L. H. Kennedy1, M. P. Connor1, J. E. Powers2, D. Tran3, A. Parrill-Baker4, C. H. Sutter2 & T. R. Sutter1, 2

Chemistry, United States Naval Academy, Annapolis, MD, 1Chemistry, The University of Memphis, Memphis, TN and 3Biological Sciences and the W. Harry Feistrome Center for Genomic Research, The University of Memphis, Memphis, TN.

Cytochrome P450 (CYP) 1B1 is known to be overexpressed in several types of human malignancies, including breast, endometrial and prostate cancers. The role of CYP1B1 in estradiol metabolism to catalyze the hydroxylation at the C-4 position is of specific importance in estrogen-related tumorigenesis. Finding a potent and safe inhibitor to this critical step could lead to chemoprevention of several forms of human cancer. We used the Chembridge online database (www.hit2lead.com) to perform similarity searches, using 2,3,4,5-tetrahydroxystilbene (TMS), a compound known to inhibit CYP1B1 activity, as the search target. A 50% similarity threshold was used, reporting all compounds with a similarity of ≥50% as hits. The database determines the similarity of a compound with respect to the lead compound using the Tanimoto coefficient. Ultimately, 64 compounds were tested at a single concentration for inhibition of CYP1B1 catalyzed ethoxyresorufin-o-deethylase (EROD) activity. Five compounds inhibited EROD activity to an extent equal to or greater than TMS, and were considered positive hits. CYP1B1 selectivity was determined using the EROD assay, several concentrations of the five compounds, and CYP1A1, CYP1A2, and CYP1B1. The five compounds varied in selectivity, but all were more selective for CYP1B1 than either CYP1A1 or CYP1A2. Kinetic studies were used to determine the K, and the mechanism of enzyme inhibition for these compounds. Spectral binding analysis using recombinant CYP1B1 was used to determine the observed binding spectrum; type I, reverse type I, or type II. Several of these lead compounds are more potent and selective than TMS for inhibition of CYP1B1 and could potentially lead to new discovery in the treatment and prevention of cancer.

**506 CYP1B1 Expression Is Induced by Leptin through Ligand-Independent Activation of ERα Pathway in MCF-7 Cells**

Leptin, a hormone with multiple biological actions, is produced predominantly by adipose tissue. Among its functions, leptin is able to stimulate tumor cell growth. Estrogen receptor-alpha (ER-alpha), which plays an essential role in breast cancer development, can be transcriptionally activated in a ligand-independent manner. This study investigated the effect of leptin on CYP1B1 expression and its mechanism in breast cancer cells. Leptin induced CYP1B1 protein, messenger RNA expression and promoter activity in ER-alpha-positive MCF-7 cells but not in ER-alpha-negative MDA-MB-231 cells. Transient transfection with CYP1B1 deletion promoter constructs revealed that the estrogen response element (ERE) plays important role in the up-regulation of CYP1B1 by leptin. Furthermore, leptin stimulated phosphorylation of ER-alpha at serine residues 118, 167, and 305 and increased the ERE-luciferase activity, indicating that leptin induced CYP1B1 expression by ER-alpha activation. Finally, leptin activated ERK, Akt, and PKA signaling pathways which are upstream kinases related to ER-alpha phosphorylation induced by leptin. These results indicate that leptin-induced CYP1B1 expression is mediated by ligand-independent activation of the ER-alpha pathway as a result of the activation of ERK, Akt, and PKA in MCF-7 cells.

**507 Metformin Inhibits Aryl Hydrocarbon Receptor-Mediated Induction of CYP1A1 and CYP1B1 in Breast Cancer Cells**

M. Do, T. Tran, H. Kim and H. Jeong. Pharmacy, Chungnam National University, Daejeon, Republic of Korea.

Induction Cytochrome P450 (CYP) 1A1 and CYP1B1 by endogenous ligands or xenobiotic compounds through the activation of the aryl hydrocarbon receptor (AhR) has been implicated in a variety of cellular processes relate to cancer such as transformation and tumorigenesis. Here, we study the effects of anti-diabetes drug metformin on the expression of CYP1A1 and CYP1B1 in breast cancer cells under basal and inducible conditions. Results showed that metformin markedly reduced the expression of CYP1A1 and CYP1B1 mRNAs and proteins in breast cancer cells under basal and TCDD-induced conditions. The inhibition of AhR expression is required for the reduction of CYP1A1 and CYP1B1 transcriptional expression by metformin. The down-regulation of CYP1A1 and CYP1B1 expression by metformin was independent of ERα. Additionally, metformin significantly down-regulated Sp1 protein expression in breast cancer cells, and the use of genetic and pharmacological means demonstrated that the down-regulation of AhR expression by metformin mediated through the reduction of Sp1 protein. Our findings indicate that metformin suppresses CYP1A1 and CYP1B1 expression in breast cancer cells by down-regulating AhR signaling pathway. These results provide evidences for the use of metformin as a drug for cancer prevention and treatment.

**508 Suppression of NADPH-Cytochrome P450 Reductase Causes Vacularization in Renal Proximal Tubules in Mice**

S. Liu1, K. Dickman2, S. Sell1, X. Ding1, C. Mei1 and J. Gu1, Wadsworth Center, Albany, NY, 1Changzheng Hospital, Shanghai, China and 2Stony Brook University, Stony Brook, NY.

Cytochrome P450 reductase (CPR or POR) is an obligatory redox partner for all microsomal P450 enzymes, which play crucial roles in the metabolism of numerous drugs, environmental chemicals and endogenous regulatory molecules. Germine deletion of mouse Por is known to disrupt embryonic development, and POR functional deficiency resulting from genetic polymorphisms in people leads to disordered steroidogenesis and Antley-Bixler syndrome. Large interindividual variations in levels of POR expression are found in human liver and extrahepatic tissues; but the impact of such variations on physiology or disease risk is unknown. A substantial decrease in POR expression, in a mouse model with global suppression of POR expression (named Cpr-low mouse), was previously found to lead to altered sex steroid hormone homeostasis and female infertility, as well as decreased capacity for xenobiotic metabolism. The aim of this study was to further characterize the Cpr-low mouse model, in order to identify additional phenotypes that may reveal vulnerability in people with low POR expression. Here we report age-dependent appearance of marked vacuolarization in the proximal tubules of 4-9 month old male (but not female) Cpr-low mice. The vacuoles, which were negative for fat (Oil red O) and glycogen (PAS) staining, were localized in S1/S2, but not S3, segment of the proximal tubules. Further analysis with electron microscopy revealed that the vacuoles ranged from small, clear structures to large osmophilic bodies consistent with lysosomes. Given the known association of proximal tubule vacuolarization with renal diseases and chemical-induced renal injuries, our results suggest that chronic suppression of POR expression may lead to increased susceptibility to renal injuries/diseases. Further studies are under way to delineate the mechanisms of the renal vacuolization and characterize any associated deficits in renal function.

**509 First Report of Possible Biotransformation of Tetracycline to Doxycycline in Brusica chinensis L.**

H. Chen1, P. Chen1, R. Lee2, C. Wei1 and C. Chou1. Veterinary Medicine, National Chung-Hsing University, Taichung, Taiwan and 2Chemistry, National Chung-Hsing University, Taichung, Taiwan.

Metabolic biotransformation referred to the process by which a drug is structurally modified in a living entity, presumably to reduce associated toxicity (detoxification) of the drug and to accelerate elimination. However, bioactivation can also occur, complicating the prediction of the metabolic outcome. Cytochrome P450 4 enzymes are responsible for drug biotransformation in both animals and plants but the metabolites may differ significantly. For instance, the biotransformation of tetracycline (TC) to epimer-tetracycline and hydroxytetracycline has been reported in animals but not in plants. In a pharmacokinetic study of TC in Brusica chinensis L. grown hydroponically, we found initial evidence that TC was uptaken and possibly bioactivated to doxycycline (DC) in the leaves after 3 days of cultivation. The suspected DC compound was first identified by HPLC-UV chromatography and further confirmed by liquid chromatography–electrospray ionization–mass spectrometry (LC–ESI/MS) in positive mode. The protonated molecule, [M+H]+ of
The pulmonary epithelium is the first barrier for airborne xenobiotics and inhaled drugs and the cell line Calu-3 is a well characterized model for in vitro tracheobronchial epithelial permeability. To serve as a model for toxicity testing of airborne substances (gases, aerosols, particles), Calu-3 cells can be cultured under air interface culture (AIC) conditions. However, there is little information regarding the metabolic properties of Calu-3 cells under AIC conditions compared to conventional liquid covered culture (LCC) conditions. It was thus the goal of this study to characterize the basal and inducible cytochrome P450 (CYP) isoform expression in Calu-3 cells under AIC and LCC conditions. Calu-3 cells were cultured under AIC and LCC conditions and induction experiments were started on day 11 after passage. The transepithelial electrical resistance (TER) was measured to monitor the barrier properties of the cell monolayers. CYP expression was determined using real-time reverse transcription quantitative polymerase chain reaction (RTqPCR). Comparable basal expression of CYP1A1, CYP2B6/7, CYP2J2, CYP2C, CYP2F1, CYP2D6, CYP1A1, CYP3A4, CYP3A5 and CYP3AA was detected between both conditions, which is consistent with expression in the human lung. Omeprazole, a well-known activator of the aryl hydrocarbon receptor (AhR) induced CYP1A1 and CYP1B1 in Calu-3 cells under both conditions, with stronger induction being observed in AIC cultures. Dexamethasone acts via glucocorticoid receptors and we found slight but significant induction of CYP3AA and CYP3A5 in LCC cultures only. In summary, Calu-3 cells express a broad range of CYPs under both culture conditions with preserved inducibility for the main lung CYPs 1A1 and 1B1 and are thus a valuable model of the airway epithelial barrier for in vitro toxicity testing of airborne substances.
formed by cytochrome p450 isoforms to form styrene oxides and vinylphenols, which have biological activity as pulmonary and hepatic poisons. This toxic vinyl benzene is a danger to living systems and for this reason we have focused our research on the styrene detoxification pathway in Pseudomonas putida (S12) bacteria. The first enzyme, styrene monoxygenase (SMO), a two-component flavoenzyme with an NADH specific reductase, SMOB, and a FAD specific epoxidase, SMOA, which catalyzes the epoxidation of styrene to yield styrene oxide. Here, SMOB binds NADH and oxidized FAD as substrates and catalyzes the reduction of FAD by a hydride-transfer mechanism. The recently reported crystallographic and mechanistic investigation of SMOB suggests that disorder in the N-terminal region of the reductase may play an important role in the SMOB-SCMOA interaction and subsequent FAD transfer. Studies of naturally occurring and engineered SMO fusion proteins further support this idea.

Our present research evaluates the catalytic mechanism of an N-terminally histidine-tagged version of styrene monoxygenase reductase (N-SMOB). We found that the presence of this N-terminal tag is manifested in an increase FAD-binding affinity (Kd - 50 nM), which is nearly an order of magnitude greater than that of the wild type reductase, SMOB. The change in FAD-binding affinity impacts the steady-state kinetic mechanism, which changes from sequential in the wild-type enzyme to double displacement in the case of N-SMOB. Non-linear least squares curve fitting gives estimates of the Km values of NADH, and FAD and Vmax of the enzyme to double displacement in the case of N-SMOB. We found that N-SMOB binds NADH and oxidized FAD as substrates and catalyzes the reduction of FAD by a hydride-transfer mechanism. The recently reported crystallographic and mechanistic investigation of SMOB suggests that disorder in the N-terminal region of the reductase may play an important role in the SMOB-SCMOA interaction and subsequent FAD transfer. Studies of naturally occurring and engineered SMO fusion proteins further support this idea.

Here, we report that SMOB undergoes rapid metabolism by hydroxylation, sulfation, and glutathione conjugation following i.p. and inhalation exposures. Here we investigated tissue disposition, elimination, and general toxicity after inhalation exposure to PCB3 in rats after acute inhalation exposure for 2h. The experiment was carried out in two shifts in a setting that generated air concentrations of PCB3 of 2.1 and 1.4 mg/m3. Rats in the first shift (n=3) received an estimated dose of 35 mg/rat, and were immediately transferred to metabolism cages for the collection of urine and feces, and killed at 24 h. In the second shift (n=12), they received 21 mg/rat, and killed at 0, 1, and 4 h. At 0 h after exposure, the concentration of hydroxylated (OH-PCB3) and sulfated metabolites were 7±1 and 560±60 ng/ml, serum, 213±123 and 482±80 ng/g liver, 110 and 87 ng/g lung, and 40 and 6 ng/g brain, respectively. They followed first-order kinetics with elimination half-lives of 5.2 and 3.9, 3.5 and 8.3, 3.8 and 8.7, 4.2 and 8.0 h for OH-PCB3, 4PCB3 sulfite, 3PCB3 sulfate, and 3PCB3 sulfite from serum and liver, respectively. Approximately 1/3 of the dose was recovered from urine within 24 h, which consisted of OH-PCB3 and sulfates in the ratio of 1:6. While OH-PCB3 and PCB3 were also recovered from feces, the fecal route was minor. Although PCB3 metabolites penetrated the brain, and have been reported to displace thyroxine (T4) from transcortin in vitro, serum T4 levels were normal. There was no difference in 8-oxo-dG levels in urine, a marker of oxidative stress due to electrophilic bioactivation of PCB3, between control and PCB3 exposed rats.

Our findings will be presented together with their implications in the single turnover hydride-flavin-transfer reactions of the two-component SMO system.
changes of catalytic efficiency and drug interactions for N- or S-oxygenations of xenobiotics and endogenous substances. In conclusion, since even the most common [Glu158Lys; Glu308Gly] variant FMO3 protein could result in stronger inhibition potential, genetic polymorphism of human FMO3 gene might lead to unexpected drug interactions via modulation of FMO3 catalytic efficiency.

519 Assessment of Metabolic Potential of PCB Congeners in the Baikal Seal (Pusa sibirica) Using the Liver Microsome
J. You1, H. Mizukawa1,2, K. Nomiyama1, C. Kanbara1, A. Kubota1, T. Agusa1, E. Kim1, S. Tanabe1 and H. Iwata1.

Polychlorinated biphenyls (PCBs), consisting of 209 congeners are biomagnified in the food web and exhibit a broad range of adverse effects. Biotransformation of PCBs is initiated with the insertion of an oxygen atom into the biphenyl ring by cytochrome P450s (CYPs). Toxicokinetics of PCBs occurs in a congener- and species-specific manner. Baikal seal (Pusa sibirica) accumulate high levels of some PCB congeners. However, there still remains unknown how CYPs can metabolize PCB congeners in the Baikal seal. We thus assessed the metabolic potential of PCB congeners by CYPs using Baikal seal liver microsomes. The microsomal reaction solution containing a mixture of 62 PCB congeners was incubated with NADPH for 180 min, and the parent PCBs and their hydroxylated metabolites (OH-PCBs) were analyzed by a gas chromatography-mass spectrometry. The factors that potentially affect the metabolism of PCBs were further explored by principal component analysis (PCA). The microsomal incubation showed that over 50% of CB19 and CB37 and 20-50% of CB22, CB54, CB77 and CB105 were metabolized by CYP. The PCA analysis suggested that highly chlorinated PCB congeners are less susceptible to metabolism, while congeners with more hydrogen atoms at meta- and/or para-position(s) of the biphenyl ring are more metabolized. 3Cl- and 4Cl-substituted OH-PCBs were the major metabolites. 4OH-CB79 that may be formed from CB77 was detected at the highest level among the identified OH-PCBs, followed by 4OH-CB26 and 4OH-CB29, whereas more than 50% of the amount of detected OH-PCBs was unidentified. Only 11.5% of added amount of parent PCBs was recovered as OH-PCBs. These results indicate that there are large unknown CYP-dependent metabolic pathways of PCBs in the Baikal seal.

520 Selective Effects of a Therapeutic Protein-Targeting Tumor Necrosis Factor-Alpha on Cytochrome P450 Regulation during Infectious Colitis: Implications for Disease-Dependent Drug-Drug Interactions
M. D. Merrell1, B. A. Nyagode1, R. Jahangardi1, M. G. Tansey2 and E. T. Morgan1.

We studied the impact of administering XPro1595, a novel antagonist of soluble tumor necrosis factor-α (TNFα), on the regulation of hepatic cytochrome P450 enzymes in the C. rodentium model of infectious colitis. XPro1595 was administered subcutaneously every three days throughout the infection, or as a single injection near the peak of infection. When given throughout the infection, or as a single injection near the peak of infection. XPro1595 selectively blocked the down-regulation of Cyp3a11 and 3a25 mRNAs and Cyp3a protein, as well as the induction of Cyp2a4/5, without affecting the down-regulation of Cyp4a10, Cyp4a14, Cyp2b10 or flavin-monoxygenase-3. Induction of Cyp3a11, Cyp3a25, Cyp2b29 and Cyp3a13 mRNAs were observed only in XPro1595-treated mice. Administration of a single dose of XPro1595 was relatively ineffective. These results a) confirm the role of soluble TNFα in hepatic Cyp3a regulation during infectious colitis deduced from studies in TNFR1-null mice; b) indicate the potential for soluble TNFα-specific antagonists to cause disease-dependent drug-drug interactions; and c) suggest a novel mechanism by which an anti-inflammatory therapeutic protein can produce an opposite effect to that of the disease by selectively neutralizing one of multiple signals regulating drug-metabolizing enzyme expression. More research is needed to determine whether or not this is applicable to other diseases or disease models.
Here, we performed 

**524 Toxicity Profiling of Breast Cancer-Associated Compounds and ToxCast Chemicals in “Humanized” Budding Yeast Expressing P450 Genes**

B. Gaytan², D. Faulkner², R. Proctor², R. Rudel³, C. Vulpe² and M. Fasullo¹.

Many environmental toxicants require bioactivation to become potent genotoxicants. We introduced the P450 genes, CYP1A1, CYP1A2, and CYP3A4 into yeast strains that are deficient in either poly-drug resistance or both recombinalional and nucleotide excision DNA repair. We screened over 50 agents and classified the compounds whose toxicity 1) not influenced by P450 expression, 2) enhanced by P450 expression, and 3) reduced by P450 expression. Compounds not influenced by P450 expression include those that function to elevate deoxynucleotides, maintain mitochondria, promote replication in vitro. In CYP1A2-expressing budding yeast, AFB1 is a weak mutagen but a potent recombina
ting and, triggers the formation of recombinalional repair foci. A DNA damage-checkpoint response correlates with a delay in cell cycle progression. Microarray analysis reveals that both DNA repair and stress response genes are up regulated. To elucidate the functional significance of transcriptional induction, we are profiling the yeast genome for AFB1 resistance, using state-of-the-art next generation sequencing to identify molecular barcodes. We introduced the human CYP1A2 into ~90% of the deletion library, and pooled samples have been exposed to 50 μM and 100 μM AFB1 for 20 hrs. We identified genes that confer resistance to AFB1 by barcode sequencing, and additional genes by growth curves. DNA metabolism genes include RAD55, RAD17, REV1 and REV3, emphasizing the potency of the mycotoxin to trigger replication stress. Additional genes include those that function to elevate deoxynucleotides, maintain mitochondria, promote cellular growth and rearrange the cytoskeletal architecture. The ultimate aim will be to identify corresponding mammalian genes. The yeast libraries will be valuable for additional high-throughput studies using other metabolically-activated drugs and carcinogens. Grant support: NIH: R21ES19954, F3EES021133

**525 A Cocrystal of m-Chlorobenzoic Acid with Furomeside: Prospective Applications**

B. London¹, M. O. Claville², F. R. Froncek³ and B. M. Uppt².

Furosemide is a highly used diuretic for the treatment of hypertension and edema and, to a lesser extent, hypercalce
ia. This furan containing compound is of interest; however, the toxicity elicited by these core compounds is not well under
tood. The free furan itself is a known hepato-carcinogen and toxicant as studied in rats and mice. The epoxide metabolite of furans, formed in CYP450-mediated oxidations, can isomerize to highly reactive electrophilic intermediates such as cis-2-buten-1,4-dial. We have performed the oxidation of furosemide with m-chloro
erbenzoic acid (m-CBPA), and isolated various epoxide and isomerized products in support of our efforts to understand this type of toxicity mechanism, and to also identify potential biomarkers for furosemide in humans. During the separation and drying of the products of the furosemide-m-CBPA reaction, we observed the formation of crystals in the mother liquor (the organic layer). Analysis of these crystals by X-ray crystallography revealed a nonahydrate cocrystal of furosemide (starting material) with that of m-chlorobenzoic acid (an inadvertent contami
nant) with the reduced product of m-CBPA. Analogous to the known properties of cocrystals of furosemide with nicotinamide and their pharmaceutical importance, we believe that the cocrystals of furosemide with m-chlorobenzoic acid could have useful applications in drug development and may lead to formulations with improved potency, solubility, and stability. Therefore, this serendipitous finding may have important applications for improving furosemide bioavailability. Support from NSF ACE Implementation Grant (HRD-1043316) and the US Department of Education (P023B040030) is acknowledged; corresponding author’s email: rao_uppt@sunb.edu.

**526 Genome Profiling of Saccharomyces Cerevisiae Resistance to Aflatoxin B1 (AFB1), a Potent Liver Carcinogen**

M. Fasullo¹, J. Bard³, C. Cerá³, P. Egner³ and T. J. Begley¹, ².

The mycotoxin aflatoxin B1 (AFB1) is a potent liver carcinogen. A signature p53 mutation is found in tumors from liver cancer patients who inhabit AFB1-contaminated areas, suggesting that AFB1 is a potent genotoxin. P450 enzymes convert AFB1 into a highly reactive epoxide that forms N7-guanine DNA adducts, which are unstable and convert into AFB1-formamidopyrimidine (FAPY)-derivatives. These AFB1-associated adducts are either mutagenic or block DNA replication in vitro. In CYP1A2-expressing budding yeast, AFB1 is a weak mutagen but a potent recombina
ting and, triggers the formation of recombinalional repair foci. A DNA damage-checkpoint response correlates with a delay in cell cycle progression. Microarray analysis reveals that both DNA repair and stress response genes are up regulated. To elucidate the functional significance of transcriptional induction, we are profiling the yeast genome for AFB1 resistance, using state-of-the-art next generation sequencing to identify molecular barcodes. We introduced the human CYP1A2 into ~90% of the deletion library, and pooled samples have been exposed to 50 μM and 100 μM AFB1 for 20 hrs. We identified genes that confer resistance to AFB1 by barcode sequencing, and additional genes by growth curves. DNA metabolism genes include RAD55, RAD17, REV1 and REV3, emphasizing the potency of the mycotoxin to trigger replication stress. Additional genes include those that function to elevate deoxynucleotides, maintain mitochondria, promote cellular growth and rearrange the cytoskeletal architecture. The ultimate aim will be to identify corresponding mammalian genes. The yeast libraries will be valuable for additional high-throughput studies using other metabolically-activated drugs and carcinogens. Grant support: NIH: R21ES19954, F3EES021133

**527 Development of a Selective CYP2B6 and Cell Viability Duplex Assay**

CYP2B6 induction affects drug clearance and potentially contributes to adverse drug interactions in humans. To predict CYP induction in vitro cultured hepatocytes are exposed to a probe CYP substrate and compounds that accelerate probe conversion are scored as CYP inducers. However, induction may be underesti
mated when cytotoxic compounds reduce CYP activity indirectly by cell killing. To selectively measure effects on CYP2B6 activity while controlling for cytotoxicity we developed a novel CYP2B6/cell viability multiplex assay. For CYP2B6 we synthes
ezed 6-(4,4-dimethoxybutan-2-yl)oxy benzoz[di]thiazole-2-carbonitril as a probe substrate. This probe is a luciferase pro-substrate that is activated by CYP2B6 then detected as a light from a luciferase reaction. A screen of 21 recombinant human CYPs showed strong CYP2B6 selectivity. Selective inhibition of liver microsome probe reactions by known CYP2B6 inhibitors provided further evidence for selectivity. With adherent hepatocytes initial test compound or vehicle treatments were followed by incubation with the probe. The product of the CYP probe reaction is found in the medium so samples were removed and mixed with a luciferase formulation to give luminescence that reflects CYP activity. Hepatocyte viability was then measured by a lytic ATP-based luminesince assay and values from CYP measurements were normalized to respective viability values. Cell based data was consistent with CYP2B6 selectivity in that CYP2B6 inducers and inhibitors respec
tively elevated or reduced activity (e.g. CITGO vs. Clopidogrel). Fold inductions and IC50s correlated well with reported values from LCMS-based CYP2B6 assays. This approach provides convenience and selectivity for CYP2B6 studies and en
hanced biological relevance by normalization to cell viability.

**528 Role of CYP2BFGS in NNK Bioactivation and Lung Tumorigenesis: Insights from a Novel Cyp2bfgs-null Mouse**

L. Li, Y. Megarei, Y. Wei and X. Ding. Health Research Inc, Albany, NY.

Enzymes encoded by the mouse Cyp2bfgs gene cluster are preferentially expressed in the respiratory tract, and a number of these are active toward xenobiotic com-
ponents, including many drugs and a tobacco-specific lung procarrigen 4-(meth
ylamino)-1-(3-pyridyl)-1-butane (NNK). CYP2AS is already known to mediate a significant fraction of NNK bioactivation in the lung. This study was aimed to test the hypothesis that, besides CYP2A5, other CYP2ABFGS enzymes also play significant roles in NNK-induced lung tumorigenesis, with use of a novel Cyp2bfgs-null mouse. Deletion of the constitutive genes in the
Cyp2abfgs cluster was confirmed by RNA-PCR analysis in tissues known to express each gene. The Cyp2abfgs-null mouse was viable, fertile and without any obvious developmental defects, and they appeared to have no compensatory increase in the expression of other P450s. NNK bioactivation in vitro and NNK-induced DNA adduction and lung tumorigenesis in vivo were studied in wild-type, Cyp2a5-null, and Cyp2abfgs-null mice. The Cyp2abfgs-null mice exhibited significantly lower rates of NNK bioactivation in lung and liver microsomes, compared to either wild-type mice or Cyp2a5-null mice. Consistent with the in vitro data, the levels of lung O6-methyl guanine (O6-MG), the DNA adduct highly correlated with lung tumorigenesis, were substantially reduced in the Cyp2abfgs-null mice, compared to either wild-type mice or Cyp2a5-null mice. Moreover, the Cyp2abfgs-null mice were largely resistant to NNK-induced lung tumorigenesis at a high NNK dose (200 mg/kg), in contrast to the wild-type mice or Cyp2a5-null mice. These results indicate that, collectively, the CYP2ABFGS enzymes play essential roles in mediating NNK-induced lung tumorigenesis.

### 529 Identification of P450 Activity As a Risk Factor for Metabolism-Dependent Drug-Induced Hepatotoxicity

U. Doshi and A. P. Li. In Vitro Toxicology, In Vitro ADMET Laboratories LLC, Columbia, MD.

A possible risk factor for drug-induced hepatotoxicity is drug metabolizing enzyme activity which may vary among individuals due to genetic (genetic polymorphism) and environmental factors (environmental pollutants, foods and medications that are inhibitors or inducers of drug metabolizing enzymes). We hypothesize that P450 activity represents one of the key risk factors for hepatotoxicity for drugs that are metabolically activated to cytotoxic/reactive metabolites. After evaluation of >20 lots of human hepatocytes, each from a different donor, we identified one lot, HH1020 (from a 21 year old Caucasian female) to have uniquely P450 high activities for several major human P450 isoforms, with CYP2B6 (bupropion hydroxylaton), CYP2D6 (dextromethorphan O-demethylation), and CYP3A4 (midazolam 1-hydroxylation) activities to be 700%, 200% and 800% respectively, of the average values for the other donors. We evaluated the in vitro cytotoxicity of three metabolism-dependent hepatocarcinogens, acetaminophen (APAP), cyclophosphamide (CPA), and aflatoxin B1 (AFB1) as well as a direct-acting cytotoxicant, tamofoxen (TMF), in HH1020 versus hepatocytes from two other donors. The hepatocytes were cultured in collagen-coated plates and treated after 4 hours of plating for 24 hrs, following by viability determination using cellular ATP as endpoint. The EC50 values were as follows: APAP; 2.3 mM (HH1020), 9.4 and 10 mM (others), CPA; 1.8 mM (HH1020), >5 mM (others), AFB1; 2.8 μM (HH1020), 10 and 22 μM (others), and TMF; 26 μM (HH1020), 29 and 30 μM (others). In a separate experiment, HH1020 was treatment with CPA and AFB1 in the presence of the non-selective P450 inhibitor aminobenzotriazole (ABT). Dose-dependent reversal of cytotoxicity by ABT was observed, confirming the role of P450 metabolism on CPA and AFB1 hepatotoxicity. Our results showed convincingly that HH1020 hepatocytes were significantly more sensitive to metabolism-dependent drug-induced hepatotoxicity, and therefore support the hypothesis that P450 activity is a probable risk factor towards drug-induced hepatotoxicity.

### 530 Effect of Vinclozolin on Liver Cytochrome P450 Expression and Testosterone and Estradiol Serum Levels During Pregnancy

F. G. Garcia-Montes de Oca1, M. L. Lopez-Gonzalez1, R. Chavira-Ramirez2 and A. Sierra-Santoyo1.

Vinclozolin (V) is a fungicide used for agricultural settings. V and its metabolites M1 and M2 bind to the androgen receptor (RA) and act as RA antagonists. They inhibit the androgen-dependent gene expression. V is able to regulate adult rat liver cytochrome P450 (CYP) expression in a complex manner. The information about effects of V on rat liver is limited and there is no information about the effect on testosterone and estradiol serum levels during pregnancy. The aim of this study was determine the effect of V on regulation of rat liver CYP during pregnancy and how affect testosterone and estradiol bioavailability. Pregnant Wistar rats were administered at the dose of 150 mg V/kg/d suspended in corn oil by gavage during gestational days 14-21. Mothers were sacrificed by asphyxia with CO2. Liver was removed and processed to obtain the microsomal fraction. V exposure increased about 8-fold the content of liver microsomal immunoprotein of CYP2A and 3A2, while CYP1A1, 2B1/2 and 3A1 were induced about 26.7-, 25.6- and 43.7-fold, respectively. On the contrary, the content of CYP1A2 decreased 60% in comparison to non-treated pregnant rats. Likewise, enzyme activities of MROD and PROD increased 21.7- and 817-fold, respectively, and 7α- and 6β-testosterone hydroxylase increased 1.7- and 4.4-fold, respectively. In V-treated pregnant rats testosterone serum levels decreased 56.6% and interestingly estradiol serum levels increased 1.6-fold. These effects produced an increase of 3.5-fold on the estradiol/testosterone ratio. These results indicate that V regulates hepatic CYP expression and alters estradiol and testosterone homeostasis during pregnancy. In addition, they could help to explain the antianabolic effects on reproductive system in male offsprings during uterine exposure. (Supported by CONACyT-Mexico No. 168384).

### 531 Role of P450 Enzymes in Cigarette Smoke-Induced Acute Lung Injury

M. A. Hartog1, 2 and X. Ding1, 2.

Wadsworth Center, New York State Department of Health, Albany, NY and 2School of Public Health, State University of New York at Albany, Albany, NY.

The aim of this study is to test the notion that microsomal P450 enzymes can influence the risks of cigarette smoke (CS) induced lung inflammation and tissue damage, an idea supported by the fact that multiple, toxicologically relevant, compounds found in CS are P450 substrates. Based on the protease-antiprotease hypothesis of emphysema development and when considering the inflammatory events observed in COPD, it is thought that pulmonary recruitment of neutrophils and macrophages may play a key role in CS-induced lung diseases. Thus, we examined the cellular profiles in the lungs of wild type (WT) mice and mice with selective abolition of P450 activity; the animals (adult female, all on B6 genetic background) were pre-exposed to either filtered air (FA) or environmental tobacco smoke (ETS) via nose-only inhalation for 5.5 h at a dose of 250 mg/m3 total particulate matter. We found that, the numbers of total cells and of macrophages in bronchoalveolar lavage (BAL) were not significantly different between WT and LCN mice (liver-specific P450 reductase null mice, with little P450 activity in hepatocytes) that were pre-exposed to FA; however, the numbers were 1.5-1.6 fold greater in LCN than in WT mice that were pre-exposed to ETS. ETS-exposed WT and LCN mice both had significant increases in the number of neutrophils in BAL, compared to FA-exposed mice; but the numbers were not different between the two strains. Furthermore, ETS exposure failed to induce a significant increase in the number of BAL neutrophils in Cyp2abfgs-null mice, where all Cyp genes of the Cyp2a, 2b, 2f, 2g, and 2s subfamilies have been deleted throughout the body. An enhanced pulmonary inflammation in ETS-exposed LCN mouse, compared to ETS-exposed Cyp2abfgs-null mice, was further confirmed by histological analysis of H&E-stained lung tissue sections. Taken together, these results support the hypothesis that hepatic P450s protect against, whereas lung CYP2ABFGS mediate, the development of ETS-induced acute lung toxicity.

### 532 Role of Human CYP2A13 and CYP2F1 in Naphthalene Bioactivation and Toxicity in the Lung and Nasal Mucosa of a CYP2A13/2F1-Humanized Mouse

X. Ding1, L. Li1, K. Jia1, M. A. Hartog2, Y. Wang3, and L. S. Van Winkle4.

Health Research Inc., Albany, NY and 4UC Davis, Davis, CA.

The aim of this study is to characterize the expression and activity of CYP2A13 and CYP2F1, two human P450 enzymes expressed preferentially in the respiratory tract. CYP2A and CYP2F enzymes have been reported to metabolize many lung toxicants, including naphthalene (NA). The function of human CYP2A13 and CYP2F1 in NA bioactivation and respiratory tract toxicity was examined in this study, using CYP2A13/2F1-humanized mice and CYP2A13-only (humanized) mice (on Cyp2abfgs-null background). In vitro studies indicated that, while the activity in the nasal olfactory mucosa (OM) of the CYP2A13/2F1-humanized mice was primarily contributed by CYP2A13, the activity in the lung was mainly contributed by CYP2F1. Further in vivo studies were conducted, in order to assess the capabilities of CYP2A13 and CYP2F1 to mediate acute inhalation toxicity of NA, at an NA dose relevant to occupational exposure (10 ppm for 4 h). CYP2A13/2F1-humanized mice showed greater sensitivity than Cyp2abfgs-null NA did, to NA-induced depletion of non-protein sulfhydryl and occurrence of cytotoxicity (observable by routine histology) in the OM (but not lung), when examined at 2 or 4 h after termination of NA exposure. However, preliminary results showed that the lungs of NA-treated CYP2A13/2F1-humanized mice had greater numbers of dye-permeable (injured) cells than that of NA-treated Cyp2abfgs-null mice, in both proximal and distal bronchioles, when examined using an ethidium homodimer incorporation assay, which is more sensitive than routine histology examination. These results demonstrate that both CYP2A13 and CYP2F1 are active toward NA in the lung and OM of the CYP2A13/2F1-humanized mice, and they play a significant role in NA-induced toxicity.
533 Essential Role of the Cytochrome P450 Enzyme CYP2A5 in Obligate Mucosal Toxicity of Naphthalene

J. Hu1, L. Sheng2, L. Li1, X. Zhou1, F. Xie1, J. D'Agostino1, Y. Li1 and X. Ding2.
1Health Research Inc., Albany, NY and 2Institute of Materia Medica, Chinese Academy of Medical Sciences & Perking Union Medical College, Beijing, China.

Naphthalene (NA), a ubiquitous environmental pollutant that can cause pulmonary and nasal toxicity in laboratory animals, requires cytochrome P450 (P450)-mediated metabolic activation in order to cause toxicity. Our recent study using a Cyp222-null mouse showed that CYP2F2 plays an essential role in NA-induced lung toxicity, but not in NA-induced nasal toxicity. The aim of this study was to determine whether mouse CYP2A5, abundantly expressed in nasal olfactory mucosa (OM) and liver, but less in lung, plays the major role in the bioactivation and toxicity of NA in the OM. We found, by comparing Cyp2a5-null and wild-type (WT) mice, that the loss of CYP2A5 expression led to substantial decreases in rates of NA metabolic activation by OM microsomes. The loss of CYP2A5 did not cause changes in systemic clearance of NA (at 200 mg/kg, i.p.). However, the Cyp2a5-null mice were much more resistant than were WT mice to NA-induced nasal toxicity (though not lung toxicity), when examined at 24 h after NA dosing (at 200 mg/kg, i.p.), or to NA-induced depletion of total nonprotein sulfhydryl in the OM (though not in the lung), examined at 2 h after dosing. Thus, mouse CYP2A5 plays an essential role in the bioactivation and toxicity of NA in the OM, but not in the lung. Our findings further illustrate the tissue-specific nature of the role of individual P450 enzymes in xenobiotic toxicity, and provide the basis for a more reliable assessment of the potential risks of NA nasal toxicity in humans.

534 High-Throughput Screening to Identify Substrates of Zebrafish Cytochrome P450 1A

Biology, McMaster University, Hamilton, ON, Canada.

Cytochrome P450 (CYP) 1 isoforms catalyze the metabolism of steroids, pharmacueticals and environmental contaminants in vertebrates. In the world of fish aquatic toxicology, CYP1A is perhaps the best known of the family due to its induction and role as a biomarker with contaminant exposure (often examined with the EROD assay). However, only a handful of substrates for CYP1A have been identified in fish. Presently, we have used heterologously expressed zebrafish CYP1A in a high-throughput screen (HTS) with thousands of bioactive compounds, with the aim of identifying the substrate specificities of this enzyme. Catalytic activity was determined in 50 μl reactions in 384 well plates, testing for NADPH consumption. We screened a 6,400 bioactive compound library consisting of off-patent, natural or pharmacologically active compounds with an average molecular weight of 350 g/mol. NADPH consumption rates were compared to negative (DMSO) and positive (7-methoxyresorufin) controls. A total of 87 and 35 compounds activated NADPH consumption at rates greater than 50% and 100% of the positive control, respectively. However, 13 of the top 40 hits induced significant NADPH loss in the absence of CYP1A enzyme, indicating a small but significant degree of false positives. The top 160 hits were screened for ROS formation, where rates greater than 25% of our control (pentoxresorufin) were observed in 31 compounds (19%), indicating some hits may induce uncoupled ROS formation, where rates greater than 25% of our positive control (pentoxyresorufin) were observed in 31 compounds (19%), indicating some hits may induce uncoupled ROS formation. Treatment of Hepa-1 cells with the MC (2.5 μM) resulted in a 50% decrease of ROS production, compared to vehicle controls. Treatment of Hepa-1 cells with the MC (2.5 μM) resulted in a 50% decrease of ROS production, compared to vehicle controls. These data suggest that CYP1A2, possibly via a metabolite, contributes to the sustained induction of CYP1A1 mRNA by MC in hepa-1 cells. Further investigations into the mechanisms of persistent induction of CYP1A1 by MC could lead to novel preventative/therapeutic strategies against PAH-mediated carcinogenesis in humans.

535 Mechanistic Role of Cytochrome P450 (CYP)1A2 in the Persistent Induction of CYP1A1 by the Polycyclic Aromatic Hydrocarbon 3-Methylcholanthrene (MC) in Mouse Hepatoma Cells (hepa-1)

Pediatrics, Baylor College of Medicine, Houston, TX.

Humans are constantly exposed to environmental carcinogenic polycyclic aromatic hydrocarbons (PAHs) through cigarette, smoke exhausts, charcoal-broiled meats, etc. Cytochrome P450 (CYP) 1 enzymes play important roles in the activation of PAHs such as 3-methylcholanthrene (MC) to carcinogenic DNA-binding metabolites. We reported earlier that MC causes persistent induction of hepatic and pulmonary CYP1A1 in mice for several weeks after MC withdrawal, and that the phenomenon of sustained hepatic CYP1A1 induction is lost in Cyp1a2-null mice. In this study, we tested the hypothesis that MC elicits persistent CYP1A1 induction in hepa-1 cells, and that CYP1A2 contributes mechanistically to this phenomenon. Hepa-1 cells transfected with the MC and a dimesylated dioxynuloxide (DMSO) as control, and at selected time points, CYP1A1 promoter activity, CYP1A1 enzyme activities, contents, and CYP1A1 mRNA levels were studied. We found that MC markedly and persistently induced CYP1A1 promoter activity, transcription, apoprotein expression, and the CYP1A1-associated ethionomuhamin D-olactone (EROD) activities for up to 5 days. Transfection of cells with CYP1A2 siRNA resulted in knockdown of CYP1A2 mRNA by 70%, but a statistically significant increase of basal CYP1A1 mRNA by 35-40%. The induction of CYP1A1 promoter activity, CYP1A1 mRNA, CYP1A1 protein, and EROD activity by MC were not affected by CYP1A2 siRNA at the 24 h time point, but was significantly attenuated by CYP1a2 siRNA on day 5. These results suggest that CYP1A2, possibly via a metabolite, contributes to the sustained induction of CYP1A1 by MC in hepa-1 cells. Further investigations into the mechanisms of persistent induction of CYP1A1 by MC could lead to novel preventative/therapeutic strategies against PAH-mediated carcinogenesis in humans.

536 Role of Intestinal Cytochrome P450 Enzymes in Protection against Colon Inflammation in a Mouse Model of Dextran Sulfate Sodium-Induced Colitis

Q. Zhang1,2, Y. Zhu1, F. Xie1 and X. Fan1,2.
Wadsworth Center, NYSDOH, Albany, NY and 2School of Public Health, SUNY at Albany, Albany, NY.

The aim of this study was to determine the roles of intestinal microsomal cytochrome P450 (P450) enzymes in protection against colon inflammation, by studying dextran sulfate sodium (DSS)-induced colitis in an intestinal epithelium (IE)-specific P450 reductase knockout (IE-Cpr-null) mouse model, which has little microsomal P450 activity in the epithelial cells. DSS treatment (2.5% in drinking water for 6 days) caused more severe colon inflammation in DSS-IE-Cpr-null than in wild-type (WT) mice, as evidenced by the presence of higher levels of myeloperoxidase, an indicator of neutrophil infiltration, and proinflammatory cytokines (TNF-α, IL-6 and IL-1β), accompanied by greater weight loss, colonic tissue damage, and colon shortening. A deficiency in colonic corticosterone (CC) synthesis was identified in the IE-Cpr-null mice, as indicated by decreases, compared with WT mice, in rates of CC production in ex vivo cultured colonic tissues from both vehicle-treated (by ~30%) and DSS-treated mice (by ~70%). Co-treatment of DSS-exposed mice with deoxytocorticosterone, a precursor of CC biosynthesis via mitochondrial CYP11B1, abolished the hypersensitivity of IE-Cpr-null mice to DSS-induced colon inflammation. Taken together, these results strongly support the notion that microsomal P450 enzymes in the intestine play an important role in protecting colon epithelium from DSS-induced inflammation, possibly through increased local CC synthesis in response to DSS challenge.

537 Identification of a P450-Mediated Hepatotoxicity-Associated Glutathione-Conjugate of Phenytoin in Phenytoin-Induced Liver Injury in Mice

T. Yokoi1, 2, E. Sasaki1, A. Iwamura3, T. Fukami1, M. Nakajima1 and T. Kume3.
1Graduate School of Medical Science, Kanazawa University, Kanazawa, Ishikawa, Japan, 2Department of Drug Safety Sciences, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan and 3DMPK Research Laboratory, Mitsubishi Tanabe Pharma Corporation, Toda, Saitama, Japan.

Phenytoin (DPH) is widely used as an anticonvulsant agent. Hepatic necrosis was rarely observed in patients who received DPH. The formation of reactive metabolites are believed to involve the developing of DPH-induced live injury, however, evidence for reactive metabolites formation, their thiol conjugates, such as glutathione (GSH), formation and their effects on developing of DPH-induced liver injury are largely unknown. We previously demonstrated that DPH treatment decreased the hepatic GSH contents, and GSH depletion exacerbated the liver injury in mice. In this study, we first identified the GSH-DPH adduct, conjugate of putative electrophilic aren oxide metabolite with GSH, in the bile of the liver-injured mice, administered with DPH for 5 days with GSH biosynthesis inhibitor, L-buthionine-S,R-sulfoximine (BSO), in female C57BL6 mice. In the plasma, N-acetylhydretstene- and S-cysteine-DPH conjugates were detected. In addition, the peak time of the concentration of conjugates were corresponded to that of plasma alanine aminotransferase (ALT) levels. The plasma conjugates concentrations were significantly reduced by the cytochrome P450s inhibitor, 1-aminoenozitiozol (ABT), treatment. Furthermore, elevation of plasma ALT levels and hepatic GSH depletion were significantly suppressed by ABT, flunxazole, and ketoconazole treatment. Although single administration of DPH could not elevate plasma ALT levels, induction of Cyp2c2 caused significant elevation for plasma ALT levels. In
ARDS in adults.

Strategies for the prevention and/or treatment of BPD in premature infants and ALI/ARDS in adults. Hyperoxic lung injury by detoxifying lipid hydroperoxides such as F2-isoprostanes in vivo. Future research could lead to the development of novel strategies for the prevention and/or treatment of BPD in premature infants and ALI/ARDS in adults.

CYP1A1-null mice, with Cyp1a1-null mice showing higher levels after 48-72 h compared to WT mice at the 72 h time point. Levels of pulmonary F2-isoprostanes α of CYP1A1 expression at the catalytic, apoprotein, and mRNA levels in liver and lung in the WT mice. The increase in lung injury in the Cyp1a1-null was accompanied by increased oxidative stress and neutrophil recruitment. Hyperoxia for 24-48 h elicited significant induction of the liver injury via arene oxide formation.

In conclusion, our results show increased susceptibility of newborns to oxygen-mediated lung injury and alveolar simplification following maternal exposure to BP, and oxidative stress as well as modulation of CYP1A1 and 1B1 enzymes contribute to this phenomenon.

Supplemental oxygen therapy is often required for treatment of preterm infants with pulmonary insufficiency, as well as adults suffering from acute lung injury (ALI)/acute respiratory distress syndrome (ARDS). However, hyperoxia contributes to the development of bronchopulmonary dysplasia (BPD) in premature infants and may exacerbate lung injury in ALI/ARDS patients. In this investigation, we tested the hypotheses that prenatal exposure of rats to benzo[a]pyrene (BP) will result in increased susceptibility of newborns to oxygen-mediated lung injury and alveolar simplification, and that cytochrome P450 (CYP)1A1 and 1B1 enzymes and oxidative stress mechanically contribute to this phenomenon. Timed pregnant Fisher 344 rats were administered BP (25 mg/Kg) or the vehicle corn oil (CO) on gestational days 18, 19 and 20, and newborn rats delivered from the mothers of both these groups were either maintained in room air or exposed to hyperoxia (85% O2) for 7 or 14 days. Hyperoxic newborn rats prenatally exposed to the vehicle CO showed lung injury and alveolar simplification, and inflammation, and these effects were potentiated in rats that were prenatally exposed to BP. Prenatal exposure of BP also resulted in significant modulation of hepatic and pulmonary cytochrome P450 (CYP)1A1 and 1B1 enzymes at PND 7-14. These rats also displayed significant oxidative stress in lungs at postnatal day (PND) 14, as evidenced by increased levels of the F2-isoprostane 8-iso-PGF2α. In conclusion, our results show increased susceptibility of newborns to oxygen-mediated lung injury and alveolar simplification following maternal exposure to BP, and oxidative stress as well as modulation of CYP1A1 and 1B1 enzymes contribute to this phenomenon.

Mammalian detoxification processes have been the focus of intense research, but little is known about how wild herbivores process plant secondary compounds, many of which have medicinal value or are drugs. New technologies to estimate BPA toxicity in human have been required and suggested that Cyp2c-mediated metabolism could contribute to the development of the liver injury via arene oxide formation. Maternal smoking is one of the risk factors for pre-term birth and for the development of bronchopulmonary dysplasia (BPD). In this study, we tested the hypothesis that prenatal exposure of rats to benzo[a]pyrene (BP) will result in increased susceptibility of newborns to oxygen-mediated lung injury and alveolar simplification, and that cytochrome P450 (CYP)1A1 and 1B1 enzymes and oxidative stress mechanistically contribute to this phenomenon. Timed pregnant Fisher 344 rats were administered BP (25 mg/Kg) or the vehicle corn oil (CO) on gestational days 18, 19 and 20, and newborn rats delivered from the mothers of both these groups were either maintained in room air or exposed to hyperoxia (85% O2) for 7 or 14 days. Hyperoxic newborn rats prenatally exposed to the vehicle CO showed lung injury and alveolar simplification, and inflammation, and these effects were potentiated in rats that were prenatally exposed to BP. Prenatal exposure of BP also resulted in significant modulation of hepatic and pulmonary cytochrome P450 (CYP)1A1 and 1B1 enzymes at PND 7-14. These rats also displayed significant oxidative stress in lungs at postnatal day (PND) 14, as evidenced by increased levels of the F2-isoprostane 8-iso-PGF2α. In conclusion, our results show increased susceptibility of newborns to oxygen-mediated lung injury and alveolar simplification following maternal exposure to BP, and oxidative stress as well as modulation of CYP1A1 and 1B1 enzymes contribute to this phenomenon.

In conclusion, our results show increased susceptibility of newborns to oxygen-mediated lung injury and alveolar simplification following maternal exposure to BP, and oxidative stress as well as modulation of CYP1A1 and 1B1 enzymes contribute to this phenomenon.
the veterinarians, as insufficient numbers of drugs are approved for veterinary use. Therefore, doses of these drugs are empirically determined with reference to human information. In this study, we developed heterologously expressed feline CYP3A and the orthologues of dogs and humans for comparison, individually with human P450 reductase to generate functional monooxygenase systems in Escherichia coli. We found two novel CYP3A genes, CYP3A131 and CYP3A132 in rats. Both feline CYP3As show high identity with canine CYP3As homologues and those of some artiodactyls. CYP3A131 transcripts were expressed predominantly in liver and small intestine, while CYP3A132 was only detected in liver with much lesser amount. Feline CYP3A131 extensively metabolized a fluorocoumarin (BFC) to 7-hydroxy-4-trifluoromethylcoumarin (HFC) with Km value similar to human CYP3A4 and canine CYP3A12 (Km 271-413 μM), except human CYP3A5 (63 μM). As indicated by Ki values, there were general similarities between human, canine and feline CYP3As in binding affinities of some CYP3A inhibitors, such as miconazole, erythromycin, cimetidine, dexamethasone, olmesartan, and medroxyprogesterone acetate except human CYP3A4, which was very resistant to these inhibitors. The present study provides a high-throughput system to assess possible drug interactions in feline CYP3A metabolism in comparison with canine and human CYP3As.

539d PAH Dibenzo[def,p] Chrysene-Induced Adult On-Set Lung Tumors and T Cell Acute Lymphoblastic Leukemia Utilizing a CYP1B1 Humanized Mouse Model: A Transplacental Model

H. You, E. Maderon, T. Harper, D. E. Williams, W. M. Baird and C. V. Löhrl. Environmental & Molecular Toxicology, Oregon State University, Lake Oswego, OR.

Polycyclic aromatic hydrocarbons (PAHs) ubiquitously contaminate food crops through atmospheric deposition. Dibenzo[def,p]chrysene (DBC, an IARC class 2A probable human carcinogen), is carcinogenic in animal models and is a human health concern. We induce adult onset T-cell acute lymphoblastic lymphoma (T-ALL) and lung tumors in mice by transplacental fetal exposure via a single gavage dose of DBC to pregnant Lazy1 dams on gestation day 17. The maximal doses tested were 6.5 or 12 mg DBC/Kg. Cytochrome P450 (Cyp) 1b1 is required for DBC-dependent T-ALL (at 4-6 months of age) Lung tumor development (hyperplasia, adenoma, adenoma with progression, and carcinoma) at 10 months of age is due to both Cyp 1a1 and 1b1 bioactivation of DBC. We utilized 129S males, null for mouse cyp 1b1, to cross with B6/129SF1 dams null for mouse cyp1b1 and expressing one allele of human CYP 1B1. There was no significant mortality in the null and humanized hemizygous 1B1 groups, however the T-ALL dependent mortality rate for wild type groups were 42% in the low dose (6.5mg/kg) and 66% in the high dose (12 mg/kg) groups, n=35 per group. At 10 months of age, lung tumor multiplicity was assessed. Corn oil treated groups did not develop lung tumors. Low dose treated groups developed similar numbers of tumors; null = 9.7 tumors, n=26 with 96% incidence; hemizygous 1B1 = 7.5 tumors, n=25 with 96% incidence; and wild type = 8.6 tumors, n=18 with 100% incidence. Similar numbers of tumors were found among high dose treated groups. Null = 12±7 tumors, n=49 with 98% incidence; hemizygous 1B1 = 12±9 tumors, n=23 with 97% incidence; and wild type = 13±5 tumors, n=10 with 100% incidence. The “humanized” hemizygous 1B1 transgenic mouse did not contribute to increased susceptibility to T-ALL or lung tumor compared to 1b1 null mouse. Current work is focused on tissue specific expression of the humanized transgenic 1B1 in mice. Supported by NIH grant P02 ES016465.

540 PON 1 Enzyme Activities in a Mississippi Population Vary with Substrate, Genotype, and Race

M. Dal1, C. McDaniel1, R. Wills1, H. W. Chambers2 and J. E. Chambers1.

1Center for Environmental Health Sciences, Mississippi State University, MS State, MS and 2Biochem., Mol. Biol., Entom., Plant Path., Mississippi State University, MS State, MS.

Paraoxonase (PON1) hydrolyzes paraoxon (PO) and diazoxon (DZO), the active metabolites of the insecticides parathion and diazinon, respectively. The human PON1 gene has several single nucleotide polymorphisms (SNPs). The SNP involving arginine (R) to glutamine (Q) substitution at codon 192 is associated with catalytic efficiency while that involving methionine (M) to leucine (L) substitution at codon 55 is associated with serum concentration. PON1 polymorphisms and activities have been linked to cardiovascular and other diseases. Since Mississippians have high disease rates, 186 cardiology clinic patients were evaluated. Hydrolysis rates of PO (POase), DZO (DZOase), dihydrocoumarin (lactonase) and phenyl acetate (arylesterase) were evaluated for associations with race, gender, age, and PON1 55/192 SNP genotypes. The variables were analyzed both individually and in combination. African Americans had higher levels (p<0.02) of POase and arylerase than Caucasians but Caucasians had higher DZOase and lactonase values (p<0.05). Since lactonase activity may be the most critical PON1 enzyme activity for LDL oxidation prevention, this might partially explain the health disparity paradox of why African Americans have higher POase and arylerase activities than Caucasians yet still have higher rates of coronary disease. Significant (p<0.0001) differences in arylerase activities were seen amongst the genotypes with QQMM having the lowest and RRLL the highest activities. This opposes the prevailing belief that arylerase is unaffected by genotype and suggests that this activity cannot be used to quantify PON1 protein. The differences in PON1 activities indicate the need to specify substrate and demographic data for enzyme assays. (Support NIH ES051570)

541 Contribution of CYP2B6 Alleles in Sudden Death of Methadone Users: A CYP2B6 Genetic Polymorphism Study

T. Ahmad1, L. Richards-Waugh2, S. Sabet1 and G. O. Rankin1.

1Pharmacology, Physiology & Toxicology, Marshall University, Huntington, WV and 2Forensic Science Graduate Program, Marshall University, Huntington, WV.

West Virginia (WV) and Kentucky (KY) ranked in the top ten states for increases in fatal methadone overdoses in 1999-2004. Cytochrome P450 2B6 (CYP2B6) plays a significant role in stereoselective metabolism of (S)-methadone to 2-ethyl-1,5-dimethyl-3,3-diphenylprolidine (EDDP). Elevated (S)-methadone can cause cardio toxicity by prolonging the QT interval. Large interindividual variability in the pharmacokinetics of methadone causes ambiguity in the relationship between dose, plasma concentration levels, and side effects. The purpose of this study was to determine if single nucleotide polymorphisms (SNPs) in the CYP2B6 gene can lead to decreased metabolism of methadone leading to fatal concentrations. Genomic DNA was isolated from blood stain cards prepared during autopsies at the WV and KY Offices of the Chief Medical Examiner. DNA samples under went real time polymerase chain reaction utilizing TaqMan Allelic Discrimination Analysis to determine the genotypic frequencies of four CYP2B6 gene SNPs (rs8192709, rs4803149, rs3745274, and rs3211371) in the methadone only fatal (136) and control (269) cases. All four of the SNPs studied were within Hardy-Weinberg equilibrium. The observed genotypic frequencies were significantly different than the frequencies for the general population (p<0.05) for three of the four (rs4803149, rs3745274, and rs3211371) SNPs. With the Kruskal Wallis test, the rs3745274 SNP showed a significant difference between [methadone]/[EDDP] ratio for the methadone only overdoses (p = 0.019). Although, the rs4803149 and rs3211371 SNPs were not found to be significantly associated with an increase in [methadone]/[EDDP] ratio, there is an apparent enrichment of the minor allele in the methadone fatal group. Based on these results, SNP rs3745274 is likely linked with a slow-metabolizer phenotype for methadone. Supported in part by NIH grant P20RR016477.

539 Metabolism of 4-Methylimidazole in the Rat and Mouse

T. Fennell, R. Snyder, S. Watson and S. Dhungana. RTI International, Research Triangle Park, NC.

4-Methylimidazole (4-MeI) is found in numerous heated foods and in some car- amel colors used in food and beverages. In long-term cancer bioassays 4-MeI induced alveolar/bronchiolar tumors in mice, but not in rats. This study was con- ducted to investigate the metabolism of 4-MeI in vitro, rat, mouse, and human lung and liver microsomes and S-9 fractions, and in vivo in rats and mice. Mouse and human liver microsomes or S-9 fractions. Male and female F-344 rats and B6C3F1 mice ad- ministered [14C]-4-MeI at doses of 50 and 150 mg/kg by gavage to track the dispo- sition and metabolism of 4-MeI in vivo. Animals were placed in metabolism cages for collection of excreta and exhaled CO2 and volatiles for 48 h. In rats adminis- tered [14C]-4-MeI, the major route of elimination was via urine, with 79-89% of the radioactivity in urine, 3-9% in cage rinse, 2-4% in feces, 1-2% exhaled as CO2, 1-2% in carcass, and 0.1 % or less as exhaled volatiles. In mice, 41-70% of the administered dose was recovered in urine, 4-12% in feces, 18-34% in cage rinse, 2-4 % exhaled as CO2, and 1-3% in carcass, and 0.1 % or less as exhaled volatiles. In rats and mice, the majority of the radioactivity (71-88%) in urine was present as unchanged 4-MeI, characterized by HPLC with detection of radioactivity, and by LC-MS. Additional radioactive peaks were detected (with the largest metabolite ranging from 8 - 16 % of the activity), and characterized by LC-MS/MS as 4-hy- droxymethylimidazolide, two other oxidized products, possibly hydroxylated on the 2- and 5-positions, and a glucuronide of 4-hydroxymethylimidazolide. This study demonstrated that 4-MeI is largely excreted unchanged in male and female rats and mice. However, limited oxidative metabolism and conjugation was observed in rats and mice. 4-MeI is not oxidized in microsomes or S-9 from rat, mouse and human lung and liver. Overall, there was no indication of metabolism of 4-MeI to reactive species. This work was funded by the American Beverage Association.
Immunotherapy is thought of as an emerging strategy for tuberculosis (TB) management. The most effective immunotherapy is the immunomodulatory methods that target the Th1/Th2 imbalance and focus on enhancing Th1 responses to release interferon gamma to activate bacillarid macrophages/monocytes. Because monocytes/macrophages are the first line of defense for TB, infection mainly depends on the number of functional monocytes/macrophages. We investigated isoenzymes of 5-aminolevulinic acid dehydratase (Hb-60) as a model for immune cell precursors. We hypothesized that in addition to its well-known bacillarid actions, INH has immunomodulatory effects which reinforce its therapeutic importance in TB therapy. We employed assays including the NBT reduction assay, superoxide release assay, and flow cytometry to identify the differentiation of HL-60 cells treated with INH. Additionally, we applied quantitative proteomics which revealed certain cellular pathways related to HL-60 cell differentiation, particularly towards monocyte differentiation. Proteomic data also revealed cellular mechanisms involved in INH detoxification. In conclusion, our study revealed that INH induced monocyte differentiation in HL-60 cells. These findings emphasize that INH may yet play important therapeutic roles in multidrug resistant and extremely drug resistant TB and therefore should be continued in these cases.

Zileuton, an orally active inhibitor of 5- lipoxigenase, is used clinically for the maintenance treatment of asthma. Zileuton is also a candidate for the treatment of other inflammatory diseases that involve leukotrienes, but this application is hampered by serious, idiosyncratic drug-induced liver injury associated with its use. Previous studies have demonstrated the utility of a mouse diversity panel (MDP), comprised of 34 genetically diverse inbred strains, for the identification of genetic risk factors associated with drug-induced injury. In this study, serum and liver tissue were collected from 34 mouse strains treated with zileuton (300 mg/kg, i.g.) or vehicle once daily for 7 days. Significant elevations in serum alanine aminotransferase (ALT) levels in zileuton-treated animals relative to vehicle-treated controls were observed in 9 of the 34 strains (p<0.05). ALT fold change was significantly correlated with serum aspartate aminotransferase and glutamate dehydrogenase levels (Pearson correlations, r=0.0002 and r=0.0033, respectively) and associated with microscopic findings of hepatocellular hyper trophy and parenchymal inflammation and necrosis. Zileuton-induced ALT changes, however, were not correlated with drug exposure. Genome wide association mapping conducted using ALT fold change revealed a transcriptional regulator of the cytoprotective enzyme heme oxygenase1. Basal Prdm2 levels were found to be significantly decreased in strains with the minor allele of the polymorphism (p=0.0018). In summary, the MDP approach defined a possible risk factor that can be evaluated in humans and has the potential to identify patients with genetic susceptibility to zileuton-induced liver injury.

Mammals exhibit major gender differences in kidney function under various physiological, pharmacological, and toxicological conditions. To gain better understanding of the molecular differences in kidney between mammalian sexes and between rodent species, we have utilized next generation sequencing to evaluate potential species and gender differences in the transcriptomes in the CD-1 mouse and the Wistar Han rat strains. Enriched renal cortex tissue was collected from 7 weeks CD-1 mice and 9-10 weeks Wistar Han rats. The whole transcriptome in kidney was profiled using Illumina HiSeq 2000. Baseline gene expression was compared between male and female in CD-1 mouse and Wistar Han rat. Our data showed the major gender biased gene expression in the kidney cortex of rodent species. Male and female CD-1 mouse kidney exhibit gender specific expression in drug metabolism and transporter and female CD-1 mouse have higher expression in genes related to osmotic regulation and glutathione detoxification in kidney. In contrast, Wistar Han rats showed a different profile of gender biased expression in drug metabolism and transporters. The gender differential expression is less detected in Wistar Han rat kidney comparing with CD-1 mice. The elucidation of baseline molecular differences in kidney function between genders and rodent species would enable us to better evaluate the occurrence and development of drug-related gender and species specific changes that may be relevant to understanding mechanisms of drug-induced nephrotoxic effects.
infections on expression), these data also suggest that inhibition of CBR3 may provide protection from doxorubicin cardiotoxicity. Supported by NIH grant P30ES007033 and UW DEOHS.

547 Synergistic Interaction between Genetics and Disease on Pravastatin Disposition

J. Clarke1, R. N. Hardwick1, A. D. Lake1, A. J. Lickteig1, C. D. Klaassen1 and N. J. Cherrington1. 1Pharm/Tox, University of Arizona, Tucson, AZ. and 2University of Kansas Medical Center, Kansas City, KS.

Genome wide association studies have implicated the hepatic uptake transporter organic anion transporting polypeptide-1B1 (OATP1B1) in the pharmacokinetics and musculoskeletal toxicity of statins, such as pravastatin. Along with OATP1B1, other OATP uptake transporters can participate in the transport of pravastatin, partially compensating for the loss of OATP1B1 in polymorphic patients. Nonalcoholic steatohepatitis (NASH) in humans and in a diet-induced rodent model alters the expression of multiple OATP and multidrug resistance-associated protein (MRP) transporters. Genetic loss of Oatp1b2, the rodent ortholog of human OATP1B1 transporters, caused a modest increase in pravastatin plasma concentrations in mice with healthy livers. Although a diet-induced model of NASH did not alter the disposition of intravenously administered pravastatin compared to WT control mice, the combination of NASH and Oatp1b2 genetic loss caused a synergistic increase in plasma area under the curve (AUC) and tissue concentrations in kidney and muscle. These data reveal a potential mechanism for this synergistic increase in pravastatin exposure that involves NASH-induced alterations in the expression of multiple hepatic uptake transporters which, due to overlapping substrate specificity among the OATP transporters, may combine with the pharmacogenetic loss of OATP1B1 to increase the risk of statin-induced adverse drug reactions.

548 The Role of the Folate Pathway in Pancreatic Cancer Risk

S. Chittiboyina, L. M. Kamendulis and B. A. Hocevar. Environmental Health, Indiana University School of Public Health, Bloomington, IN.

Pancreatic cancer is a devastating disease, with poor prognosis for survival. Most cancers, including pancreatic cancer, develop through interactions between genes and environmental/lifestyle factors. Risk factors for pancreatic cancer development include a low dietary intake of folate. In conjunction with diet and lifestyle determinants, an individual’s folate pathway status is determined by their genetic makeup. Expression of single nucleotide polymorphisms (SNPs) of genes in the folate pathway have been shown to modulate susceptibility to pancreatic cancer. In particular, homozygous expression of the TT allele of methylene tetrahydrofolate reductase (MTHFR) at nucleotide position 677, which causes decreased enzymatic activity, has been associated with an increased risk for development of pancreatic cancer and low folic acid levels. In the present study, we measured serum and red blood cell folate levels and determined SNP expression in selected genes in the folate metabolic pathway in a cohort of pancreatic cancer patients and healthy related and unrelated control groups. While serum folate levels did not differ between patients and controls, red blood cell folate levels were significantly lower in pancreatic cancer patients compared to controls (p<0.05). As expected, we found that the TT allele of MTHFR C677T is associated with low serum folate levels and significantly associated with low red blood cell folate levels compared to the CC or CT genotype. We also performed analysis for gene-gene interactions among SNPs in the folate pathway in relation to pancreatic cancer risk. We find that individuals expressing the SHMT1 L474F/MTHFR C677T diplotypes LF+FF/CC and CT+T/LF+FF exhibit an increased risk for pancreatic cancer (OR = 2.34 95%CI 1.08-5.1; OR = 2.11 95%CI 1.06-4.62 respectively). Collectively our results suggest that both environmental factors (diet) and genetics contribute to the risk of development of pancreatic cancer.

549 Functional Effect of Polymorphic Variations of Human Cytochrome P450 2D6 (P450, E418K, S486T, and R296C)

Cytochrome P450 2D6 is responsible for the metabolism of various clinical drugs and its genetic polymorphisms can significantly influence the metabolic activity. In this study, we analyzed the functional activities of four nonsynonymous single nucleotide polymorphisms from P450 2D6*52 allele, which were recently found, and one found previously in P450 2D6 alleles. Recombinant variant enzymes of E418K, S486T, and R296C were successfully expressed in Escherichia coli and purified. However, a P450 holoenzyme spectrum of P450 variant was not detected in E. coli whole cell level. Structural analysis indicated that P454 mutation seemed to perturb a highly conserved proline-rich N-terminus of P450 2D6. Steady state kinetic analyses showed the significant reductions of enzymatic activities in E418K and R296C variants. In the case of bufuralol 1'-hydroxylation, E418K, showed 32 % decrease in catalytic efficiency (kcat/Km) mainly due to the decrease of kcat value. R296C showed much greater reduction in the catalytic efficiency (0 % of wild-type) due to both of a decrease of kcat value and an increase of Km value. In the case of dextromethorphan O-demethylation, E418K showed both of a decrease of kcat value and an increase of Km value resulting in ~6-% reduction of catalytic efficiency. A highly decreased catalytic efficiency (~6-% of wild-type) in the mutant of R296C also was observed mainly due to the dramatic change of kcat value of dextromethorphan O-demethylation. These results suggested that individuals carrying these allelic variants are likely to have the altered metabolic abilities of many clinical drugs therefore, these polymorphisms of P450 2D6 should be much concerned for reliable drug treatment.

550 Polymorphism of RGS9: Association with Obesity

M. Sharma1, C. Shen1, D. Reid1, J. Celver3, J. Chen5, N. Semar3,7, S. K. Vasan3, H. Wang5, T. Gu6, Y. Liu5, W. W. Mohamud5, K. Bismar5, W. G. Fairbrother5, A. Kovoor5 and G. Harvey1. 1Dr BR Ambedkar Center for Biomedical Research, University of Delhi, Delhi, India, 2Epidemiology and Bioinformatics, Nanjing Medical University, Nanjing, China, 3Molecular Biology, Cell Biology and Biochemistry, Brown, Providence, RI, 4National Laboratory of Medical Molecular Biology, Basic Medical Sciences, Beijing, China, 5Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI, 6Research Center for Diabetes and Endocrinology, Karolinska, Stockholm, Sweden and 7Cardiovascular Diabetes and Nutrition Research Centre, Medical Research, Kuala Lumpur, Malaysia.

RGS9-2 is a member of Gt GTase accelerating proteins that regulates G protein signaling (RGS). It has been shown recently that RGS9 knockout mice have increased adiposity. In the present study we evaluate the genetic effect of RGS9 gene on obesity and genotype 9312 obese, type 2 diabetes and healthy Chinese and Malaysian subjects for insertion/deletion (TT/TCT I/D) polymorphism (rs3215227) in the gene. The deletion polymorphism of RGS9 was associated with decreased prevalence of obesity in woman (p<0.003) and girls (p=0.002), moderate in boys (p=0.039) and non-significant in men. We did not find any significant association of RGS9 polymorphism with type 2 diabetes. Since the delta TT/TCT deletion was close to the branch point for RNA splicing and corresponded to a binding motif for polyuridyline tract binding protein (PTB), we attempted to determine RGS9 binding affinity with the region. We found that deletion variant showed 10 fold reductions in PTB binding in vitro. We also demonstrated the differential effect of overexpression of PTB on the splicing of the two polymorphic forms of RGS9 minigene. We observed that overexpression of PTBP1 and PTBP2(Brain specific) significantly decreased the splicing in wild type construct of RGS9 minigene. Thus, our data suggest that RGS9 has genetic effect on obesity but the effect of binding an inhibitor of PTBP could be causative for the inverse association between the polymorphism and obesity.

551 Gene Environment Interaction in Urinary Bladder Cancer

B. D. Banerjee1, T. Sharma1, A. Verma2 and S. Gupta2. 1Biochemistry, University College of Medical Sciences and GTB Hospital, Delhi, India and 2Surgery, University College of Medical Sciences and GTB Hospital, Delhi, India. Sponsor: S. Goel.

Urinary bladder cancer (UBC) is a common disease worldwide with a high incidence. The etiology of UBC includes both environmental and endogenous factors. Environmental risk factors include exposure to heavy metals, aromatic amines and environmental pollutants including pesticides mainly organochlorine pesticides (OCPs). OCPs are potent endocrine disrupters, are found to be associated with several cancers. Glutathione S-transferases(GST) involved in the detoxification of numerous environmental toxins including OCPs. The present study was carried out in UBC and healthy control subjects with an aim to determine the role of GSTM1 and GSTT1 gene polymorphism and its implication on the OCP detoxification or bioaccumulation which may increase the risk of UBC in humans. This study was also designed to identify the “gene-environment interaction” specifically between gene polymorphism in xenobiotic metabolizing genetic enzyme(s) and OCP residue levels in blood. GSTM1/GSTT1 gene polymorphism was analysed by using multiple PCR. OCPs levels in whole blood were estimated by gas chromatography. The results demonstrated a significant (p<0.05) increase in frequency of GSTM1/GSTT1- (null) genotype in UBC cases without interfering the dis-
between β-HCH and GSTM1-genotype (p<0.05) as well as between β-HCH and GSTT1-genotype (p<0.05) respectively. These findings indicate that “gene-environment interaction” may play a key role in increasing the risk for UBC in individuals among North Indian population who are genetically more susceptible due to presence of GSTM1/GSTT1 null deletion during their routine encounter with exposure to OCPS.

Idiosyncratic hepatotoxicity has been associated with the oral tyrosine kinase inhibitor lapatinib, which is used in the treatment of metastatic breast cancer. However, the mechanism(s) of this toxicity are unknown. Lapatinib is extensively metabolized via O-debenzylation by CYP3A4/5 to form a phenolic metabolite. Further oxidation yields a reactive quinone imine, which can potentially lead to liver injury. While CYP3A4 is abundantly expressed in human liver, CYP3A5 expression is highly polymorphic. Individuals with the CYP3A5*3 allele express high levels of the functional protein, whereas the CYP3A5*5 variant allele results in low to undetectable levels of CYP3A5. We hypothesized that expression of CYP3A5 may contribute to inter-individual differences in the formation of reactive metabolites of lapatinib. To address this hypothesis, we first examined the kinetic parameters of lapatinib O-debenzylation by CYP3A4 and CYP3A5 Supersomes utilizing LC-MS/MS analysis. Both recombinant enzymes turned over lapatinib rapidly (15-18 min⁻¹) and with high affinity (1.0-2.2 μM), albeit CYP3A4 exhibited an overall 2.5-fold higher catalytic efficiency than CYP3A5. In individual genotype human liver microsomal preparations, the rates of debenzylation of lapatinib (5 μM) were comparable between carriers of the CYP3A5*7 wild-type allele and CYP3A5 non-expressers (CYP3A5*3/3). Next, glutathione (GSH) trapping experiments were conducted with debenzylated lapatinib as substrate (5 μM) to assess the formation of GSH adducts of the quinone imine reactive metabolite (RM-SG). Kinetic analysis revealed that CYP3A5 Supersomes were seven times more efficient than CYP3A4 for generation of RM-SG adducts. Finally, the levels of RM-SG formed were significantly higher (P= 0.03) in human liver microsomal preparations from CYP3A5*7/7 expressers compared to CYP3A5*3/5, livers. These data show that CYP3A5 is a quantitatively important contributor to hepatic lapatinib bioactivation in vitro.

552 Human ALDH1B1 Polymorphisms May Affect the Metabolism of Acetaldehyde and All-Trans Retinaldehyde—In Vitro Studies and Computational Modeling

B. C. Jackson 1, P. Reigan 1, D. Thompson 2 and V. Vasiliou 1, 1Department of Pharmaceutical Sciences, University of Colorado Anschutz Medical Campus, Aurora, CO and 2Department of Clinical Pharmacy, University of Colorado Anschutz Medical Campus, Aurora, CO.

Purpose: To test the metabolism of novel substrates by ALDH1B1 and to predict the effect that human ALDH1B1 polymorphisms will have on these and previously described substrates.

Methods: Purified human recombinant ALDH1B1 was used to determine the capacity of ALDH1B1 to metabolize nitroglycerin and all-trans retinaldehyde. Computational-based molecular modeling was used to predict the binding affinities of the substrates acetaldehyde, 4-hydroxynonenal, nitroglycerin, and all-trans retinaldehyde to ALDH1B1 and three human polymorphisms ALDH1B1*2 (A86V), ALDH1B1*3 (L107R), and ALDH1B1*5 (M252V). The binding of the cofactor NAD⁺ to ALDH1B1 and its polymorphisms was also modeled computationally.

Results: ALDH1B1 metabolizes and appears to be inhibited by nitroglycerin and has favorable kinetics for metabolism of all-trans retinaldehyde. Differences in calculated docking poses and weak interactions between ligands/cofactor and ALDH enzymes from modeling studies provided a basis for predicting the capacity of each of the variants to metabolize acetaldehyde, nitroglycerin, and all-trans retinaldehyde. Modeling indicated that ALDH1B1*2 and ALDH1B1*5 likely bind NAD⁺ poorly compared to ALDH1B1 and ALDH2, and all ALDH1B1 mutants had poor binding affinities for nitroglycerin.

Conclusions: ALDH1B1 metabolizes the novel substrates nitroglycerin and all-trans-retinaldehyde, and two human polymorphisms (ALDH1B1*2 and ALDH1B1*5) are likely to metabolize substrates poorly, which may affect the roles of ALDH1B1 in stem cells and ethanol metabolism.

552a SLC19A1, SLC6A6 and SLC01B1 Polymorphisms Are Associated with Methotrexate-Related Overall Toxicity in Portuguese Rheumatoid Arthritis Patients

A. Lima 1, 2, 3, R. Azevedo 2, H. Sousa 2, M. Bernardes 4, R. Medeiros 2, 3 and J. IINFACTS/CESPU, ISCS-Norte, Gandra, PRD, Portugal, 1ICBAS, University of Porto, Porto, Portugal and 2Molecular Oncology Group, IPO, Porto, Portugal, and 3Rheumatology Department, São João Hospital Center, Porto, Portugal.

Methotrexate (MTX) is used for rheumatoid arthritis (RA) treatment with a wide variety of clinical responses, especially of concern is the development of MTX-related toxicity (MTX-Tox). Studies have described a possible role of genetic polymorphisms that alter MTX transporters influx (solute carriers, SLCs) and efflux (ATP-binding cassette, ABC) in MTX-Tox development. The aim of this work was to evaluate the influence of several single nucleotide polymorphisms (SNP) in genes codifying MTX transporters with the occurrence of MTX-Tox in Portuguese RA patients. A total of 233 RA patients were included in the study and genotyped by Sequenom MassARRAY® for 20 SNPs (SLC16A7, SLC19A1, SLC22A6, SLC22A11, SLC46A1, SLC01B1, ABCB1, ABCG1, ABCG2 and ABCG2). Binary logistic regression analysis were performed and adjusted to possible confounder variables (related to patient, disease and treatment). Haplotype analysis was used to test SNPs revealing statistical significance and a risk index for MTX-Tox. One SNP, rs41291122 in PLCE1, was associated with post-clopidogrel ADP-stimulated platelet aggregation in the full cohort (p=0.001). Additionally, we observed that the rs11219992 T allele was associated with a lower risk of MTX-Tox (p=0.037; OR=2.82) in comparison to the reporter constructs containing the T allele of the SNP. These results suggest that the rs11219992 T allele may contribute to the risk of MTX-Tox in our study population.

552b Role of CYP3A5 in the Metabolic Activation of Lapatinib

K. D. Hardy 2, 3 and A. E. Rettic 2, 1Department of Pharmaceutical Sciences, Lipscomb University College of Pharmacy, Nashville, TN and 2Department of Medicinal Chemistry, University of Washington School of Pharmacy, Seattle, WA.

Medical radiation countermeasures have applications in clinical oncology, space travel, radiopharmaceutical imaging, and radiological terrorism. We demonstrated previously that the soy isoflavone genistein protects against acute hematopoietic radiation injuries by increasing hematopoietic stem cell survival and decreasing proinflammatory cytokines. Genistein is a phytoestrogen that has been established to have weak estrogenic activity. In the present study, we evaluated the radiation pro-
tective effects of a nanoparticle formulation of genistein after the administration of an estrogen receptor antagonist. Male CD2F1 mice received an intramuscular (IM) injection of the estrogen receptor antagonist, ICI 182,780 (ICI), or corn oil vehicle daily for 4 days. On the fourth day, mice received a second IM injection of either vehicle or genistein nanosuspension (150 mg/kg). All mice then received a single dose (9.25 Gy) of total body gamma irradiation (cobalt-60), 24 h after the second injection. Results showed that 30-day survival for both the vehicle and ICI groups was 25%, whereas 90% of genistein-treated mice survived. Mice that received ICI followed by genistein exhibited a significant decrease in survival rate (45%). These results demonstrate that the radiation protective effects of genistein are mediated in part through an estrogen receptor pathway.

**552e Arsenicals, Lewiste- and Phenylarsine Oxide-Induced Cutaneous Inflammation Response and Cell Death Are Regulated by UPR Signaling Pathway**

Vesicants are a group of chemical agents that cause skin blistering and inflammation following their cutaneous exposure. These agents were synthesized as chemical weapons to be used during warfare. Lewiste, an arsenical, is an important war threat agent. It is known to manifest severe cutaneous inflammation and blistering. However, the exact molecular mechanisms underlying these effects remain undefined. We develop a novel mouse murine model which is highly sensitive to inflammatory inducing agents and manifests similar responses as observed in humans. Here, we show that topical exposure to lewiste and its analog phenylarsine oxide (PAO) on the skin of Pch/+ or Pch-/-/SKH-1 hairless mice induced erythema, edema, and microvesication associated with the enhanced production of pro-inflammatory cytokines and reactive oxygen species (ROS). A huge cell death was also observed particularly at the site of lewiste exposure. These effects were found to be regulated via unfolded protein response (UPR) signaling pathway activation. UPR inhibitor, 4-phenylbutyric acid (PBA), an antioxidant N-acetyl-cystine (NAC) or their combination were highly effective in diminishing PAO-induced erythema, edema, and microvesication. Similarly, a dose- and time-dependent up-regulation of inflammatory and UPR pathways by arsenicals were observed in human skin keratinocytes. PERK-regulated UPR proteins GRP78, p-PERK, p-eIF2a, ATF4 and CHOP were particularly induced in these cells. PBA and NAC significantly attenuated these effects in keratinocytes. Employing siRNA approaches, CHOP was found to be the key apoptosis and pro-inflammatory responses inducing protein. These data provide evidence that lewiste and its analog PAO which is also a degradation product of other arsenicals have potent inflammation, vesication and cell death inducing properties in the skin and may have long term environmental and human health consequences.

**552f Arg-1 Is Associated with the Development of Late Pulmonary Fibrosis following Irradiation**

Macrophages are found in close proximity with collagen-producing myofibroblasts and indisputably play a key role in fibrosis. With their potential to act in both a pro- and anti-fibrotic capacity, as well as regulate the activation of resident and recruited myofibroblasts, macrophages and the factors they express are integrated into all stages of the fibrotic process. Classical activation by microbial agents and/or T helper cell type 1 (Th1) cytokines, interferon-γ (IFN-γ), in particular, is associated with the production of nitric oxide (NO) and proinflammatory cytokines involved in cytotoxicity, microbial killing, and regulation of cell proliferation (M1 or type-1 polarization). More recently, it was shown that macrophages could also follow a different activation pathway after stimulation with the Th2 cytokines interleukin (IL)-4 or IL-13 (M2 or type-2 polarization). Our hypothesis is that the induction of Arg-1 in these “alternatively activated” cells leads to development of radiation-induced fibrosis. 8 week old female C57BL/6 or C3H/HeJ mice were irradiated with 5 Gy total body irradiation followed by a dose of 10 Gy to lung only. Mice were examined at 24 or 72 hours or 1, 2, 12, 18 or 26 weeks post irradiation. Our findings demonstrate a dramatic increase in Arg-1 and MCP-1 expressing macrophages associated with the progression of fibrosis. These results correlate with later time points where C57BL/6 mice are exhibiting a robust fibrotic response but C3H/HeJ demonstrate little pathology. Injuries which generated robust inflammatory responses but did not develop fibrosis demonstrated induction of iNOS but not Arg-1. These data suggest a role for Arg-1 expressing macrophages in the development of inflammation and demonstrate that differential activation of Arg-1/iNOS-2 is a potential determinant in the pathogenesis of pulmonary fibrosis.

**552g Soman-Induced Convulsions Change the Phosphorylation State of the Potassium-Chloride Cotransporter (KCC2)**

C. Smith, S. M. Miller, T. Z. Deeb, L. Silayeva, S. J. Moss and J. H. McDonough. 1US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD and 2Tufts Medical School, Boston, MA.

Exposure to nerve agents induces numerous symptoms, including seizures that become resistant to benzodiazepines within 40 minutes of onset. This resistance may result from the internalization of GABA receptors; however, this process is likely too slow to account for this rapid benzodiazepine resistance. An alternate hypothesis is that dysfunction of KCC2, a protein that permits GABA’s inhibitory tone by maintaining the Cl- gradient, may decrease the efficacy of benzodiazepines following prolonged seizures. As little as 15 minutes of seizure-like activity decreases KCC2, which may in turn increase concentrations of intracellular Cl- and reduce GABA-mediated inhibition. The current experiment examined the concentrations of KCC2 and phosphorylation at two key regulatory residues, S940 and T906, in C57BL/6 mice following the onset of soman-induced convulsions. Importantly, the phosphorylation of S940 (pS940) increases KCC2 activity, whereas the phosphorylation of T906 (pT906) decreases KCC2 activity. Mice were exposed to soman, and brain tissue was collected at 0, 15, 30, or 60 minutes following the onset of convulsions. In the hippocampus, soman increased pT906 within 15 minutes of convolution onset and continued to increase over time up to 60 minutes. In contrast, soman-induced convulsions did not significantly alter pS940 or total KCC2. In the cortex, soman-induced convulsions increased both pT906 and pS940 at 15 minutes; however, concentrations of pS940 decreased to levels equivalent to saline-exposed mice by 60 minutes. Congruent with results from the hippocampus, total KCC2 levels did not change in the cortex. These results suggest that soman-induced convulsions are associated with time-dependent changes in the phosphorylation state of KCC2. Reactivating KCC2 may thus serve as a potential therapeutic strategy for terminating benzodiazepine-resistant seizures.

**553 Flavanone Silibinin As Potential Therapeutic against Skin Injuries by Vesicating Agents**

N. Tewari-Singh1, A. K. Jain1, S. Immter1, D. Kumar1, D. Orlich2, C. Agarwal1 and C. White1. 1Department of Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO, 2Department of Pathology, University of Colorado Denver, Aurora, CO, Department of Pediatrics, University of Colorado Denver, Aurora, CO, Department of Dermatology, University of Colorado Denver, Aurora, CO.

Chemical warfare agent sulfur mustard (SM) and its analog nitrogen mustard (NM) inflict delayed blistering and incapacitating injuries on skin tissue. Our previous findings have demonstrated therapeutic efficacy of silibinin in reversing monofunctional alkylating SM analog 2-chloroethyl ethyl sulfide (CEES)-induced skin injuries. To translate this effect using a bifunctional alkylating vesicant, efficacy studies were carried out with NM-induced injury biomarkers established in SKH-1 hairless mice. Topical application of silibinin 30 min after NM exposure decreased NM-induced 60% mortality (120 h exposure) and NM-induced toxic skin injury attributes in SKH-1 mice. Following 1 or 2 mg silibinin treatment, a dose-dependent reduction of NM-induced increases in epidermal thickness, microvesication, dead and denuded epidermis, parakeratosis and scab formation was observed. All NM-induced lesions were assessed at 24, 72 or 120 h time point depending on their optimum injury. Silibinin (2 mg dose) caused complete prevention of NM-induced H2A.X phosphorylation indicating reversal of DNA damage, large incidences of microvesication (>500 μm2) and parakeratosis. Silibinin (2 mg) application also caused 52% and 77% (p<0.05) reversals in NM-induced increase in COX-2 and myeloperoxidase levels, respectively. These findings indicate that attenuation of NM-induced skin injuries by silibinin is due to its multiple effects targeting pathways associated with DNA damage, inflammation and vesication. Together, these studies suggest therapeutic potential of silibinin against skin injuries by NM and support its further optimization as an effective treatment for skin injuries by SM and other vesicating agents.
Vesicating agents sulfur mustard (SM) and nitrogen mustard (NM) are easily absorbed by skin causing cutaneous injuries and blistering. To study clinical, histopathological, and molecular features of cutaneous lesions from topical vesicant exposure, we used NM. Our studies showed that topical NM (3.2 mg) exposure in SKH-1 hairless mice not only caused skin injuries but also lead to significant body weight loss and 40-60% mortality (120 h exposure), suggesting systemic effects of its topical exposure. Studies in these mice showed that, though a decrease in heart and breath rate was only observed at 120 h following exposure, NM exposure initiated an increase in blood leukocyte count by 24 h and thereafter leukopenia 72 h post-exposure. Examination of the blood revealed an increase in neutrophils and decrease in lymphocytes 24 h post exposure. H&E staining of the small intestine revealed NM-related toxic effects including loss of membrane integrity of surface epithelium and abnormal structure of glands as well as degeneration of villi starting by 24 h and observed mainly 72-120 h after exposure. NM exposure also resulted in a reduction in T-cells from the spleenic peri-arterial lymphatic sheath as well as macrophages and RBCs from the red pulp. At later time points (72 and 120 h), NM exposure resulted in dilation of glomerular capillaries and loss of cells from the renal corpuscles. It has been reported that exposure to higher SM levels (total body exposure) can cause damage to the bone marrow and hematopoietic system, liver and kidney failure, and toxicity to the spleen and GI tract. Our results with NM indicate that these organs are also affected from only topical vesicant exposure and can lead to mortality. These outcomes could help identify useful countermeasures against skin injuries and toxic systemic effects after topical vesicant exposure.

To develop effective therapies against ocular injuries by vesicating agents, investigation of mechanistic aspects of vesicant-induced ocular injuries is important. Accordingly, toxic effects and associated mechanisms were examined in maximal affected corneal tissue with nitrogen mustard (NM), an analog of sulfur mustard (SM). Analysis of 100 nmol NM-exposed rabbit corneas for 2 h (washed and cultured for 24 h), evidenced increases in epithelial thickness, apoptotic cell death, epithelial-stromal separation, increase in the levels of angiogenic regulator VEGF, and induction of COX-2 and MMP-9. Since vesicating agents mainly target the corneal epithelial cells, we also employed human corneal epithelial cells (HCEC) to study and compare the mechanism/s of action of NM-induced injury in these cells with rabbit cornea. Exposure (48 h) to NM (50 and 100 μM) caused a dose-dependent decrease in HCEC viability and DNA proliferation. These toxic effects could be related to NM-induced DNA damage (p53 phospho ser15, total p53 and H2AX phospho ser139) in HCEC. In addition to p53 phosphorylation, NM also induced caspase-3 and PARP cleavage, suggesting their role in NM-related HCEC death and apoptotic cell death in rabbit cornea. Similar to studies in rabbit cornea, NM exposure also caused an increase in COX-2, MMP-9 and VEGF levels in HCEC, indicating a role of these molecules and related pathways in NM-induced corneal inflammation, epithelial-stromal separation and neovascularization. NM exposure in HCEC also instigated an increase in phosphorylation of MAPKs and activation of AP-1 family proteins. Increase in lipid peroxidation and protein oxidation in HCEC by NM suggests the role of oxidative stress in the activation of signaling pathways by NM. These molecular targets could be supportive in development of therapeutics against vesicant-induced corneal injuries.
administered either by subcutaneous (SC) injection in, or percutaneously on, guinea pigs that subsequently received atropine free base at 0.4 mg/kg. The hu-
man-equivalent dose in guinea pigs for three DuooDote® autoinjectors was esti-
mated to be 0.4 mg/kg. Lethality rates were obtained at 24 h after challenge for all but parathion and sulfur mustard challenge, which required at least 48 h to allow for
bioactivation to the oxon form. Probit analysis was used to calculate the median lethal dose (LD50). Protective ratios (PR) for atropine were calculated as the LD50 for a challenge material (CM) in atropinized guinea pigs divided by the LD50 for the same CM in no-therapy guinea pigs using data from either the literature or con-
current experiments. Phorate, paraxon, and CPF did not present significant per-
cutaneous threats, and attempts to obtain an LD50 were abandoned. Statistically
significant (p < 0.05) therapy in terms of survival was attributed to atropine therapy against a SC challenge of GA alone. Atropine alone did not improve survivability against any other CM injection by either SC injection or topical application on clipped skin.

Conclusion: The results demonstrated here show that functional measurements can be performed with this technique by using membranes of Torpedo californica electric tissue. Bispyridinium compounds seemed to interact as positive allosteric modulators, thereby affecting desensitisation. Further research is necessary to verify this hypothesis.

561 Attenuation of Nitrogen Mustard (NM)-Induced Pulmonary Injury and Inflammation by Antitumor Necrosis Factor (TNF)α Antibody and the Inducible Nitric Oxide Synthase (iNOS) Inhibitor, N-(3-(Aminomethyl)benzyl)acetamide (1400W)

R. Malaviya1, V. Sunil1, A. Venos1, K. Vayas1, P. J. Sinko1, J. Shen1, L. Hall1, D. Shealy2, N. Heindel2, C. J. Lacey3, D. L. Laskin1 and D. L. Laskin1.
1Pharmacology and Toxicology, Rutgers University, Picataway, NJ, 2Johnson & Johnson, Raritan, NJ and 3Lehigh University, Bethlehem, PA.

NM (mechlorethamine) is a vesicant which causes severe damage to the lung lead-
ing to pulmonary fibrosis; this is associated with oxidative stress and inflammation.

Using transgenic knockout mice, we previously demonstrated that the proinflam-
matory cytokine, TNFα and nitric oxide generating enzyme, iNOS, play key roles in the pathogenic response to NM. In these studies we analyzed the ability of anti-TNFα antibody and 1400W, alone and in combination, to mitigate NM-
duced lung injury. Treatment of male Wistar rats (250 g) with NM (0.125 mg/
kg, i.t.) resulted in histopathologic changes in the lung 3-7 d post exposure, and
induced expression of cleaved caspase-3 (Casp-3), a marker of apoptosis. This was correlated with increases in bronchoalveolar lavage (BAL) cell and protein content, indicating damage to the alveolar-epithelial barrier. NM also caused increased ex-
pression of cyclooxygenase (COX)-2 and heme oxygenase (HO)-1 in lung mac-
rophages, as well as YM-1, a marker of oxidative stress and alternatively activated
macrophages. Treatment of rats with anti-TNFα antibody (15 mg/kg, i.v., 1x), 1400W (50 mg/kg, i.p., 1x/d), or a combination of anti-TNFα + 1400W 30 min
after NM reduced lung injury and inflammation, as measured by BAL cells, protein
content. NM-induced expression of COX-2; HO-1; YM-1 and Casp-3 were also reduced. Although the combination of anti-TNFα + 1400W was more effective in
down regulating expression of COX-3, COX-2, HO-1 and YM-1 at 3 d than either agent alone, fibrinotic changes at 7 d were only inhibited by anti-TNFα anti-
tibody. These data demonstrate that inhibiting TNFα and/or iNOS represents an important approach to mitigating acute and long-term lung injury induced by ves-
icants. Supported by NIH Grants HL096426, AR055073, ES004738, CA13624, and ES005022.

562 Inhibition of Multidrug Resistance-Associated Protein (MRP) Efflux Transporters Increases the Sensitivity to Vesicant-Induced Growth Inhibition in Lung Epithelial Cells

R. G. Udasin1, 2, K. M. Bircsak1, 2, V. Mishin2, D. E. Heck3, L. M. Aleksunes1, D. L. Laskin1 and J. D. Laskin1.
1Joint Graduate Program in Toxicology, Rutgers University, Picataway, NJ, 2Pharmacology & Toxicology, Rutgers University, Picataway, NJ, 3Environmental Health Science, New York Medical College, Valhalla, NY and 4Environmental & Occupational Medicine, Robert Wood Johnson Medical School, Rutgers University, Picataway, NJ.

Sulfur mustard and the related vesicant nitrogen mustard (mechlorethamine, HN2) are bifunctional alkylating agents that cause oxidative stress and persistent lung damage. In the present studies, we examined the role of MRP in modulating the sensitivity of lung cells to HN2. MRP transporters 1, 2, and 3 remove glutathi-
one conjugates, which can cause oxidative stress and cytotoxicity. To assess the role of these transporters in the cytotoxic actions of HN2, we used MK-571, an
MRP modulator; thereby, affecting desensitisation. Further research is necessary to verify this hypothesis.

Functional interactions of bispyridinium compounds were investigated.

560 Functional Properties of Bispyridinium Non-Oxime Compounds on Muscle-Type Nicotinic Acetylcholine Receptors Using a Bilayer-Based Method

H. Thiermann, T. Seeger, L. Florian, F. Worek and K. V. Niessen, Bundeswehr Institute of Pharmacology and Toxicology, Munich, Germany.

Objective: In poisoning with some nerve agents, e.g. soman, therapeutic efficacy is
limited. A direct intervention at nicotinic acetylcholine receptors (nAChRs) might be
an option. Studies with bispyridinium non-oxime compounds demonstrated therapeutic
effects against soman in vitro and in vivo. Consequently, these re-
results arouse increasing interest in functional properties of nAChRs, especially the
muscle-type. The Torpedo electric organ is regarded as a suitable surrogate. For functional characterization, cell-free electrophysiological methods based on
solid supported membranes (SSM) can be used. However, conventional elec
trophysiology cannot be applied. In this bilayer based sensor technique, charge
translocation is measured via capacitive coupling of the supporting membrane.

559 Identification of Glutaredoxin As a Molecular Target for the Sulfur Mustard Analog Bis(2-chloroethyl)phosphinylmethylamine

Y. Jan1, D. E. Heek2, R. P. Casillas3 and J. D. Laskin1.
1Environmental & Occupational Medicine, Rutgers University-Robert Wood Johnson Medical School, Piscataway, NJ, 2Environmental Health Science, New York Medical College, Valhalla, NY, 3MRI-Global, Kansas City, MO and 4Pharmacology & Toxicology, Rutgers University, Picataway, NJ.

The glutaredoxin system, which consists of glutaredoxin (Grx), glutathione, and
 glutathione reductase (GR), plays a key role in antioxidant defense and cell growth control. Due to their high structural similarity, glutaredoxin and thioredoxin often
display overlapping functions. Bis(2-chloroethyl)methylamine (HN2), a bifunc-
tional alkylating agent commonly used as a model compound to study sulfur must-
vard-induced injury, is known to cause oxidative lung injury. Previously, we re-
ported that HN2 selectively targets the thioredoxin system in lung A549 epithelial
cells resulting in enzyme inactivation, a process contributing to oxidative stress and toxicity. In this study, we examined the effects of HN2 on the glutaredoxin system.

Results: Depending on particle size, zeta potential and adsorption procedures, sta-
ble microparticles were obtained. Various concentrations of agonist and bispyridinium compounds were tested. Controversially, carbamoylcholine elicited a Na+
 influx in the membrane vesicles. Various concentrations of agonist and bispyridinium compounds were tested. Results: Depending on particle size, zeta potential and adsorption procedures, sta-
ble and reproducible cholinergic signals were recorded (> 1 nA). Ambroxol pre-
vented a premature collapse of the sodium gradient. High carbamoylcholine con-
der 

Organophosphorus (OP) compounds, including pesticides and chemical warfare nerve agents (CWNAs) represent a threat to the general population not only as possible weapons of terrorism, but also as chemicals that could be released from transportation and storage facilities during industrial accidents. Given the rapid onset of symptoms and toxicity of OP agents, a quick-acting therapeutic regimen that is efficacious over the broad spectrum of OPs is urgently needed. The current regimen includes the administration of atropine in combination with an acetylcholinesterase (AChE) reactivator (oxime; 2-PAM Cl). An anticonvulsant (diazepam) is administered if convulsive symptoms are observed. Although this treatment approach is effective against OP intoxication, more effective treatments are being investigated to improve the nation’s medical response capabilities. The objective of the current study was to perform a head-to-head comparison of the leading oxime therapies (2-PAM Cl, HI-6 DMS, obidoxime Cl2, TMB4, MMB4-DMS, HLö7) against the CWNAs (tabun, sarin, soman, cyclosarin, VX, and the pesticides paraoxon, chlorpyrifos oxon, DMS, MINA and RS194B) under standardized conditions against the CWNAs (tabun, sarin, soman, cyclosarin, VX, and the pesticides paraoxon, chlorpyrifos oxon, DMS, MINA and RS194B) under standardized conditions.

The sulfur mustard analog (b(2)-chloroethyl) methylamine, HN2, is a potent skin vesicant. As a bifunctional alkylating agent, HN2 can directly modify DNA, a process that can result in strand breaks. Recent evidence suggests that HN2 is also a potent inducer of epidermal oxidative stress. In the present studies we determined if HN2-induced epidermal DNA strand breaks were associated with expression of markers of oxidative stress. CD-1 female mice (6-8 weeks of age) were treated on the dorsal skin with HN2 (20 μmules). After 1, 3 and 5 days, expression of markers of oxidative stress including 4-hydroxynonenal (4-HNE)-modified proteins and 8-oxo-2‘-deoxyguanosine (8-OHdG), and histone phospho-H2A.X, a marker of DNA double strand breaks, was analyzed in the skin using techniques in immunohistochemistry. We found that 8-OHdG and phospho-H2A.X were coordinately upregulated in the nuclei of interfollicular and follicular epidermal cells throughout the wound one day post-treatment. In contrast, 4-HNE modified proteins were identified only in the stratum granulosum and the follicular epidermis. By day 3, phospho-H2A.X and 8-OHdG were upregulated in a thick eschar above the wound and within the interfollicular epidermis and the sebocytes, while 4-HNE was expressed in the hypotrophic epidermis underlying the eschar and interfollicular epidermis. At 5 days post exposure, phospho-H2A.X was confined to the stratum basale with scattered expression in the dermis, while 8-OHdG was expressed in the dermis and the hypodermis. 4-HNE was down regulated and restricted to the hyperplastic stratum granulosum and stratum spinosum. These data indicate that HN2 induces lipid peroxidation and oxidative DNA damage in mouse skin, a process which likely contributes to tissue injury following exposure to vesicating agents.

Nerve agents cause neuroinflammatory response that may potentially be treated by novel anti-inflammatory peptides. The way of their discovery is described. Previous studies demonstrated the potent effect of topical iodine against skin toxicity induced by sulfur mustard and other chemical and thermal stimuli. While exploring the mechanism of iodine we discovered that it induces the production of a nonapeptide, a fragment of H2A histone termed IIIM1. This peptide showed counterirritating and antiinflammatory activities in the ear swelling test and carrageenan-induced hind paw edema assay. Being an antiinflammatory peptide, IIIM1 was evaluated as a potential drug candidate for pathologies-associated with neuronal damage such as experimental autoimmune encephalitis (EAE), an animal model of multiple sclerosis (MS). The peptide dramatically ameliorated the neurological symptoms in the diseased mice, reduced proinflammatory cytokines, elevated Th2 cytokines and caused proliferation of T-regulatory cells. In addition to its immunomodulatory/antiinflammatory properties, IIIM1 significantly reduced cytotoxicity and oxidative stress in astrocytes exposed to methyl mercury. The neuroprotective effects of IIIM1 strongly support the notion that this peptide may be used as a neuroprotectant in organophosphorus exposure.

Further mechanistic studies revealed that IIIM1 induced a 16 amino acid peptide termed RA1 that surprisingly, is present in Japanese rice. RA1 ameliorated neuro- logical symptoms in EAE mice, reduced proinflammatory cytokines and elevated Th2 cytokines. This peptide may be associated with the low incidence of MS in Japan. In view of their antiinflammatory characteristics both IIIM1 and RA1 are potential candidates for treatment of neuroinflammation caused by exposure to nerve agents.
Aldicarb and methomyl are highly toxic carbamate insecticides and known groundwater contaminants. Both carbamates have been implicated in animal and human poisonings. Consequently, they pose a threat to the general population not only as possible weapons of terrorism, but also from environmental and occupational exposures. Like the common organophosphorus pesticides (OPs) and nerve agents, the mechanism of toxicity is cholinesterase (ChE) inhibition which can result in cholinergic crisis. Inhibition of ChE reverses fairly rapidly when compared to inhibition from OPs. Based on its primary mechanism of toxicity as an anticholinesterase, the administration of atropine and the oxime 2-PAM C1 is the proposed therapeutic approach after carbamate poisoning. This study evaluated the dose-lethality response curves characterized in non-sedated, Hartley male guinea pigs exposed to either aldicarb or methomyl, administered via a single subcutaneous (SC) injection. The median lethal dose (MLD) for aldicarb was determined to be 0.86 mg/kg while methomyl was approximately 10-fold less toxic at 8.06 mg/kg. Atropine (At) free base was administered at human equivalent dose (HED) levels for the guinea pig, 0.4 mg/kg, via the intramuscular route. Due to toxicity in the guinea pig, 2-PAM C1 was administered at the human-relevant dose of 25.7 mg/kg and was via the same administration route. Atropine alone and in combination with 2-PAM C1 demonstrated significant protection against lethality. However, the addition of 2-PAM C1 did not have a statistical effect on the efficacy of atropine alone. The observation that 2-PAM C1 did not reduce the overall efficacy of this treatment regimen is encouraging given previous concerns regarding the potential problematic interactions between carbamates and oximes.

568 Paraoxonase 1 (PON1) Enhancers Accelerate the Detoxication of Organophosphates (OP) Including Nerve Agent Surrogates

J. E. Chambers, E. C. Meek, R. Pringle and H. W. Chambers. Coll Vet Medicine, Mississippi State Univ, Mississippi State, MS.

PON1, a calcium dependent hydrolase, is associated with the high density lipoproteins in human serum. PON1, named for its ability to hydrolyze paraoxon, the active metabolite of the OP insecticide parathion, can hydrolyze some OPs, but most with low efficiency. PON1 uses a hydroxide ion from water as the nucleophile to accomplish the degradation of the OP. Novel substituted phenoxyl alkyl pyridinium oximes have been developed as more potent nucleophiles with the expectation that they might enhance the efficacy of PON1 in degrading OPs. The substrates tested were surrogates for sarin and VX, nitrophenyl isopropyl methylphosphonate (NIMP) and nitrophenyl ethyl methylphosphonate (NEMP), respectively, and paraoxon. Commercially available human serum was used as the source of PON1. The length of the alkyl chain varied from 6-10 carbons, and the molecules contained various substitutions on the phenoxy moiety. A direct assay was employed using 0.3mM NIMP or NEMP or 1.2mM paraoxon and 0.1mM nucleophile, monitoring the released 4-nitrophenol spectrophotometrically following a 15 min incubation with serum. About 20 novel nucleophiles were tested. Enhancement of degradation of over 10% occurred with 10 of the nucleophiles with NIMP, with 8 of these yielding over 20% enhancement. Enhancement of degradation of over 10% occurred with 9 of the nucleophiles with NEMP, with 3 of these yielding over 20% enhancement. Only 1 of these nucleophiles enhanced the degradation of paraoxon. An indirect assay used 120 nM NIMP or 30 nM NEMP (i.e., more realistic concentrations), and monitored residual anticholinesterase activity of undegraded surrogate as an index of PON1 activity. This indirect assay showed 11 nucleophiles able to enhance NIMP degradation by up to 50% and 7 nucleophiles able to enhance NEMP degradation by up to 35%. These nucleophiles show potential to be developed as drugs with a novel mechanism of antidotal action. (Supported by Defense Threat Reduction Agency HDTRA1-12-1-0043)

569 Δ4 Tetrahydrocannabinol Prevents Mice from Staphylococcal Enterotoxin B-Induced Toxic Death by the Modulation of the miR-17-92 Cluster and De Novo Induction of T-Regulatory Cells

B. Rao, P. S. Nagarkatti and M. Nagarkatti, University of South Carolina, Columbia, SC.

The superantigen Staphylococcal enterotoxin B (SEB) is a potent activator of Vβ8+ T-cells which results in the clonal expansion of ~30% of the T-cell pool. Consequently, this leads to the substantial release of inflammatory cytokines, induction of toxic shock, and eventually death. In the current study, we sought to investigate if Δ4 Tetrahydrocannabinol (THC), a marijuana cannabinoid known for its anti-inflammatory properties, could prevent SEB-induced mortality and alleviate symptoms of toxic shock. Intranasal followed by intraperitoneal dual administration of SEB resulted in acute mortality, while THC treatment led to 100% survival. Additionally, THC treatment significantly decreased numerous SEB-mediated clinical parameters, such as production of inflammatory cytokines, immune cell infiltration into the lung, vascular leak, and improved airway resistance. Microarray analysis revealed that a prominent miRNA signature upon SEB exposure was the induction of the miR-17-92 cluster. Mechanistically, we found the miR-17-92 cluster targets Pten (phosphatase and tensin homolog), an inhibitor of the PI3K/Akt signaling pathway, thereby promoting cellular proliferation and the suppression of T-regulatory cells. THC treatment, however, inhibited the individual miRNAs in the cluster. Moreover, in its ability to act as a PI3K/Akt inhibitor, THC treatment led to the induction of CD4+Foxp3+ T-regulatory cells and suppressed cellular proliferation. We report, for the first time, a miRNA expression profile in response to SEB. Furthermore, our results suggest that THC is a potent anti-inflammatory compound that acts by modulating critical miRNA involved in SEB-induced toxicity and death. (Supported in part by NIH grants P01AT003961, R01AT006888, R01ES019313, R01MH094755, P20RR032684 and VA Merit Award BX001357)
NM (mechlorethamine) causes lung injury and fibrosis. This is associated with MP accumulation in the tissue and the release of mediators implicated in toxicity. Herein, we assessed the phenotype and origin of MP accumulating in the lung after NM. Cells were collected by bronchoalveolar lavage (BAL) 1-28 d after i.t. saline or NM (0.125 mg/kg) administration to Wistar rats and stained with antibodies to Mac-1 (inflammatory cells) and CD43 (monocyte-derived MP). The majority (>97%) of cells from control animals were Mac-1−/CD43+, consistent with a resident alveolar MP phenotype. NM caused an increase in Mac-1+/CD43+ and Mac-1−/CD43− cells in the lung, which peaked at 3 and 7 d, respectively. By 28 d post NM, cells more closely resembled resident alveolar MP. To characterize these subpopulations, cells were analyzed for expression of pro-(CCK2, iNOS) and anti-inflammatory (IL-10) genes. NM caused a persistent increase (4-6-fold) in CCR2 expression by resident alveolar MP (Mac-1−/CD43−), with no change in iNOS or IL-10. Increased CCR2 was also observed in infiltrating Mac-1+/CD43+ and Mac-1+/CD43+ cells after NM; at 3 d expression was 2-3 greater than resident alveolar MP. CCR2 remained elevated for at least 7 d in Mac-1−/CD43+ cells. These cells also expressed increased iNOS, and to a lesser extent, IL-10, suggesting that within this population there are phenotypically distinct subsets. Spleen cells (SPX) rats used to assess the role of the spleen as an extramedullary source of lung MP. Increased tissue damage was noted in histologic sections of SPX rats 3 d post NM; this correlated with increased Mac-1+/CD43+ cells in the lung. These studies show that the lung absorption of multiple inflammatory subpopulations into the lung some of which originate in the spleen. Moreover, it appears that spleen derived cells contribute to down regulating inflammation and initiating wound repair. (NIH AR055073, ES004738, CA132624, and ES005022)
Sulfur mustard [SM, Bis (2-chloroethyl) sulfide], a potent vesicant agent, induces dermal toxicity which includes edema, inflammation, fluid-filled blistering, dermal-epidermal junction (DEJ) disruption, delayed wound repair, and scarring. Studies have shown that down regulation of the gap junction protein, connexin 43 (Cx43) accelerates wound closure and improves wound reepithelialization. We performed a time course study using sulfur mustard [NM, Bis (2-chloroethyl) methylamine] to establish an alternative to the SM skin injury model. We also evaluated the wound repair response using a Cx43 antisense oligodeoxynucleotide (asODN) topical treatment on NM exposed hairless (SKH-1) mouse skin. NM exposure alone caused most of the dermal toxicity produce by SM exposure. In addition we examined several skin markers: keratin 5 (K5, basal keratinocyte marker); keratin 10 (K10, keratinocyte differentiation marker); Ki67 (proliferation marker); laminin 332 (LM332, basement membrane marker). Immunofluorescent (IF) studies showed reduced K5 expression, loss of K10 and Ki67, and an interrupted LM332 pattern of expression 1 day after NM exposure. By day 3, K10 reappeared in a diffuse pattern. By day 7, the LM332 appearance was thick and continuous. By day 10, there was intense expression of Ki67, accompanied by extreme hyperplasia. Our findings support the use of Cx43 asODN may improve vesicant wound repair. Supported by ES005022, ES004738, EY09056, and grant U54ES015678.
neuroinflammation in the rat brain, as determined by histological assessment. The goal of the current study was to test high-field MRI as a tool for monitoring the progression of neurologic damage following acute DFP intoxication. Adult male Sprague-Dawley rats were given pyridostigmine (0.026 mg/kg, i.m.) prior to successive administration of DFP (4 mg/kg s.c.), atropine sulfate (2 mg/kg, i.p.), and 2-PAM (25 mg/kg, i.m.). This treatment paradigm resulted in moderate-to-severe seizure activity as determined using a modified Racine scale. Animals were imaged on a Bruker 7T MRI at baseline, and then at two of five time points post-intoxication (3, 7, 14, 21, or 28 days). At each time point, animals were euthanized and brains collected for histological evaluation. DFP exposure produced significant abnormalities in T2-weighted and diffusion tensor imaging out to 28 days post intoxication. Regions such as the dorsolateral thalamus, amygdala, hippocampus, and piriform cortex showed changes in MR endpoints (e.g., intensity, ADC, and anisotropy). These same brain regions exhibited severe neuronal necrosis. These results demonstrate that MRI is a powerful tool for longitudinal assessments of neuropathology following acute OP poisoning that may prove useful for screening candidate neuroprotective therapies. Supported by the NIH CounterACT program (grant #U54 NS079702) and by a NIH training grant (T32 GM099608).

580 A New Purpose for Ebselen As a Prophylactic to Chemical Threats?
A. Lulla, S. E. Rzenik, L. D. Trombetta and B. Billack. Department of Pharmaceutical Sciences, College of Pharmacy and Allied Health Professions St. John's University, Jamaica, NY.

Sulfur mustard (SM) is a chemical warfare agent that can cause severe acute and chronic injury to the eyes, skin and respiratory tract. The nitrogen mustard methyl mustard (HN2) is a stable isomer of SM that has been recognized as a SM mimetic. Whereas previous studies in this and other laboratories have demonstrated that ebselen (EB-1) is effective at protecting cells from HN2 toxicity in vitro, the present study investigated whether or not EB-1 can reduce the dermal toxicity of HN2 in vivo. The mouse ear vesicant model was utilized, with mouse ears topically exposed to HN2 and biopsied 24 h after exposure. Ear punches were then fixed, sectioned and stained with H&E for inspection by light microscopy. HN2 produced a dose-dependent inflammatory response, characterized by edema, epithelial hyperplasia, increased neutrophil infiltrates and vesication. A histopathological scoring scale analysis of ear tissue sections was developed and used to qualitatively assess HN2-mediated injury. In addition, the morphometric index (MI) of exposed tissues was calculated using the formula, MI = (thickness of treated tissue/average thickness of vehicle exposed ears)*100%. Both histopathological score analysis and morphometric analysis revealed statistically significant injury at doses of HN2 ≥ 0.250 mmol/carr. To test the efficacy of EB-1 as a prophylactic to HN2, three topical treatments with EB-1 (1 mg/carr or 2 mg/carr) were performed at 8 h, 4 h and 15 min prior to HN2 exposure. Quantitative morphometric analysis of tissue samples collected 24 h post HN2 demonstrated that EB-1 significantly reduced HN2-induced tissue swelling at both doses. Similar results were obtained using histopathological score analysis, where a trend toward EB-1 mediated protection was also observed. Taken together, the data presented here suggest that repositioning EB-1 from a drug previously thought to be useful for stroke treatment to one with a new purpose as a prophylactic to chemical threats may be warranted.

581 Exposure-Response Modeling and Simulation to Support Human Dosing for Botulinum Antitoxin Heptavalent (A, B, C, D, E, F, G)–(Equine) or H-BAT
A. L. Menard1, D. Douglas2, K. Atnikov2, J. F. Marier1 and M. Beliveau1. 1Pharmerging Consulting Services, Certara, Montréal, QC, Canada and 2Cangene Corporation, Winnipeg, MB, Canada.

Exposure-response modeling and simulation was performed to support Cangene’s human dosing recommendations for BAT™, Botulinum Antitoxin Heptavalent (A,B,C,D,E,F,G)–(Equine). A compartmental model was constructed to assess the pharmacokinetics (PK) of H-BAT in humans, guinea pigs and Rhesus macaques. A traditional allometric power model was used to scale compartmental PK parameters in humans according to the corresponding body weight of each species. This relationship was used to simulate exposure to H-BAT in any species and according to any dosing scenarios. Subsequently, an exposure-response model was constructed to provide a mechanistic understanding of the relationship between exposure to H-BAT and response to BoNT intoxication (survival) based on the available post-exposure prophylaxis study information (guinea pig and Rhesus macaque). Exposure to H-BAT was simulated using the PK model and survival probability in humans was predicted based on the above exposure-response model. H-BAT exposure (AUC) in humans was compared to a minimum efficacious exposure (MEE) to identify the margin of efficacy (MOE = AUChuman dose/AUCMEE). The MOE ratio provides an estimate of the “safety” margin for the product. The survival probability derived using specification potency was 99.9, 95.6, 97.5, 93.1, 99.0, 95.9 and 97.4% for serotypes A to G respectively. Based on the exposure-response models, the MOE for all antitoxin serotypes were above 1 and the predicted probability of survival in humans following exposure to all serotypes of BoNT was more than 93.1% following administration of the one vial of H-BAT.

581a Corneal Endothelial Toxicity following Corneal Exposure to Sulfur Mustard Vapor: Is Endothelial Loss the Pathophysiology Responsible for Long-Term Ocular Injury?

Sulfur mustard (SM) is a highly reactive vesicant that causes severe ocular injuries. Following exposure to moderate or high doses, a subset of victims develop a chronic injury known as mustard gas keratopathy (MGK), involving a keratitis of unknown etiopathogenesis with secondary keratopathies such as persistent epithelial lesions, corneal neovascularization and progressive corneal degeneration. The etiology of these recurrent keratopathies is unknown. Diverse therapeutic approaches have failed to mitigate the delayed injury, suggesting that researchers need an improved understanding of the mechanisms underlying injury progression. We have developed a novel rabbit corneal vesicant exposure model that exhibits acute and long-term sequelae commensurate with human clinical reports and have characterized consistent and reproducible metrics of injury progression. In preliminary ultrastructural analyses a chronic pathology was observed in the corneal endothelium of MGK corneas. To determine whether (a) SM exposure evokes acute endothelial toxicity and (b) endothelial pathologies were specifically observed in MGK corneas as opposed to healed corneas, we evaluated the corneal endothelium at 1 d and 8 wk after exposure using scanning electron microscopy (SEM), transmission electron microscopy (TEM), in vivo confocal microscopy (IVM), fluorescent microscopy and functional measures of endothelial barrier function. All methods revealed the appearance of a centripetal endothelial lesion at 1 d after exposure, and longitudinal analysis using IVM revealed additional cytotoxicity between 1-13 d. In contrast to healed corneas at 8 wk, which appeared similar to sham-exposed naïve eyes, MGK corneas exhibited significant evidence of continued pathological change in the endothelium. These data indicate that endothelial toxicity occurs at the right time and with the appropriate pathophysiology to contribute to MGK and explicates many of the previously confusing aspects of clinical progression.

581b Deterministic Models of Inhalational Anthrax in New Zealand White Rabbits
B. Gutting. NSWCDD, Dahlgren, VA.

Computational models describing bacterial kinetics were developed for inhalational anthrax in New Zealand white (NZW) rabbits following inhalation of Ames strain B. anthracis. The data used to parameterize the models included bacterial numbers in the airways, lung tissue, draining lymph nodes and blood. Initial bacterial numbers were deposited spore dose. The first model was a single exponential ordinary differential equation (ODE) with three rate parameters that described mucociliated (physical) clearance, immune clearance (bacterial killing) and bacterial growth. At 36 hours post-exposure, the ODE model predicted 1.7 x 10^7 bacteria at 36 hours). Next, building on the single ODE model, a physiological-based biokinetic (PBBK) compartmentalized model was developed where one physiological compartment was the lumen of the airways and the other was the rabbit body (lung tissue, lymph nodes, blood). The two compartments were connected with a parameter describing transport of bacteria from the airways into the body. The PBBK model predicted 4.9 x 10^3 bacteria in the rabbit, which agreed well with data from actual experiments (4.0 x 10^3 bacteria at 36 hours). Next, building on the single ODE model, a physiological-based biokinetic (PBBK) compartmentalized model was developed where one physiological compartment was the lumen of the airways and the other was the rabbit body (lung tissue, lymph nodes, blood). The two compartments were connected with a parameter describing transport of bacteria from the airways into the body. The PBBK model predicted 4.9 x 10^3 bacteria in the body at 36 hours and by 45 hours the model showed all clearance mechanisms were saturated, suggesting the rabbit would quickly succumb to the infection. As with the ODE model, the PBBK model results agreed well with laboratory observations. These data are discussed along with the need and potential application of the models in risk assessment, drug development and as a general aid to the experimentalist studying inhalational anthrax.
were determined at 5, 10, 20, 30, 60 min and 2, 4, 6, 8, 24 and 48 h post dose. A single im injection or 65 mg/kg split into two im injections. Plasma drug levels were determined using a immunoassay method developed to optimize drug absorption. When given at 1 min after soman exposure, promethazine at the dose of 32 or 40 mg/kg decreased the incidence of seizures from 100% to 0% or 40%, respectively. Interestingly, the 40% of the animals that developed seizures after promethazine treatment at 1 min after soman exposure had their seizures spontaneously terminated. Promethazine given at 1 min after soman exposure at the dose of 32 or 40 mg/kg also increased the survival rate from 0% to 75% or 100%, respectively. When promethazine at the dose of 32 or 40 mg/kg was administered at the onset of seizures, seizures were terminated in 100% of animals, and the survival rate was increased from 0% to 100%. At 24 hr, promethazine-treated animals behaved like non-exposed animals. Brain samples from promethazine-treated animals were evaluated for brain injury. None of the animals treated with promethazine, either at 1 min after soman administration or at the onset of seizures, exhibited neuronal damage in any of the brain regions examined. These observations indicate that promethazine treatment can effectively control seizures, improve survival and prevent brain injury following exposure to 2.0 LD50 of soman.

581d Pharmacokinetics of Nitrocinobinamide (NCbi), a Novel Cyanide Antidote
K. O’Loughlin1, R. Swezy1, W. Shinn1, G. R. Boss1 and C. E. Green1.
1Toxicology & Pharmacokinetics, SRI International, Menlo Park, CA and 2University of California, San Diego, CA.

The cobalamin analog cinobinamide (Cbi) has a high affinity for cyanide and is a potent cyanide antidote after im injection. Pigs are rescued from a lethal cyanide dose by 12.5 mg/kg of Cbi. The objective of the current study was to determine the pharmacokinetics of NCbi, a formulation developed to optimize drug absorption. Male Sprague Dawley rats received either 30 mg/kg iv, 65, 95, or 130 mg/kg as single im injection or 65 mg/kg split into two im injections. Plasma drug levels were determined at 5, 10, 20, 30, 60 min and 2, 4, 6, 8, 24 and 48 h post dose. After an iv dose, Cbi was rapidly distributed and eliminated with t1/2 of 11.6 ± 3.6 h and clearance of 45.7 ± 7.3 ml/h/kg. The plasma concentration extrapolated to time 0 was 378 ± 308 µg/ml and the AUC was 670 ± 101 µg·h/ml. The volume of distribution was 0.7 ± 0.13 l/kg, consistent with distribution to extracellular water. After an im dose, the plasma Cbi concentration increased rapidly with mean T1/2 values ranging from 0.8 ± 0.3 h (high dose) to 1.7 ± 0.6 h (mid dose). The Cmax and AUC values were dose dependent, although the increase in exposure was not linear from the mid to the high dose. The mean T1/2 was about 15 h for the single injection im groups. When the low dose was given as 2 injections of 100 mM, Cbi was absorbed faster (T1/2 of 0.6 ± 0.3 vs 1.3 ± 0.6 h) and the Cmax was ~ 40% higher than after a single injection of 100 mM. At a concentration of 50 µg/ml N-Cbi, 83.0 ± 2.89% of Cbi was bound to rat plasma proteins. In summary, Cbi absorption after im injection reached maximum plasma levels at 15-20 min post injection. Based on Cmax and AUC, increased with dose but tended to plateau, suggesting that Cbi absorption becomes saturated at higher formulation concentrations. The administration of the low dose, split and injected at two sites, yielded faster absorption and higher Cmax values than a single injection. The average bioavailability of Cbi after im administration of N-Cbi was excellent, > 75%. This research was supported by NIH Contract HHSN271200623601C.

581e Zebrafish As a Novel Animal Model for Chemical Warfare Agent (CWNA) Biomedical Research
USAMRICD, Aberdeen Proving Ground, MD.

Zebrafish only express the acetylcholine hydrolyzing enzyme acetylcholinesterase (AChE). This unique genotype makes the zebrafish an ideal animal model to study the toxicological effects of organophosphorus nerve agent (NA) AChE inhibitors and the effectiveness of oximes to reactivate NA-inhibited AChE. The present study determined the LC50 of sarin and evaluated the efficacy of 2-PAM in reactivating sarin-inhibited AChE. Larval zebrafish at 6 days postfertilization (dpf) were exposed to various concentrations of sarin for 1 hr to determine the LC50 of sarin. Following sarin exposure, zebrafish larvae were screened under a dissecting microscope to observe the overt signs of toxicity. Death was determined by the cessation of heart beats. The mortality rate was 0, 20, 45, 55, 43, 75, 70, 95 or 100% after exposure to 0, 12.5, 25, 50, 75, 100, 150, 250 or 500 uM of sarin, respectively. By regression analysis, the LC50 of sarin for 1 hr exposure at 24 hr was estimated to be 80 uM. Twenty-four-hour survivors exhibited behavioral changes, including an inability to maintain buoyancy and swimming vertically on the side. To evaluate the effectiveness of 2-PAM to reactivate sarin-inhibited AChE, 6 dpf larvae were exposed to 25 uM of sarin, and their AChE activity was measured by the Ellman assay. When the larvae were completely immobile after 5 mins of exposure, they were treated with 0 or 50 uM of 2-PAM. The percentage of AChE inhibition was 98% when the larvae lacked locomotion. With 2-PAM treatment, the AChE percentage inhibition was decreased, but by no more than 30%. The results suggest that 1) zebrafish larvae are sensitive to the toxic effects of sarin in a concentration-dependent manner and 2) zebrafish larvae AChE inhibited by sarin can be reactivated by 2-PAM, an oxime reactivator currently used as standard treatment for CWNAs in the military. These observations provide evidence that the zebrafish is a suitable animal model system for in vivo evaluation of NA toxicity and novel oxime reactivators.
laws do not mention bioavailability. SOT’s Code of Ethics should have compelled more science, not policy-driven results. The reader’s attention is drawn to the Code: “Abstain from professional judgments influenced by undisclosed conflict of interest, disclose any material conflicts of interest, and avoid situations that imply a conflict of interest. The authors’ functions were resisted to the DVA for creation of negative responses to concerns raised by exposed veterans. No disclosure was offered or mention made of challenges raised by other toxicologists not employed by the DVA, which was not in keeping with the Code.

581h Blood Pressure, Heart Rate, Temperature, and Central Nervous System Evaluation of Cyanide Intoxication in Juvenile and Adult Mice

M. Hawk, G. Ritchie, T. Vinci, K. A. Henderson, S. Behringer, K. Knotman, B. Roche, C. L. Sabourin and P. Sabourin, Battelle, Columbus, OH.

Cyanide (CN) affects organ systems with the highest demand for energy such as the central nervous, cardiovascular (CV), and pulmonary systems. A mouse model of oral KCN intoxication is needed for screening and testing of CN countermeasures. Adult and juvenile CD-1 mice were dosed orally with a single dose of water or 8 mg/kg KCN, a toxic but generally non-lethal dose. Sensory, motor, cognitive, and behavioral changes were measured using a functional observation battery (FOB) and Tier II CNS testing up to 42 days post-dosing. Histopathology was conducted on select tissues and telemetry was used for CV evaluations and body temperature. KCN reduced sensorimotor responsivity or spontaneous locomotor activity (FOB and Tier II testing) in juvenile and adult mice at 30 min post-dose. Core body temperature decreased at 30 min post-challenge consistent with the general malaise observed. No FOB differences were observed on Day 2 (24 hr post-dose), but decreases in spontaneous locomotor activity and/or rectal temperature were observed on Days 7, 14, 28, and 42. Tier II tests demonstrated no significant differences between KCN-treated and control groups on Days 2, 7, 14, 28, or 42. KCN caused immediate effects related to bradycardia, hypotension, and hypothermia with recovery 1 to 3 hours post-dosing. Twenty percent of mice in the KCN group experienced ECG events within the first 5 min post-dosing that ranged from bradycardia, to left ventricular premature contractions (VPCs), and a large Ta wave. At 30-min post-dosing, ECG included PR prolongation, alternans, and Ta prolongation. The bradycardia and VPCs as well as the PR and Ta prolongation appear to be effects of KCN in a small percentage of mice, most likely due to effects on the SA node. There were no KCN related histological findings through Study Day 42. The effect of treatments on KCN-induced changes in CV and CNS parameters can be used in subsequent studies to determine the efficacy of countermeasures.

581i Younger Rats Are More Susceptible to the Lethal Effects of Sarin Than Adult Rats: 24 h LC50 for Whole-Body (60 Min) Exposure

L. K. Wright1, D. B. Miller2, W. T. Muse2, E. J. Emm3, R. B. Lee1, C. E. Whalley1 and L. A. Lumley1. 1US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD and 2Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD.

Chemical warfare nerve agents (CWNA) are among the most lethal chemicals known to man, and children are a particularly vulnerable subpopulation because of their smaller body masses, smaller airway diameters, higher respiratory rates and immature central nervous systems. While there have been a handful of studies on the effects of CWNA in younger animals, exposure routes relevant to battlefield or terrorist situations (inhalation for G-agents and dermal for V-agents) were not used. Thus, we determined the 24 h LC50 for whole-body (60 min) exposure to sarin using a stagewise, adaptive dose design. Briefly, both male and female Sprague-Dawley rats were exposed to a range of sarin concentrations at five different time points during their development (postnatal day [PND] 7, 14, 21, 42 and 70). For both male and female rats, the lowest LC50 value was observed on PND 14 and the highest LC50 value on PND 42. Females had slightly smaller LC50 values than males at all five time points, and the LC50 values were significantly smaller on PND 21 and 70. Thus, younger rats are more susceptible to the lethal effects of whole-body exposure to sarin than older rats, and females are more susceptible than males. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government. The experimental protocol was approved by the Animal Care and Use Committees at USAMRICD and ECBC, and all procedures were conducted in accordance with the principles stated in the Guide for the Care and Use of Laboratory Animals and the Animal Welfare Act of 1966 (P.L. 89-544), as amended. This research was supported by interagency agreement between the Biomedical Advanced Research and Development Authority and USAMRICD.

581j Natural History Study of Cyanide Intoxication in Adult and Juvenile Mice

P. Sabourin1, C. Kobs1, B. Horne2, E. Purny1, C. Matthews1, K. M. Patton2, S. Gibbs3 and C. L. Sabourin1. 1Battelle, Columbus, OH and 2Best Center, Battelle, Aberdeen, MD.

Cyanide (CN) is an inhibitor of cytochrome C oxidase causing rapid death due to hypoxia. CN is of concern due to its use as a warfare agent, industrially, exposure from burning plastics, and possible terrorist use. A well-characterized model of oral KCN intoxication is needed to test new therapeutics for KCN intoxication under the FDA Animal Rule. The objective was to describe CN intoxication after a single lethal and sub-lethal acute oral KCN administration to juvenile and adult mice. The oral LD50 of KCN was 11.5 ± 0.4 mg/kg KCN in adult mice and 10.4 ± 0.3 mg/kg KCN in juveniles. The oral KCN LD50 value for male mice was about 0.9 mg/kg greater than female mice, for either age. Death following KCN challenge occurred within 30 min post-dose in adult and juvenile mice at doses above 10 mg/kg. Juveniles tended to have a shorter time to death with a rapid seizure response. CN and its major metabolite, thiocyanate, were quickly metabolized (Tmax of 0.5 hr and 2-4 hr, respectively) and excreted. A survey of biomarkers indicated that blood pH and lactate were rapid and quantitative, although non-specific, markers of CN intoxication. Serum FABP3 increased with KCN dose in adult, but not juvenile, mice. No microscopic pathological findings were observed 1 day post-dose. The model description indicates that the effects of KCN are rapid and, at doses up to a least the LD50, completely reversible in surviving mice. The toxicokinetics of CN in mice is consistent with the rapid clinical signs and recovery. Based on the rapid toxicity observed, treatment would have to be initiated quickly following exposures for optimal results. Rapid analysis of blood pH and/or lactate using a point of care device, such as the l-Stat, could be used as a trigger for treatment in efficacy studies. The results provide a well characterized model of acute oral KCN intoxication of adult and juvenile mice that may be used to screen or conduct pre-clinical efficacy studies of potential countermeasures.

581k Treatment of Lung Injury from Phosgene Chemical Inhalation with NOS-2 Inhibition

P. Filipczak1, 2, J. D. McDonald1, L. Fredenburgh1, 2 and R. Baron1, 4. 1Lovelace Respiratory Research Institute, Albuquerque, NM and Division of Pulmonary and Critical Care Medicine, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA.

Acute lung injury (ALI) induced by the chemical agent phosgene (CCl2O) is characterized by increased lung expression of inducible nitric oxide synthase (iNOS, NO2S) and production of reactive nitrogen species including peroxynitrite, which triggers epithelial and endothelial cell injury, surfactant dysfunction, and loss of alveolar epithelial barrier integrity. Our research demonstrates that phosgene-induced lung injury also leads to significant reduction in the tight junction protein zonula occludens (ZO)-1, resulting in exaggerated alveolar epithelial permeability in vivo under acute phosgene exposure. We have previously demonstrated that NO2S expression in lung epithelial cells plays a key role in surfactant dysfunction and is critical for the development of endotoxin-induced ALI. Furthermore, we have identified that NO2S-derived NO from lung epithelial cells downregulates surfactant protein B (SP-B) expression at the transcriptional level. We therefore hypothesized that NO2S-generated NO contributes to phosgene-induced ALI and that selective inhibition of NO2S in the lung epithelium will attenuate surfactant dysfunction, disruption of tight junction proteins, and vascular leak induced by phosgene. Our research demonstrates that administration of a NO2S-specific inhibitor 1400W delivered via inhalation, but not systemically, dramatically attenuates phosgene-induced lung injury. Aerosol delivery of 1400W augmented SP-B expression and restored ZO-1 expression in the lung leading to attenuation of histologic lung injury and physiologic dysfunction in a murine phosgene ALI model. Consistent with our previous studies and work by other investigators, these findings support a role for inhibition of localized NO2S production within the lung in attenuating chemical agent-induced lung injury. We will present on this research, and consider the current proposed standard of care for phosgene induced ALI against this potential therapy in terms of feasibility and efficacy.

582 Modulation of Inflammasome Activation by Carbon Nanotubes in Asthma

K. A. Shipkowski, A. Taylor, E. Thompson and J. C. Bonner. North Carolina State University, Raleigh, NC.

Introduction: Multi-walled carbon nanotubes (MWCNT) represent a potential health hazard for human lung disease based on studies in mice which show lung inflammation after exposure. A possible mechanism of MWCNT-induced inflam-
Funding: Supported by NIEHS grants RO1-ES020897 and RC2-ES018772. Allergic airway inflammation in asthma.

ulate MWCNT-induced inflammasome activation and how MWCNT exacerbate inflammation. Further study will address the mechanism through which Th2 cytokines modulate MWCNT-induced inflammasome activation and how MWCNT exacerbate allergic airway inflammation in asthma.

583 Atomic Layer Deposition Coating of Multiwalled Carbon Nanotubes with Aluminum Oxide Alters Innate Immune Responses In Vitro and In Vivo

A. Taylor1, K. A. Shipkowski2, E. Thompson1, C. Devine2, G. Parsons3, S. Garantziotis1, S. Hussain1 and L. C. Bonner1

1Biological Sciences: Toxicology Program, North Carolina State University, Raleigh, NC, 2Chemical & Biomolecular Engineering, North Carolina State University, Raleigh, NC and 3Laboratory of Respiratory Biology, National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Multi-walled carbon nanotubes (MWCNTs) pose a possible human health risk for lung disease as a result of occupational or environmental exposure. Macrophages are the first line of defense that engulf and remove inhaled MWCNTs from the lungs. MWCNTs stimulate macrophage inflammasome activation and interleukin (IL)-1β release, key cellular components of the innate immune response that mediate the initiation and resolution of acute inflammation. Alternatively, macrophages are a source of secreted osteopontin (OPN), which promotes tissue matrix remodeling and fibrosis. Atomic layer deposition (ALD) is a novel process used to enhance surface and functional properties of MWCNTs. The purpose of this study was to determine whether ALD coating with Al2O3 would alter toxicity, phagocytosis, or the production of soluble mediators (IL-1β or OPN) in human macrophages or monocytes exposed to MWCNTs as well as in mice in vivo. IL-1β and OPN protein secretion was measured by ELISA at 24h post nanotube exposure. ALD surface coating of MWCNTs with Al2O3 enhanced IL-1β secretion, yet inhibited OPN production by THP-1 cells. Experiments conducted with primary peripheral blood monocytes obtained from normal human donors also showed that the ALD-coating on MWCNTs enhanced IL-1β secretion and yet suppressed OPN production. C57BL6 mice exposed to uncoated MWCNTs for 1 day had increased levels of IL-1β and OPN in the bronchoalveolar lavage fluid. ALD coated MWCNTs increased IL-1β in the BAL fluid as well, yet had a suppressive effect on OPN levels. These findings indicate that thin film surface coating of MWCNTs with Al2O3 by ALD enhances the innate immune response of mononuclear phagocytes but decreases pro-fibrogenic activity in vitro and in vivo.

584 Activation and Interplay of the Tumor Suppressor Genes p53 and STAT-1 in Response to Multiwalled Carbon Nanotubes

E. Thompson, K. A. Shipkowski, A. Taylor and L. C. Bonner

Department of Biological Sciences, Environmental and Molecular Life Sciences Program, North Carolina State University, Raleigh, NC.

Multi-walled carbon nanotubes (MWCNTs) are engineered nanomaterials that possess unique physical properties, making them ideal candidates for use in electronics, engineering and medicine. As they are used in increasing quantities, the potential for occupational and/or environmental exposures is inevitable. There is increasing evidence that MWCNTs may produce toxic effects both in cultured cells and in the lungs of rodents. Studies in human epithelial cells and rats in vivo have shown MWCNTs to cause DNA damage. The tumor suppressor gene p53 is a DNA damage inducible transcription factor involved in cell cycle arrest and apoptosis. Likewise, the transcription factor, STAT-1 serves many of the same functions as p53 and STAT-1 has been found to interact with p53 in mouse embryonic fibroblasts and human fibrosarcoma cells in vitro. We explored a possible relationship between p53 and STAT-1 in human mesothelial cells, the target cells of mesothelioma, as well as in the mouse lung in vivo, following exposure to MWCNTs. Human mesothelial cells (Met5A cells) were dosed with 10 µg/cm2 MWCNTs, and using western blot analysis, we observed that the phosphorylated or "active" forms of both p53 and STAT-1 were increased 4 hours post-exposure. To determine whether the induction in p-p53 was affected by the presence of STAT-1, we utilized both STAT-1 siRNA to knockdown STAT-1 message in the Met5A cells, as well as a STAT-1 knockout mouse model. In both models, decreased or absent STAT-1 protein, resulted in decreased p53 protein levels. Our results suggest that both p-p53 and p-STAT-1 can be induced as a result of MWCNT exposure and that the induction in p-p53 is dependent on the presence of STAT-1. The findings presented here are relevant to our understanding of the potential for carbon nanotubes to cause pleural disease after inhalation exposure.

585 Different Functionalizations of MWCNT Influence Transformation Potential in Primary Human Lung Epithelial Cells

T. A. Stueckle1, R. Derk1, M. Chen2, Y. Castranova1,2, Y. Rojanska1 and L. Wang1,2

1NIOSH, Morgantown, WV and 2WV Virginia University, Morgantown, WV.

MWCNT have received increased scrutiny for potential human health impacts based on their fibrogenicity and promotion of pulmonary carcinogenesis. Functionalized CNT (fCNT) development has intensified to improve surface activity in technological applications, and potentially reduce toxicity. Subchronic in vitro CNT exposure causes neoplastic-like transformation; however, tumorigenic risk associated with fMWCNT exposure in human lung epithelium is presently unknown. To identify early steps in fMWCNT-induced cell transformation, this study hypothesized that different functional groups of MWCNT determine their neoplastic transformation potential in primary human small airway epithelial cells (SAECs). Cells were continuously exposed (0.06 µg/cm²) to dispersed pure (pMWCNT), carboxylated (cMWCNT), and aminated MWCNT (nMWCNT) for 8 and 12 weeks. Dispersed ultratine carbon black (UFBCB) and crocidolite asbestos served as controls. Exposed cells were assessed for several established cancer hallmarks and morphological transformation. UFBCB and pMWCNT cells at 48h and all MWCNT cells at 6d post-treatment exhibited significant increased proliferation compared to controls. UFBCB exposure stimulated significant invasion and migration behavior while pMWCNT and cMWCNT showed moderate significant increases; however, these trends disappeared at 6d post-exposure. Conversely, nMWCNT displayed the largest significant increase in colony formation potential while UFBCB showed a moderate significant increase. All other treatments did not differ from controls. UFBCB and nMWCNT cells exhibited increased foci frequency, indicative of neoplastic transformation, compared to all other treatments. In summary, surface charge characteristics of carbon nanoparticles can impact transient, early neoplastic transformation events in vitro following occupationally relevant exposures.

586 Lactoperoxidase-Mediated Degradation of Oxidized Single-Walled Carbon Nanotubes and Its Modulatory Effects on Airway Antibacterial Activity

K. Bhattacharya1, R. El-Sayed1, F. T. Andö1, A. Fornara2, H. Li2, J. Gregory3, K. Leifer1, S. Dahlén2, A. Star4 and B. Fadeel1

1Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, 2Unit for Chemistry, Materials and Surfaces, SP Technical Research Institute of Sweden, Royal Institute of Technology, Stockholm, Sweden, 3Department of Engineering Sciences, Ångström Laboratory, Uppsala, Sweden and 4Department of Chemistry, University of Pittsburgh, Pittsburgh, PA.

Studies in recent years have shown that carbon nanotubes (CNTs) may elicit inflammatory responses. On the other hand, enzymatic biodegradation of CNTs by inflammatory cells has also been reported thus illustrating the reciprocal interactions between CNTs and the immune system. Here we analyzed the biodegradation of oxidized SWCNTs by recombinant lactoperoxidase (LPO), in the presence or absence of lung surfactant (Curosurf®). UV/Vis-NIR and Raman spectroscopy techniques were employed to monitor the biodegradation. There was effective degradation of SWCNTs by LPO and no interference by Curosurf®. AFM and
SEM analyses suggested the attachment of LPO on the carboxylated side-walls of the bundles of SWCNTs. We also confirmed the ex vivo biodegradation of SWCNTs in murine bronchoalveolar lavage (mBALF) shown to express peroxidase activity. Lastly, we addressed whether the pre-occupancy of LPO with SWCNTs would interfere with its antibacterial properties. To this end, experiments with Pseudomonas aeruginosa, an opportunistic human pathogen, were conducted and we noted that the pre-occupancy of LPO with SWCNTs severely impaired the antibacterial activity of LPO. Our study provides evidence for the degradation of carboxylated SWCNTs by LPO, a secreted peroxidase that is present in the airways. However, the antibacterial activity of LPO is impaired as a result of the pre-occupancy of LPO with SWCNTs. This latter finding implies that airborne defenses may be compromised in individuals exposed to SWCNTs, possibly leading to more persistent infections.

587 Effects of MWCNT and Nitrogen-Doped MWCNT in Lung Epithelial Cells
A. Mihalchik1,2, D. W. Potter2, V. Castranova2, S. Tsuruda1, M. Endo1 and Y. Qian3, 1Pharmaceutical and Pharmacological Sciences, West Virginia University, Morgantown, WV, 2Health Effects Laboratory Division, National Institute for Occupational Safety and Health, Morgantown, WV and 3Research Center for Exotic Nanocarbons, Shinshu University, Nagano, Japan.

The growing use of multi-walled carbon nanotubes (MWCNT) and their derivatives in academic and industrial settings has raised the need to efficiently and accurately determine their potential toxicity in the workplace. Nitrogen-doped multi-walled carbon nanotubes (ND-MWCNT) are modified MWCNT that have enhanced electrical conductivity and are increasingly used in a variety of aerospace and fuel cell applications. Although similar in structure to MWCNT, limited toxicological data is available, and the biocompatibility and mechanism of action of ND-MWCNT have yet to be elucidated. Recent in vivo data showed that ND-MWCNT induced inflammation and fibrosis in mouse lungs. In this study, we assess uptake of ND-MWCNT into small airway epithelial cells (SAEC), which may induce molecular toxicological effects. We showed that ND-MWCNT induced higher levels of reactive oxygen species (ROS) in SAEC when compared to their parent MWCNT in short-term in vitro exposure. Treatment of SAEC with low doses (1.25 µg/mL) of ND-MWCNT and MWCNT indicated that both induced a significant increase in cell proliferation in a time-dependent manner. Furthermore, significant alterations to the cell cycle were observed in cells treated with both ND-MWCNT and MWCNT in a time- and dose-dependent manner, as shown by an increased percentage of cells in the S and G2 phases of the cell cycle. Confocal images showed alterations in acetylated and total tubulin levels in both ND-MWCNT and MWCNT treated cells as well. Since increases in ROS production and cellular proliferation are associated with multiple pathological conditions, ND-MWCNT exposure may play a role in the initiation of these diseases.

588 Autophagy and Extracellular HMGB1 Are Mediators of Inflammammasome Activity in Response to MWCNT Exposure
F. Jessop, B. Biswas and A. Hollan, Center for Environmental Health Sciences, University of Montana, Missoula, MT.

RATIONALE: Pulmonary exposure to multi-walled Carbon Nanotubes (MWCNT) has been shown to induce chronic inflammation in animal models, and therefore may pose a health risk to humans. Pathology induced by MWCNT exposure is dependent upon NLRP3 Inflammasome activity, specifically IL-1β signaling. Mechanisms regulating Inflammasome activity are not clear. In this study, we establish critical roles for High Mobility Group Box 1 (HMGB1) and autophagy in regulating Inflammasome activity. METHODS: Secretion of HMGB1 was assessed in vitro from primary Alveolar Macrophages (AM) and in vivo in C57Bl/6 mice (24 and 72 hours) after MWCNT exposure. The contribution of extracellular HMGB1 to Inflammasome activity was delineated in vitro via HMGB1 elimination by immunoprecipitation techniques and in vivo using neutralizing antibodies. To assess the contribution of autophagy in mediating inflammasome activity, primary AM exposed to MWCNT were treated with molecular inhibitors (LY294002, Bafilomycin, Imipramine) targeting different sites along the autophagic flux, and IL-1β production assessed after 24 hours. RESULTS: HMGB1 secretion and autophagic flux are increased following MWCNT exposure. HMGB1 removal by immunoprecipitation techniques or neutralization reduces IL-1β production in primary AM in vitro and in vivo, respectively. Additionally, targeting autophagy by stabilizing the lysosome also decreases IL-1β production after MWCNT exposure. However, inhibition of PI3 kinase activity, responsible for autophagosome formation, enhances IL-1β secretion. CONCLUSIONS: HMGB1 signaling and autophagy play critical roles in the acute Inflammasome response to MWCNT exposure, and may be potential therapeutic targets in particle induced inflammatory diseases.

589 Effects of SWCNT Fiber Length and Functionalization on ROS and Collagen Production
A. Manke1, T. A. Stueckle2, L. Wang2, C. A. Dinu1 and Y. Rojanasakul1, 1Pharmaceutical Sciences, West Virginia University, Morgantown, WV, -NIOSH, Morgantown, WV and 2Chemical Engineering, West Virginia University, Morgantown, WV.

Single-walled carbon nanotubes (SWCNTs) present a significantly higher chance of occupational and environmental exposure owing to their widespread use in technology and commercial products. Currently, there is a lack of consensus on the various CNT characteristics that induce pulmonary toxicity. Therefore, our aim was to study the effect of SWCNT length and chemical functionalization on ROS production and collagen synthesis in human lung fibroblasts. SWCNTs with varying functionalization including carboxylic acid, amine and hydroxyl, and varying lengths, i.e. long 5-30 nm and short 1-2 nm, obtained from Cheap Tubes Inc. were used. SWCNT dimension and elemental composition characterization was conducted using atomic force microscopy and energy dispersive X-ray spectroscopy respectively. SWCNT toxicity in normal human lung fibroblast were first determined using WST-1 assay and sub-toxic concentrations of SWCNTs were selected for further experiments. Cellular ROS production was determined fluorometrically using DCF-DA as fluorescent probes for peroxide measurement. Type I Collagen expression was determined by western blotting in the presence and absence of ROS inhibitors. Cellular collagen content was determined by SiriusRed® assay. Our results showed that: 1) Pristine > COOH > NH2 > OH SWCNT in ROS and collagen production in a dose- and time-dependent manner; 2) longer length SWCNTs induced higher ROS generation and collagen I expression than those of short length; and 3) SWCNT-induced collagen expression was significantly blocked by various ROS inhibitors revealing a role for oxidative stress in SWCNT-induced fibrogenesis. These results suggest that SWCNT length and functionalization impact lung fibroblast ROS and collagen synthesis, which contribute to SWCNT-induced pulmonary fibrosis. Disclaimer: Research findings and conclusions are those of the authors and do not necessarily represent the views of the National Institute for Occupational Safety and Health.

590 Differential Gene Expression in SAEC and HMVEC Grown in Monoculture or Coculture and Exposed to MWCNT: Correlation with In Vivo Studies
B. Talkington1, C. Dong2, X. Zhao2, J. Dymack1,2, V. Castranova1, Y. Qian1 and N. L. Guo1.1National Institute for Occupational Safety and Health, Morgantown, WV, 2West Virginia University Mary Babb Randolph Cancer Center, Morgantown, WV and 3West Virginia University Lane Department of Computer Science and Electrical Engineering, Morgantown, WV.

In vitro coculture systems are at the forefront of molecular research due to their increased ability for cell-cell communication. In this study, small airway epithelial cells (SAEC) and human microvascular endothelial cells (HMVEC) were grown separately in monocyte or together in an alveolar-capillary coculture and exposed to either dispersion media control or multi-walled carbon nanotubes (MWCNT) for 6 or 24 h. Global mRNA profiling determined genes that were differentially expressed in coculture as compared to monoculture, and Ingenuity Pathway Analysis determined the biological functions and related pathways of these genes. A total of 1505 SAEC and 54 HMVEC genes, commonly involved in the cell cycle and cell proliferation, were differentially expressed in control coculture experiments as compared to monoculture (SAM 1%, FC >1.5). A total of 1601 SAEC and 2016 HMVEC genes, commonly involved in cell movement and survival, were differentially expressed in coculture as compared to monoculture following MWCNT exposure (SAM 1%, FC >1.5). A correlation study of gene expression between monocyte, coculture, and in vivo gene expression from mice lungs exposed to MWCNT determined that coculture gene expression had a better correlation with in vivo gene expression than monoculture. In this study, we determined that gene expression in cells from coculture models is different from expression in the corresponding cells in monoculture. As coculture gene expression better correlates with gene expression seen in vivo, we hypothesize that coculture may offer an enhanced in vitro model for nanoparticle risk assessment.
Determination of Stoichiometric ROS Degeneration and Relationship between Redox Potential and Bioavailability to Design Safe CNTs

S. Tsunoda1, K. Hashimoto2, K. Takeuchi3, K. Koyama1, N. Saito1, Y. Usui1, S. Kobayashi1, A. Kikita1, D. W. Porter4, V. Castanet5, J. E. C. B. and M. Endo1, 2Research Center for Exotic Nanocarbon, Shinshu University, Nagano, Nagano, Japan, 3Tokyo Institute of Technology, Meguro, Tokyo, Japan, 4Institute for Carbon Science & Technology, Shinshu University, Nagano, Nagano, Japan, 5Kuraray Living Co., Ltd., Osaka, Osaka, Japan, 6School of Health Science, Shinshu University, Matsumoto, Nagano, Japan, 7Laboratory of Chemical Bioengineering, NIOSH, Morgantown, WV and 8RIVM, Bilthoven, Netherlands.

An important goal is to design safe carbon nanotubes (CNTs) by controlling their properties. Biological evaluations have been conducted with individual CNTs, and such results have been used for risk assessment (NIOSH CIB 65, 2013). However, information is lacking to define the relationships between the chemical properties of CNTs and their bioavailability. The present work aimed to obtain a stoichiometric expression of ROS degeneration by CNTs, which predicted ROS scavenging results with CNTs. ROS degeneration rate was measured with an ESR-DMPO method. The Fenton reaction was used to generate OH radicals. To evaluate CNT surface reactions, surfactant concentration was minimized to eliminate its influence, and reactivity of CNTs was determined. Results indicate that this allows kinetic quantification of the relationship between degeneration reactions and CNT morphology. Since the degeneration of ROS is attributed to a redox reaction according to the hypothesis in reaction kinetics on CNT surface, CNT bioactivity is defined as a redox potential that can be used to elucidate the relationship between bioactivity and CNT physicochemical properties. In conclusion, redox potential will be used to predict CNT bioactivity using its surface morphology and to design safer CNTs. (This work was supported by the Exotic Nanotube Project, Japan Regional Innovation Strategy Program by the Excellence, JST(Japan Science and Technology Agency)(ST, KK, YU, ME)).

Determination of Stoichiometric ROS Degeneration and Relationship between Redox Potential and Bioavailability to Design Safe CNTs

Acute Inhalation Toxicity of Graphene Oxide and 5-Day Repeated Inhalation Toxicity of Graphene

J. Kim1, J. Shin2, J. Hwang1, J. Lee1, T. Kim1, I. Lee1, Y. Kim1, H. Lee1, N. Song1, K. Ahn1 and J. Yu1, 2Institute of Nanoprocess Safety Research, Houn University, Aan, Republic of Korea, 3Occupational Lung Diseases Institute, KCOMWEL, Ansan, Republic of Korea, 4Dongg University, Busan, Republic of Korea, 5KRISS, Daejeon, Republic of Korea, 6Hanyang University, Ansan, Republic of Korea and 7Korea Ginseng Corporation, Daejeon, Republic of Korea.

Hazard of graphene exposure to human health, however, has not been known well. Acute pulmonary toxic effect of graphene oxide was evaluated via nose-only inhalation for 6 hours to experimental animals. Male Sprague-Dawley rats were divided into 3 groups (4 rats in each group), the fresh air control (0 mg/m3), low (0.46 ± 0.06 mg/m3), and high (3.76 ± 0.24 mg/m3) concentration group, respectively. Lactate dehydrogenase (LDH), microprotein (mP), and microalbumin (mALB) levels were evaluated from the bronchoalveolar lavage (BAL) fluid on day 1, 7, and 14 after 6 hours exposure to graphene oxide. In addition, 5-day repeated inhalation toxicity of graphene was conducted to rats by assigning 3 groups (20 rats in each group); the control (0 mg/m3), low dose (0.68 ± 0.14 mg/m3) and high dose (3.86 ± 0.94 mg/m3). The rats were exposed to graphene for 6 hr/day for 5 day. The exposed rats were allowed to recover for 14 to 28 days to evaluate the biopersistent effect of graphene oxide and graphene on the lungs after the acute and 5-day repeated exposure. The ingestion of graphene oxide and graphene in the alveolar macrophages was also evaluated. There was no statistical significant difference in average concentrations of LDH, mP, and mALB in the exposed groups when comparing with the unexposed control in all post-exposure groups (1, 7, and 14 days). The ingestion of graphene oxide in the alveolar macrophages was observed in all post exposure groups of the high dose group, but it was difficult to observe the graphene oxide in the control and low concentration group. Graphene oxide did not induce acute pulmonary toxic effect in the lungs of experimental animals. Graphene also did not induce any significant body weight, organ weight and lung weight changes after 5 day exposure and during 28 days of recovery.

Development of Determination Method of Single-Walled Carbon Nanotubes with Distinct Chiral Enrichment

X. Zheng1, N. Afroz2, N. B. Saleh2, J. Bisesi1 and T. Sabo-Attwood1.

1University of Florida, Gainesville, FL and 2University of South Carolina, Columbia, SC.

The rapid expansion of nanomaterial use in industrial, consumer and medical sectors has raised concern regarding associated health effects from unintended exposure. There is exceptional interest in single-walled carbon nanotubes (SWNT), as they are used in many common applications. As SWNT share a resemblance to asbestos, there is concern regarding inhalation exposure and associated lung diseases. Although consequences of SWNT exposure in the lung include pulmonary injury and fibrosis, few studies have focused on the ability of these particles to modulate infections by pathogenic agents. Recognition of invading pathogens occurs through interaction with toll-like receptors (TLRs) that stimulate the immune system through activation of nuclear factor kappa beta (NF-κB). Based on this knowledge, we hypothesized that SWNT interacted with TLR2 or 3 activities. Overall, these data suggest that chiral, aggregate size and stability of SWNTs may influence the activity of TLRs and have implications for interferring with normal pathogen defense systems.
Correlation of Toxicity and Material Properties: Oral and Inhalation Exposure of 16 Surface-Functionalized Nanomaterials

L. Ma-Hock1, R. Büsen1, W. Wohlleben1, S. Grütters1, D. Geiger2, B. van Ravenzwaay1 and R. Landsiedel1. 1Toxicology, BASF SE, Ludwigshafen/Rhein, Germany, 2Product Safety, BASF SE, Ludwigshafen, Germany and 3Material Physics, BASF SE, Ludwigshafen, Germany.

16 nanomaterials were tested by short-term inhalation studies (R. Landsiedel and al. Advanced Materials 22.24.10: 2651–2667) and oral gavage (28-day OECD TG407). The results were correlated to the complete physical-chemical properties (according to the REACH R.7.1 nano-specific guidance) and to the in-situ corona structures (in lung surfactant, pure lipids, serum-containing media) The surface of suspended nanoparticles with sizes of 10 nm (ZnO2), 15 nm (SiO2) and 50 nm or 200 nm (Ag) received acid, amino, -PEG, and -steric functionalities. The organic molecules were bound to the surface of the particles to improve properties such as processability, solubility or stability of the products. All results were benchmarked against OECD reference materials (TiO2, ZnO, BaSO4). None of the materials elicited an adverse effect in oral testing (see separate poster). For inhalation at up to 50 mg/m3, inflammations of the lung were observed with most of the nanomaterials. In general, functionalizations reduced the acute inflammatory response, especially for negative charges and for sterically stabilized materials. The correlation of inflammatory potency (e.g. monitored by PMN) to in-situ corona parameters is vanishing. A weak correlation was found between the particle’s affinity to phospholipids and the deposition rate, but not further correlated to clearance. In contrast, correlations are strong with the chemical composition of the core particle, suggesting grouping and prioritization for in-vivo testing by surface charge and by core substances. The project NanoGEM (Nanostructured materials – Health, Exposure and Material Properties, 2010 – 2013) involved 19 research institutions and companies, supported by the Federal Ministry of Education and Research (BMBF).

Determination of Nanomaterial Single Nanoparticle and Nanoparticle Aggregation in Complex Biological Environments

Y. Zhang1, S. V. Jenkins2, T. Ingle1, R. Wang1, J. Chen2 and P. C. Howard1. 1NCTR/ORA Nanotechnology Core Facility, Office of Scientific Coordination, NCTR/ FDA, Jefferson, AR and 2Department of Chemistry and Biochemistry, University of Arkansas, Fayetteville, AR.

The plasmonic nanomaterials are attractive for a variety of biomedical applications such as drug delivery and bio-imaging agents. Many of these nanomaterials were introduce to human or animals through intravenous injection and work most effectively following cellular uptake. However, aggregation/agglomeration of nanoparticles will affect their biological behavior, distribution and toxicity. Rapid 'in situ' characterizations are urgently needed to monitor the physical nature of the nanoparticles as they were introduced into blood and intracellular compartment representing extremely complex environments. We proposed that the confocal Raman microscopy (cRM) and hyperspectral dark field microscopy (hpDFM) are able to discriminate the status of the gold nanoparticles (AuNPs) and aggregates in biological fluid blood and cultured macrophage. Citric acid coated Au nanoparticle (50 nm) and nanoparticle aggregates were characterized using transmission electron microscopy (TEM), Zetaizer, Nanoparticle Track Analysis (NTA), UV/Vis spectroscopy and induced-coupled Plasma microsopy (ICP-MS). A series of complementary methods are used to characterize the single Au NPs and status of particle aggregates following incubation in rat blood and cultured macrophage. hpDFM was demonstrated to monitor Au NPs and aggregates in blood in situ, and the spectra were shifted from 540 nm with single nanoparticles to 600-700 nm for the nanoparticle aggregates. In contrast, Au NPs aggregates were detected in the cytosol of macrophages after exposure to Au nanoparticles. Additionally, cRM was demonstrated as complementary to detect Au NPs aggregation state. This detection method was further confirmed by single particle ICP-MS analysis. The study suggested that the hpDFM imaging system is likely robust and can be used to assess physiological status of new plasmonic material in biological system.

CCEF-LRI N1 Project: Oral Toxicity of a Synthetic Amorphous Silica (SAS) in Rats

The test item was a synthetic amorphous silica (SAS) coded NM-200 and available at the EU JRC nanomaterials repository. It is a nanostructured, precipitated SAS. As NM-200 is used as an ingredient in food it was the objective of this study to...
evaluate oral toxicity. The toxicity of NM-200 after daily oral gavage in male rats for 28 days with an additional 14-day recovery period (OECD TG 407; in addition: Si ion and Si particle analysis in selected organs) was tested. Dose levels of 100, 300 and 1000 mg/kg bw (vehicle: 0.5% methylhydroxypropylcellulose) were used. Each group (control, recovery high dose recovery) was kept for the 14 days of post-observation. Body weights, food consumption, the functional observation battery (FOB) and hematology and clinical chemistry did not reveal any treatment-related effects. Also organ weights, necropsy, and histopathological examination did not show any substance-related findings in the high dose group, as compared to controls. Chemical analysis of silicon ions in blood, kidney and liver tissues did not reveal differences between the control and the high dose group. As a result, NM-200 did not cause any substance-related effects at doses up to 1000 mg/kg bw. After oral exposure for 28 days in male Wistar (WU) rats. Therefore, the highest dose tested (1000 mg/kg bw.) was determined to represent the NOAEL in this study. By exemplary TEM analysis no particles of NM-200 could be detected in selected tissues.

602 Modulation of Macrophage Phenotype and Function by Engineered Nanoparticles

V. K. Kodali1, M. H. Littke1, S. C. Tilton1, H. D. Jolley2, J. G. Teegarden1, C. F. Frevert2, S. J. Skerrett2, G. Pounds3 and B. D. Thrall4 System Toxicology, Pacific Northwest National Laboratory, Richland, WA and Department of Comparative Medicine, University of Washington, Seattle, WA.

Epidemiological studies have established a correlation between exposure to ambient air pollution particulates and the incidence of pneumonia and lung infections. Using an in vitro assay of macrophage phagocytic function, we investigated the effects of an array of 18 different ENP types on the ability to macrophages to recognize and phagocytize S. pneumoniae. We identified three major groups of ENPs based on their effect on macrophage function. ENPs which most potently inhibited macrophage phagocytosis included metals and metal oxides which are expected to undergo significant dissolution and have direct cytokotoxic effects. An additional group of materials, including iron oxide and MWCNTs, were found to cause dose-dependent inhibition of phagocytic function, yet had no direct cytokotoxic or proinflammatory effects of their own. The third group of benign ENPs had no effect on direct cytokotoxicity or phagocytic capacity. Oropharyngeal instillation of superparamagnetic iron oxide (SPIO) an ENP from group 2 in C57BL/6 mice confirmed the in vitro results, demonstrating SPIO exposure decreased S. pneumoniae lung clearance in vivo. Macrophage transcriptional response to two ENPs silica and SPIO from class 2 and class 3 before and after bacterial lipopolysaccharide (LPS) challenge showed that while SPIO treatment modulated nearby 500 genes, silica pretreatment regulated only 67 genes. Macrophages exposed to SPIO displayed a phenotype suggesting an impaired ability to transition from an M1 to M2-like activation state, characterized by suppressed IL-10 induction, enhanced TNFα production, and diminished expression of complement and phagocytic receptors. Our results illustrate adverse biological consequences of nanomaterials may not always be directly mediated, but may be manifested by altering susceptibility to other common environmental exposures. Supported by NIEHS Grant U19-ES019544

603 Amphiphilic Polymer-Coated CdSe/ZnS Quantum Dot-Induced Hemolysis and Glutathione Depletion Are Enhanced in Gclm Null Mouse Erythrocytes

C. Carosino1, H. Wang1, C. White1, J. Shang2, X. Gao2 and T. Karaghoglou1
1Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and 2Bioengineering, University of Washington, Seattle, WA.

Quantum dot (QD) nanoparticles have unique fluorescent properties, making them ideal for biomedical imaging. However, QDs contain heavy metals such as cadmium (Cd) and selenium (Se) and have been demonstrated to generate reactive oxygen intermediates, elevate oxidative stress biomarkers such as heme oxygenase-1 (Hmox1) and to cause pulmonary inflammation in vivo. Glutamate cysteine ligase (GCL), the rate-limiting enzyme in glutathione (GSH) synthesis, is important for antioxidant defense. Absence of GCLM (GCL modifier subunit) results in greatly diminished GSH. GCLM polymorphisms exist in humans some of which have been linked to increased risk of cardiovascular disease. We tested the effects of QDs on cultured erythrocytes obtained from Gclm wild-type (+/+) and heterozygous (+/-) and null (-/-) mice. Gclm+/+ and Gclm+/- erythrocytes had diminished GSH as compared to Gclm++/+ erythrocytes (51% and 6%, respectively). Erythrocytes from Gclm++/+ and Gclm+/+ mice greatly resisted QD-induced hemolysis until 48 hours at which point a mild dose-response increase in hemolysis was observed. However, Gclm--/- erythrocytes experienced increased hemolysis as early as 12 hours with all QD treatments yielding equally high levels of hemolysis at 48 hours. Interestingly, after 24 hours of exposure to 40 nM QDs, erythrocytes from Gclm++/+ and Gclm+/+ mice (but not Gclm--/- mice) had higher total GSH levels. This may be due to enhanced formation of GCL holoenzyme in these erythrocytes, thus increasing GSH synthesis. These findings suggest that QDs are capable of producing oxidative stress-mediated hemolysis and raise concerns regarding the effects of prolonged exposure to QDs or other engineered nanomaterials that cause oxidative stress, especially in individuals having genetic or epigenetic modifications to DNA resulting in low expression of GCLM. Supported by NIH Grants U19ES01945, P30ES007053, T32ES007052 and UW DEOHS.
Dermal exposure to metals may result in irritant contact dermatitis. The objective of this study was to examine the in vitro potential of metal-containing nanoparticles to elicit irritant dermatitis in human-derived epidermal keratinocytes (HDEK). Dermal exposure to metals may result in irritant contact dermatitis. The objective of this study was to examine the in vitro potential of metal-containing nanoparticles to elicit irritant dermatitis in human-derived epidermal keratinocytes (HDEK). The cells examined were non-malignant, human epidermal keratinocytes (HDEK) derived from fetal foreskins. The HDEK were cultured as monolayer cultures in 24-well plates. The HDEK were incubated with metal nanoparticles at concentrations ranging from 100 to 1000 μg/mL for 24 hours. The HDEK were then examined for cytotoxicity using a number of different assays, including the MTT assay, the LDH assay, and the Annexin V/7-AAD assay. The MTT assay was used to measure cell viability, the LDH assay was used to measure cytotoxicity, and the Annexin V/7-AAD assay was used to measure apoptosis. The results of these assays were then compared to the results obtained from the control groups, which were cultured in media alone. The results of these assays showed that the metal nanoparticles had a significant effect on cell viability and cytotoxicity. The MTT assay showed that the HDEK treated with metal nanoparticles had significantly lower cell viability compared to the control groups. The LDH assay showed that the HDEK treated with metal nanoparticles had significantly higher cytotoxicity compared to the control groups. The Annexin V/7-AAD assay showed that the HDEK treated with metal nanoparticles had a significantly higher percentage of apoptotic cells compared to the control groups. These results suggest that metal nanoparticles have the potential to elicit irritant contact dermatitis in human skin.
The aim of the study was to assess potential fibrogenic risk upon real occupational exposure to multi-walled carbon nanotubes (MWCNT) using biomarkers tested in preceding animal experiment. The study was conducted at 2 MWCNT-producing enterprises with the same reactor type. 11 workers who had more than 1 year contact with MWCNT aerosol composed the exposure group, the control group consisted of 14 people. Elemental carbon was evaluated in air samples and the CNT presence was confirmed by TEM-analysis. Blood and induced sputum samples were obtained from workers, TGF-β1, KL-6 and osteopontin levels evaluated. To assess the relationship between MWCNT exposure and biomarker levels (age, gender, smoking have been chosen as cofounders) general linear models including main effects and interactions in-pairs were created. The regression coefficients confidence intervals were refined by bootstrap analysis. TWA respirable MWCNT fraction was up to 6.11 mg/m³. TEM has shown the presence of MWCNT agglomerates sized 0.5-10 μm in all air samples. It was found that exposure to MWCNT aerosol at workplaces may alter the fibrosis biomarkers in blood serum and induced sputum. The levels of TGF-β1 in serum were dependent on exposure to MWCNTs (β=10.5, 95%BCa=1.2-51.8), the KL-6 levels in induced sputum were significantly higher in exposure group (β=235.9, 95%BCa=21.2-482). Osteopontin proved to be as an uninformative indicator. Data suggest that MWCNT exposure may lead to the changes in serum and induced sputum samples specific fibrogenic biomarkers content in workers. MWCNT-producing companies have to introduce control measures, as well as provide the adequate medical services organization.
In this project, the synthesis, characterization and antimicrobial activity of calcium alginate nanocapsules containing active ingredients of Matricaria chamomilla and Catharanthus roseus were evaluated. Plants were collected from Puebla, Mexico, and stem, flowers and leaves were used to obtain hexane, chloroform and methanol extracts of both plants, and extracts were dissolved in glycerol and/or water. Synthesis of calcium alginate nanocapsules was developed by microemulsion method, employing the dissolved extracts during the process. The nanocapsules obtained were characterized by Low Voltage Electron Microscopy (LVEM) at 45 kV, Dynamic Light Scattering (DLS) and DRIZZLE method. Antimicrobial activity of extracts and nanocapsules was evaluated employing antibiograms containing 10 μL of suspensions containing 10, 1, 0.1 and 0.01 mg/mL of extracts, upon Staphylococcus aureus and Escherichia coli as Gram positive and Gram negative models, growth in Mueller-Hinton agar and adjusting the inoculum with the standard 0.5 McFarland. Antimicrobial activity of capsules was evaluated employing the same protocol, however their quantity was determined by DLS. Results obtained by LVEM showed that nanocapsules size range was between 35-100 nm, with morphology previously reported for soft spheres (1). DLS demonstrated a hydrodynamic ratio between 13-100 nm, and large aggregates on 1 nm. DRIZZLE analysis showed that aggregates were conformed by nanocapsules in a size range of 50-100 nm. Antimicrobial activity showed that nanocapsules containing chloroform extracts of flower and leaves in M. chamomilla, and nanocapsules containing hexane extracts of C. roseus inhibited the bacterial growth.

605 Estimating an Acceptable Daily Intake of Anthraquinone (AQ) in Paper-Packaged Food

P. Sheehan, K. T. Bogen and A. Singhala. Exposures, Oakland, CA.

AQ is used in the pulping process in making paper and may be present in finished paper products used for food packaging. IARC recently concluded that AQ was carcinogenic based on NTP chronic dietary AQ bioassay results for B6C3F1 mice and F344/N rats, possibly with a genotoxic mode of action (MOA). This conclusion raised questions about AQ in food packaging. Exponent performed a margin of exposure (MOE) evaluation for AQ to estimate derived maximum exposure levels (DMELs) assuming that AQ is a genotoxic carcinogen, and alternatively assuming a scientifically supported nongenotoxic MOA. AQ is not genotoxic as questionable because: 1) tests directly comparing purified vs. commercial sources of AQ found genotoxicity was induced only with AQ containing detectable levels of mutagenic contaminants; 2) NCI found no evidence that dietary AQ exposure of male or female B6C3F1 or B6AKF1 mice increased tumor incidence, and the NCI vs. NTP data for B6C3F1 mice are significantly inconsistent; 3) hydroxy-AQ derivatives have long been hypothesized and 1-hydroxy-AQ is known to promote tumorigenesis by PGE2-mediated target-tissue inflammation (a nonlinear MOA). In view of the contradictory NCI and NTP results for mice, a reference point of 14 mg/kg/day was identified for increased tumor risk based on benchmark dose analysis of NTP rat tumor data. Applying EU guidelines for MOE assessments, and assuming AQ is a genotoxic carcinogen with an MOE of 10,000, yields a DMEL of 98 ug/day. Assuming instead, based on the overall weight of evidence indicating that contaminant-free AQ and its in vivo metabolites are probably nongenotoxic at relevant doses, a DMEL value of 9,800 ug/day is derived using an effective MOE value of 100, the safety factor typically applied for a classical toxicity endpoint. More conservatively under this interpretation, a DMEL value of 980 ug/kg/day was derived by applying an effective MOE value of 1,000 to address uncertainty concerning any form of genotoxicity that might dominate an otherwise predominant inflammation-mediated MOA expected for AQ and its metabolites.

606 Updated Dose-Response Assessment and Derivation of Acceptable Drinking Water Levels for O-Phenylphenol

The general population may be orally exposed to O-phenylphenol (OPP) or its water-soluble sodium salt (SOPP) through industrial applications that result in food and drinking water contact. Both an oral RfD and a cancer slope factor have previously been derived for OPP-induced bladder tumors in male rats, the most sensitive tested species and sex. Lacking from these analyses is a dose-response assessment for bladder hyperplaasia, a precursor key event, for consideration as a point-of-departure for a threshold mode of action. In contrast to previous assessments, the key study in the present evaluation was considered the Nho et al. (2002) chronic oral study with SOPP in F344 rats, since it included additional and lower dose levels than other studies in F344 or SD rats that examined bladder lesions, thus potentially increasing confidence in quantitative dose-response modeling. Use of data for the more potent SOPP is supported by limited data suggesting SD rats may be more susceptible to bladder toxicity than F344 rats, the only strain tested chronically. The relationship of the necessary non-cancer precursor key events (cytotoxicity and regenerative hyperplasia) and the lack of DNA-OPP adducts in target tissue in vivo support the most plausible mode of action for OPP or SOPP being the ability of the reactive metabolite, phenylbenzoxquinone, to react with the urothelium, possibly forming urothelial protein adducts if detoxification pathways become saturated. Benchmark dose modeling suggests only a marginal (1.5x) increased potency of SOPP compared to OPP in F344 rats when high doses associated with sodium ion-induced bladder calculi are excluded. The oral RfD for OPP of 1 mg/kg/day based on a human equivalent benchmark dose (BMDL10) of 33 mg/kg-day for bladder hyperplasia corresponds to a total allowable concentration of 7 mg/L in drinking water. A short-term exposure level (STEL) of 20 mg/L was derived based on maternal toxicity in rats, since the weight-of-evidence does not indicate any specific effects on reproduction or development.

607 Mode-of-Action Evaluation and Oral Risk Assessment of Hydroquinone

The general population may be exposed to hydroquinone through dietary sources, pharmaceuticals, drinking water, cigarette smoke and metabolism of benzene and phenol. Exposure to hydroquinone may also occur by ingestion of arbutin (hydroquinone-1-O-β-D-glucopyranoside), a naturally-occurring conjugate of hydroquinone present in plant-derived foods. A recent oral risk level incorporating current risk assessment methodology and new data was not identified for hydroquinone and thus was the purpose of the present assessment. Due to insufficient quantitative data in humans, hazard identification relies on laboratory animal data. In chronic bioassays, hydroquinone induced atypical tubule hyperplasia and benign neoplasms in the kidneys of male F344/N rats dosed orally either by gavage or diet, and in kidneys of male B6C3F1 mice dosed via the diet. The renal lesions in male F344/N rats occurred only in areas of the kidney with severe or end-stage chronic progressive nephropathy. In female F344/N rats, a dose-related increase in mononuclear cell cellularity was observed; however, the incidences in the exposure groups were within the historical control range. Findings of hepatic adenomas in mice were not consistent between two chronic bioassays; hydroquinone exposure was associated with hepatocellular adenomas in female B6C3F1 mice in one study and in male B6C3F1 mice in another study. No increases in hepatocellular carcinomas were observed in either chronic bioassay. The combined incidence of renal tubule adenoma and atypical tubule hyperplasia observed in the male F344/N rats was selected as the critical effect with a resulting Human Equivalent BMDL10 of 3.1 mg/kg-day. The evidence for a prooxidant, cytotoxic mode of action potentiated in male F344 rats by chronic progressive nephropathy supports a threshold. Recognizing the F344 rat as being a multiple-site and species carcinogen, a hydroquinone nephrotoxicity relative to other animal models, an interspecies uncertainty factor (UF) was not applied. Using a 10x UF to account for possible human variability, an oral RfD of 0.3 mg/kg-day was determined for hydroquinone.

608 Derivation of Acceptable Drinking Water Levels for N-Nitrosomorpholine That Accommodate Susceptibility during Early Life Stages

N-Nitrosomorpholine (NMOR) is a drinking water contaminant that may be present in source water and as a byproduct of disinfection. Successful methods of remediation have not been identified. The general population can also be exposed to NMOR through tobacco, air, food and consumer and industrial products. The purpose of this assessment was to establish acceptable lifetime drinking water levels for NMOR that account for potential increased susceptibility during early life stages (i.e. birth to 16 years of age). No epidemiology studies that specifically evaluated NMOR were identified, but rubber industry exposure to elevated combined NMOR/N-nitrosodimethylamine concentrations in the workplace was associated with increased relative risks for cancer of the esophagus, oral cavity, and pharynx. In laboratory animals NMOR is a multiple-site and species carcinogen. Target tissues following oral exposure include the liver, esophagus, nasal cavity, lung, and kidneys. Hepatocellular tumors were seen in both sexes of NMRI mice, rats of several strains, and Syrian golden hamsters. Dose-response assessment identified the liver in rats as the most sensitive target tissue and species. The weight-of-evidence for a mutagenic mode of action included mutagenicity, clastogenicity, and oxidative DNA damage in vitro, in vivo evidence for genotoxicity in the liver included the induction of micronuclei, DNA adducts, and unscheduled DNA synthesis. A 103 cancer risk level was estimated from the human equivalent benchmark dose (BMDL10) of 250 μg/kg-day based on the incidence of hepatocellular carcinomas in female F344 rats from a chronic drinking water study in which the exposure commenced at eight weeks of age. After adjusting for potential increased susceptibility by post-natal life stage, the drinking water unit risk was 2.9 x 10-5/L-1 corresponding to a total allowable concentration for NMOR of 40 ng/L in drinking water. Contemporary methods permit quantification of nitrosamine in water at less than part-per-trillion levels.

SOT 2014 ANNUAL MEETING 162
Arsenic, boron, nickel, and vanadium are four elements for which data suggest beneficial roles in physiological processes in some species; however, the data are incomplete in humans and nutritional levels such as Recommended Dietary Allowances (RDAs) have not been set for any of these elements. Key information for these elements has been evaluated, including their potential essentiality and toxicity, current areas of research, and the basis for the following human health benchmarks: Institute of Medicine’s Tolerable Upper Intake Level; EPA’s Reference Dose, Maximum Contaminant Level, or lifetime Health Advisory; Agency for Toxic Substances and Disease Registry’s Minimal Risk Level; California EPA’s Public Health Goal; International Programme for Chemical Safety’s Tolerable Daily or Weekly Intake; and other benchmarks developed by States or private organizations. An analysis of the human health benchmarks shows that the range of human health benchmarks for boron and vanadium are within a 3-fold difference between the highest and lowest benchmarks for boron and within a 6-fold difference for vanadium, while there is a large range between the human health benchmarks for arsenic and nickel (10,000-fold difference for arsenic and 254-fold for nickel). A comparison between the human health benchmarks and the average adult intake of the elements in the U.S. revealed that for boron, vanadium, and nickel, all of the benchmarks exceed the mean adult intake by 4- to 150-fold, while for arsenic, the mean adult intake exceeds two of the human health benchmarks by 100- to 1000-fold. An analysis of the reasons for the large spread between the human health benchmarks for arsenic is also presented in this work.

The Texas Commission on Environmental Quality (TCEQ) has developed a conservative 24-hour AMCV based on Glaser et al. (1990) study in comparison studies available in the CrVI toxicological database. Consequently, the TCEQ has only evaluated 24-hour data in terms of comparability of the resulting annual averages to chemical-specific chronic Air Monitoring Comparison Values (AMCVs) to evaluate the potential for chronic health and/or neurological effects in workers. Overall, through integration of epidemiology, monkey, and toxicokinetic data, our preliminary WoE analysis suggests that predicted brain concentrations in welders at Mn exposure concentrations of 100-200 μg/m³ are not likely to lead to more than a very small (10%) increased risk of slight to mild (subclinical) neuromotor effects; therefore, a Mn occupational exposure level of 100-200 μg/m³ is protective for welding workers. Our results are in contrast to the recently adopted American Conference of Industrial Hygienists (ACGIH) 8-hour time-weighted average threshold limit value (TLV-TWA) for respirable particulate Mn of 20 μg/m³. A more statistically robust approach for derivation of the TLV (i.e., benchmark dose) would be more consistent with the current standard of risk assessment practice, and would result in a TLV approximately 5- to 10-fold higher.

The European Chemical Agency (ECHA) previously released manufacturer/importer REACH (Registration, Evaluation, Authorization and Restriction of Chemicals) chemical registration files, making available the Derived No Effect Levels (DNELs) for hundreds of substances. The DNEL is defined as “the level of exposure above which humans should not be exposed” and needs to reflect the likely route(s), duration and frequency of exposure. Specifically, worker DNELs are levels intended to protect workers during manufacture. Typically, DNELs are developed by industry using ECHA’s guidance; the registrant has the final decision on the selection of the key studies, endpoints of concern, and the assessment factors to account for sources of uncertainty. By comparison, currently accepted occupational exposure limits (OELs), such as permissible exposure limits (PELs) or threshold limit values (TLVs) developed by the Occupational Safety and Health Administration (OSHA) and the American Conference of Industrial Hygienists (ACGIH), respectively, may have been derived using different methods, some of which incorporate economic and technical feasibility concerns and/or health-based assessment. In addition, these other occupational values may have been based on different toxicological data and endpoints. Because the worker DNELs may potentially be used as guideline levels for worker exposures in Europe and have the potential to become de facto OELs in other regions due to the global extent of REACH, a comparison analysis between the long-term inhalation DNELs for the worker population and OELs developed within Europe and by OSHA and ACGIH was completed for eighteen common inorganic and insoluble metals (in powder form). This analysis showed that in most cases the long-term inhalation worker DNELs for metals that were used for comparison were equivalent to or lower than the accepted OELs.

Although there are thousands of chemicals in use in the US, there are only several hundred Occupational Exposure Limits (OELs) for these chemicals. Many chemicals have sufficient toxicological data to generate OELs. However, there is still a limited pool of experts to evaluate the data and create a consensus-based OEL. One such mechanism is the approach used by the Workplace Environmental Exposure Level (WEELOEL committee under the Occupational Alliance for Risk Science (OARS), a collaborative initiative managed by the not-for-profit Toxicology Excellence for Risk Assessment (TERA). The goal of this arrangement is to promote worker health through increased access to high quality OELs, enhancement in methods for establishing worker-health exposure guidelines, and education and training in occupational risk assessment methods. The OARS-WEELOEL Committee is...
a volunteer group of toxicologists and industrial hygienists from academic, governmental, corporate, and consulting backgrounds, who create health-based guideline values for chemical agents, called WEELs. WEELs are limits that represent “safe” or “relatively safe” air concentrations that will protect most workers from adverse health effects related to occupational chemical exposures over a lifetime. They can be used across industries as a central tool for worker health protection. OARS promotes the development of WEELs by encouraging stakeholder engagement. This is achieved through open and transparent processes, invitation of stakeholders to attend science deliberations, free online access to WEELs and associated documentation, and active outreach, while using a scientifically-based methodological approach to evaluate the toxicological data including the application of appropriate safety & uncertainty factors. The WEEL development process will be explained using a selected WEEL as an example.

614 Derivation of a Human Equivalent Concentration for Diacetyl for Hyperplasia of the Bronchiolar Epithelium

R. Adami1, M. Glynn1, L. S. Pierce1 and B. L. Finley2. 1Cardno ChemRisk, Chicago, IL and 2Cardno ChemRisk, Brooklyn, NY.

Severe respiratory disorders, including bronchiolitis obliterans (BO), have been alleged in some cases in which workers and consumers were exposed to diacetyl in microwave popcorn and other products. Recently, results have become available from an unpublished study conducted by the National Toxicology Program in which rodents were exposed to diacetyl for 6 hours per day, 5 days per week for 13 to 14 weeks. Using these data, we performed a BMC analysis to estimate the diacetyl concentration associated with a 10% excess risk (BMCL10) of hyperplasia of the bronchiolar epithelium and a 95% lower confidence bound concentration estimate (BMCL5%) of the endpoint of interest in the upper airways (minimal to mild peribronchial lymphocytic inflammation). Our range of HECs is based on a sensitive endpoint and new-toxicity factors. The estimated BMCL10 values were adjusted to human equivalent concentrations (HECs) using the following procedure: 1) the computed BMCL10 were converted to an equivalent exposure of 8 hours per day; 2) a scrubbing factor was applied using the computational fluid dynamics model developed for diacetyl for rodents and humans; and 3) a regional gas dose ratio (RGRD) was calculated and applied using EPA methods. Based on our analysis, the BMCL10 ranged from 39.7 ppm to 92.9 ppm, and the BMCL5% ranged from 31.9 ppm to 60.4 ppm over all models; the HECs were estimated to range from 15.9 ppm to 30.1 ppm. The results of our analysis were consistent with those reported by Maier et al. (2010), which calculated an HEC of 1.8 ppm for an endpoint of interest in the upper airways (minimal to mild peribronchial lymphocytic inflammation). The developmental effects of NMP are well studied in rats following oral, inhalation, and dermal exposure routes. A hazard identification and dose-response assessment was conducted. Based on consideration of the dose-response range covered, on the inclusion of late-gestational exposures, and on consistency with current test guidelines, the oral and inhalation studies were considered to be more robust than the dermal study. Fetal body weight changes in rats are considered to be the most sensitive endpoint for NMP. However, this effect appears to be reversible, and because it reflects a cumulative response, is not expected to result from acute (1-day) exposures. Because other developmental endpoints (e.g., delayed ossification) were highly variable and occurred only at higher internal doses, these effects were considered secondary to fetal body weight changes and an inappropriate endpoint for risk assessment. Instead, two developmental endpoints were identified as suitable for human health risk assessment: (1) for acute exposures, the increased incidence of skeletal malformations, an effect noted only at doses that were toxic to the dam and fetus, was assessed using the maximum daily AUC (as estimated using a PBPK model); and (2) for repeated exposures to NMP, changes in fetal body weight were assessed using cumulative AUC. Benchmark dose methods were used to estimate a point of departure for skeletal malformations (BMDL5%) and fetal body weight changes (BMDLSD). Where possible, data from multiple studies were pooled to increase the predictive power of the data set. BMDL5% values for skeletal malformations ranged from approximately 1200-1500 mg/kg*hr (in terms of daily maximum AUC). Similarly, BMDLSD values for fetal body weight changes ranged from approximately 270-710 mg/L*hr (in terms of cumulative AUC). These BMD values can be used to support margin-of-exposure analyses for human health risk assessments of NMP conducted in terms of internal dose.
Cocamide diethanolamine (DEA) has been listed on the State of California’s Proposition 65 List as a chemical known to the state to cause cancer. This listing is based on the results of a National Toxicology Program (NTP) 2-year dermal carcinogenicity study which found clear evidence of carcinogenic activity in B6C3F1 mice based on increased incidences of liver neoplasms in both sexes, and increased incidences of renal tubule neoplasms in males. Although controversy exists regarding the relevance of the NTP study to humans, industries are obligated to comply with the Proposition 65 labeling requirement and drinking water discharge prohibition, unless they are able to demonstrate that cocamide DEA levels in their products are below a specific No Significant Risk Level (NSRL). The State of California has not published a NSRL for cocamide DEA. In accordance with the guidelines of California EPA, ToxServices derived a NSRL of 13.3 μg/day for cocamide DEA based on the incidence of hepatocellular carcinoma or hepatoblastoma in female mice obtained from the NTP carcinogenicity study using benchmark dose modeling. The U.S. EPA’s Benchmark Dose Software (BMDS) was used to model the cancer slope factors for the combined incidence of hepatic neoplasms. These slope factors were scaled to human equivalent doses and used to determine the lifetime average daily dose that would result in one excess cancer case in an exposed human population of 100,000. This NSRL value can be used as part of an exposure and safety assessment to evaluate compliance with Proposition 65 requirements for products sold in the State of California.

Titanium dioxide (TiO2) is widely used as a colorant in consumer products. Recently, TiO2 was listed by the State of California on the list of chemicals known to the state to cause cancer or reproductive toxicity (i.e., Proposition 65), due to its classification by the International Agency for Research on Cancer (IARC) as a Group 2B possible human carcinogen. Products containing Proposition 65 substances are subject to labeling requirements, unless exposure is below California’s “safe harbor” level. For potential carcinogens, the safe harbor level is termed the No Significant Risk Level (NSRL). As no NSRL for TiO2 has been established by California, we derived a NSRL according to CalEPA guidelines.

We performed benchmark dose (BMD) modeling on combined lung tumor incidence data from 3 published long-term, inhalation-route rat studies. BMD modeling was based on TiO2 particle deposition in the lung, expressed as particle surface area per gram of lung tissue. The surface area metric resulted in best fit of the data and normalized strain-specific anatomic differences and differences in exposure duration across studies. This approach also accounted for the impact of different particle sizes (which have different surface areas). When extrapolating modeled animal doses to human doses, a particle dosimetry model was used to account for particle size distribution, respiration pattern, and deposition and clearance mechanisms specific to humans. Using this approach, separate NSRLs were calculated for TiO2 particles with different surface areas. For fine TiO2 particles (1-2.5 μm), the NSRLs is 27 μg/day, and for ultrafine particles (< 0.1 μm) the NSRL is 2.8 μg/day. The derivation of two NSRLs is consistent with observations in animal inhalation studies that indicate that TiO2 toxicity is particle size-dependent. Although route-specific safe harbor levels exist for other chemicals, this is the first instance of particle size-specific Proposition 65 NSRLs and thus represents a novel, toxicologically-driven approach to safe harbor determination.
Tetrabromobisphenol A (TBBPA) is an important flame retardant used primarily as a reactive chemical in the synthesis of printed circuit boards. In this application, it is incorporated into the epoxy and serves a vital role in fire safety. Despite its use primarily as a reactant with limited release to the environment, some concerns have been raised regarding exposure. The objective of this study was to develop non-cancer based toxicity values (reference doses, or RfDs) and to compare such to appropriate estimates of human exposure. An array of potential RfDs was developed using data reported as part of a recent 2-year bioassay conducted by the National Toxicology Program (NTP); these data indicated that chronic exposure to TBBPA induced hepatic and kidney lesions in male mice, and forestomach lesions in male and female mice. In rats, notable lesions included uterine hyperplasia and rete ovarii cysts at study termination, as well as decreased serum thyroxin levels after 13 weeks of exposure. These endpoints were modeled using benchmark dose (BMD) modeling; the 95% lower confidence interval values (BMDLs) were derived with a benchmark response set to 10% extra risk for dichotomous endpoints and one standard deviation for continuous endpoints. BMDL values were adjusted by allometric scaling and subsequently reduced by uncertainty factors to derive RfD values ranging from 0.03 to 3.0 mg/kg-day. In comparison, exposure estimates ranged from 0.0000003 to 0.000007 mg/kg-day based on an evaluation of exposures for infants (based on intakes due to breastmilk and solid/dust), and for children, adolescents, and adults (based on intakes due to diet, drinking water, and soil/dust ingestion). The total daily exposure estimates were generally driven by soil/dust ingestion for most receptors (and by breastmilk for infants) in reasonable maximum and upper-end regulatory default exposure scenarios. These data indicate that there is a sufficiently large margin of safety between potential RfD values and current exposure to TBBPA.

**Provisional Advisory Level (PAL) Development for 4-Aminopyridine**

S. Milaney1, L. D. Keller2, D. C. Dormann3, C. Bain4 and F. Adeshina5.

PAL values developed for hazardous materials by the US EPA represent general public emergency exposure limits for oral and inhalation exposures corresponding to three different severity levels (1, 2, and 3) for 24-hr, 30-d, 90-d, and 2-yr durations. PAL 1 represents the threshold for mild effects; PAL 2 represents the threshold for serious, irreversible or escape-impairing effects; PAL 3 represents the threshold for lethal effects. PALs have not been promulgated nor have they been formally issued as regulatory guidance, but are intended for use at the discretion of risk managers in emergency situations when site-specific risk assessments are not available. Application of PAL protocols has been performed for 4-aminopyridine to estimate oral exposure limits; inhalation PAL values are not recommended (NR) due to insufficient data. 4-Aminopyridine blocks voltage-sensitive potassium channels in nerves by binding to sites within the channels. PAL values for 4-aminopyridine are based on clinical nervous system effects in humans using the SOP and QAPP requirements. The mention of trade names does not imply EPA endorsement.

4-Aminopyridine oral PAL 1 values are 0.25 mg/L for 24-hr, and 30-d, 90-d and 2-yr.

4-Aminopyridine oral PAL 2 values are 1.0 mg/L for 24-hr, and 30-d, 90-d and 2-yr.

4-Aminopyridine oral PAL 3 values are 1.5 mg/L for 24-hr, and 30-d, 90-d and 2-yr.

**Provisional Advisory Level (PAL) Development for Chlorine Gas**

S. Milaney1, L. D. Keller2, D. C. Dormann3, C. Bain4 and F. Adeshina5.

PAL values developed for hazardous materials by the US EPA represent general public emergency exposure limits for oral and inhalation exposures corresponding to three different severity levels (1, 2, and 3) for 24-hour, 30-day, 90-day, and 2-year durations. PAL 1 represents the threshold for mild effects; PAL 2 represents the threshold for serious, irreversible or escape-impairing effects; PAL 3 represents the threshold for lethal effects. PALs have not been promulgated nor have they been formally issued as regulatory guidance, but are intended for use at the discretion of risk managers in emergency situations when site-specific risk assessments are not available. PALs are developed with appropriate human and animal data, using standard protocols based on the SOP and QAPP requirements.

Chlorine is a greenish-yellow gas with a pungent odor, a strong oxidizing agent, and very reactive. Large amounts are made worldwide, primarily for use in making PVC plastics, but also insecticides, pesticides, and bleach. It has been used as a chemical warfare agent. Chlorine gas is a contact irritant, and in both humans and animals, the respiratory tract is the primary target for toxicity. Effects include sensory irritation, increased airway resistance, and lesions in the lungs and other organs. Death follows quickly at high concentrations. PALs were derived using controlled studies with monkeys, rats, mice, and humans. The resulting inhalation PAL 1, PAL 2, and PAL 3 values, respectively, for a 24-hour exposure are 0.096, 0.19, and 5.1 ppm; for a 30-day exposure are 0.018, 0.11, and 0.32 ppm; and for a 90-day exposure are 0.036, 0.036, and 0.32 ppm. For a 2-year exposure, the PAL 1 and PAL 2 are 0.0346 and 0.0346 ppm, respectively; a 2-year PAL 3 was not developed due to insufficient data. Oral PAL values were not developed. The PAL values were approved by the Expert Consultation Panel for PALs in April 2013.

**Provisional Advisory Level (PAL) Development for Chronic Health Effects following Acute Exposures to TICs**

D. Winkel1, B. Hawkins1, J. Jackson1 and L. E. Rossell1.

1Battelle Memorial Institute, Columbia, OH and 2US Army Public Health Command, APG, MD.

Joint Chemical, Biological, Radiological, and Nuclear doctrine requires military commanders to minimize total risk in operational planning and execution. Incorporation of Military Exposure Guidelines (MEGs) into risk estimates can provide a mechanism to consider short- and long-term chemical exposure risks. However, current MEGs (and civilian guidelines) do not address chronic non-cancer health effects that may result from a single acute exposure. This gap is a source of concern for planners in the medical community, as these effects may have im-

**Development of Exposure Guidelines for Chronic Health Effects following Acute Exposures to TICs**

D. Winkel1, B. Hawkins1, J. Jackson1 and L. E. Rossell1.

1Battelle Memorial Institute, Columbia, OH and 2US Army Public Health Command, APG, MD.
In its current state, dose-response modeling employs analytical methods that include numerous candidate mathematical functions from which the analyst must choose in order to develop toxicity values such as reference doses and slope factors. Smoothing regression splines offer a much simpler approach to dose-response modeling and have a number of desirable properties. They are flexible, require no pre-specification of a functional form, achieve optimal fit under a wide range of circumstances, and need little-to-no intervention by the analyst. In addition, the same smoothing regression splines can be used to unambiguously identify various types of points of departure (e.g., threshold and benchmark doses), as well as address important questions about a dose-response curve such as its overall non-linearity and non-linearity within specific regions. We compared more traditional modeling approaches with smoothing splines to illustrate how the latter provide a unified mathematical framework for estimating dose-response functions and critical quantities and often provide superior performance. For example, we compared threshold doses estimated via smoothing regression splines with other published bilinear models. Although smoothing regression splines regularly provide similar results to older approaches, when differences emerge the smoothing spline curve compares favorably to existing guidelines (both military and civilian) in that only severe exposures have the potential to cause chronic health effects. This approach is believed to be novel and may be applicable to other TICs with a limited data set.

**629 Is Nonparametric Method Suitable for Benchmark Dose Analysis Using Typically Available Toxicity Study Data?**

K. Shao, NCEA, U.S. Environmental Protection Agency, Research Triangle Park, NC.

Model uncertainty is one important problem associated with benchmark dose (BMD) analysis and has gained much attention in recent development of BMD methodology. In addition to the model averaging approach, which produces one weight-averaged BMD/BMDL estimate according to the posterior model weights, nonparametric method has been proposed as another alternative to avoid issues associated with model uncertainty. One advantage of nonparametric method for BMD estimation is that it does not assume any particular format for the dose-response model. However, it has some limitations. This study addresses two questions: (1) Is nonparametric method as reliable as parametric methods for deriving BMD/BMDL estimates from typically available dose-response data? (2) What are the general toxicity study design criteria that are suitable for nonparametric BMD analysis? These two questions are going to be answered based on results from a large simulation study using both dichotomous and continuous endpoints. The adequateness of the BMD and BMDL estimates is judged by their accuracy and coverage rate. Given a typical chronic study setting (i.e., 200 animals exposed for 2 years), the simulation study will mainly examine how dose spacing and animal distribution among dose groups can affect the nonparametric BMD analysis. Preliminary results suggest that the dose-response data from current toxicity studies may present difficult challenges for nonparametric analysis due to the limited number of dose groups used in most toxicity bioassays.

**630 Standardized Benchmark Dose Calculation: Opportunities to Inform Science-Based Decisions in Human Health Assessments**

S. Escher1, I. Tluczkwicz1, M. Batke1, R. Kühne1, R. Ebert2, G. Schüürmann2, and I. Mangelsdorf1. 1Chemical Risk Assessment, Fraunhofer Institute for Toxicology and Experimental Medicine - ITEM, Hannover, Germany and 2Ecological Chemistry, The Helmholtz Centre for Environmental Research, Leipzig, Germany. Sponsor: C. Dasenbrock.

The TTC concept derives thresholds to structural groups of compounds below which a risk for human health is not assumed for a life-time exposure. Thresholds were derived by analyzing datasets of oral in vivo studies to which the Cramer decision tree was applied. Inhalation is, however, an important route in human risk assessment e.g. for workers and consumers. The application of the Cramer decision tree to datasets of repeated-dose studies with inhalation exposure resulted in very low thresholds compared to oral TTC values. Reasons might be route specific differences e.g. an observed high sensitivity of the respiratory tract to local effects (Carthew et al. 2009, Escher et al. 2010). We present an integrative approach to derive inhalation specific threshold values, which are based on a dataset of 296 chemicals with repeated-dose toxicity studies (www.fraunhofer-repdose.de). Systemic and local NOEC values were discriminated. Groups of compounds with specific structural features (SF) were identified based on atom centered fragments (Kühne et al. 2009). Few SF were explicit for local or systemic activity indicating that this mode of action is not a determining factor. The structural and toxicological boundaries of the initial SFs were further evaluated considering differences in absorption, published data on mechanism/metabolism and sensitive targets/effects observed in the in vitro studies. 28 SF groups resulted, 9 low (L) and 19 toxic (T) groups. About 20% of the compounds are, however, not yet grouped. Compared to the Cramer classes the T and L-groups better discriminate low toxic and toxic compounds. Two clearly distinguished TTC values are proposed.

Threshold of Toxicological Concern (TTC) is a tool developed to provide scientific advice about possible human health risks from exposure to low levels of chemicals in the diet, when specific toxicity data are not available. It provides health protective human exposure threshold values for chemicals from a three broad ranges of structural categories (Cramer classes).

The aim of the work, as part of the EU COSMOS Project, has been to adapt the TTC concept and extend its applicability to cosmetics which are applied to the skin. A decision tree approach has been developed based on estimated usage/skin exposure, maximum possible dermal absorption derived from the J max prediction or experimental absorption data to estimate systemic dose for ranking against TTC, incorporating structural categories and Cramer class. A new dermal absorption database enriched with cosmetics-related chemicals has been established; the chemical space and domain of cosmetics-related chemicals have been also defined. Where available, experimental dermal absorption data have been ranked with predicted Jmax values. Also assessed is the importance of local metabolism in determining differences between the oral and dermal exposure routes and its influence in decision making and use of TTC. The potential for use of TTC for cosmetics is indicated and the findings support application of TTC approaches by regulators.

Supported by the EU FP7 COSMOS Project.

**632a How Much Do Shapes of Toxicological Dose-Response Relationships Vary?**

A re-analysis of a large number of historical dose-response data for continuous end points showed that the shapes of the dose-response relationships were surprisingly homogenous. The datasets were selected on the sole criterion that they were expected to provide relatively good information on the dose-response shape, and included a variety of end points and both in vivo and in vitro studies of various types. Both the four-parameter exponential and Hill model adequately described all toxicological dose-response data we considered. For a given endpoint and study type, dose-response shapes did not differ statistically significantly among chemicals in the in vitro studies considered, while a mild among-chemical variation in the steepness parameter seemed to be present in the in vivo studies. These findings have various practical consequences. For continuous endpoints, model selection in the BMD approach is not a crucial issue. The often-applied approach of using constraints on the model parameters to prevent "infinite" slope at dose zero in fitting a model is not in line with our findings, and appears to be unjustified. Instead, more realistic ranges of parameter values could be derived from re-analyses of large numbers of historical dose-response datasets in the same endpoint and study type, which would then be used as parameter constraints or informative priors in the analysis of future individual datasets. This approach would be particularly useful for weak datasets (e.g. few doses, much scatter). In addition, this approach may open the way to use fewer animals in future studies. Finally, we argue that distinctions between linear, sub/supralinear or thresholded dose-response shapes, based on visual inspection of plots, are not biologically meaningful nor useful for risk assessment. This abstract does not necessarily reflect EPA policy.

**632b Variation in Scaling Factors Used for In Vitro to In Vivo Extrapolation (IVIVE) and Its Impact on Internal Dose in Rats: A Case Study with Bromodichloromethane (BDCM)**

Physiologically based pharmacokinetic (PBPK) models can include values for metabolic parameters extrapolated from in vitro studies using scaling factors (SF) such as mg of microsomal or cytosolic protein per gram of liver (MPPGL and CPPGL) and liver volume (FVL). Variation in SF values impacts metabolic parameter estimates (Vmax) and hence estimates of internal dose used in dose response analysis. The impact of variation in MPPGL, CPPGL and FVL on toxicologically relevant dose metrics was assessed using a rat PBPK model for BDCM and Monte Carlo analysis. Values for SF were determined experimentally or obtained from the literature. Dose metrics examined included area under the curve for blood BDCM (AUCV) and amount metabolized in liver via detoxification (oxidative, AM1) and toxication (glutathione, AM2) pathways. At relatively low doses (5 mg/kg) all dose metrics evaluated were changed by less than 20%, probably because metabolism is blood flow-limited at lower doses. In contrast, at biossary dose levels (100 mg/kg) differences of 5-, 3- and 9-fold were observed for AUC, AM1 and AM2, respectively. Sensitivity analysis for both AUC and AM1 revealed that MPPGL and FVL were highly and moderately influential parameters, respectively. The larger difference observed for AM2 is likely a consequence of higher variability in CPPGL (3 times higher coefficient of variation compared to other SF) suggesting that more accurate estimates are needed for CPPGL and distribution of cytosolic enzymes in rat liver. This analysis demonstrates: 1) that variability in SF used for IVIVE of metabolic rate parameters can have a significant impact on estimates of internal dose metrics at toxicologically relevant doses, and 2) the need to evaluate both uncertainty and variability for scaling factors used for IVIVE. (This abstract does not reflect USEPA policy).

**632c Toluene PBPK Models to Extrapolate Neurological Effects between Rats and Humans, across Acute Durations and Severity Categories**

Acute exposure to volatile organic compounds (e.g., toluene and ethanol) impairs neurological function. The degree of impairment has been quantified as a dose-response relationship using a variety of behavioral tasks, including reaction time (RT). Brain toluene concentrations (Br-TC) have been related quantitatively to blood ethanol concentrations (BEC) via changes in RT associated with each chemical (Benignus et al., 2005). A BEC of 0.08 g/dl (legal intoxication) and a Br-TC of 119 µM both produce a 13% reduction of RT. The current interim level 2 acute exposure guideline levels (AEGL-2) are based on a 70-min exposure to 2400 ppm toluene, and results in an effect level consistent with a BEC of 0.17 g/dl, as determined by our analyses. An alternate set of AEGL-2 values based on a doubling of RT in Long-Evans rats (1600 ppm for 34-mins) was determined using a rat PBPK model (Kenyon et al., 2008). The rat Br-TC at the end of exposure (535 µM; 49.2 mg/kg) was reduced by a factor of 3 to derive the target concentration. AEGL-2 values (10- and 30-min, 1-, 4- and 8-hr durations) were determined from the target concentration with a human (GPAT: Benignus et al., 2006). The same PBPK model construct was applied to determine AEGL-3 values based on a rat lethality NOAEL. The estimate of a human LC-50 was also derived for comparison to a Dutch Probit method for land-use planning. The final results were toluene exposure levels for durations from 10-mins up to 8-hrs at three levels of severity in humans: a clear decrement in RT; the threshold for lethality; and an LC-50. These analyses led to a quantitative methodology to inform revisions of AEGL values for toluene which were reviewed and approved by the National Academy of Sciences. The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the US EPA.

**632d Modeling of Blood Lead Levels in Astronauts Exposed to Microgravity-Accelerated Bone Loss**

H. D. Garcia1, J. S. Tuji1 and J. T. James1, 1Wyle Laboratories, Houston, TX, 2Exponent Corp., Bellevue, WA and 3NASA (Retired), Houston, TX.

Setting Spacecraft Water Exposure Guidelines (SWEGs) for lead (Pb) in spacecraft drinking water has special challenges related to estimating blood lead levels (PbB) during the increased release of lead into systemic circulation via microgravity-in-
duced bone loss. The effects on the PbB of Pb in drinking water (PbW), Pb released from bones, and change in lead exposure before, during, and after spaceflight were evaluated using a physiologically based pharmacokinetic (PBPK) mathematical model (2013, Aviation, Space, & Environmental Medicine 84:1229-1234) that incorporates environmental lead exposure for PbB, and in flight and calculates temporarily increased rates of osteoporosis during spaceflight. The model predicts that the average American astronaut in 2030 (the earliest anticipated launch date for a long-duration mission) would have a PbB of 1.7 μg/dL at launch and that PbB levels would decrease in microgravity at PbW values less than about 9 μg Pb/L, because of reduced lead exposure during spaceflight. Currently, PbW on the International Space Station (ISS) averages <1 μg Pb/L. A SWEG of 9 μg Pb/L would protect most astronauts on long-duration spaceflights by ensuring that PbB values will not exceed pre-launch levels. At in-flight PbW concentrations <9 μg Pb/L, Pb concentrations in both bone and blood would gradually decrease below their pre-launch values. On the other hand, astronauts who have high concentrations of Pb stored in bones (an unlikely possibility) could experience increased PbB levels in microgravity due to release of lead from bones. While the resultant in-flight PbBs would depend on their pre-flight bone lead levels, their PbBs will not be significantly further elevated (<1 μg/dL) by consuming water with a PbW of <9 μg/L. Because individuals with a history of clinical lead poisoning would likely have high concentrations of lead stored in their bones, we recommend that such individuals avoid exposure to microgravity of more than a few days' duration to prevent in-flight lead poisoning.

In 2007, the intentional adulteration of pet food products with melamine and cyanuric acid, caused kidney failure and death of hundreds of cats and dogs in the U.S.. Early investigation revealed that co-exposure to these compounds can elicit nephrotoxicity due to the formation of highly insoluble melamine cyanurate (MC) crystals in the nephrons. In response to these events, and later events in China in 2008 involving the contamination of infant formula with melamine, it became apparent to regulatory agencies, including the U.S. Food and Drug Administration (FDA), that further in-depth studies addressing the toxicity of melamine, cyanuric acid, and their combination were warranted. We report the design and outcome of studies conducted at the FDA in male and female F344 rats on the combined nephrotoxicity of melamine and cyanuric acid. The current tolerable daily intakes (TDI) established by the FDA for dietary exposure to melamine and its derivatives are based upon a NOAEL of 63 mg/kg bw/day for dietary exposure to melamine in a 13-week rat study. The data from our current studies demonstrate that in F344 rats, oral co-exposure to melamine and cyanuric acid results in a NOAEL value 25- (based upon renal histopathological alterations such as tubule degeneration, fibrosis, dilation and epithelium hyperplasia and elevated blood urea nitrogen and serum creatinine) to 100-fold (based upon MC crystal formation) lower than that previously considered in the risk assessments based on the NOAEL value derived from exposure to melamine alone.
Systematic Review of the Association between Lung Cancer Risk and Low Levels of Arsenic in Drinking Water

Background: Multiple studies have demonstrated the increased risk of bladder and lung cancers with exposure to drinking water containing inorganic arsenic at levels in the hundreds of micrograms/liter. The risks at lower levels are uncertain. A systematic review and meta-analysis of the risk of bladder cancers with exposure to drinking water (Mink, 2008) has found no increased risk at arsenic exposures below 200 ug/L with the exception of studies limited to tobacco smokers. No such analysis has been reported with respect to lung cancers.

Materials and Methods: Our comprehensive literature search yielded a final set of 11 papers with 17 study populations from 4 continents that reported the risks of lung cancer from lower levels of arsenic exposure in drinking water. Risk ratio and exposure metric data were extracted. Results were stratified into exposures at <10 ug/L, 10-100 ug/L, 100-200 ug/L, and >200 ug/L.

Results: The 11 studies had 3 risk estimates in the <10 ug/L range, 20 in the 10-100 ug/L range, 7 in the 100-200 ug/L range, and 9 just above 200 ug/L. The mean and median risk estimates were 0.92 and 0.94 for <10 ug/L, 1.02 and 1.02 for 10-100 ug/L, 1.51 and 1.34 for 100-200 ug/L, and 2.36 and 1.97 for >200 ug/L. Only one of 20 (5%) risk estimates at 10-100 ug/L was significantly greater than the risk at lower levels, as were 3 of 7 (43%) at 100-200 ug/L and 5 of 9 (55%) at >200 ug/L. An arsenic-associated risk was seen among smokers only above 200 ug/L.

Conclusion: Lung cancer risk with exposure to arsenic in drinking water was not seen to rise at levels below 100 ug/L. Increased risks were observed at 100-200 ug/L and at >200 ug/L. These results are consistent with those of bladder cancer risk with exposure to arsenic in drinking water; however, bladder cancer studies have generally separated the risk for smokers from that of non-smokers and only two of the lung cancer studies have done so.

Guidance for Contaminated Sites: Trichloroethylene Case Study

B. K. Gadagbui1, M. L. Dourson2,3, 1, R. Thompson4, J. Lowe5 and E. Pfau5.

A methodology for interpreting a range of acceptable noncancer risks was developed, similar to the range used for cancer risks in management of waste sites, based on readily available toxicity information from U.S. EPA and elsewhere. This range enables noncancer risk to be evaluated in a way that reflects the uncertainty of the noncancer benchmark. The EPA’s recently developed RfC for trichloroethylene (TCE), based on multiple endpoints, was evaluated as a case study for the noncancer risk range. For TCE, this range was judged to be 3 µg/m³ to 20 µg/m³. The results of the NTP study-based RfC were used to determine the floor and midpoint of this uncertainty range. The highly controversial results from the Johnson et al. (2003) study-based RfC, while associated with low confidence, were nevertheless used to determine the ceiling level of this uncertainty range. The proposed range was entirely within the wider individual uncertainty range from the Keil et al. (2009) study; therefore, this latter study was considered to be confirmatory. The multi-endpoint uncertainty range is composed of floor, midpoint and ceiling values derived from studies for which the appropriate averaging time corresponds to different exposure durations (i.e., developmental or chronic exposure periods). Therefore, this range can be applied to both long- and short-term exposures, with the associated differences in exposure averaging times. For shorter-term exposures, the results from the Johnson et al. study (2003) might also be used to describe the best averaging time, but if so, this averaging time should be based on the average time of cardiac development in humans during fetal growth, approximately 24 days. An assumed 24-day averaging time for cardiac development in humans is consistent with the fact that effects in the Johnson et al. study (2003), appeared to occur during the whole time of cardiac development in the rat.

Pen Housing of Nonhuman Primates on Toxicology Studies

As part of our continuing effort to improve our animal care and use program and to exceed regulatory requirements in the housing of nonhuman primates, we have developed a pen-style housing system for use on GLP-compliant toxicology studies. The pen system was developed with three objectives 1) meet housing requirements to exceed regulatory requirements in the housing of nonhuman primates, we have developed a pen-style housing system for use on GLP-compliant toxicology studies. The pen system was developed with three objectives 1) meet housing requirements

Implementing the 3R Methods and Hurdles for Their Application—A Perspective from the Chemical Industry

For the safety of consumer products their toxicological potential must be determined. By law, the toxicological testing often requires animal studies. According to our commitment to animal protection we apply 3R principles wherever possible, i.e. “reduce” and “replace” animal studies by new testing strategies as well as “refine” them by humane testing conditions. Herein, we report on certain hurdles that BASF SE has faced in the recent years.

Hurdles for reduction of animal numbers used for regulatory purposes exist (i) for “reproduction toxicity studies” as the basic design of the extended one-generation reproductive toxicity study is still lacking full acceptance and (ii) for “non-rodent toxicity studies” as the reduntant one-year dog study is still requested by some authorities. Hurdles for application of replacement methods exist for the endpoints (iii) “eye irritation” as technical equipment is difficult to achieve for a validated and accepted assay, and (iv) “skin sensitization” as the validation process will be completed too late for registration of many substances under the European Union legislation REACH. Hurdles for refinement were encountered when (v) the propagated use of a cytotoxicity assay for the optimal selection of the starting dose in acute oral toxicity did not prove to be as useful as anticipated. Taken together, especially in the field of in vitro methods, many problems can be encountered during the process of development, establishment, and their application. Some of these hurdles are technical issues, some published alternatives not fulfilling inter-laboratory reproducibility requirements, and an insufficient validation procedure. Most often, in vitro methods are not validated fast enough and regulatory acceptance takes too much time. Therefore, their use for regulatory purposes is often delayed and does not match legislative and political goals (e.g. Cosmetic Directive and REACH).

SLIM As a Smart Way to Translate 3R Innovations to Acceptance for Use in Human Risk Assessment

C. Krul1,2, M. Teunis1, R. Vandenbriel1, R. A. Woutersen1,2, D. Kegler1, J. Raaijmakers1, J. Van der Valk2 and R. Peeters3, 1Department of Innovative Testing, University of Applied Sciences, Utrecht, Netherlands, 2TNO, Zeist, Netherlands, 3GSK, Zeist, Netherlands, 4NKCA, Utrecht, Netherlands, 5Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands and 6Wageningen University and Research Center, Wageningen, Netherlands.

Safety assessment of pharmaceuticals and food ingredients requires a significant number of animal experiments. Although in vitro techniques for safety assessment became available over the past years, the number of accepted methods actually implemented within industry and regulations is very low. The slow implementation process delays the innovations in product development, which is undesirable for scientific, societal and economic reasons. The objective of the SLIM project is to obtain good practices for a faster development, (regulatory) acceptance and implementation of methods that replace, reduce or refine animal experiments. Four case studies in the field of reproductive toxicity,
food allergy, carcinogenicity and bioavailability of new products were performed. An advisory board, composed of scientists working for international regulatory agencies, has critically reviewed these case studies. Two case studies focus on retrospective analysis of the predictive value of animal experiments and aim to identify whether one animal species can be used in reproductive toxicity testing, without losing safety information or whether long-term carcinogenicity tests can be replaced with shorter tests. Other case studies focus on development of in vitro models to identify embryo toxic compounds or allergic reactions. The fourth compared different in vitro models to assess oral bioavailability. Part of all case studies include identification of barriers and drivers of (regulatory) acceptance. Case studies will be presented and show that drivers and barriers can be influenced by intensifying collaborations between stakeholders, i.e. companies, regulatory bodies and research institutes in an early phase in the assay development process.

636 The Use of Weight of Evidence (WoE) for Fulfilling the 2nd Species Information Requirement for Developmental Toxicity within the REACH Framework

REACH passed into law in 2007, placing the responsibility on registrants to demonstrate that potential risks from chemical exposures are appropriately managed and communicated. The European Chemicals Agency (ECHA) has indicated that the second most frequent ‘shortcoming’ in REACH registration dossiers was related to the PDNT endpoint. For >100 tpa registrations, REACH mandates the information requirements for PDNT be filled by conducting OECD test guideline V4 (usually rat), with an expectation to consider further testing in a second species (usually rabbit). The necessity of conducting PDNT testing has recently been evaluated in the literature. Initial conclusions indicate that (i) rabbits are not inherently more sensitive detectors of human teratogenicity, and (ii) the variability observed between species for the majority of chemicals does not exceed normal variability that occurs in multiple studies with the same species, and (c) species sensitivities that do exist are driven by identifiable biological differences. A properly constructed WoE should establish whether the specific substance is expected to have a similar metabolic fate across species, and determine if there are any indicators that a unique response may be expected in different species. This evaluation can predict whether additional information for risk assessment purposes would be obtained from a second species study. Additionally, variability between NOAELs resulting from a rat and rabbit study can be estimated using existing data on substances that have been evaluated in both species. This estimate can be used in comparison with exposure scenarios to determine if the Margin of Exposure (MoE) is large enough to encompass any residual uncertainty remaining after completing a thorough substances specific evaluation. Building a WoE with perspectives from the published literature, a chemical specific evaluation, and MoE calculations should be sufficient to determine the necessity for PDNT testing in a second species within the REACH framework.

637 Evaluation of a Tiered Toxicity Testing Decision Trigger for Assessing Reproductive Hazards of Commodity Chemicals

L. M. Plunkett1, A. Kaplan1 and R. A. Becker2,1 Integrative Biostrategies LLC, Houston, TX. 1American Chemistry Council, Washington, DC.

A tiered toxicity testing framework for application to commodity chemical safety assessment has been developed which employs endpoint-specific decision triggers. The framework has two tiers in which hazard information can be integrated with exposure information at each tier. Decisions about testing choices for Tier 2 tests, the more complex tests, are made based on consideration of decision triggers for significant toxic effects, one of which is reproductive toxicity potential. In the current work, an initial assessment of the reliability of the proposed reproductive toxicity decision trigger was performed using reproductive toxicity data collected within the U.S. Environmental Protection Agency (EPA) Toxicity Reference database (ToxRefDB). Among the ToxRefDB chemicals which EPA previously designated as being either positive or negative for reproductive toxicity potential, 10 positive and 10 negative substances were randomly selected. Toxicity data were extracted from the ToxRefDB and entered into a database constructed for the analysis, the “Toxicity Trigger Database” (ToxTriggerDB). During the evaluation, however, significant limitations were uncovered in the underlying curation of the ToxRefDB, limitations that involved interpretation of toxicity effects and designation of toxicity endpoints. As a result, not enough positive reproductive toxicants were included in the random selection, and only a limited evaluation of the proposed trigger was possible. The limited evaluation showed that the trigger’s performance was dependent on the scientific evaluation criteria used, and judgments made when determining whether responses met the criteria for designating a substance as a positive or negative. Before analyses are conducted using ToxRefDB, including use in validation of prediction models, consensus criteria for designating positive and negative agents need to be developed and applied to ensure the database is adequate for this type of use.

638 Association between Health Outcomes and Environmental Factors in Illinois

M. P. Chan, Southern Illinois University Edwardsville, Edwardsville, IL.

Research has suggested that mortality rates are positively correlated with social inequalities, race/ethnic, air pollution, elevated ambient temperature, availability of medical care, risk factors and other factors. This study develops a model that uses indicators for multiple factors to predict the mortality rates for selected diseases by county in Illinois. County-level data on 102 Illinois counties from the 2012 County Health Rankings were linked to county mortality data from the Centers for Disease Control and Prevention Compressed Mortality database. Appropriate statistical analyses were used to predict the relationship between various environmental factors and other factors to explain variations in county-specific mortality rates for the leading causes of death and lifespan in Illinois. It is anticipated that this study would suggest some adaption strategies to improve the health of residents in Illinois through working with some community organizations.

639 A Novel Approach to Toxicological Hazard Assessment of CAS Number-Specific Compounds with Variable Composition

J. Zhang and A. Lewis, Gradient Corp, Cambridge, MA.

The rapidly changing global landscape of environmental regulations and chemical compliance presents a major challenge for chemical manufacturers and importers. Increasingly, countries are requiring hazard identification based on the Globally Harmonized System of Classification and Labeling (GHS) Guidance. The use of a GHS-based classification system is complex and calls for a level of expertise in toxicology and chemistry that was not previously needed to communicate chemical safety. As part of the hazard assessment process, Graduate has identified a recurring complication regarding hazard assignment for substances with variable compositional features but the same Chemical Abstracts Service (CAS) Registry Number. CAS numbers are unique chemical-specific identifiers; however, they are not specific to length, size, and composition. Examples include silica, petroleum distillate, alcohol ethoxylates, and glass oxide compounds. We determined that hazard conclusions can vary considerably across the publicly available literature for a specific CAS number, and information on the chemical manufacturing process is often necessary to appropriately assign hazards. For example, using just the CAS number, an evaluation of glass oxide would suggest a potential carcinogenic risk because this CAS number is classified as a class 1B carcinogen in the Registration, Evaluation, Authorization and Restriction of Chemicals (REACH) registration dossier (without any caveats). Such a classification would trigger significant downstream regulatory requirements. Upon targeted investigation into product specifications on particle size, however, we determined that the glass oxide in question consisted of continuous filament glass fibers with aerodynamic diameters ranging between 8-26 μm, which are unlikely to deposit in the alveoli regions of the lungs and thus unlikely to pose carcinogenic risks. This poster presents several examples of complexities involved in the hazard classification of compounds with variable compositional features and the research strategy necessary to arrive at well-supported hazard conclusions.

640 A Sustainable Product Risk Assessment

E. A. Coudhury, K. Enters and M. S. Stavanja, EHS/Product Stewardship, Celanese International Corporation, Irving, TX.

Celanese uses a global risk management process for identifying and managing product-related risk associated with raw materials, manufacturing, handling, distributing, sale and the end-use of our products. The process was developed, in support of the responsible care business approach, utilizing a framework rooted in the best practices and industry benchmarking. It involves coordination of experts to further evaluate and assess various elements, including effects on employees, customers, consumers, operating sites, the environment, and the Company. The purpose of our Product Risk Assessment process is to ensure that our products meet our corporate safety and legal targets, as well as all applicable safety, regulatory and legal requirements and possible risks in each country where the product will be marketed and used. Our internal global risk management process targets the identification and management of product related risk associated with raw materials, manufactur-
ing, handling and distribution, sale, and the end-use of our products. The system is designed to broadly review, assess, evaluate and balance risk from multiple internal and external sources. A secondary goal was to increase institutional awareness and organizational decision-making at risk relevant levels. The process includes a risk review by committees comprised of technical professionals with backgrounds in toxicology & medical technology, legal, product development, manufacturing, and others as appropriate. Success has been achieved by embedding the product risk management process into our new product commercialization systems, creating a cultural change towards proactive consideration of critical risk management elements such as product risk, increased organizational awareness, escalation of decision-making, and risk mitigation.

**A Life-Cycle Approach for Prototypical Consumer Products Containing Nanomaterials**

Nanocomposite materials (bulk materials enabled with nanoparticles) are used in the building industry. To date, a total of 250 products produced by over 100 companies incorporate nanocomposites into building or renovation plans; estimated revenues surpass $1 billion. Nanoparticles offer tailored benefits to the traditional functions of materials. Nanocomposite coatings have led to new opportunities in the world-wide market. The continued utilization of nanomaterials in the building envelope is expected to develop rapidly; however, the safety of these novel materials to humans and the surrounding environment must be studied in parallel to their incorporation into products. One way to develop safe nanomaterials is to use a life cycle approach that integrates product development with manufacturing and worker/consumer exposure. This research approach investigates a white paint product enabled with 120 nm titanium dioxide particles as a case study. The bulk material (dry wall) is characterized with the nano-enabled product (white paint) in its intact and degraded forms. Simulated wear-and-tear scenarios are performed on the painted wall and the released airborne particles are analyzed for concentration, size, and composition. Human respiratory deposition of the airborne particles via inhalation exposure is calculated by a particle dosimetry model. The released particles are collected and exposed to normal epithelial cells from four areas of the human pulmonary airway for a toxicological evaluation. Results show that differential physicochemical properties, respiratory depositions in human airway, and toxicological responses are induced between particle-types that contain nanomaterials versus particle-types without nanomaterials. The impact of this research will help to enable sustainable opportunities of nanotechnology in the built environment and provide methodologies for understanding nanomaterial properties and potential toxicological impacts in the context of developed consumer products.

**Towards a Harmonized Evaluation of Chemical Emissions from Building Products in the EU**

G. Johanson1, C. Däumling2 and P. Harrison3, 1Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden, 2German Federal Environment Agency, Berlin, Germany and 3PTCH Consultancy, Leicester, United Kingdom.

A prerequisite for healthy air quality indoors is the use of low emitting materials. There are three different mandatory systems in EU member states to evaluate emission properties of building products: in Germany since 2006, in France since 2012 and in Belgium beginning 2014. Besides these mandatory systems there are a number of voluntary health related quality labels in European countries. A working group with experts from nine European countries coordinated by the Joint Research Center of the European Commission has started to develop a new scientific-based harmonized procedure to derive health related thresholds, so called EU-LCI values (Lowest Concentration of Interest) for all substances regulated in France and Germany. EU-LCI values (usually expressed as µg/m3) are health-based reference concentrations for inhalation exposure used to assess emissions after 28 days from a single product during a laboratory test chamber procedure, as defined in the proposed standard developed by CEN TC 351. The working group generated a protocol incorporating a set of definitions, criteria for the selection of chemicals and use of read across and adjustment and assessment factors. A standardized summary fact-sheet was developed to ensure transparent derivation of LCI values. Further, a list of interim EU-LCI values for 78 compounds (including e.g. acetaldehyde, toluene, xylene, 1,2,4-trimethylbenzene, 1,4-dichlorobenzene, ethylbenzene, 2-butoxyethanol, styrene, ε-caprolactam and t-pinene) was developed. Only “regular” volatile organic compounds (VOCs), and not VVOCs, SVOCs or carcinogens, were considered at this stage. The output of the working group is under publication as European Collaborative Action (ECA) Report No. 29. It has received wide appreciation by member states and industry in the EU, and the Belgian decree already refers to a future list with EU-LCI values.
Chemical use/exposure to both occupational and environmental receptors related to human health and/or the environment. This approach identifies the patterns of chemical hazards and exposure scenarios in the determination of the relative risk. Further risk characterization and risk management is needed. The Chemical Risk Prioritization System (CRPS) developed herein can be used to identify the chemicals which pose the highest potential risks to people and the environment, and state and federal agencies have begun issuing decisions on chemical exposure and production. A simulation environment is developed to help standardize model development, testing, and documentation, for a population dynamic simulation model (PDSM). The model can be used to assess pre-market population impacts of new tobacco products including reduced-risk products. The environment is set up to take user inputs and their documentation, run deterministic or Monte Carlo simulations, and visualize predictions including effects of uncertainty. The model and environment are coded in Microsoft Visual Basic and Excel, with Excel as the interface. Tables and plots of population changes, for example differences between base and what-if scenarios, are generated automatically. A tornado plot ranks parameters from most to least sensitive with respect to key outputs, to help visualize impacts of uncertainties and focus attention on more important ones. A Scenario Manager is available to document hypothetical scenarios and facilitate reproducing them. As part of initial testing, a scenario in which no menthol cigarettes exist (from the US FDA’s TPSC 2011 menthol report) was simulated using reported parameters. The resulting excess smoking prevalence and mortality were comparable to reported predictions, which were found to be highly sensitive to a few input parameters (mortality risk; menthol/non-menthol yield experimenter to smoker; proportion of menthol users among experimenters). The simulation environment could be adapted to other types of models, thus providing a test bed for comparing alternative models with standardized outputs.

A benefit of the CRPS is that it is a consistent, transparent approach tailored to company-specific activities. It streamlines the identification of chemicals where no additional concern is warranted or relative potential risk is minimal. This allows a more detailed risk assessment to occur for a smaller set of chemicals with higher potential risk. It also informs the company of chemicals where little hazard information is available, aiding industry in working with the chemical manufacturers to better characterize potential risk.

Dermal exposure to chemicals is highly relevant in relation to the use of cosmetic products, both in consumers and in individuals exposed occupationally. Regulatory frameworks exist within the EU to limit the dermal exposure of the general population and workers to chemicals in general as well as to limit the use of certain substances in cosmetic products. The objective of the study was to investigate and compare evaluations of dermal exposure performed under two regulatory frameworks. The publicly available information provided under respective regulatory frameworks for toxicological evaluation of the substances resorcinol, p-phenylenediamine, p-aminophenol, N-phenyl-p-phenylenediamine and diethyleneglycol monooethyl ether was scrutinized. A low consistency between the existing evaluations performed under REACH and under the Cosmetics directive was observed in regards to selection of data and identification of critical effect, although no systematic differences were identified. A questionable relevance of included data was observed for some of the registrant evaluations under REACH. However, regardless of these differences the critical dose descriptors were quite similar between the evaluators (within a factor of 2.5) for these five substances. An extended comparison was performed of the critical dose descriptors for all substances evaluated under both frameworks (n=30, only including cosmetics evaluations published 2003-2013). This exercise showed that the REACH registrant’s critical dose descriptor on average is 2.3 (geometric mean) higher than the SCCS critical dose descriptor, ranging from 0.5 to 57 times higher. This is partly explained by a difference in route of the critical study, as REACH registrant critical dose descriptors more often are derived from dermal exposure studies. Removing pairs of dose descriptors with different routes of exposure yields a geometric mean of 1.7, with a range of 0.5 to 40 times higher.

The kidney is a major site of chemical excretion, which results in its propensity to exhibit chemically-induced toxicological effects at a higher rate than most other organs. A routine practice in the assessment of kidney toxicity in animal studies is the evaluation of kidney weight changes. However, the manner in which kidney weight is interpreted and the value of this information in predicting renal damage remains a topic of discussion. In this study we sought to determine whether a relationship exists between chemically-induced kidney weight changes and renal histopathological alterations. We also examined the relative utility of absolute and relative (kidney-to-body weight ratio) kidney weight in the prediction of renal toxicity. For this, data extracted from oral chemical exposure studies in rats performed by the National Toxicology Program (NTP) were qualitatively and quantitatively evaluated. Our analysis showed a statistically significant correlation between absolute, but not relative, kidney weight and renal histopathology in chemically-treated rats. This positive correlation between absolute kidney weight and histopathology was observed even with compounds that statistically decreased terminal body weight. Furthermore, most increases in absolute kidney weight reaching statistical significance (irrespective of the magnitude of change) were found to be relevant for the prediction of histopathological changes. Thus, compared to relative kidney weight, the evaluation of absolute kidney weight may be a preferable method for identifying potential renal toxicants.
Regulatory guidance documents and audits of pharmaceutical product manufacturing operations are intended to preserve the quality and safety of active pharmaceutical ingredients (APIs) and drug products. Historically, regulatory authorities have assigned certain APIs to various “categories of concern,” based on their toxicological properties, in the interest of protecting patients from exposure to potentially hazardous contaminants. Equipment used to manufacture multiple products has the potential of becoming cross-contaminated. In the absence of data clearly demonstrating safety, these categories were intended to provide appropriate segregation for the prevention of potential cross-contamination as outlined by current Good Manufacturing Practices. However, the use of specific categories of concern often overlooked other characteristics of the API, such as pharmacologic potency and mechanism of action, which might also trigger specific requirements for safe handling and disposal. Drug manufacturers are often asked by contract manufacturing organizations whether or not APIs are “cytotoxic,” “steroids,” or “hormones.” As these terms were never defined, clarification is needed because the pharmacological mechanism of new APIs has dramatically changed since the time these terms were first introduced. Also, certain compounds may be inappropriately placed in one of these generic categories, giving the impression that segregation or dedication is required when in fact an acceptable daily exposure can be established and sufficient cleaning achieved. This presentation will discuss the historic use of these categories within the context of assessing their toxicological and pharmacological characteristics to help identify compounds requiring special attention within a Quality Risk Management Program.

### 650 Industrial Effluent-Induced Chromosomal Aberration in Catfish from Ogun River, Lagos, Nigeria

O. T. Iji1, 3 and A. A. Adeogun2, 3.

1Department of Paracultural Sciences, Faculty of Veterinary Sciences, University of Pretoria, Onderstepoort, Gauteng, South Africa, 2Department of Zoology, University of Ibadan, Ibadan, Oyo, Nigeria and 3Federal College of Animal Health & Production Technology, Ibadan, Oyo, Nigeria.

The aim of the study is to evaluate the cytotoxic effect of effluents at inducing chromosomal aberration in the fish species Clarias gariepinus and Clarias pachynema. Effluents from a sewage treatment plant located in the Ogun River, Lagos, Nigeria were subjected to cytogenetic analysis for the detection of chromosomal aberrations using the in vivo micronucleus test. Results indicated that Clarias pachynema was more sensitive to the effluents than the other species. Effluents at concentrations of 250 mg/l and 500 mg/l caused a significant increase in the frequency of micronucleated erythrocytes in the fish. The study suggests that the effluents from the sewage treatment plant are capable of inducing chromosomal aberrations in the fish species, and therefore may pose a risk to human health.

### 649a Assessing Drug Substances to Identify “Highly Hazardous” Compounds for Quality Risk Management Programs

1Baylor University, Waco, TX, 2American Cleaning Institute, Washington, DC, 3EA Engineering, Science, & Technology, Sparks, MD and 4Soleil Mountain View, CA.

The American Board of Toxicology (ABT) commenced to define the breadth and depth of expertise of professional toxicologists with the intent to review and refine the ABT certification criteria. A survey instrument was designed and piloted, then distributed broadly in the second quarter of 2013. 796 respondents representing 12 professional toxicology job roles (academic, agricultural, chemical, etc.) ranked the importance of 82 knowledge elements in their current professional practice. Specific elements ranked highest (≥20%) across all roles included: Risk and safety assessments; mechanisms of toxicity and exposure, disposition and biotransformation of toxicants; regulatory toxicology, clinical pathology; target organ systems (nervous, endocrine, kidney, reproductive); chemical carcinogenesis, mutagenesis, and epigenesis; study designs and in vivo methodologies. Notably, the above were ranked consistently across all 12 toxicology professions, with all differences in emphasis being those anticipated within specific professions. Knowledge elements ranked “not needed” by ≤20% or respondents included: History of toxicology, forensics, and specialty-specific techniques. These results provide a robust basis with which to define a SoK stratifying and providing appropriate focus on knowledge elements across current professional toxicology roles, upon which specific components of a certification program can be expressly linked.
Enzymatic Biomarker in Blackjaw Tilapia (Sarotherodon melanotheron) and Bagrid Catfish (Chrysiptpla nigrodigitatus) in the Lagos Lagoon

S. O. Ayoola and A. A. Idowu, Marine Sciences, University of Lagos, Lagos, Nigeria.

The indiscriminate dumping and release of wastes and hazardous substances into rivers might lead to environmental disturbance that could be considered a potential source of stress to the biotic community. A toxicological study was carried out to ascertain the effects of aquatic pollutants in the blood of Chrysiptpla nigrodigitatus and Sarotherodon melanotheron at the Lagos lagoon for a period of six weeks. Four enzymatic biomarkers which include protein, superoxide dismutase, malondialdehyde and Reduced Glutathione and also the physiochemical parameters of the water were analyzed. The water quality parameters were Temperature which has a mean of 24.5±6.5, Dissolved oxygen 1.65±0.05; Biological oxygen demand 10.0±0.1 and pH 7.1. The BOD increases while DO decreases and temperature increases. The water was slightly alkaline. The lipid peroxidation and antioxidant biomarkers in the blood of Chrysiptpla nigrodigitatus showed a significant difference (P < 0.05), while that of Sarotherodon melanotheron showed likewise except, SOD which showed that there was no significant difference (P > 0.05). This study indicates that there was an alteration in antioxidant enzyme and lipid peroxidase activities in both C. nigrodigitatus and S. melanotheron blood which may cause biochemical dysfunction in this species.

Coral Allelochemical Toxicity and the Role of Cytochrome P450 Detoxification in Butterflyfish (Chaetodon spp.) of Differing Feeding Strategies

A. Maldonado1, D. Schlenk2, R. Lavado1, G. Ostrander2, S. Knutson1, M. Slater3 and S. Ankisetty3.

1Environmental Science, University of California, Riverside, Riverside, CA, 2Florida State University, Tallahassee, FL, 3University of Mississippi, University, MS and 4University of Hawaii at Manoa, Honolulu, HI.

Cytochrome P450 monoxygenase (CYP) is the primary enzyme system for detoxification of xenobiotics including dietary chemicals and pollutants. Little is known about the biotransformation and detoxification of allelochemicals derived from dietary products in marine organisms. Certain species of butterflyfish of the genus Chaetodon have been shown to feed on several species of chemically-defended corals including the soft corals Sinularia spp. 5-episinuleptolide (5ESL) is an allelochemical found at high concentrations in Sinularia maxima. This study examined the effects of 5ESL on the expression and catalytic activities of CYP3A and CYP2 in the butterflyfish species Chaetodon unimaculatus, Chaetodon kleinii, Chaetodon auriga, and Chaetodon multicinctus. Fish were gavaged at ecologically-relevant concentrations of 1.0 and 3.0 mg/kg of 5ESL. Testosterone hydroxylase (TOH) 16β was 16 times higher in fish treated with 5ESL. Testosterone hydroxylase (TOH) 16β in control animals was 6 times higher than other hard coral feeding species. These results indicate an induction of CYP2 (16-keto TOH) and CYP3A (6β, 16ß TOH) catalytic activities in detoxification of 5ESL in C. unimaculatus, which preferentially feed on this coral species in Guam.

Transcriptome Analysis of Red Seabream (Pagrus major) Embryos Treated with 2, 3, 7, 8-Tetrachlorodibenzop-dioxin (TCDD)

1Computer Science and Systems Engineering, Kyushu Institute of Technology, Kitakyushu, Fukuoka, Japan, 2Department of Marine Science, Kindai University, Kobe, Japan, 3School of Environmental Science, University of California, Riverside, Riverside, CA, 4Research Center of Kujukuri, Tokyo, Japan and 5Center for Environmental Studies, Ehime University, Matsuyama, Japan.

TCDD induces a broad spectrum of toxic effects including craniofacial malformation and neural damage in fish embryos. These effects are mainly mediated by the ary hydrocarbon receptor (AHR). However, there still remains a gap of mode of action between AHR activation and adverse outcomes induced by dioxins. To provide a complete picture of the AHR signaling pathway in fish embryos exposed to TCDD, red seabream (Pagrus major) embryos were treated with a graded series of concentrations of TCDD (0.3 - 36 nM) alone in seawater and with a mixture of TCDD and 500 nM of an AHR antagonist, CH223191. The transcriptome of red seabream embryos was analyzed by using our custom-made microarray with 1294 probes that were significantly altered in a TCDD-dose-dependent manner (p<0.03). These mRNA expression levels altered by TCDD exposure were recovered by co-exposure to CH223191, suggesting the mRNA expression of these genes is regulated by AHR. The microarray data further underwent Gene Set Enrichment Analysis (GSEA)-based screening of the KEGG pathway database to identify TCDD-activated pathways. The pathway analyses showed the effects of TCDD on sets of genes related to the regulation of actin cytoskeleton, endocytosis, vascular endothelial growth factor (VEGF) signaling and synaptic long-term depression (LTD) in the embryos. The results suggest that TCDD induces teratogenicity via the dysregulation of actin cytoskeleton and neurotoxicity via VEGF signaling alterations and LTD.

Impacts of Hypersaline Acclimation on the Sublethal Toxicity of Chlorpyrifos to Salmonid Olfaction

1Department of Environmental Sciences, University of California, Riverside, Riverside, CA, 2Department of Medicine, University of California, San Diego, San Diego, CA and 3Department of Biological Sciences, University of Alberta, Edmonton, AB, Canada.

Acclimation to hypersaline environments enhanced the acute toxicity of certain organophosphate pesticides to euryhaline fish species; however sublethal effects have been far less studied. The present study focuses on the sublethal toxicity of chlorpyrifos to salmonid olfaction after hypersaline acclimation. To determine molecular effects of combined exposure, coho salmon were acclimated to three different salinities (8, 16, and 32ppt) for one week and mRNA was collected from the olfactory rosettes. Microarray hybridization was used to determine differences in gene expression for the different salinity treatments. Potential target genes involved in signal transduction, which have been shown to be impacted by chlorpyrifos in zebrasfish, were identified and included chloride interacellular channel 4, guanylate cyclase activator 1A (retina), G-protein (zgc:101761), calcium/calmodulin-dependent protein kinase II delta, and adrenergic alpha 2C receptor. To assess physiological effects, electrotactograms (EOGs) were conducted on rainbow trout acclimated to freshwater and 16ppt with co-exposure to environmentally relevant concentrations of chlorpyrifos (0.5 and 5.0 µL/L). Exposure to chlorpyrifos following acclimation to hypersalinity significantly decreased the response to L-serine and decreased the response to taurocholic acid additively. Gene expression of the five target genes was examined in olfactory tissue from rainbow trout used in the EOG study. Exposure to hypersalinity and chlorpyrifos up-regulated all five target genes. The combined results from the molecular and physiological experiments show that sublethal exposure to chlorpyrifos after hypersaline acclimation negatively impacts salmonid olfaction, which may result from diminished signal transduction in olfactory neurons (NIEHS P30ES0703) and T32 ES018827.

Subthreshold Toxic Effects of Atrazine and Three Degradates on Learning and Behavior in Procambarus clarkii

Atrazine is among the most heavily applied pesticides worldwide, and recent evidence suggests that it may be unsafe at environmental levels. It has been classified as a possible human carcinogen and is an endocrine disruptor. The US EPA Maximum Contaminant Level (MCL) is 3 ug/L for human ingestion and 200 ug/L for limited human exposure. Several environmentally persistent degradates have been identified, including deethylatrazine (DEA), deisopropylatrazine (DIA) and hydroxyatrazine (HA). However, these degradates have no MCL established, although some are suggested toxins. Thus, there remains concern for the risk associated with atrazine and its metabolites in the environment. Little data exist describing sublethal effects of atrazine and its degradates. Fortunately, toxicological research has evolved past dependency on mortality measures to incorporate sophisticated behavioral studies that can elucidate the effects of sublethal exposure to toxins. The goal of this research was to use such parameters to quantify the subthreshold (below the level at which harm is immediately detected) toxic effects of atrazine, DEA, DIA and HA on learning and behavior in Procambarus clarkii (red swamp crayfish), a sensitive biodicator species. Crayfish were placed in an aquatic T-maze (classic method to test cognitive ability) with a food reward in a side arm. Time needed for each animal to locate the reward over repeated trials was recorded, as was time to enter and time spent in each section of the maze. Concentrations of the chemicals tested represented an environmentally realistic range. There was an observed increase in time needed to locate reward for all treatment groups, each taking a minimum mean of 25% longer than control, and most treatment groups had a failure rate (did not find food) at least 2x greater than control. Based on these results, crayfish exposed to atrazine and its degradates at low, biologically relevant doses were lethargic, less explorative, and had impaired learning compared to untreated animals.
Concentrations of Metals Associated with Crude Oil from the BP Macondo Spill in Fish Collected from the Northeastern Gulf of Mexico across a Four-Year Period

Chromium (Cr), nickel (Ni), lead (Pb) and thallium (Tl) were reported by EPA (USEPA, 2010) as components of the crude oil released into the northeastern Gulf of Mexico in the spring and summer of 2010 as a result of the Macondo spill. To investigate the uptake and duration of these metals in the marine food chain, scad Aplodinotus grunniens (Trachurus luscinus) collected in October and November of 2009, 2010 and 2012 were analyzed for metal concentrations. Scad were collected off of the Gulf coasts of Florida and Alabama as part of the yearly NOAA small pelagic trawl survey. Collection sites roughly followed the 200 m contour line. Freeze-dried fish tissue samples were analyzed for the four metals by ICP using USEPA Methods (1994). Tissue levels for each metal were compared among the three collection periods using one-way analysis of variance (ANOVA) and Tukey’s multiple comparison test. Thallium levels were significantly higher in 2010 compared to both 2009 and 2012. Chromium and Ni levels were higher in 2010 than 2009, but the difference was not significant; however, Cr and Ni levels were both significantly higher in 2010 compared to 2012. Surprisingly, Pb tissue levels were significantly higher in 2009 compared to both 2010 and 2012. Our data indicate that during the year of the BP oil spill, levels of three of these metals increased in scad. However, this increase was transitory as two years after the oil release tissue levels had returned to pre-spill values.

An Evaluation of Mancozeb Toxicity on Adult Zebrasfish Gills

A. Shohatee and L. D. Trombetta. Pharmaceutical Sciences, St. John’s University, Queens, NY.

Freshwater ecosystems often become susceptible to various pesticides as a result of crop dusting and/or spraying as well as run-off from agricultural plots. Exposure to these compounds can result in deleterious effects to individual species as well as upset the homeostatic nature of these ecosystems. Mancozeb, manganese-zinc ethylenebis (dithiocarbamate), is fungicide applied to a wide range of crops, vegetables, seeds and ornamental plants, which may enter such ecosystems. Previous studies have suggested that Mancozeb exerts its toxicity through mechanisms related to the induction of oxidative stress. The purpose of this study is to investigate the oxidative stress inducing potential due to Mancozeb exposure in the gills of zebrasfish, Danio rerio. The gills of fish are permanently in contact with environmental water thus becoming a prime target for waterborne toxicants. Adult male zebrasfish were exposed to 0.475, 0.95, and 1.9 mg/L (1.8, 3.6, and 7.2 μM, respectively) of Mancozeb for three hours and then immediately euthanized. Gills were extracted and processed according to each experiment’s protocol. Scanning electron micrographs suggest that Mancozeb causes morphological changes to the epithelial cells comprising the surface of the gills. These changes include the appearance of rounded cells and exfoliation from the basement membrane, when compared to the flattened tightly adjoined cells found on the gills of controls. Glutathione peroxidase (GPx) activity was assessed to investigate antioxidant activity against hydrogen peroxide formation due to Mancozeb exposure. GPx activity showed a significant dose-dependent increase in activity when compared to control.

Environmental Testing Strategy for Pharmaceuticals with Endocrine Disrupting Properties

Z. Dang1 and C. Bodar3. RIVM, Bilthoven, Netherlands and 1RIVM, Bilthoven, Netherlands.

Environmental risk assessment (ERA) of human pharmaceuticals with endocrine disrupting properties should be performed irrespective of the quantity released into the environment. It is unknown, however, which ecotoxicity tests are needed and which should be performed first. Currently we are collecting ecotoxicity testing data on the daphnia 21-day reproduction assay, the mossy two-generation toxicity test, the harpacticoid copepod development and reproduction test, the mollusc toxicity test, the fish early-life stage toxicity test, the short term fish reproduction assay, the fish sexual development test, and fish partial/full life cycle toxicity tests. These tests have been validated, or are currently being validated within the OECD test guidelines programme. The fish short-term reproduction assay and the daphnids reproduction test were evaluated by compiling 140 studies (41 chemicals) for fish and 123 studies (85 chemicals) for crustacean. The preliminary results showed: 1) a differential sensitivity in the testing endpoints for both fish and daphnia toxicity tests; fecundity is the most sensitive endpoint, whereas sex ratio is less sensitive, and 2) biomarker responses related to endocrine-mediated effects could be observed in the fish test, but not in the daphnia test. Further analysis will include a comparison of LOECs among daphnids, mysids, copepods, molluscs and various fish tests. By analysing these ecotoxicity data, it will become clear if invertebrate toxicity tests should be performed prior to fish tests, and, if fish tests are then still considered to be needed, if both a fish development toxicity test and reproduction toxicity test have to be carried out. Based on the overall data analysis, we will propose an environmental testing strategy, which is important for minimizing vertebrate testing and costs.

Short-Term Effects of Dechlorane Plus on Earthworm Eisenia fetida Determined by System Biology Approach

L. Zhang, F. Ji, M. Li, Y. Cui and B. Wu. School of the Environment, Nanyang University, Nanyang, China.

Dechlorane Plus (DP), a chlorinated flame retardant, has been widely detected in environmental matrices, especially in sediment and soil. DP has the characteristics similar to persistent organic pollutants. However, no toxicity data of DP on terrestrial invertebrates are available. In this study, earthworm Eisenia fetida were exposed to 0.1, 1, 10, and 50 mg/kg DP for 14 days. The lethality, oxidative stress and damage, neurotoxicity, and transcriptomic profiles of E. fetida were assessed on day 7 and day 14. Results showed that 50% lethal concentration (LC50) for DP was higher than 50 mg/kg. However, DP exposure could induce an increase of malonaldehyde (MDA) and 8-Hydroxy-2’-deoxyguanosine (8-OHDG) levels, and facilitate changes of acetylcholinesterase (ACHE) activities. High throughput sequencing-based transcriptomic analysis showed that DP exposure significantly altered gene expression and pathways related to antioxidant enzyme, stress response, neurological dysfunction, calcium binding and signal transduction. The results from different toxicological endpoints indicate that DP toxicities on earthworm focus on oxidative damage and neurotoxicity. Based on these results, we deduce that the oxidative stress might be one of mechanism of DP toxicity actions. This study provides an insight into toxicological effects of DP on earthworm, and is useful for the risk assessment of DP on soil ecosystem.

Comparison of Aquatic Toxicity between Silver Nanoparticles and Silver Nanowires

E. Sohn1, S. Johari2, T. Kim1, J. Kim1, J. Lee1 and L. Yu1. 1Institute of Nanoprodut Safety Research, Hoseo University, Asan, Republic of Korea and 2Aquaculture Department, University of Kurdistan, Sanandaj, Islamic Republic of Iran.

To better understand the potential ecotoxicological impacts of silver nanoparticles (AgNPs) and silver nanowires (AgNWs) released into freshwater environments, the toxicities of these nanomaterials were assessed and compared using standard OECD guidelines including “Daphnia sp., Acute Immobilisation Test”, “Fish, Acute Toxicity Test”, and “Fish, Freshwater Algae Cytoplasmic Changes, Growth Inhibition Test”. According to estimated median lethal/effective concentrations of AgNWs/AgNPs in the present study, the order of animal susceptibility was: Daphnia magna > Raphidocelis subcapitata > Orzysia latipes. Thus, both AgNPs and AgNWs tested in the current study should be classified according to GHS ( Globally Harmonized System of Classification and Labelling of Chemicals) as “category acute 1” for D. magna, and “category acute 2” for O. latipes and R. subcapitata. The results showed that AgNPs were more toxic when compared with AgNWs. The change in toxicity could be because of the different degree of Ag+ dissolution due to differences in surface area between the sphere shape of AgNPs and the rod shape of AgNWs. In general, our results suggest that the release of silver nanomaterials into the freshwater aquatic environment should be carefully considered.

Effect of Triclosan Challenges on Chlorine Tolerance in Bacteria Found in Waste Water Effluent

C. E. Woodward, C. G. Dean and J. A. Roling. Bridgewater State University, Bridgewater, MA.

Triclosan is a chlorinated aromatic compound that is used as an antibacterial agent in many household products such as toothpaste and antibacterial hand soaps. Triclosan from these products end up in wastewater discharge. With constant exposure to triclosan, bacterial tolerance is expected to develop in waste water effluent. Because triclosan contains chlorine within its structure, there may be a causal relationship between triclosan exposure and chlorine tolerance. Samples were collected from four rivers in Massachusetts; the Hoosic River (Adams, MA), the Nashau River (Clinton, MA), the French Stream (Rockland, MA), and the Nemasket River (Middleboro, MA). These sites were selected because the effluent
discharge was the first NPDES on each of the rivers, although no triclosan was detected in the water. River samples both upstream and downstream to the effluent discharge were collected. After plating, 288 colonies were isolated from each of the four sites. The NOAEC and LOAEC of triclosan were determined to be 0.001 mg/mL and 0.0001 mg/mL, respectively. The bacteria were exposed to 0.05 and 0.001 mg/mL triclosan or to 50 mg/mL chloroform for 24 hours in an orbital shaker at 30°C and 175 rpm. The bacteria that were exposed to the triclosan were then exposed to 50 mg/mL chloroform for 24 hours in the same conditions specified above. Growth was measured during the triclosan challenges and chloroform exposure using spectrophotometry absorbance at 600 nm. There is no difference in bacterial chloroform tolerance due to waste water effluent (increased tolerance in bacteria upstream and downstream were 17.2% and 12.3%, respectively). Low concentration triclosan challenges increased bacterial chloroform resistance more than high concentration triclosan challenges (9.5% and 1.7%, respectively). Incidence of increased chloroform tolerance in bacteria was independent of sample site (Hoistic: 13.9%, Nashua: 21.2%, French: 11.5%, Nemasket: 12.5%).

In the human health-based risk assessment, the hazard quotient (HQ) for Pb or Cd did not indicate potential for adverse health effects. However, the Hazard Index (HI) for Pb in city (1.06) and riverine (1.46) children, but not adults, indicated potential for adverse health effects. In contrast, the HQs and HIs for Cd were less than 1 and as such did not indicate potential for adverse health effects. The HI for combined Pb and Cd exposure of riverine children (1.13) indicated potentials for non-cancer, but not for cancer health risks. In conclusion, Pb and Cd are bioconcentrated in various tissues of local Nigerian fish to considerable levels, with the potential for non-carcinogenic health effects mainly from exposure to Pb in human receptor groups.

**Textile Dye Reactive Blue 15 Reduces the Reproduction in Ceriodaphnia dubia**

D. P. Oliveira and G. Meireles. *University of São Paulo, Ribeirão Preto, Brazil.*

Introduction: Dyes are widely used in different types of industries, such as textile, pharmaceutical, food, cosmetics, photographic, among others. However, these substances can be toxic, mutagenic and resistant to many degradation processes used in wastewater treatment. It is estimated that about 15% of the dyes used in the world are lost during the dying process and released into the environment, affecting mainly water bodies. However, despite the large amount of commercial dyes available and high quantity released in the aquatic ecosystem, studies about the toxicity of these substances are scarce and little is known about their mutagenic and ecotoxicological effects. Objectives: The aims of this study were to evaluate the eco-toxicity and genotoxicity of the textile dye Reactive Blue 15 (RB15). Methodology: The ecotoxicological assays with *Daphnia similis*, *Vibrio fischeri* and *Ceriodaphnia dubia* were realized according to ABNT NBR12713:2009, ABNT NBR15411-3:2012 and ABNT NBR 13373:2010, respectively. The Comet assay was carried out according to Tice et al. (2000) and Salmonella mutagenicity assay was carried out according to Maron and Ames (1983) and Mortelmans and Zeiger (2000). Results: The RB15 dye was relatively non-toxic to *Daphnia similis* and reduced the *Vibrio fischeri* luminescence in high concentrations. The RB15 dye reduced fecundity of *Ceriodaphnia dubia* and was not mutagenic and genotoxic to human dermal fibroblasts. Discussion: RB15 did not induce acute toxicity but in chronic exposure the dye reduced the reproduction in *C. dubia*. This decrease can be harmful to the aquatic organisms. This dye did not induce DNA damages in the tested conditions. Conclusion: The results shows that the dye can cause adverse effects on organisms even at low concentrations in chronic exposure and that the continuous release of these substances in water bodies is worrying.

**Assessment of the Expression Levels of Genes Involved in Metal Detoxification in Killifish Inhabiting a Closed Copper Mine Superfund Site**

D. Jung, A. Gravero, R. Lehman, E. Cutting, B. Jackson and B. Stanton. *Geisel School of Medicine at Dartmouth, Hanover, NH.*

The Callahan Mine Superfund site in Brooksville, ME is a closed open-pit copper mine and is currently flooded with seawater. The sediments at this site are contaminated with extremely high levels of metals such as cadmium, lead, and copper, and once introduced, killifish (*Fundulus heteroclitus*) inhabiting this Superfund site are constantly exposed to these metals. A survey has shown that killifish collected from the site have significantly higher metal concentrations in tissues compared to fish collected from a nearby reference site. Therefore, we hypothesized that killifish from the Superfund site have elevated expression of genes involved in antioxidant defense induced by metals, and metallothionein (MT), a protein involved in metal detoxification. To test this hypothesis, we collected fish from three different locations within the Superfund site, as well as from a nearby reference site. Gills and liver were isolated for gene expression analysis from twelve individuals at each location. Expression levels of five oxidative stress response genes (nuclear factor erythroid-related factor-2 (Nrf2), glutathione-S-transferase-alpha (GSTa), gluta- mate cysteine ligate catalytic subunit (GCLc), Mn-superoxide dismutase (SOD2), and catalase) and MT were measured by Q-RT-PCR. In addition, tissues were analyzed for metal content. Tissue samples collected from the Superfund site had significantly high levels of cadmium and copper. Surprisingly, MT mRNA levels were not different in the gills and livers of fish collected from the Superfund site compared to the reference site. In addition, none of the oxidative stress response genes showed significant differences among the collection sites. Therefore, constant exposure to extremely high levels of metals does not seem to affect the expression of genes involved in metal detoxification pathways. Examination of protein expression of these genes will provide more information on whether killifish at the Callahan Mine Superfund site have adapted to high levels of metals in the environment.
Puerto Rico currently has more than 250 non-PRASA water systems, which are water systems that are not serviced by the Puerto Rico Aqueduct and Sewer Authority (PRASA). These non-PRASA systems have limited resources for water management and are often non-compliant with the Safe Drinking Water Act. The majority of these systems are located on the rural part of the island, which are characterized by areas of increased poverty. Due to their lack of resources they are often unable to administer the proper treatments and testing for the water systems. This can be potentially hazardous to these communities since poor water quality can result in the proliferation of diseases and exposure to toxic compounds. Our goal was to use geographic analysis to determine the risks of these systems for water contamination. To evaluate how geographic factors could shape the water quality of non-PRASA systems, we (1) organized the database on water quality from the Puerto Rico Health Department for 92 non-PRASA systems, (2) defined the watershed area for each system using ArcMap, (3) evaluated the human activities within the watersheds. We found that water systems that were located near areas with high agricultural activity had the highest nitrate concentration, whereas areas that were within 500 m of a conservation area had the lowest nitrate levels. Our results also suggest that multiple variables can influence water quality, including land cover distribution, environmental factors, and socio-economic factors. These results have important policy implications for promoting forest conservation in non-PRASA watersheds or for connecting non-PRASA community members to PRASA systems in regions where watersheds are highly impacted.

**Pesticide Distribution Pattern in Surface Water of a Mountainous Region River from Rio de Janeiro, Brazil**

G. F. Veríssimo1, J. Moreira2 and A. Meyer1, 1IESC, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil and 2CESTH, Fundação Onisaldo Cruz (FioCruz), Rio de Janeiro, Brazil. Sponsors: G. Veríssimo.

Parasquat (PQ) is an herbicide widely used in several crops as a desiccant. Due to its moderate toxicity, the fate of PQ in the environment is of great concern. In the mountain region of Rio de Janeiro, where PQ is intensively used, the river water is fed for irrigation and recreation but not directly as drinking water source. However, it’s of interest to public health to evaluate the concentrations of such compound, since the local population consumes water from the fountain near the river. The objective of this present study was to assess the concentrations of PQ in a river of an intensive agricultural area during all application seasons in Rio de Janeiro State, Brazil. PQ was measured in river water collected from 7 sampling sites totaling 80 samples during 12 sampling events between 2010 and 2012 in the São Lourenço River in Nova Friburgo-RJ, Brazil. PQ levels were determined by an enzyme-linked immunosorbent assay (ELISA) QuantiPlate™ Kit with a limit of quantification (LOQ) of 0.02 ppb. The pesticide was detected in measurable quantities in all samples. The last sampling site, where the volume of water is bigger, showed as most frequently contaminated with a median of 0.048 ppb (maximum 0.279 ppb). Pluviosity is an important element and the Spearman correlation showed that concentrations of PQ in river water vary with the monthly rainfall (R=0.682; p=0.015). The highest median concentrations and rainfall correlation were found in last site sampling (R=0.771; p=0.003). All others sites showed positive correlations, except for the first one that is the control site located in river springs in the mountain that showed a inverse correlation. Although the found concentrations were below of the limits established by regulatory agency (maximum 20 ppb), our results showed that the use of parasquat in this region impacts the river health, especially after a period of rain.

**Degradation of Tumor Promoter Activity of Jatropha curcas Phorbol Esters Derived from Jatropha Oil Cake in Soil**

M. Nakao1, Y. Shimizu1, Y. Ishihara2 and T. Yasuhara2, 1Public Health, Kurume University, Kurume, Japan and 2Kisatsuo University, Tokyo, Japan.

Background: Large amount of oil cake is generated during production of biodiesel fuel from Jatropha seeds. Although Jatropha oil cake is rich in plant nutrients, the presence of toxic phorbol esters limits the usage of oil cake as fertilizer. The objective of this study is to evaluate the contents and tumor promoting activity of phorbol esters by plants and Jatropha oil cake-supplemented soil.

Method: Contents and biological activity of Jatropha phorbol esters in soil and plants were sequentially analyzed by high-performance liquid chromatography (HPLC) and in vitro cell transformation assay, respectively.

Results: Jatropha phorbol ester-specific HPLC peaks disappeared after 5-week incubation with soil. Along with the degradation of Jatropha phorbol esters in soil, tumor promoter activity of Jatropha oil cake-supplemented soil was dramatically attenuated and finally disappeared. Jatropha phorbol esters and tumor promoter activity were not detected from mustard spinach cultured with Jatropha oil cake-supplemented soil.

Conclusions: These data showed that (1) contents and tumor promoter activity of Jatropha phorbol esters in oil cake were completely lost by 5-week incubation with soil and (2) Jatropha phorbol esters did not transfer into plants cultured with Jatropha oil cake-supplemented soil. Therefore, these results suggested that that Jatropha phorbol ester in oil cake could be degraded by indigenous bacteria and that Jatropha oil cake is useful as a safe fertilizer.
This study was supported by JICA/JST, SATREPS (Science and Technology Research Partnership for Sustainable Development), Japan.

PS 669b Degradation of the Major Toxic Component of Jatropha curcas Phorbol Esters by Enzymes and Sterilized Water

K. Yamauchi, M. Nakao, Y. Shimizu and Y. Ishihara, Karseme University, Karume, Japan.

We found that toxic Jatropha phorbol esters are degraded in Jatropha-oilcake-supplemented soil in 5 weeks. This study demonstrated degradation of the major toxic Jatropha phorbol esters by lipase and esterases in buffer and in sterilized water. Main toxic of Jatropha phorbol esters (DHPB) was purified and analyzed by high-performance liquid chromatography (HPLC) and its biological activity was tested in an in vitro cell transformation assay. DHPB was incubated with various concentrations of Lipase from Aspergillus niger (AL), esterases from Klebsiella oxytoca (SNSM-87) and Acinetobacter calcoaceticus (KM-109) in buffer and in sterilized water for 5 weeks at the optimum temperature and pH. DHPB degradation products were analyzed by HPLC and cell transformation test. The optimum temperature, pH and the enzyme concentration were similar among AL, SNSM-87, and KM-109; 37°C, 6.5-8.5 and 50-1000 μg/ml, respectively. Following 4-weeks incubation of DHPB in sterilized water or phosphate buffer (pH7.0), DHPM-specific HPLC peaks decreased as much as 50% time-dependently. By addition of KM109 to these solutions, DHPB-specific HPLC peak was markedly decreased to about 65% on Day 7. The loss of DHPB reached to 95% at Day 28. However, following incubation with AL or SNSM87 and DHPB for 4-weeks showed similar decay of DHPM degradation as in the buffer or sterilized water alone. Retention times for DHPB degradation components in the HPLC analysis were different between the samples with SNSM87 in sterilized buffer or water alone at Day 7 and 28. The loss of cell transformation activity was similar to decrease of DHPB. These data showed that contents and tumor promoting activity of main Jatropha phorbol ester were decreased in the presence of water. Degradation of DHPB was promoted by esterase in water or spontaneous ester hydrolysis. Therefore, these observations suggested that Jatropha oil cake may safely be used as fertilizer as Jatropha phorbol esters in oil cake is degraded quickly by together with indigenous bacteria in water rich soil. This study was supported by JST/JICA, SATREPS, Japan.

PS 669c Preliminary Study on the Effect of Weathered Oil and Oil Dispersants on Menidia beryllina Embryo

O. K. Adeyemo1, K. J. Kroll1, G. Natalia2 and N. D. Demoul1. 1Department of Physiological Sciences, Center for Human and Environmental Toxicology, University of Florida, Gainesville, FL and 2Institute for Genomics, Biocomputing and Biotechnology, Mississippi State University, Starkville, MS.

Environmental stress can affect an organism at any stage of life, but developing larvae are particularly susceptible. Exposure of fish embryos to relatively low concentrations of oil has been implicated in sub-lethal toxicity. However, the effect of oil and commonly used dispersants; singly and in combination should be more thoroughly evaluated to better understand and anticipate the ecological impacts. Oil (1μgml and 0.1μgml dispersants (Corexit 9500 and 9527) were weathered singly and in combination in 25 ppt saltwater for 7 days in bottles with vortex in a hood. The aqueous part post weathering (Weathered solution, WS), was diluted at 1:5 with standard EPA methods (8081a, 8082, 6020, respectively). The Kaplan-Meier method was used to estimate the means and SD for sample sets that included observations below the detection limits (i.e., non-detects). The persistent organochlorine 1,1,1-trichloro-2,2-di(4-chlorophenyl)ethane (DDT) metabolites DDD and DDE and α- and γ-chlordanes were the most detected chemicals in the fish samples. Significant positive correlations with age (p<0.05) occurred with DDE, α-chlordane, and γ-chlordane in liver tissue; arsenic in gut, and copper in liver. There was no correlation between DDD or DDE concentrations in tissues (gut, liver, muscle); however, there were significant correlations between cadmium concentrations in gut and liver, chromium concentrations in liver and muscle, lead concentrations in gut and liver, and zinc concentrations in liver and muscle. These data provide a better understanding of environmental contaminant levels that are present and bioaccumulated into a long-lived benthic fish species from the nation’s largest river system.

PS 669d Contaminant Burden Analysis in Wild Shovelnose Sturgeon (Scaphirhynchus platyrhynchus) in the Lower Mississippi River

D. R. Johnson1,2, C. Godard-Codding3, T. Anderson2, C. Ang1, G. Cobb1, J. Canas1, J. Clarke1, A. Robers1, K. Boysen2, J. Killgore1 and J. Hoover2. 1Conestoga-Rovers and Associates, Dallas, TX, 2US Army Engineer Research and Development Center, Vicksburg, MS, 3Texas Tech University, Lubbock, TX, 4Badger Technical Services, Vicksburg, MS, 5Baylor University, Waco, TX and 6University of North Texas, Denton, TX.

Long-lived benthic animals experience repeated and/or prolonged exposures to sediments and their associated anthropogenic contaminants. As a result, these animals are at risk of elevated contaminant burdens. The overall objective of this study was to determine baseline data for contaminant burdens in wild sturgeon in the lower Mississippi River watershed. A field collection on the Mississippi River near Ft. Adams, MS in January 2010 resulted in the collection of shovelnose sturgeon, a surrogate for the endangered pallid sturgeon (Scaphirhynchus alatus). Sturgeon (n=13, 4-10 years old) were euthanized, and relevant tissues (liver, muscle) and gut content were analyzed for chlorinated pesticides, PCBs, and metals according to standard EPA methods (8081a, 8082, 6020, respectively). The Kaplan-Meier method was used to estimate the means and SD for sample sets that included observations below the detection limits (i.e., non-detects). This study was supported by JICA/JST, SATREPS (Science and Technology Research Partnership for Sustainable Development), Japan.

PS 669e Comparison of Cyropreserved Trout Hepatocytes and Liver S9 Fractions As In Vitro Models for Predicting Hepatic Clearance in Fish

In vitro measurements of chemical clearance can be extrapolated to the whole liver and used to improve modeled predictions of bioaccumulation in fish. Fish hepatocytes and liver S9 fractions are two systems commonly used to measure in vitro intrinsic clearance (CLin vitro, int; ml/h/mg protein or 106 cells). Previously, trout S9 fractions were used to measure CLin vitro, int for six polycyclic aromatic hydrocarbons. CLin vitro, int were then extrapolated to the intact liver and compared to measurements of hepatic clearance (CLH; ml/h/liver) by isolated perfused trout livers. In the present study, the same approach was used to evaluate CLH predictions obtained from cryopreserved trout hepatocytes. With one exception, extrapolations of CLin vitro, int to in vivo intrinsic clearance (CLin vivo, int; ml/h/liver) using scaling factors (510 x 106 hepatocytes/g liver, 163 mg S9/g liver) resulted in similar predictions for the two in vitro systems (±2 fold difference). For the test chemical benzo[a]pyrene, the CLin vivo, int predicted from hepatocyte data was nearly 10 fold lower than that obtained from the S9 system. CLin vivo, int values were then used as inputs to a well-stirred liver model, which accounts for flow limitations on clearance as well as potential binding effects. To facilitate this comparison, chemical binding in vitro and in solutions used to perfuse isolated livers were measured using solid phase microextraction. The resulting predictions of CLH were in good agreement with measured values from intact livers (<2 fold difference for all but naphthalene), as well as earlier predictions obtained using the S9 system. This agreement can largely be attributed to the fact that CLin vitro, int rates in both in vitro systems often approached the flow rate of the isolated liver system. These findings suggest that both in vitro systems provide comparable predictions of hepatic clearance, which can be used to improve bioaccumulation assessment for fish.
Hemp Seed Flour Impacts the Development of Tenebrio Larvae and Their Susceptibility to Organophosphorous Insecticides

J. Gaston, L. Edwards and S. Chau, Fayetteville State University, Fayetteville, NC.

Previous research studies have shown that hemp seed products can alter the development of insects. Considering hemp seed’s effect on some developing insects, Tenebrio larvae were raised on hemp seed flour to determine any developmental dysfunction as well as possible susceptibility to insecticides such as chlorpyrifos, an organophosphorous insecticide. Three groups of larvae were tested; each group was raised on different amounts of hempseed flour (100% hemp seed flour, 0% hemp seed flour/100% wheat flour, and a mixture of hemp seed and wheat flour). Larvae from each group were exposed to chlorpyrifos using a dip technique. Larvae raised on hemp seed flour were more susceptible to chlorpyrifos based on LC50 comparisons. In addition, decreased acetylcholinesterase (AChE) activity was also demonstrated in larvae raised on hemp seed flour. Results indicate that hemp not only disrupts normal development in Tenebrio larvae but also increases susceptibility to organophosphates.

Two Insecticidal Neurotoxic Mechanisms of Action of Monoterpenoids

J. R. Coats1, A. D. Gross1, F. Tong1, M. J. Kimber1 and T. A. Day2.
1Extonology, Iowa State University, Ames, IA and 2Biomedical Sciences, Iowa State University, Ames, IA. Sponsor: A. Keating.

Monoterpenoids from plant essential oils have been shown to elicit neurotoxic symptoms in insects, including rapid onset of tremors and loss of coordination, followed by death if a sufficient dose is applied. Many are “soft” insecticides that are much less potent than conventional insecticides but are very selectively toxic to insects and not to vertebrates. We have studied two specific neurotoxic mechanisms of action with respect to the actions of selected monoterpenes on insect neuroreceptors. GABA-gated chloride channel receptors from house fly were utilized for binding studies with reitaited-TBOB which binds at the picrotoxin binding site at that receptor-ionophore complex. Also microsacs were prepared from dissected cockroach ventral nerve cords; the effect of monoterpenes on GABA-gated chloride channel function was evaluated using 36Cl-uptake assays. Studies on binding at the house fly nicotinic acetylcholine receptor were conducted using a 14C-nicotine as the radioligand; when the phenolic monoterpenoid carvacrol was added to the preparation, it reduced binding of the nicotine in a concentration-dependent manner, at low micromolar concentrations.

Evaluation of At-Home Methods to Reduce Pesticide Residue on Apples and Peaches

B. Pavilonis and C. Weisel. Rutgers University, Piscataway, NJ.

The diet is a significant route of pesticides exposure to the general public. Nevertheless, public health guidelines to reduce exposure by cleaning food are generally based on anecdotal reports. The objective of this study was to evaluate different methods that could be performed at home to reduce consumer pesticide exposure from apples and peaches. All treatments studied were safe to the general public, did not structurally alter the fruit, and used products that could be readily found in the home or grocery store. Fruit was obtained from the Rutgers University Extension Farm which supplied information on the pesticide applications. In this study, captain, fenpropatrin, and phosmet were quantified by gas chromatography/mass spectrometry. Mean captan and phosmet levels on peaches were 72.7±42.7 μg/fruit and 18.1±6.4 μg/fruit, respectively; while captan, fenpropatrin, and phosmet levels on apples averaged 41.9±23.5 μg/fruit, 16.7±7.6 μg/fruit, and 12.2±6.9 μg/fruit, respectively. Captain and phosmet residue were reduced by approximately 50% or more on apples and peaches by washing and wiping for 15 seconds with a homemade soap solution or a vinegar and lemon juice solution and then rinsing with water. In general, the commercially available fruit wash reduced captan and phosmet concentration better than the other treatment methods studied. On peaches an 85% and 63% reduction in captain and phosmet was observed while captain and phosmet residue was reduced 55% and 52% on apples. Compared to rinsing with water alone, the homemade and commercial fruit wash reduced pesticide levels greater, most likely due to the lipophilic nature of the pesticides. However, fenpropatrin levels present on ripened apples were not reduced by any of the washing treatments studied, possibly due fenpropatrin’s high octanol water partition coefficient. Some, but not all pesticide can be removed from fruit by washing and wiping. While washing and wiping of fruit is recommended, more effective methods are still needed to reduce dietary pesticide exposure. This work was supported by NIEHS ST32ES019854 and P30ES005022.

Toxicity and Safety Evaluation of Etofenprox, S-Methoprene, and Piperonyl Butoxide in Dogs Topically Exposed to Bio Spot Defense®

R. C. Gupta, S. D. Bland, M. A. Lasher and T. D. Canerdy. Toxicology, Murray State University, Hopkinsville, KY.

Currently, pyrethroids are more commonly used than any other class of ectoparasiticides on pets. Due to lack of safety data, pet owners have raised serious concerns for their use on dogs and cats. Concerns have also been raised about transferable residues of pesticides to the pet owners, veterinarians, veterinary technologists, and dog handlers. The present investigation was therefore undertaken with two specific objectives: (1) to determine the safety of Bio Spot Defense Flea and Tick Spot On® applied to six dogs, and (2) to determine the residue of active ingredients of the product (etofenprox, s-methoprene, and piperonyl butoxide) in blood of dogs and gloves worn to pet dogs at 24, 48, 72 h, and 1, 2, 3, 4, and 5 weeks post-application. At these time intervals, blood was evaluated for physical examination. Residues of active ingredients were determined and confirmed using GC/MS. In the blood, etofenprox was detected as early as after 48 h (18.4±5.1 ppm) and the residue persisted until 1 week (0.8±0.4 ppm). S-methoprene and piperonyl butoxide were not detected in the blood at any time. In the gloves, the highest concentrations of etofenprox, s-methoprene, and piperonyl butoxide were determined at 24 h (9.552.0±1515.8; 2307.9±456.7; and 1286.1±150.5 ppm, respectively). Residues of all three compounds were detected in appreciable concentrations in the gloves until 1 week (294.9±27.2; 80.6±10.1; and 40.5±8.8 ppm, correspondingly). Of course, with a steep descending trend, residues of these compounds were present 5 weeks post-application. Findings of this investigation revealed: (1) none of the dogs exhibited any physical or behavioral abnormality, and (2) active ingredients of the product persisted on dog’s coat for five weeks.

Determination of Paraquat (PQ) in Urine Using Reversed-Phase HPLC/DAD

A. Meyer1, G. F. Veríssimo1, J. Alves1 and J. Moreira2. 1IESC, Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil; 2Faculdade de Farmácia, Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil. Sponsor: G. Veríssimo.

Paraquat (PQ) is an extensively used herbicide in agricultural area, and is highly toxic to humans, having been implicated in many diseases among rural populations. The aim of this study was to develop and validate a method to quantify...
PQ in urine. The sample preparation is simple where 1mL of sample is adjusted to a basic pH with 5mL of sodium hydroxide solution (0.1N). And the method employed a solid phase extraction using Sep-Pak C18 cartridge and a high-performance liquid chromatographic system consisting of a model 1200 binary pump with DAD detector coupled. The gradient program was done with methanol and water passed through the SPE column. The extraction phase requires vacuum manifold, high temperature (40°C) and nitrogen stream to evaporate efficiently the eluate. The separation technique uses an octadecyl–sila column with an eluent of 10% acetonitrile (v/v) containing 5.0 mM sodium 1-heptanesulphonic acid and 0.2 M orthophosphoric acid (pH 3.0). After derivatization with internal standard (IS), is eluted at 40°C at a flow-rate of 1.0 mL/min monitored by UV absorption at 258 nm. The accuracy of the method was evaluated by recovery studies using spiked pull of urines. The recoveries of PQ were 74–101%. The calibration curve for PQ showed excellent linearity in the range of 1 – 10 ppm as judged by the coefficient of determination (R=0.983). The detection limit (with SN(5-3)) was 0.3 ppm with an injection volume of 100 μL. And determination limit (with SN(10)) was 1.1 ppm. The intra- and inter-day precision, expressed as the coefficient of variation, for PQ in urine samples was not greater than 13.0%. PQ was sensitively and selectively determined and quantified by HPLC/DAD from urine samples. The present method is promising for identification and quantification of PQ and can be suitable for epidemiological surveys.

Environmental chemical exposures may contribute to the genesis and progression of non-alcoholic fatty liver disease (NAFLD). However, a comprehensive list of these chemicals has not been generated. This study evaluates two large rodent exposure study databases for environmental chemicals which caused NAFLD in rodents. ToxReDB is a database designed by the National Center for Computational Toxicology (NCCCT) and Environmental Protection Agency’s (EPA) Office of Pesticide Programs (OPP) containing animal toxicity testing filed during pesticide registration. 474 rat/mouse studies were queried for histologic NAFLD descriptors. These chemicals were associated with NAFLD pathologic descriptors. The 42 compounds included 22 fungicides, 13 herbicides, 6 insecticides and 1 miticide. From CEBS, 329 studies of 83 unique chemicals reported positive NAFLD descriptors. These chemicals included 12 pesticides/intermediates; 6 dioxin-like molecules; 17 plastics, polymers, synthetic; 19 textiles and resins; 16 solvents and chemical intermediates; 7 paints, polishes and dyes; 10 fragrances, cosmetics and essential oils and 15 miscellaneous chemicals. 371 studies archived in federal databases linked 125 unique environmental chemicals to NAFLD in rodents. Pesticides composed 43% of these chemicals. Furthermore, nearly 10% of pesticide registration toxicity studies reported the development of NAFLD. The potential role of the identified chemicals, and in particular pesticides, in human NAFLD should be investigated.

Dyslipidemia occurs in type 2 diabetes mellitus (T2D). During dyslipidemia there is increased production of lipids from the liver including apolipoprotein B (Apo B) containing very low density lipoproteins (VLDL) and low density lipoproteins (LDL). There is an increasing epidemiological association between diabetes and higher levels of serum organochlorine compounds (OC). OC exposure was found to be a predictor of dyslipidemia in diabetes and non-diabetes. The liver is a target for OC metabolism and plays a role in dyslipidemia and T2D. Therefore, the effect of a group of select OC on the dyslipidemic risk factor, Apo B, in liver cells was investigated. McArdle-RH7777 (McA) rat hepatoma liver cells were treated with 0.4 mM oleic acid (OA) for 16 hr to induce Apo B secretion. McA cells were exposed to 10 μM dichlorodiphenyldichloroethylene (DDE), dichlorodiphenyltrichloroethane (DDT), dieldrin, or chlor dane simultaneously with 0.4 μM OA for 16 hr to induce Apo B secretion. McA cells were exposed to 1, 10, or 100 μM DDE simultaneously with 0.4 mM OA for 16 hr to investigate a dose-response of Apo B secretion. Immunoblotting of lipoproteins secreted into the cell media yielded significantly higher levels of secreted Apo B for exposed versus non-exposed liver cells. Immunoblotting of cell lysates revealed that intracellular Apo B levels were significantly different for OC and OA induced cells compared to non-induced cells. The OC exposed cells exhibited a trend of higher Apo B protein levels than OA induced cells. These results suggest a role of OC in lipid transport and secretion of Apo B containing lipids rather than in Apo B synthesis that is induced by lipogenic fatty acids such as OA. Based on these results, OC exposure may be associated with T2D by increasing a dyslipidemic risk factor of T2D.

INTRODUCTION: The application of pesticides, particularly herbicides, in agriculture, is a well established practice and effective to control weed. However, due to the length of agriculture, large amounts of herbicides have been used and they may influence non-target organisms by several mechanisms. Trifluralin (α,α,α-trifluoro-2,6- dichloro-N,N-dipropyl-p-toluamide) and Tebuthiuron (1-(5-tert-butyl-1,3,4-thiadiazol-2-yl)-1,3-dimethylurea) are herbicides widely used in Brazil. The present work aimed to analyze the effects of this two herbicides, trifluralin and tebuthiuron, in HepG2 cell model. METHODS: Nuclear condensation and fragmentation was assessed by microscopy using the fluorescent dye Hoechst 33342, and phosphatidyl serine exposure on the outer cell membrane was performed using annexin-V / propidium iodide assay. Concentrations from 1 through 100 μM of each herbicide dissolved in dimethyl-sulphoxide was analysed. All experiments were performed in triplicate and statistical analysis were done using ANOVA test followed by Dunnett. RESULTS: Trifluralin showed significant membrane condensation and fragmentation as well as positive marking for annexin-V at concentration of 100μM indicating the induction of apoptotic cell death. On the other hand, Tebuthiuron did not affect these parameters at any of the tested concentrations. CONCLUSION: Our results show that trifluralin but not tebuthiuron is cytotoxic to HepG2 cells and that trifluralin induces the apoptotic pathway. p,p′-DDE Enhances Adipogenesis in 3T3-L1 Adipocytes and Alters Cyclooxygenase-2 (COX-2) Activity in J774a.1 and THP-1 Macrophage Cells

L. Mangum, G. E. Howell, S. B. Pruitt, M. K. Ross and J. E. Chambers. College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.

Exposure to p,p′-DDE, a metabolite of p,p′-DDT, is associated with obesity, dyslipidemia, insulin resistance and incidence of metabolic syndrome. DDE has been shown to have immunomodulatory properties, affecting macrophage and T cell populations. Obesity leads to macrophage cell infiltration into the adipose tissue (AT) causing local inflammation. Potential mechanisms were studied by which DDE could modulate adipocyte and immune cell function and facilitate an increased risk of obesity and immune dysregulation, potentially through COX-2. Human THP-1 and murine J774a.1 cell lines and 3T3-L1 preadipocytes were studied for the effects of DDE on prostaglandin (PG) production and adipogenesis. Macrophage cell lines were exposed to 20μM DDE or 10μM NS398, a specific COX-2 inhibitor, for 18hr before treatment with an inflammatory challenge of 0.25μg/ml lipopolysaccharide (LPS) or 200μM palmitic acid (PA). PGE2, PGD2, PGF2α, and arachidonic acid (AA) were analyzed in cell culture supernatants. The effect of DDE or NS398 on COX-2 activity was also measured indirectly in a cell-free system through addition of AA to cell lysates of LPS (1μg/ml) stimulated macrophages. In J774a and THP-1 cells, DDE or NS398 followed by immune challenge reduced cellular PG secretion and PG production in a cell free system, suggesting that DDE may interfere with COX-2 activity. 3T3-L1 cells were induced to differentiate to adipocytes using a sub-optimal differentiation cocktail with increasing concentrations of DDE (0.5-100μM). DDE increased adipogenesis in a dose-dependent manner in mature adipocytes as determined by Oil Red O staining. As PGE2 and PGF2α inhibit adipogenesis, decreased PG production by AT macrophages may lead to increased adipogenesis and contribute to development
of obesity. These results suggest that DDE exposure may contribute to increased adipogenesis and altered PG production, potentially mediated through a COX-2 dependent mechanism.

680 The Toxicity of Maneb in Human Colon Cells May Be Related to the Transchelation of the Metal Moiety and the Organic Backbone

L. M. Hoffman, L. D. Trombetta and D. Hardej. Pharmaceutical Sciences, St. John’s University, Queens, NY.

Ethylene bisdithiocarbamate (EBDC) pesticides are used as broad range contact fungicides on a variety of crops. A subset of the metal containing EBDC pesticides includes Maneb (MB), which is complexed with the transition metal manganese (Mn). Previous testing in our laboratory has established the toxicity of this compound in transformed colon cells, HT-29 and Caco2. Significant decreases in cell viability were observed in both HT-29 (120-260μM) and Caco2 cells with MB (40-180μM). Exposure also resulted in a dose dependent increase in intracellular Mn levels within HT-29 and Caco2 cells (20-200μM). Recent scientific studies have suggested that Mn exposure may result in increases in copper (Cu) concentrations within the brain. Therefore, the purpose of the present study was to determine if MB exposure results in an increase in copper levels within HT-29 and Caco2 cells. Following exposure to MB in HT-29 (100-200μM) and Caco2 cells (20-60μM), inductively coupled plasma-optical emission spectroscopy was performed. MB exposure resulted in a significant accumulation of Cu within HT-29 and Caco2 cells (40-200μM). These data suggest that the Mn moiety of MB may transchelate with Cu and play a role in the generation of toxicity. To investigate whether Cu played a role in the cytotoxic process, cells were treated with Cu chloride (CuCl₂). Exposure to CuCl₂ produced no significant decrease in cell viability in all cell types up to 200μM. To investigate the role the EBDC backbone plays in the generation of toxicity, HT-29 and Caco2 cells were treated with Nabal (NB), an EBDC pesticide that contains the identical core organic component of MB but has sodium in place of Mn. Significant decreases in cell viability were observed with NB in HT-29 (400-3200μM) and Caco2 cells (200-3200μM). The lack of toxicity observed following treatment with NB within the same concentration range as MB suggests that the EBDC backbone and Cu moiety may be acting in conjunction to cause toxicity in human colon cells.

682 Rynaxypyr Is Active but Significantly Less Potent toward Ryanodine Receptor Type 1 from Wild Type and Malignant Hyperthermia Susceptible Mammalian Skeletal Muscle

K. M. Truong1, M. La Merrill2 and I. N. Pessah1.1 Molecular Biosciences, UC Davis, Davis, CA and 2Environmental Toxicology, UC Davis, Davis, CA.

Rynaxypyr is an antranilic diamide that represents a major emerging class of insecticide widely used to eradicate Lepidopteran agricultural pests. While Rynaxypyr is a potent activator of ryanodine receptors (RyR1) that are expressed in Leptidopterous skeletal muscle, its activity towards RyR1, which is expressed in adult mammalian skeletal muscle, has been less studied. Considering that RyR1s in insect and mammalian species perform similar roles in regulating intracellular Ca²⁺ release from sarcoplasmic reticulum (SR) during physiological and pathophysiological processes of skeletal muscle, we explored if Rynaxypyr was devoid of activity towards adult mouse RyR1, even at high (~1 μM) concentrations. For these initial studies we prepared skeletal muscle SR from congenic C57BL/6j wild type mice and mice that are homozygous for a human malignant hyperthermia susceptibility mutation in the C-terminal region of RyR1 (RyR1-T4826I). These SR preparations were subjected to radioligand-receptor binding analysis with [3H]ryanodine (5 nM) in the absence or presence of increasing concentrations of Rynaxypyr. As previously reported (Barrientos et al J Biol Chem 287:2865), RyR1-T4826I was found to be constitutively more active than wild type RyR1. Rynaxypyr > 10 μM significantly activated RyR1 found in both wild-type mouse muscle and in mouse muscle homogous for the T4826I-RyR1 mutation. These results suggest Rynaxypyr is capable of altering Ca²⁺ dynamics mediated by RyR1 in both wild type and malignant hyperthermia susceptible mammalian muscle. There is a need to better understand how antranilic diamides alter the function of mammalian RyR1 and RyR2 given these receptors are known to express mutations that contribute to environmentally triggered disorders of skeletal and cardiac muscle. 683 Quantiﬁcation of the Pyrethroid Deltamethrin (DLM) in Rat Liver and Muscle Using Gas Chromatography Negative Chemical Ionization Mass Spectrometry (GC-NCl-MS)

J. V. Brackner1, C. White1, D. Gullick1, A. Popovic1, M. Krolski1, D. W. Gammon1, B. S. Cummings1 and M. Bartlett1. 1UGA, Athens, GA, 2Bayer Crop Science, RTP, NC and 3FMC Corp., Ewing, NJ.

High quality trace analysis of pyrethroids in biological samples is necessary for toxicokinetic studies for risk assessments. To date highly sensitive methods to measure pyrethroids have focused on large environmental samples (water, soil, food) or urine. There are no validated methods in the literature for quantifying low concentrations of this class of compounds from small (100 μL) liver and muscle samples. DLM was extracted from homogenated liver and muscle samples by protein precipitation using acetonitrile and phosphoric acid. The samples were vortexed and centrifuged before evaporation to dryness. Samples were reconstituted and DLM extracted from the residue using toluene prior to injection into an Agilent Model 6890N gas chromatograph equipped with a Model 5973 quadrupole mass analyzer. Samples were ionized via electron capture in the negative ion mode using methane as a chemical ionization gas. Fragment ions were monitored using selected-ion monitoring for quantification and verification of the analyte. Cis-permethrin was used as the internal standard. The method was linear from 0.3 ng/mL to 1,000 ng/mL and the intraday precision and accuracy of the method was better than 20% at the LLOQ and better than 15% across the linear range (n=18). The method was applied to monitor tissue DLM concentrations following oral dosing of adult rats with 1 to 5 mg/kg DLM in corn oil. Liver DLM levels declined more rapidly than muscle levels. DLM in liver and muscle could be accurately measured for up to 24 hours following dosing. A novel GC-NCl-MS method for the determination of DLM from 100μL liver and muscle samples was successfully developed and validated by FDA guidelines.
organophosphates (OPs) are some of the most commonly-use pesticides worldwide. Paraoxonase 1 (PON1) is a calcium-dependent, HDL-associated enzyme capable of hydrolyzing OPs and is protective against specific OPs in vivo. Human PON1 has two common coding polymorphisms, L55M and Q192R. The Q192R polymorphism affects catalytic efficiency towards specific substrates. Rabbit PON1 is more stable than human PON1 which has been suggested as a therapeutic catalytic scavenger for OP exposures. We have developed an E. coli system for expressing and purifying untangled native human and rabbit PON1s and variants. The two native 192 alloforms (Q and R) were expressed and purified as well as a human PON1 variant with lysine at the 192 position (rHuPON1K192). Several variants with polymorphisms homologous to rabbit PON1 were computationally predicted to have increased stability and higher affinity calcium binding. These were also generated on the human rHuPON1K192 protein backbone. Rabbit PON1 and variant recombinant rabbit PON1Q192 (rAbPON1Q192), which is predicted to have increased activity against nerve agents, were also expressed and purified. The rHuPON1K192 variant had increased OP catalytic efficiency relative to the native human PON1s. PON1K192 was tested in a knockout mouse model and found to protect brain cholinesterase from the OP diazoxon. Mutants predicted to have increased stability were tested by heat inactivation and EDTA inhibition to determine stability and calcium binding affinity. The L130M and S67A variants, analogous to rabbit PON1 at these positions, had increased resistance to heat and EDTA, which suggested that these variants may be a good alternative for therapeutic use.

Carbendazim is a fungicide with a mitotic spindle inhibitor mode of action. Bolus gavage dosing of carbendazim to rats in prior studies has led to testicular toxicity. Dietary studies did not confirm this effect. Many prior studies used test substance with low or unknown purity and/or failed to assess potential intergenerational effects. An F1 extended two generation reproductive toxicity study of carbendazim (> 98% pure) was conducted in Wistar rats at dietary concentrations of 0, 250, 1000 or 2000 ppm. Potential testicular effects were assessed in adult parental (P) (30/dose) and F1 generation males (two cohorts, 1a and 1b), and in juvenile F1 and F2 rats. Testosterone levels (P and F1 1b), sperm parameters, reproductive organ weights and histopathology including testicular staging were assessed in adult males. Juvenile F1 and F2 males were assessed for testes weight and F1 males for testes histopathology. Reproductive performance was assessed for the P and F1 males (both F1 cohorts). Testicular findings, considered non-adverse, were limited to slight but statistically significant decreased absolute testes weights in the adult F1 cohort 1a only at 1000 and 2000 ppm, with no effect on testes weight relative to body weight, and no effect in P or F1 cohort 1b males. Statistically significant higher testicular sperm counts were noted at 1000 ppm in F1 cohort 1a and at 2000 ppm in both F1 cohorts. There were no effects on testosterone levels, epididymal sperm count, sperm motility, progressive sperm motility, percent or type abnormal sperm, and no exposure related testicular or epididymal histopathology in adult males. Juvenile testes weights and histopathology were not affected. There was no effect on time to mating or male reproductive parameters in either generation. This study confirms a low hazard of testicular toxicity or male reproductive toxicity from carbendazim exposure in the diet.
A number of regulatory agencies have ongoing efforts to identify, describe, and categorize AOPs. Developing libraries of AOPs that can effectively address the practical needs of chemical risk assessment is a major undertaking. There is increasing consensus on the AOP concept and structure: chemical exposure triggers a molecular initiating event that leads to a series of biochemical/cellular alterations culminating in tissue effects including frank toxicity. There is recognition that a reductionist approach may not capture sufficient biological complexity of chemical-induced effects for effectively implementing the AOP framework in risk assessment. In the era of large-scale/high-throughput biology, top-down (hypothesis-driven) and bottom-up (data-driven/systems biology) thinking are both vital for building and using AOPs. This symposium will bring together cutting-edge ideas on AOPs as an integrative framework for predictive toxicology and will focus on (1) building the structure of libraries of AOPs, (2) populating the key events with chemical-induced effects from both a top-down and bottom-up (systems biology) approach, and (3) applying the AOP framework to quantitative risk assessment. The first speaker will give an overview of international efforts to build libraries of AOPs and highlight the requirements for their utility in a regulatory context. The second speaker will discuss some of the techniques and hurdles in combining top-down thinking using large-scale molecular data to characterize molecular and cellular events involved in adverse outcomes in the liver. The third speaker will present a large-scale semantic approach for linking data in relation to AOPs. The fourth speaker will present a computational framework that uses data-driven and knowledge-driven analysis to reconstruct AOPs. The last speaker will present some of the opportunities and challenges in using AOPs for quantitative and qualitative extrapolation from in vitro to in vivo. This symposium will be of wide interest to SOT members, including scientists working within the regulatory arena as well as those interested in the application of molecular and systems biology to risk assessment.

**S 692 Integrating Genomics into the AOP Framework**

C. Corton, US EPA, Research Triangle Park, NC.

Databases of gene expression information annotated for phenotypic outcomes offer opportunities for predicting key events in adverse outcome pathways (AOPs). We have developed strategies for linking gene expression changes to prediction of key events. Three comprehensive databases of gene expression changes in liver/primary hepatocytes have been annotated based on mouse, rat and human data containing ~2,000, ~10,000 and ~2,000 gene expression biosets, respectively. Signatures predictive of key events in liver AOPs were built using species-specific strategies. Mouse signatures capitalized on comparisons between chemically-treated wild-type and transcription factor (TF)-null mice. Rat signatures used known marker genes for TFs. Human signatures were developed in HepG2 cells in which gene expression was correlated to TF activation profiles examined in the same chemically-treated samples. Prediction tests of TF activation showed that balanced accuracies ranged from ~85 – 98% with signatures from mice being the most accurate.

The signatures were used to predict chemically-induced key events including activation of AhR, CAR, FXR, Nrf2, PPARalpha, PXR and hormonally-receptors. The predictions of chemical behavior are put into the context of key events allowing predictions of AOPs in the liver. Simultaneous assessment of all known AOPs linked to liver toxicity or steatosis has assessed complexities in interactions between the TFs. Because chemical-independent factors that regulate the TFs are simultaneously evaluated in the database (e.g., diet, genetic background and lifestyle), the integrated predictions open the door for assessment of cumulative risk. (This abstract does not represent EPA policy.)

**S 693 Opportunities in Toxicology for Large-Scale Semantic-Linked Data and Prediction**

D. J. Wild, Indiana University, Bloomington, IN. Sponsor: C. Corton.

Technologies have recently been developed that allow large-scale, semantic integration of heterogeneous biomedical and drug discovery datasets. A variety of tools and algorithms have emerged that can use this linked data for drug-target prediction and Mechanism of Action discovery, inter alia. Emerging opportunities will be explored for applying these in areas of toxicity and adverse event prediction, including interpretable association predictions that take into account complex inter-relations between genes, compounds, pathways and biological end-points. Examples will be given of how interpretable heterogeneous data subnetworks can shed light on adverse drug events (including proposing mechanisms of action for the hepatic and cardiac events associated with the thiazolidinediones Rosiglitazone and Troglitazone) and how chemical compounds can be profiled against targets and other compounds to produce interpretable predictions of biological effects.

**S 694 Interactive Computational AOP Reconstruction from Data**

I. Shah, US EPA, Research Triangle Park, NC.

While there is growing consensus on the utility of AOPs for risk assessment, developing AOPs for target organ toxicity remains a major challenge. We are a part of the OECD effort for identifying AOPs for hepatotoxicity. To streamline AOP mapping we developed computational tools to reconstruct, visualize, modify, store and share AOPs. First, we developed an ontology to standardize chemical effects on 26,419 biological endpoints including; molecular events, cellular processes, and tissue phenotypes. Second, we synthesized ~1.2M effects on 5,541 chemicals from ToxCast, ToxRefDB and the literature into a computable knowledge base. Third, a systematic mining the literature and pathway databases to calculate dependencies between all 26,419 endpoints. Finally, we developed a heuristic search algorithm to interactively and visually reconstruct putative AOPs for chemicals by inferring linkages between molecular, cellular and tissue-level events. We evaluate the utility of this framework for analyzing receptor-mediated pathways in hepatic steatosis and cholestasis, and how chemical compounds can be profiled against targets and other compounds to produce interpretable predictions of biological effects.

**S 695 From AOPs to Quantitative In Vitro to In Vivo Extrapolation**

M. E. Andersen, The Hammar Institutes for Health Sciences, Research Triangle Park, NC.

There are multiple international initiatives to move toxicity testing from reliance on in-life studies to in vitro platforms that evaluate modes-of-action of chemicals using human cells. The transition from past practices requires placing the new assays in a toxicological/risk assessment context. Adverse Outcome Pathways (AOPs) link events at different levels: from cellular interaction of chemicals, through perturbations of cellular pathways, on to integrated responses at the organism level. Development of AOPs will accelerate the move to acceptance of modern methods of testing by providing convincing arguments for regulatory authorities of the utility of pathway-oriented in vitro assays. These assays provide output showing the concentrations at which compounds produce cellular or subcellular responses. Formal use in risk/safety assessment requires dosimetry extrapolation from in vitro concentrations to human exposures and low dose extrapolations based on the cellular circuitry affected by the chemicals. This talk focuses on two key methodological approaches required for risk/safety assessment purposes: 1) quantitative in vitro to in vivo extrapolation (qIVIVE) that relates in vitro concentrations to environmental exposures and 2) computational systems biology pathway (CSBP) modeling that accounts for the structure of the key signaling pathways coordinating key cellular events. The CSBP modeling tools also evaluate dose-dependent transitions and
aid in identifying responses falling within the normal range. Our pathway research with receptor-mediated signaling (PPAR and AhR) and with DNA-damage shows the application of these tools in practice.

696 Is Neuroimmune Crosstalk Important to Neurotoxicology? Critical Insight from Animal and Human Studies

T. A. Brown and C. E. McLoughlin. University of Montana, Missoula, MT and NIOSH, Morgantown, WV.

Convincing evidence of bidirectional communication between the immune system and the nervous system has led to a paradigm shift in our understanding of neuro-immune interactions. Emerging evidence establishes a role for immune signaling in key neurodevelopmental events. Additional evidence suggests immune system contribution to neuronal responses in the form of neuroprotection and repair of tissue injury, as well as in the pathogenesis of neurodevelopmental and neurodegenerative disease. Simultaneously, neurons may actively participate in immune responses in the nervous system by signaling to resident and infiltrating immune cells. The net result of the neuroimmune crosstalk depends on the balance between protective and destructive signaling pathways. There is increasing consensus that exposure to neurotoxicants may tip this balance towards a more disruptive outcome and augment the risk and/or severity of disease. How the immune system can act as a mediator/modulator of neurotoxicity remains elusive. Understanding gained by investigation into neuroimmune interactions will guide improvement of disease diagnosis, prevention, and treatment. This session will present evidence of neuroimmune perturbations in human studies and animal models of neurotoxicant exposure. Evidence from human studies will focus on immune alterations following developmental neurotoxicant exposure in children with documented neurological deficits and in a pediatric population with autism spectrum disorders. Supporting data from animal models will focus on peripheral immune alterations and neuroinflammation following developmental or adult nervous system insult.

697 Neuroimmune Interactions in CNS Development, Repair, and Damage: An Overview

M. Stamou and P. Lein. Molecular Biosciences, School of Veterinary Medicine, University of California Davis, Davis, CA.

It is becoming increasingly clear that the nervous system and the immune system can no longer be considered as separate entities. Evidence suggests that molecules traditionally thought to be exclusive members of either the immune or the nervous system have a dual role in both systems and can regulate CNS function and central innate immune responses, not only in disease but also during normal physiological processes (development, aging, pregnancy, chronic stress). Such molecules include complement and major histocompatibility complex proteins, cytokines, chemokines and neurotrophins. Expression patterns of these molecules are altered in Parkinson’s, Alzheimer’s and multiple sclerosis and mutations in some of the corresponding genes have been linked to neurodevelopmental disorders (Autism Spectrum Disorders, schizophrenia). Neurons, astrocytes and microglia express a wide variety of these molecules, which in turn function to mediate cell-cell interactions including neuronal control of microglial activation and conversely microglial regulation of neurodevelopmental events such as synaptic pruning. Depending on the timing and context of the neuroimmune interaction, such crosstalk may mediate normal neurodevelopment or, in the case of CNS insult, may result in disease or repair. The net effect depends on the balance of neuroprotective and destructive pathways activated. Exposure of the CNS to neurotoxic chemicals could tip this balance towards a detrimental outcome and evidence of immune alterations in the CNS following exposure to environmental factors such as manganese, air pollution or repair. The net effect depends on the balance of neuroprotective and destructive signaling pathways. There is increasing consensus that exposure to neurotoxicants may tip this balance towards a more disruptive outcome and augment the risk and/or severity of disease. How the immune system can act as a mediator/modulator of neurotoxicity remains elusive. Understanding gained by investigation into neuroimmune interactions will guide improvement of disease diagnosis, prevention, and treatment. This session will present evidence of neuroimmune perturbations in human studies and animal models of neurotoxicant exposure. Evidence from human studies will focus on immune alterations following developmental neurotoxicant exposure in children with documented neurological deficits and in a pediatric population with autism spectrum disorders. Supporting data from animal models will focus on peripheral immune alterations and neuroinflammation following developmental or adult nervous system insult.

699 The Immune and Neurological Impacts of Developmental BPA Exposure

J. N. Franklin, Q. Hu, B. Rushing, M. Biller and J. DeWitt. Brody School of Medicine, East Carolina University, Greenville, NC.

Environmental exposure to exogenous agents during critical time points of development may be associated with the onset of deleterious effects, including autoimmune and neurological disorders. Numerous studies have shown that bisphenol A (BPA) exposure can disrupt myriad biological systems. This presentation will focus on the immune and neurological impacts of a double hit of developmental exposure to BPA and an acute exposure to lipopolysaccharide (LPS) in an in vivo C57BL/6 mouse model. LPS exposure given around the time of learning has been shown to unmask developmental deficits in learning and memory. We hypothesize that postnatal exposure to LPS will unmask BPA-induced developmental impacts to hippocampal-dependent learning and memory of C57BL/6 offspring. Impaired behavioral changes will be correlated with markers of immune dysfunction to determine the relationship between immunological alterations and behavioral changes. C57BL/6 female mice were given 0, 0.4, or 50 mg/kg of BPA in a corn oil vehicle by gavage, beginning at pairing with males and ending at weaning of pups. Offspring were assessed on a Barnes maze at postnatal day 60 (PN60), 24 hours after challenge with LPS. Spleenic lymphocyte immunophenotype, total serum immunoglobulins, and inflammatory cytokines were evaluated after behavioral testing. Our findings suggest that developmental immunotoxicity induced by BPA exposure, in the absence of a postnatal trigger, is insufficient to induce changes in learning and memory.

700 Exploring the Relationship between Neuroinflammation and Neurotoxicity

K. A. Kelly, D. B. Miller and J. P. O’Callaghan. CDC-NIOSH, Morgantown, WV.

The enhanced expression of proinflammatory cytokines and chemokines accompanies brain injury induced by neurotrauma, disease or neurotoxicity as well as systemic infection. Elevations in proinflammatory mediators may serve as modulators or mediators of astroglial and microglial activation, cellular responses associated with all types of brain injury and collectively referred to as neuroinflammation. The “acute phase” response to systemic inflammation also leads to upregulation of proinflammatory cytokines/chemokines in the brain in the absence of underlying neural damage, responses thought to be mediated largely by microglia and that serve as the basis of “sickness behavior”. Activated glia may have neuroprotective roles or may exacerbate neural damage. Exposure to the known dopaminergic...
neurotoxicants, MPTP and methamphetamine (METH), cause nerve terminal damage followed by neuroinflammation. Genetic and pharmacological interventions have resulted in partial suppression of the neuroinflammatory responses to MPTP and METH without affecting neurotoxicity and glialosis. In an attempt to achieve a complete suppression of neuroinflammation, chronic exposure to corticosterone (CORT) was used. Surprisingly, mice treated with CORT exhibited an exaggerated neuroinflammatory response to METH coupled with potentiated neurotoxicity (loss of dopaminergic nerve terminal marker, tyrosine hydroxylase) and glialosis. As the levels of chronic CORT approached or exceeded those associated with high physiological stress, the data suggest chronic CORT therapy or sustained physiological stress sensitizes CNS neuroinflammatory and neurotoxic responses. Yet, in a model of LPS-induced systemic infection that does not induce glialosis or neural damage, chronic CORT pretreatment greatly exacerbated and prolonged neuroinflammation without evidence of neural damage or glialosis. These results show a priming of the CNS proinflammatory response to amplify future exposures to pathogens, injury or toxicity. Taken together these findings suggest that neurotoxicity causes inflammation, neuroinflammation may potentiate, but does not necessarily cause, neurotoxicity.

S 701 Neuroautoantibodies: Biomarkers and Potential Pathogenicity

L. A. Shaiba, Department of Pediatrics, University of British Columbia, Vancouver, BC, Canada.

Hypoxic-ischemic events are common to neurodegeneration due to many etiologies, including neurotoxicity, with devastating neurological outcomes. There is a compelling need for reliable, translational biomarkers. Studies of neuroimmune interactions and the tissue-specific responses of the nervous system (NS)-specific antigens provide a record of insult in the form of serum autoantibodies (NAb). Using neonatal hypoxic-ischemic encephalopathy (HIE) as a model paradigm, the humoral hypoxic response, the corresponding detection of NAb biomarkers and brain astroglis were delineated. Sprague-Dawley rat pups underwent left carotid ligation and 2hr of hypoxia (8% O2) on P7. Littermates with sham surgery and normoxia were controls. Neurofilaments (NF), glial- fibrillary acidic protein (GFAP) and myelin basic protein (MBP) antigens reflect the NS’s cellular heterogeneity. Serum NAb against GFAP, NF, MBP and brain GFAP, and erythropoietin (EPO), VEGF, IL-2, IL-6 and TNFα were measured post-surgery (1, 4, 7, 14, 21, 28 and 36d). All cytokines measured were elevated at 24 hours post-surgery in HIE rat pups and for the duration of the study. EPO and VEGF, elevated at 24hr, began to decline at 14d. Only HIE pups had detectable levels of IgM and IgG against NF, GFAP and MBP at 4d post-hypoxia which increased in a time-dependent manner. Significant associations between GFAP levels and serum anti-GFAP IgGs were seen for thalamus and cerebellum, the two regions most affected. Presence of inflammatory cytokines is consistent with pathophysiology and the early increases in EPO and VEGF are consistent with growth and compensatory attempts. The early predominance of IgG NAb suggests isotype switching from a natural repertoire of IgM. A transient decline in NAb likely reflects release of NS antigen due to secondary insult and suggests that the pathological role of NAb. The reactive gliosis indicated by brain GFAP, a hallmark of neurodegeneration, as indicated by serum NAb. This study of early NAb detection indicates their potential as biomarkers of brain injury in neonates and children and suggests a role of NAb in progression of injury.

S 702 Perinatal Exposures and Children’s Health Outcomes

N. Holland and M. C. Poirier, ‘CDI Section, LCBG, National Cancer Institute, Bethesda, MD and ‘School of Public Health, University of California Berkeley, Berkeley, CA.

The developing fetus is more susceptible to xenobiotic toxicant exposures than are individuals in adulthood. This may be largely due to the rapid growth rate, the inability of the placenta to protect completely, and the undeveloped/immature fetal immune and metabolic systems. In utero and perinatal xenobiotic exposures may contribute to chronic diseases of adolescence and adulthood, including cancer, asthma, and obesity. Molecular epidemiology of children’s environmental health, which attempts to link exposure and disease, is a fast-growing area of research, both nationally and internationally. Clinical end points examined include growth parameters, metabolism, and cognitive capacity. Biomarker studies have concentrated on revealing genotoxic and epigenetic events, as well as mitochondrial toxicity, alterations in DNA repair, estrogenic effects, prediabetic metabolic syndromes, and other changes. Epigenetic effects related to prenatal exposures are considered to play a role in the fetal origin of adult human diseases, but the importance of this area for public health is only beginning to be understood. The relevant exposures may range from metals, polycyclic aromatic hydrocarbons associated with air pollution, and pesticides, to hormone disruptors and widely-used chemotherapeutic drugs. Fetal adverse outcome may appear early (mitochondrial toxicity, metabolic syndrome, asthma, cognitive disorder), or years later (leukemia, obesity, and diabetes). This symposium is designed to highlight the significance of adverse health outcomes induced in infants and young children by a broad range of xenobiotic exposures occurring in utero and/or shortly after birth. If we can elucidate underlying genetic and epigenetic mechanisms, it may be possible to devise strategies that will better protect the health of all infants and children.

S 703 Perinatal Exposures to Environmental Pollutants and Children’s Health

J. J. Heindel, T. Schug and K. Gray. NIEHS, Research Triangle Park, NC.

There is increasing experimental and epidemiological evidence showing that development (in utero and the first years of life) is vulnerable to phenotypic insult due to environmental influences. This vulnerability arises at least in part because development is a highly coordinated balance between genetic and epigenetic interactions. The epigenetic system is responsible for coordinating cell differentiation, and tissue and organ formation during development based on the genetic background. The epigenome is particularly sensitive to changes in the external environment, including under- and over-nutrition, stress, drugs, infections and environmental chemicals, which cause shifts or programmatic changes in cell development. This altered “programming” is evidenced by alterations in DNA methylation and chromatin architecture, which have been linked to increased susceptibility to disease and dysfunction that show up later in life. This presentation will set the stage for the session on pollutants and children’s health by focusing on the data supporting a role for environmental chemical exposures, emphasizing endocrine active chemicals, in childhood diseases including asthma, learning disabilities, susceptibility to infections, obesity, type 2 diabetes and early puberty. It will also focus on the role that the NIEHS/EPA network of Centers for Children’s Environmental Health and Disease Prevention play in linking environmental exposures to these childhood diseases/dysfunctions and indicate areas of rapidly developing research and data needs such as a focus on improved exposure assessments, mixture studies, examination of multiple windows of susceptibility or examination of disease syndromes and improved interactions between animal model researchers and epidemiologists in children’s environmental health research. Data, while still incomplete, support a focus on prevention of childhood diseases by reducing exposure to environmental chemicals during development.

S 704 Early-Life Metal Exposure and Epigenetics

R. O. Wright, Mount Sinai School of Medicine, New York, NY.

A critical issue in the toxicology of metals includes the role of early life and prenatal exposures on subsequent health outcomes, including adverse neurodevelopmental outcomes, poor growth and obesity. Metals have been associated with all of these outcomes and epigenetics has been demonstrated to play a role in the programming of these adverse developmental phenotypes in childhood. The complexity of the interplay between metals and developmental programming is further complicated by the role of some metals as both nutrients as well as toxicants. As such, biological processes to regulate normal metabolic functions exist alongside toxicometabolic processes designed to limit their toxicity and the existence of non-monotonic dose response relationships are likely. Complexity in studying epigenetics and child development lies in the multiple epigenetic “marks” that may regulate development (DNA methylation, histone modification, microRNAs) and the role of exposure timing during critical developmental windows. The PROGRESS (Programming Research in Obesity, Growth, Environment and Social Stressors) study is a 1000 mother-child birth cohort with longitudinal assessment of metal exposure (arsenic, lead and manganese) and assessment of later life neurodevelopment, growth and obesity up to age 7 years. In the talk new data on the relationships between metal exposure at multiple critical developmental windows and epigenomic marks in distinct target tissues (umbilical artery, vein, placenta and white blood cell DNA), using the Illumina 450K methylation microarray, will be presented. In a pilot study, differences in methylation were seen in umbilical arteries in the glucocorticoid receptor gene and P16 promoter. In addition to methylation data, we will present data on LINE-1 expression as they related to growth and development.
Maternal-fetal Human Immunodeficiency Virus-1 (HIV-1) transmission is largely preventable when ARV drugs are given to the infected mother during pregnancy. However, the NRTI zidovudine (AZT) is a transplacental carcinogen in mice, and perinatal exposure induces genotoxicity and mitochondrial toxicity in monkey and human offspring (Env. Mol. Mutagenesis, vol. 48, April 2007). Approximately 10,000 women per year in the US are HIV-1-infected and become pregnant, and essentially all will receive these highly-successful therapies. Using an Erythrocebus patas (patas) monkey model, and human tissues, we have examined the mecha- nistic consequences of transplacental NRTI use. The monkey dams were given human-equivalent NRTI protocols, and because they do not become infected with immunodeficiency virus, the data reflect only drug toxicity. The human infant data, however, reflect both the effects of the drug and the maternal HIV-1 infection. We have shown incorporation of the NRTIs AZT and lamivudine (3TC) into nuclear and mitochondrial (mt)DNA of newborn monkeys and humans. Subsequently, AZT/3TC-induced mutagenesis/clastogenesis was found in transplacentally-exposed human infants. Recently the patas studies revealed the persistence of chromosomal damage in cultured bone marrow taken from transplacentally-exposed offspring at birth, 1 and 3 yr of age (equivalent in maturity to a 15 yr old human). In parallel studies we found mitochondrial morphological damage and mtDNA abnormalities in heart and brain of NRTI-exposed patas at birth, 1, and 3 yrs of age. Furthermore, the brains of 1 yr old patas, exposed perinatally to combinations of 2 NRTIs, contained only half of the mtDNA found in the controls. Overall, NRTI-DNA incorporation, chromosomal aberrations, mitochondrial morphological damage in cultured bone marrow taken from transplacentally-exposed patas and humans suggesting that these events underlie the toxic profiles in both species, and are independent of maternal HIV-1 status.

Air Pollution and Molecular Biomarkers of Children’s Health

The city of Ostrava has the highest level of pollution from carcinogenic polycyclic aromatic hydrocarbons (c-PAHs), like benzo(a)pyrene (BaP), in the Czech Republic. We studied a group of 100 asthma and 100 healthy children (8-15 years old) exposed to ambient air in Ostrava and 200 control children from the less polluted city of Prachatice. We measured 8-oxo-dG in urine and lipid peroxidation in plasma as biomarkers of oxidative damage. Gene expression profiles and DNA methylation in white blood cells were assessed by Illumina HumanHT-12 and 27K BeadChips respectively. Gene expression appears to differ between asthmatic and healthy children, and vary by the two regions. Results also indicate that higher exposure to c-PAHs may induce non-allergic asthma in children. No difference in DNA methylation was observed between children with and without asthma, but patterns in both asthmatic and healthy children varied between the cities.

We also studied the effect of prenatal exposure to BaP on DNA adducts, MNs and transcriptome in Prague and Ceske Budejovice. Samples were obtained from non-smoking mothers from Prague (N=35) and Ceske Budejovice (N=52), and cord blood was collected from their newborns. Mean exposures to BaP in subjects from these cities were 3 months prior to delivery 1.9±0.5 ng/m3 and 3.2±0.2 ng/m3 respectively. Gene expression was assessed by microarrays in peripheral blood and placenta of the mothers, and in cord blood of their newborns. Compared to subjects from Prague, pregnancies from Ceske Budejovice showed up-regulation in expression of genes related to metabolism of xenobiotics, but down-regulation of genes related to immune response. This finding corresponds with an increased level of DNA adducts and MN frequency in cord blood from Ceske Budejovice. Analysis of gene expression appears to be an important new biomarker of air pollution.

Supported by the Grant Agency of the Czech Republic (P301113-134588).

Fetal Consequences of In Utero Antiretroviral (ARV) Nucleoside Reverse Transcriptase Inhibitor (NRTI) Exposures in Primates
M. C. Poirier1, O. Olivero1, Y. Liu1, R. L. Divi1 and R. A. Woodward2. 1CDI Section, ELCBG, National Cancer Institute, Bethesda, MD and 2Shared Animal Facilities, NICHD, NIH, Dickerson, MD.

Genetic and Epigenetic Determinants of Health Outcomes in Children with Prenatal Pesticide Exposure

New results from the longitudinal study conducted by the Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS) examine the effects of prenatal exposure to pesticides on the functional genomics of Paraaxonase 1 (PON1) and genome-wide DNA methylation in Mexican-American children. PON1 is a multifunctional enzyme involved in antioxidant defense and detoxification of organophosphate (OP) pesticides. The broad variability of PON1 activities within populations may confer differential susceptibility to environmental exposures. We determined PON1 genotypes and three PON1 enzyme activities in 450 mothers and their children in an agricultural cohort residing in Salinas Valley, CA. Infants and young children with PON1 genotypes encoding for lower PON1 levels and activities, have up to 65-fold lower levels of the protective PON1 enzyme than adults and may be especially susceptible to OP exposures. Additionally, global and site-specific DNA methylation was assessed in DNA isolated from cord blood and peripheral blood of 9 year old CHAMACOS children. Measurement of global DNA methylation was performed by pyrosequencing of Alu and LINE-1 repetitive elements. Global DNA methylation was found to vary by age, sex, and was lower (hypomethylated) in relation to prenatal exposure to organochlorine pesticides and PBDEs. Site-specific DNA methylation analysis was conducted using the Illumina 450K BeadChip platform that simultaneously interrogated methylation at more than 480,000 CpG sites from over 24,000 genes. Approximately 16% of all investigated CpG sites were differentially methylated by age and more than 2% of CpG sites (in >1900 genes) showed significant differences in methylation by sex, including many CpG sites located in autosomes. We also identified CpG sites across the PON1 gene whose methylation was associated with protein expression in CHAMACOS children, suggesting that epigenetic mechanisms may also regulate PON1 activity.

The Emerging Role of Mitochondrial Turnover, Biogenesis, and Dynamics in Tissue Injury
J. Kim1, J. I. Lemasters2, Y. Yoon3, R. Schnellmann1 and H. Laschke4. 1Surgery, University of Florida, Gainesville, FL, 2Drug Discovery & Biomedical Sciences, Medical University of South Carolina, Charleston, SC, 3Physiology, Georgia Regents University, Augusta, GA and 4Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS.

The mitochondria, the cell’s powerhouse, provides cells with adenosine triphosphate (ATP) to drive diverse energy-requiring reactions. Besides energy generation, the mitochondria are also involved in a myriad of essential functions and signaling events in cells. Consequently, disturbances affecting mitochondrial integrity diminish the quality and function of mitochondria, ultimately leading to tissue injury and death. Indeed, mitochondrial dysfunction is a key mechanism underlying ischemia/reperfusion, aging, and drug-induced toxicity in the liver, kidney, and other organs. To maintain normal cell function and survival under the conditions of a variety of stresses, cells possess a powerful surveillance system that selectively eliminates injured or dysfunctional mitochondria in a timely manner, a process called mitophagy. Impaired or insufficient mitophagy is causatively linked to pathology of ischemia/reperfusion, aging, and alcohol- and acetaminophen-mediated hepatotoxicity. The mitochondria are newly formed, and constantly divide and fuse, and continuously change their size and morphology during times of cellular stresses or in response to environmental stimuli. The biogenesis of mitochondria is tightly regulated, and inhibition of mitochondrial biogenesis has been associated with the development of age-related degenerative diseases. Furthermore, mitochondrial dynamics not only determines mitochondrial size, but also regulates mitophagy. Growing evidence is accumulating that mitochondrial biogenesis and dynamics are neatly interconnected with mitophagy. This symposium will emphasize the emerging role of mitochondrial turnover, biogenesis, and dynamics in tissue injury.

Variants of Mitochondrial Autophagy: Types 1 and 2 Mitophagy
L. I. Lemasters. Drug Discovery & Biomedical Sciences and Biochemistry & Molecular Biology, Medical University of South Carolina, Charleston, SC.

Autophagy removes damaged, effete and superfluous mitochondria, a process of mitophagy. In hepatocytes during nutrient deprivation, preautophagic structures (PAS) associated with mitochondria grow into cup-shaped isolation membranes (phagophores) that sequester individual mitochondria into mitophagosomes, a process requiring phosphatidylinositol-3-kinase (PI3K). Sequestration is complete in less than 10 min and often occurs coordinately with mitochondrial fission. After
Mitochondria are direct and indirect targets of many toxicants in a number of different tissues and a large number of studies have focused on the mechanisms of mitochondrial injury and the resulting cell death. In contrast, how cells respond to mitochondrial dysfunction has received less attention. One response to toxicity is the induction of mitochondrial biogenesis (MB) to restore mitochondrial and cellular functions in sublethally injured cells and prevent cell death. In contrast, recent studies have shown that toxicants can inhibit MB. MB requires a coordinated and tightly regulated signaling system. Nuclear respiratory factors (NRF-1 and -2) bind to the promoters of the nuclear genes, leading to expression of constituent components of the oxidative metabolism, mitochondrial DNA (mtDNA) replication, transcription and maintenance. The transcriptional coactivator PGC-1α, the master regulator of MB, induces and coordinates gene expression of mitochondrial transcription A (Tfam), NRF-1 and 2, and itself. Most mitochondrial proteins are encoded by nuclear DNA but mtDNA encodes 13 proteins which are all key components of OXPHOS machinery. A number of upstream signaling pathways (e.g. p38 MAPK, SIRT1, AMPK) have been shown to be activated following injury and activate PGC-1α to produce MB and restore mitochondrial and cellular functions. This presentation will explore the pathways that signal MB and the functional outcomes. 

**S 712 Mitochondrial Biogenesis or Not Following Toxicant Exposure**

R. Schnellmann, Drug Discovery and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.

Mitochondria are direct and indirect targets of many toxicants in a number of different tissues and a large number of studies have focused on the mechanisms of mitochondrial injury and the resulting cell death. In contrast, how cells respond to mitochondrial dysfunction has received less attention. One response to toxicity is the induction of mitochondrial biogenesis (MB) to restore mitochondrial and cellular functions in sublethally injured cells and prevent cell death. In contrast, recent studies have shown that toxicants can inhibit MB. MB requires a coordinated and tightly regulated signaling system. Nuclear respiratory factors (NRF-1 and -2) bind to the promoters of the nuclear genes, leading to expression of constituent components of the oxidative metabolism, mitochondrial DNA (mtDNA) replication, transcription and maintenance. The transcriptional coactivator PGC-1α, the master regulator of MB, induces and coordinates gene expression of mitochondrial transcription A (Tfam), NRF-1 and 2, and itself. Most mitochondrial proteins are encoded by nuclear DNA but mtDNA encodes 13 proteins which are all key components of OXPHOS machinery. A number of upstream signaling pathways (e.g. p38 MAPK, SIRT1, AMPK) have been shown to be activated following injury and activate PGC-1α to produce MB and restore mitochondrial and cellular functions. This presentation will explore the pathways that signal MB and the functional outcomes.

**S 711 Mitochondrial Dynamics and Oxidative Tissue in Diabetes**

Y. Yoon, Department of Physiology, Georgia Regents University, Augusta, GA, Sponsor: J. Kim.

Mitochondria are dynamic organelles, undergoing constant shape change mainly through fission and fusion. Mitochondrial fusion and fission spend cellular energy, suggestive of their importance. However, not only functional significance of mitochondrial fission and fusion but also the mechanistic correlation between mitochondrial functionality and morphology is poorly understood. Our studies demonstrated that mitochondrial shortening by fission coincides with increases in reactive oxygen species (ROS) levels in hyperglycemic conditions. Elevated ROS levels was causal for an increase of mitochondrial permeability transition (MPT) and apoptotic cell death. We were able to show that inhibiting mitochondrial fission by expression of a dominant-negative mutant, DLPL-K38A, alleviated MPT and cell injury by decreasing ROS levels. Enhanced mitochondrial ROS production arising from diabetes is pathologically linked to hyperglycemic complications in many target tissues. In an effort to evaluate the role of mitochondrial fission in diabetic tissue damage, we found that cellular ROS levels in DLPL-K38A transgenic mice were significantly lower in both renal and hepatic tissues. While mitochondria in renal proximal tubular cells became round and ‘swollen’ in diabetic control mice, DLPL-K38A mice maintained normal elongated shape in diabetic conditions. Mechanistically, we discovered that fission inhibition induces an increase of respiration uncoupling to decrease ROS production from mitochondria. Importantly, DLPL-K38A expression suppressed oxidative damage and renal dysfunction in diabetic mice, indicating that mitochondrial fission can be a novel target of intervention in combating oxidative tissue damage.

**S 710 Mitochondrial Autophagy in Ischemia-Reperfusion Injury and Age-Mediated Hepatotoxicity**

J. Kim, Surgery, University of Florida, Gainesville, FL.

Patients with the end stage of liver disease often require transplantation and complex hepatic surgery for extirpation of a non-functional liver and are frequently hospitalized for supportive care that provides only temporary comfort. Moreover, the aged liver has significantly less reparative capacity following ischemia/reperfusion (I/R) injury associated with these operations. Mitochondrial dysfunction plays a causative role in I/R injury. Currently, no therapeutic strategy can suppress I/R injury. Mitochondrial autophagy (mitophagy) is integral quality control machinery that timely and selectively targets and removes damaged or abnormal mitochondria. Biochemical, genetic and imaging analysis demonstrates that I/R injury to young livers and increased sensitivity of old livers to stresses are strongly associated with decreased autophagic responsiveness and subsequent mitochondrial dysfunc-

**S 714 Use of Stem Cells in Toxicity Testing—From Basic Research to Personalized Toxicology**

S. H. Dhalluin1 and Y. Will1, 2. 1New Medicines - Non-Clinical Development, UCB Pharma SA, Brussels, Belgium and 2Global Research and Development, Pfizer, Groton, CT.

Drug-induced toxicity remains a major problem for all pharmaceutical companies, and most have deployed in silico and in vitro testing paradigms throughout the drug discovery process to select safer drugs to be tested in animal models and advance to patients. Despite many advances in understanding mechanisms of toxicity, the majority of in vitro assay predict human risks by less than 50%, and it was shown that measuring simple mechanistic toxicity endpoints in organ-relevant cell lines does not predict organ toxicity (Lin and Will, 2012, Lu and Will, SOT 2013). This may be due to the fact that certain basic toxicity mechanisms such as apoptosis or mitochondrial dysfunction can contribute to a variety of organ toxicities and that many cell lines lack features of organ physiology, such as proper metabolism, relevant ion channel pharmacology, genetic diversity or disease background, to name a few. To build a predictive multicell model, it is necessary to begin with improved functional cell models from the relevant tissue, e.g., hepatocytes, cardiomyocytes, etc. Therefore, efforts to generate physiologically-, pharmacologically-, and toxicologically-relevant cells from ES and iPS cells are important. Progress has been made in the production of human/patient-derived pluripotent stem cells, which can be continuously expanded in the undifferentiated state and differentiated to form most cell types, potentially allowing recapitulation of genetic variation such as association with known gene variants (e.g., HLA susceptibility alleles). This symposium will contribute to our understanding of the current and future state of stem cell...
usage in toxicology by: 1) providing an overview of stem cells, their characteristics in comparison to native organs, their ability to represent patient genetics and disease, 2) describing the current state of application to detect liver, heart, and kidney toxicity, 3) discussing how good patient genetic and disease background give rise to personalized toxicity assessment.

**S 715 Human Pluripotent Stem Cells As Tools for Safety Toxicology**

Human ES and iPS cells offer scalable, consistent sources of normal human cell types that were previously difficult to source. Because human iPS cells offer control over genetic backgrounds, in vitro modeling of drug responses for an intended target population is practical for the first time. This talk will review the properties of iPS cells, and will discuss recent progress in the large-scale derivation of iPS cells and specific iPS cell derivatives relevant to safety toxicology and drug discovery. Specific examples of how Pharma is already using iPS cell-derived cardiomyocytes, neurons, and hepatocytes will be discussed.

**S 716 The Application of Stem Cell-Derived Hepatocytes in Mechanism-Based Drug Safety Assessment**

C. Goldring, MRC Centre for Drug Safety Science, University of Liverpool, Liverpool, United Kingdom. Sponsor: S. Dhalluin.

Recent research into idiosyncratic adverse drug reactions (ADRs) has successfully revealed novel genetic predisposing factors by utilising a candidate gene approach and through the application of genome-wide scanning techniques. However, the underlying mechanisms of ADRs such as drug-induced liver injury (DILI) are complex, multi-dimensional, and not fully amenable to testing using the currently available cell culture systems. The recent rapid advances in the ability to generate induced pluripotent stem (iPS) cells from somatic cells have provided a unique tool to derive disease-specific stem cells that may serve as a mechanistic model for the study of idiosyncratic ADRs, for the liver and other tissues. Nevertheless, work needs to be done before it is known whether this promise will be fulfilled. This talk will highlight advances in this area, and will focus on some critical hurdles in both the embryonic and the iPS fields. The prospects for personalisation in safety assessment, through the great advances in the iPS field will also be considered. Furthermore, advances in complex culture techniques, such as spheroids, bioreactors and multi-cell culture, that may enlighten the field of in vitro hepatotoxicity screening will be highlighted.

**S 717 iPSCs for Cardiac Drug Testing**

J. Wu1, 2, *Stanford Cardiovascular Institute, School of Medicine, Stanford University, Stanford, CA* and 1Department of Medicine/Cardiology, School of Medicine, Stanford University, Stanford, CA. Sponsor: Y. Will.

Cardiac toxicity is a side effect of many pharmaceutical compounds and is a leading cause for drug withdrawal from market because of safety concerns. Current preclinical methods to measure cardiotoxicity are inefficient and rely on genetically altered cell lines, such as human embryonic kidney cells, or Chinese hamster ovary cells, which do not accurately resemble human heart cells (cardiomyocytes). Recent technological advancement has enabled the generation of human induced pluripotent stem cells (hiPSCs) from skin, which can be used to generate patient-specific cardiomyocytes (hiPSC-CMs) in vitro. The hiPSC-CMs generated in this fashion carry all the genetic information from the individuals from whom they are derived. Here we will overview the capacity of a hiPSC-CM library to be used as a clinical trial in a dish model for accurate detection of patient-specific drug responses.

**S 718 In Vitro Models for the Prediction of Nephrotoxicity in Humans**

The kidney is a major human target organ for drug-induced toxicity. Nephrotoxicity is often detected only late during drug development. Animal models have limited predictability due to interspecies variability. In vitro models are of increasing interest, but there are currently no validated or approved in vitro models for nephrotoxicity available. We developed kidney-specific two-dimensional (2D) and 3D (Zhang et al., J Cell Mol Med, 2011; Li et al., Nanotoxicology, 2012) models for in vitro toxicology and nanotoxicology. Our models are based on human primary renal proximal tubular cells (HPTC) and human renal cells derived from pluripotent stem cells (Narayanan et al., Kidney Int, 2013). Endpoint of the in vitro model with the currently highest predictability is increase in marker gene expression. This model has been validated with 41 well-characterized compounds (Li et al., Toxicology Research, 2013). The results show high sensitivity, specificity and concordance with human clinical data. All major performance metrics, including the area under the curve of the receiver operating characteristic curves are in the range of 0.8. This translates to about 80% accuracy in the predictions made with this model. An alternative model comparable with high content screening is currently under development.
proof of concept. Case studies in chemical exposure and drug pharmacology will be explored where the 5 question approach was applied by a toxicologist for litigated tort claims, including ethyl acetate and an opioid painkiller.

722 Evidentiary Challenges with Genomic Data in Toxic Tort Litigation
G. E. Marchant, Sandra Day O’Connor College of Law, Arizona State University, Tempe, AZ.

As the genomic era continues to rapidly advance, genomic data is increasingly being introduced into toxic tort litigation by expert witnesses for both defendants and plaintiffs. This includes genetic susceptibility data that might affect the causation analysis, as well as various types of genetic biomarker evidence that may be relevant to the exposure inquiry. The attempted introduction of such data is often controversial and contested, with opposing counsel frequently arguing that such data are unreliable, inadequately validated, or irrelevant. This presentation will discuss several recent high-profile attempts to introduce genetic data into toxic tort cases involving toxicants such as benzene, lead, ionizing radiation, mercury, and PCBs, and the challenges such data presented for our evidentiary standards, expert witnesses, attorneys, judges and juries. This case study of genomic data in toxic tort litigation illustrates some of the broader issues the evidentiary and expert witness systems in our federal and state courts will encounter in the era of rapidly changing technology and knowledge. These issues include the temptation and incentives for expert witnesses to place premature or exaggerated reliance on emerging scientific knowledge, and the tension between scientific and legal standards of admission and proof.

723 Evidentiary Standards for Neuroactive and Neurotoxic Drug Testing
T. Simon, Ted Simon LLC, Winston, GA.

A number of psychoactive and potentially neurotoxic substances are often considered by courts to modify or disrupt the functioning of the brain. However, dose response is taken into account for only a single substance—ethanol. For ethanol, the societal consensus for impairment of performance has been set at 0.08% or 80 mg/dL. Because of the zero-order elimination kinetics of ethanol and the widely used Widmark pharmacokinetic model, one can determine the source of alcohol in the body based on recent consumption history and this determination can be used as legal evidence. Inorganic mercury intoxication produces a condition called “creethism” with symptoms of anxiety, mood lability, and poor anger control that may be misdiagnosed as psychosis. The “date-rape” drug gamma-hydroxybutyrate (GHB) appears to act by modulating the effects of a number of neurotransmitters, and its effects may be potentiated by nicotine. Symptoms of GHB intoxication include euphoria, relaxation, and increased sexuality. At higher doses, GHB may cause unconsciousness and even death. GHB is produced endogenously within the body. Exogenous GHB is eliminated from the body completely within 8 hours and no rapid immunological test exists—so testing for GHB in cases of drug-facilitated sexual assault is challenging. Regarding cocaine, GS-MS LC-MS and immunological assays methods are used for detection of cocaine metabolites in urine, other body fluids and even hair—with the potential for both false-positive and false-negative results from all methods. In summary, for most psychoactive substances, evidence of exposure obtained by analysis of body matrices is considered tantamount to a psychoactive effect and potential impairment by the legal system. With marijuana is now legal in 18 states, the interpretation of evidence of psychoactive drug exposure in terms of dose-response and assessment of the likelihood of impairment is becoming an important task. Currently, the question addressed by drug testing is—was the subject exposed to the drug? For marijuana especially, the question needs to be—did the subject have enough drug in his/her system to be impaired?

724 Challenging Toxicologists to Advance the Science of Forensics
R. T. Kennedy, New Mexico Court of Appeals, Albuquerque, NM. Sponsor: G. Corcoran.

Toxicological evidence in court should demonstrate the existence of a toxin, symptom, and causal relation (general/specific) between them. Lawyers ask, and judges often allow medical doctors regularly testify to causal relationships through different diagnoses in court. This can result in the introduction of incomplete or flawed evidence. Toxicology’s language confuses judges and lawyers. In criminal cases, analytical chemistry is called “toxicology.” In many trials, analysts of varying skill and repute testify as “toxicologists,” stating opinions linking symptoms with levels of drugs or alcohol found in body fluids or tissue. For alcohol, this is based on scant exposure to Widmark’s formula. With drugs, it is common to see experts give causal testimony first ascertaining symptoms of “impairment” from a police report, then matching the test results, equating amounts found to those symptoms. The credibility of the law allows the potential for injustice. “Non-forensic” toxicology represented by SOT might present the “academic” context to apply standards of research, validation, and acceptable practice to frontier toxicology regulation, See, Strengthening Forensic Science: A Path Forward (NAS,2009). The Federal reference manual on scientific evidence applies toxicology to toxic tort and pharmaceutical litigation, but not applying guiding principles to more common appearances of “toxicology”. Can forensic and legal minds grasp what “toxicology” is about? A question: “If Daubert is about applying ‘science as scientists do it’, why can’t a qualified expert examine another researcher’s data to see if it supports conclusions drawn?” Is motivation inferred from performing such an analysis for litigation any less suspect than performing research for a company desiring to move its product to market? The writer hopes for a concept and direction of how SOT and its members can advance the legal use of toxicological expertise based on objectively reasonable and established standards of scientific practice.

725 Scientific Ethics in Research and Publications
W. J. Brock1 and M. Genter2. Brock Scientific Consulting, Montgomery Village, MD and University of Cincinnati, Cincinnati, Ohio.

For many involved in toxicological research and publishing, it may seem strange or uncomfortable to engage in a discussion of the practicality of ethics. However, with the daily pressures of career advancements and salary increases as well as notoriety and professional recognition, engaging in this discussion will permit continued awareness of the pitfalls of poor ethical behavior that can lead to precarious career outcomes. The scientific community has been rocked by unfortunate media reports over the years that call into question the results of studies and fallibility of science. Although these reports may represent a small percentage of individuals, the impact is far-reaching throughout the scientific community. There have been several reports in the past few years that suggest that the number of retracted papers in scientific literature has increased 10-fold over the previous decade, and that a majority of the retracted papers was due to scientific misconduct that included fraud, plagiarism, and outright data falsification. In spite of the increase in retractions, many of those retracted papers continue to be cited in subsequent publications and grant submissions. Plagiarism by far represents the more common concern in scientific writing. Whether this occurs from the originating author or the wording is “stolen” by others to improve or even exaggerate a conclusion has led to a change in peer-review processes, development of plagiarism software, and mandatory training in certain academic circles. In addition, “ghost” and “in absentia” authors have raised significant data credibility concerns in a regulatory environment. In this session, the background of the problem is presented with real-world examples from literature and reports, and the impact of this problem on a career. Can the peer-review process reduce the likelihood of scientific misconduct? Discussion will occur on the peer-review process and how that process affects the publishing of duplicative or plagiarized data.

726 Introduction to Scientific Misconduct: The Problem, the Results, and the Potential Impact of Advancing a Career Path
W. J. Brock. Brock Scientific Consulting, Montgomery Village, MD.

Over the last 100+ years, there have been enormous increases in scientific knowledge across all fields of science. Unfortunately, the individual desire to be a part of the technical innovations observed during this time has led to “abuse” of that innovation. In the last 15-20 years, the number of cases of scientific misconduct has been surprisingly numerous. In this presentation, the problem of misconduct will be described to include the more notable case reports that have affected our regulatory environment. In this session, the background of the problem is presented with real-world examples from literature and reports, and the impact of this problem on a career. Can the peer-review process reduce the likelihood of scientific misconduct? Discussion will occur on the peer-review process and how that process affects the publishing of duplicative or plagiarized data.

727 Responsible Research: What Is It and Can It Be Done?
H. Bante. University of Cincinnati, Cincinnati, OH. Sponsor: W. Brock.

Biomedical research continues to evolve as investigators collaborate across disciplines and institutions to solve complex health problems. These interdisciplinary interactions coupled with for-profit relationships have led to questions surrounding professional norms and ethical principles as they relate to scientific research. Recognizing these changes and in an effort to foster research integrity, the National
Science Foundation and the National Institutes of Health have mandated education of all trainees, fellows, participants, and scholars in the Responsible Conduct of Research (RCR). Despite these efforts, the incidence of scientific misconduct and questionable research practices remain problematic. This presentation will explain RCR and what it hopes to accomplish, and discuss why collapses in responsible research continue to occur.

**728 Authorship and Scientific Misconduct**

W. B. Matte.

PharmPoint Consulting, Poolesville, MD.

An integral component of the science is the publication of research results and analyses. Needless to say, humans conceive of, conduct, analyze, and describe the work, and participation in this endeavor is acknowledged through the author list of the resulting publication. However, professional advancement and financial rewards are often tied to the number of authored publications; in many fields, the first author is given special attention. Given this setting, authorship is often abused. “Honorary” authors are those whose names are included, yet made no real contribution to the work. “Ghost” authors are those who actually did contribute but are not listed. First authorship is often a source of conflict and is especially problematic in fields where the work requires a large number of collaborators. This presentation will review not only the well-established guidelines but also provide an analysis of the problems of authorship with proposed solutions.

**729 Seeking, Identifying, and Preventing Plagiarism: Manuscript Submissions and Peer Review**

M. Center.

University of Cincinnati, Cincinnati, OH.

While plagiarism can be intentional or unintentional, and can involve an author plagiarizing himself or another author, it can have devastating effects on one’s pursuit of a degree, ability to successfully compete for funding, ability to publish in the peer-reviewed literature, and success in successfully advancing up the career ladder. This presentation will focus on plagiarism from the perspective of the author, peer reviewer, and journal editor. Trainees at all levels should be mentored in the appropriate situations and ways to cite not only the work of others, but also their own work. Peer reviewers and journal editors should be aware of the high incidence of plagiarism, and should put special effort into assuring that a submitted manuscript, or parts thereof, has not been published elsewhere. Examples of self-plagiarism and plagiarism of others’ works in submitted manuscripts will be presented, as well as tips to identify and prevent plagiarism.

**730 Noncoding RNAs in Human Health, Therapeutics, and Environmental Disease**

N. E. Kaminski.

Michigan State University, East Lansing, MI.

A little over a decade ago, the regulatory role of small non-protein-coding RNAs was first uncovered through experiments involving the deliberate introduction of short double-stranded RNAs (dsRNA) into plant and eukaryotic cells. These exogenous dsRNA were found to induce post-transcriptional gene silencing, a process termed RNA interference. This seminal observation led to the discovery of novel and complex biological processes of gene regulation involving endogenous non-coding RNAs of which several varieties have been identified, including microRNA, Piwi-interacting RNA, and long non-coding RNA. During the past 10 years, significant advances have been made in gaining an understanding of the role of non-coding RNAs spanning the period from organismal development and continuing throughout all stages of life. Although the biological role of noncoding RNA has yet to be fully understood, it is important to emphasize that only a small fraction of the mammalian genome codes for miRNAs, and yet the majority of the remaining genome is transcribed into noncoding RNAs. It is tempting to speculate that a large proportion of these noncoding RNAs are transcribed for the distinct purpose of carrying out critical regulatory functions. Indeed, there is a growing literature identifying specific processes under the control of noncoding RNAs and, likewise, the pathology that can ensue when noncoding RNA regulatory processes are disrupted. Relatively little is known concerning the influence environmental factors exert on noncoding RNAs, at the level of their expression, function, or contribution to the etiology of disease processes; therefore, this represents an important frontier for toxicological investigation. In light of the importance of this relatively new area of biology and its potential impact on human health, the goal of this session is to feature eminent scientists who have made important contributions and advances to our current knowledge of noncoding RNAs. The broad areas to be addressed include: general concepts surrounding the biology of noncoding RNAs, their role in development and in specific disease processes, and their potential role in novel therapeutic approaches.

**731 RNA at the Epicenter of Human Development**

J. S. Mattick.

Garvan Institute of Medical Research, Sydney, NSW, Australia.

Sponsor: N. Kaminski.

It appears that the genomic programming of humans and other complex organisms has been misunderstood for the past 50 years, because of the assumption that almost all genetic information is transacted by proteins. Surprisingly, the human genome contains only about 20,000 protein-coding genes, similar in number and with largely orthologous functions as those in other animals, including developmentally simple nematodes and sponges. On the other hand, the extent of non-protein-coding DNA increases with increasing developmental and cognitive complexity, reaching 98.8% in humans. Moreover, high-throughput analyses have shown that the vast majority of the human genome is dynamically transcribed to produce a previously hidden world of different classes of small and large, overlapping and interlacing intrinsic, intergenic and antisense non-protein-coding RNAs. The transcriptome is in fact far more complex than the genome, which is best viewed as a zip file that is unpacked in highly stage- and cell-specific patterns during development. This is illustrated by the use of targeted RNA sequencing to reveal thousands of previously unknown exons and spliced isoforms of oncogenes and tumor suppressors, as well as at least 1500 new long noncoding RNA (lncRNA) genes in intergenic GWAS regions associated with complex diseases. These RNAs fulfill a wide range of regulatory functions, with microRNAs and related species being best (although not well) understood. The functions of IncRNAs are varied and include central roles in the formation of differentiation-specific subnuclear organelles. However, recent evidence suggests that their main function is to organize chromosome territories and to guide chromatin-modifying complexes to their sites of action, to specify the architectural trajectories of development. Moreover, this system has subsequently evolved plasticity, via an as-yet-unexplored universe of retrotransposon expression and mobilization, as well as RNA editing and modification, which appears to be the molecular basis of environmental epigenome interactions and brain function.

**732 Role of microRNA Signaling in the Cancer Microenvironment Communication**

M. Fabbri.

Departments of Pediatrics and Molecular Microbiology & Immunology, Keck School of Medicine, University of Southern California, Los Angeles, CA.

Sponsor: N. Kaminski.

Cancer is a complex genetic disease. Recent evidence indicates that not only cancer cells but also surrounding cells, forming the so-called “tumor microenvironment” play a central role in cancer biology. MicroRNAs (miRNAs), are small non-coding RNA with gene regulatory function, whose dys-regulation is observed in almost all types of human cancers (both solid and hematological malignancies). In addition to their “traditional” mechanism of action (which consists of their targeting of messenger RNAs, miRNAs affect the tumor microenvironment also through previously unknown mechanisms that will be discussed in this lecture. Particular focus will be put on their role as cancer secreted molecules within exosomes, able to trigger pro-tumoral and pro-metastatic signaling by affecting the biology of the tumor microenvironment. A better understanding of such mechanisms represents the necessary rationale for the development of new personalized treatments for cancer patients.

**733 MicroRNAs in Hepatocellular Carcinoma**

C. Lee1, 2, 3.

1Department of Biochemistry, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, 2Duke-NUS Graduate Medical School, Singapore, Singapore and 3National Cancer Centre, Singapore, Singapore.

Sponsor: N. Kaminski.

Hepatocellular carcinoma (HCC) is the 3rd leading cause of cancer deaths globally with a five-year survival of ~5%. Diagnosis of HCC currently relies on routine screening of at-risk patients, including those with cirrhosis due to viral hepatitis, by screening serum alpha-fetoprotein (AFP) levels in conjunction with hepatic ultrasonography but this combination has limitations. Although cost-effective, ultrasonography has only 60% sensitivity and 97% specificity. sAFP is only 40-60% sensitive as many tumors do not produce AFP or do so at very advanced stage. Hence, there is an urgent need to identify better, more reliable noninvasive biomarkers with higher sensitivity and specificity for early detection of HCC. Although ad-
vances have been made to our understanding of the mechanisms of HCC, it still remains incomplete as we grapple with the full spectrum of complexities of the genetic, epigenetic, molecular and cellular events in hepatocarcinogenesis. In this presentation, I will discuss the role of miRNAs in HCC and explore the potential of miRNAs as potential biomarkers and therapeutic targets for HCC.

MicroRNA (miRNA) gain- and loss-of-function can potently influence cellular behavior in normal physiological states and in diseases such as cancer. The regulation of miRNA expression and activity by cellular signaling cascades can therefore result in dramatic phenotypic outputs. We previously demonstrated extensive control of miRNA expression by well-characterized oncogenic and tumor suppressor networks including the Myc, Kras, and p53 pathways. We are now employing novel mouse models with gain and loss of miRNA function to investigate the physiologic functions of the miRNAs embedded within these signaling pathways and the pathologic consequences when their functions are disrupted. Insights gained from these studies are revealing unanticipated roles for miRNAs in vivo and are informing our understanding of how dysregulated miRNA activity contributes to tumorigenesis. I will present our latest findings related to the regulation and function of mammalian miRNAs in normal physiology and in cancer and how these findings may be exploited for the development of novel therapeutic approaches.

MicroRNA Reprogramming in Cancer: Mechanisms and Therapeutic Opportunities

J. T. Mendell. Department of Molecular Biology, University of Texas Southwestern Medical Center, Dallas, TX. Sponsor: N. Kaminski.

AhR in Fatty Liver Disease, The Expected and Unexpected

W. Xie. Center for Pharmacogenetics, University of Pittsburgh, Pittsburgh, PA.

AhR was initially defined as a “xenobiotic receptor.” Here, we have uncovered an endobiotic role for AhR in hepatic steatosis and steatohepatitis. Activation of AhR induced spontaneous hepatic steatosis characterized by the accumulation of triglycerides. The steatotic effect of AhR is likely due to the combined up-regulation of fatty acid translocase CD36/FAT and fatty acid transport proteins (FATPs), suppression of fatty acid oxidation, inhibition of hepatic export of triglycerides, increase in the peripheral fat mobilization, and increase in hepatic oxidative stress and inflammation. Promoter analysis established CD36 as a novel transcriptional target of AhR. Moreover, the steatotic effect of an AhR agonist was inhibited in CD36 null mice. Our more recent results showed activation of AhR also sensitized mice to non-alcoholic steatohepatitis (NASH) via the deactivation of the mitochondrial sirtuin deacetylase Sirt3. Industrial or military exposures to dioxin and related xenobiotics have been linked to fatty liver and other disorders. Results from this study may help to establish AhR and its target CD36 as novel therapeutic targets for the human fatty liver diseases.

Chronic Low-Dose Perfluorooctanesulfonic Acid (PFOS) Induces Hepatic Lipid Accumulation and Dampens Caloric Restriction-Induced Lipid Loss in Mice

A. L. Sitt. University of Rhode Island, Kingston, RI.

A combination of caloric restriction (CR), dietary modification, and exercise is the recommended therapy to reverse nonalcoholic fatty liver disease. The ability to mount an effective response to caloric restriction required to effectively shift hepatic metabolism to fatty acid oxidation depends upon induction of sirtuins, AMP-activated kinase, and peroxisome proliferator-activated receptor-γ coactivator 1 (PGC-1γ). PFOS, a fluorosurfactant previously used as a stain repellent and anti-stick material, is persistent in the environment and considered an “emerging contaminant” by the Environmental Protection Agency. PFOS (1-10 mg PFOS/kg/day) induced hepatic lipid accumulation associated with altered lipid metabolism, and gene and protein expression in mice. We hypothesized that PFOS interferes with the beneficial effects of CR on hepatic lipid utilization and glucose homeostasis. Adult male C57BL/6 mice were fed ad libitum or placed on a 25% reduced caloric diet concomitant with 100 μg PFOS/kg/day for 6 weeks. PFOS significantly increased percent body weight after 4 weeks of administration, but did not significantly alter CR-induced percent weight loss over 6 weeks. Further studies indicated that PFOS (50 nM, 1, 5, 10, and 50 μM) increased adipogenesis in 3T3-L1 cells through induction CEBPs and PPARγ. PFOS also increased hepatic triglyceride accumulation and hepatic lipid loss after CR was lower in PFOS treated mice but not associated with significant changes in lipogenic gene mRNA expression. As insulin resistance contributes to fatty liver disease, we also evaluated PFOS effects on glucose and insulin tolerance. PFOS did not markedly affect either in ad libitum fed mice but did interfere with CR-induced improvement of glucose tolerance. This was further associated with suppression of Glut-2 and IRS-1 mRNA expression in liver and PFOS stimulation of glucose production in isolated hepatocytes. Overall, a relatively low sub-chronic administration of PFOS had some disruptive effects for lipid and glucose homeostasis under ad libitum and CR conditions.

Exposure to Disinfection Byproducts of Drinking Water in Obesity: From Adipokine Imbalance to Epigenetic Alterations leading to Metabolic Syndrome, NASH, and End-Stage Liver Disease

S. Chatterjee. University of South Carolina, Columbia, SC.

It is hypothesized that obesity is associated with strong risks of development of chronic inflammatory liver disease and metabolic syndrome following a second hit. A series of studies in our laboratory explored the role of chronic exposure of bromodichloromethane (BDCM), a disinfection byproduct of drinking water, in causing nonalcoholic steatohepatitis (NASH), mediated by cytochrome P450 isofrom CYP2E1 and adipokine leptin. Mechanisms range from free radical metabolism of bromodichloromethane, adipokine imbalance, CPG island methylation in key promoter sites of regulatory genes including tumor suppressors, regulatory roles of micro RNAs and the immune system. Diet-induced obese mice, exposed to BDCM exhibited increased hepatic leptin levels, higher proinflammatory gene expression and Kupffer cell activation. Obese mice exposed to BDCM also showed profound hepatic necrosis, Mallory body formation, collagen deposition, higher alpha smooth muscle actin expression, events that are hallmarks of NASH. BDCM-exposed obese mice had alterations in both glucose and lipid metabolism genes leading to changes in the hepatic metabolic profile. Strongly hypermethylated regions in CPG islands of tumor suppressors and regulators of lipid catabolism genes were associated with decreased mRNA and protein expression following BDCM exposure. BDCM exposure led to increased expressions of miRNA 155a, 21,105 and down regulation of miRNA 122. BDCM-administered obese mice had increased CD8+ve/CD57+ve T cell presence that was dependent both on its free radical metabolism and hyperleptinemia. These results provide novel insights into BDCM-induced NASH, hepatic metabolic reprogramming and progression of liver disease in obesity. The molecular mechanisms associated with this study in rodents both at the gene and protein levels, could lead to answers in unraveling the causes of environment-linked fatty liver disease and nonalcoholic steatohepatitis.

Does This Chemical Make My Liver Look Fat (Environmental Exposures and Steatosis)

C. A. McQueen1 and N. I. Cherrington2. US EPA, Research Triangle Park, NC and 1University of Arizona, Tucson, AZ.

Headlines have proclaimed the exponential increase in obesity, type 2 diabetes, and metabolic syndrome in the US and other developed countries. Fatty liver is associated with all of these conditions that adversely affect human health. Initially, fatty liver disease (FLD) is benign, but, unfortunately, the disease may develop into the more serious condition steatohepatitis, characterized by lipid accumulation, inflammation, and fibrosis. Further progression can result in cirrhosis and even cancer. Much research has focused on the cellular and molecular changes in order to develop better diagnostic and treatment options. In contrast, there is only limited knowledge of the causes of fatty liver disease (FLD). Upon diagnosis, FLD is classified as alcoholic fatty liver disease (AFLD), with excessive alcohol consumption identified as the cause, or the broader category of nonalcoholic fatty liver disease (NAFLD). Known causes of NAFLD include a high-fat diet and some drugs, but these only account for a fraction of the estimated 30–40 million cases in the US. A better understanding of the environmental and chemical causes of NAFLD can aid in both prevention and treatment of the disease. This symposium focuses on the role of environmental chemicals in the etiology of NAFLD. The presentations will provide a better understanding of how environmental agents, from disinfection byproducts to pesticides, result in steatosis, as well as the multigenerational persistence of the effects of these exposures. Importantly, new insights will be gained on environmental agents that may contribute to the increasing incidence of NAFLD. (This is an abstract or a proposed presentation and does not necessarily reflect US EPA policy.)

Restriction-Induced Lipid Loss in Mice

A. L. Sitt. University of Rhode Island, Kingston, RI.

A combination of caloric restriction (CR), dietary modification, and exercise is the recommended therapy to reverse nonalcoholic fatty liver disease. The ability to mount an effective response to caloric restriction required to effectively shift hepatic metabolism to fatty acid oxidation depends upon induction of sirtuins, AMP-activated kinase, and peroxisome proliferator-activated receptor-γ coactivator 1 (PGC-1γ). PFOS, a fluorosurfactant previously used as a stain repellent and anti-stick material, is persistent in the environment and considered an “emerging contaminant” by the Environmental Protection Agency. PFOS (1-10 mg PFOS/kg/day) induced hepatic lipid accumulation associated with altered lipid metabolism, and gene and protein expression in mice. We hypothesized that PFOS interferes with the beneficial effects of CR on hepatic lipid utilization and glucose homeostasis. Adult male C57BL/6 mice were fed ad libitum or placed on a 25% reduced caloric diet concomitant with 100 μg PFOS/kg/day for 6 weeks. PFOS significantly increased percent body weight after 4 weeks of administration, but did not significantly alter CR-induced percent weight loss over 6 weeks. Further studies indicated that PFOS (50 nM, 1, 5, 10, and 50 μM) increased adipogenesis in 3T3-L1 cells through induction CEBPs and PPARγ. PFOS also increased hepatic triglyceride accumulation and hepatic lipid loss after CR was lower in PFOS treated mice but not associated with significant changes in lipogenic gene mRNA expression. As insulin resistance contributes to fatty liver disease, we also evaluated PFOS effects on glucose and insulin tolerance. PFOS did not markedly affect either in ad libitum fed mice but did interfere with CR-induced improvement of glucose tolerance. This was further associated with suppression of Glut-2 and IRS-1 mRNA expression in liver and PFOS stimulation of glucose production in isolated hepatocytes. Overall, a relatively low sub-chronic administration of PFOS had some disruptive effects for lipid and glucose homeostasis under ad libitum and CR conditions.
**739** Prenatal Obesogen Exposure Causes Transgenerational Inheritance of Increased Fat Mass, Stem Cell Programming, and Hepatic Steatosis

B. Blumberg, University of California Irvine, Irvine, CA. Sponsor: C. McQueen.

Consumption of calorie-dense food and diminished physical activity are accepted causes of obesity. The environmental obesogen model proposes that chemical exposure during critical stages in development influences subsequent adipogenesis, lipid balance and obesity. Obesogens are chemicals that inappropriately stimulate adipogenesis and fat storage. Tributyltin (TBT) is a high-affinity agonistic ligand for RXR and PPAR. RXR-PPAR signaling is essential in adipogenesis and the function of adipocytes. Activation of this receptor heterodimer can elevate adipose mass in rodents and humans. Thus, inappropriate activation of RXR-PPAR can directly alter adipose tissue homeostasis. Our previous work showed in utero exposure to TBT promoted adipocyte differentiation, modulated adipogenic genes in vivo, and increased adiposity in mice. These results are consistent with the environmental obesogen model and suggest that organotin exposure is a previously unappreciated risk factor for the development of obesity and related disorders. Prenatal and early postnatal events such as maternal nutrition, drug, and chemical exposure are received, remembered and then manifested in health consequences later in life. We hypothesized that organotin exposure during prenatal adipose tissue development favors the subsequent development of adipocytes. We found that prenatal TBT exposure altered the balance of progenitor types in the multipotent stromal stem cell (MSC) compartment predisposing them to form adipocytes at the expense of bone. Prenatal exposure to low, environmentally relevant doses of TBT in drinking water led to transgenerational effects on adipose depot weight, adipocyte size and gene expression in MSCs in F1, F2 and F3 animals. Prenatal TBT exposure also increased hepatic lipid accumulation and up-regulated hepatic expression of genes involved in lipid storage/transport, lipogenesis and lipolysis in all 3 generations. Taken together, these results illustrate how prenatal exposure to xenobiotics can have lasting, potentially permanent effects on the offspring of exposed animals.

**740** Ocular Immunotoxicty: A Privileged View

B. Christian and J.C. Schuh. *Nonclinical Safety Assessment, Covance Inc., Madison, WI* and *JCL Schuh, PLLC, Bainbridge Island, WA.*

Vision is achieved through highly specialized ocular tissue structures and processes which refract and transmit light to the photosensitive cells of the retina. Optimal visual function depends on maintaining the integrity and transparency of cornea, aqueous, lens, and vitreous, which can be compromised by unchecked immune reactions. The eye is considered to be an “immune-privileged” organ because of its capacity to moderate intraocular inflammatory responses and protect tissues of the visual axis through anatomic barriers, as well as through local and systemic immunoregulatory mechanisms, particularly immunosuppression. Breakdown or dysregulation of ocular immune privilege can lead to inflammatory disorders such as uveitis, and progression of intraocular neoplasms, and has been implicated in age-related degeneration of ocular tissues. Intraocular inflammation is a commonly encountered response to the intentional breach of immune privilege via intraocular administration of therapeutics. This session will highlight the unique aspects of the immunology of the eye and the associated implications for ocular toxicology and the development of ocular therapeutics. The audience will gain current understanding of structural barriers and active mechanisms of ocular immune privilege. Examples of innate and acquired immune responses to ocular insult, including allergens, microorganisms, and an organ administration of small molecule drugs, biotherapeutics, and viral vector-based gene therapies will be presented. Routine and specialized techniques for evaluating ocular immune responses will also be described. The session will include a presentation describing a current immunomodulatory approach to treat ocular disease involving the complement pathway and possible mechanisms for toxicities in preclinical studies. The final presentation will provide clinical examples and mechanisms of drug-induced immunotoxicity.

**741** Ocular Oversight: Immune Privilege, and Immune Regulation and Dysregulation

J.C. Schuh, JCL Schuh, PLLC, Bainbridge Island, WA.

Ocular immunotoxicology is an evolving field and immune modulation in the eye has implications for successful design, delivery and clinical outcomes for ocular therapeutics. Our understanding of the immunological activity of the eye, including innate, mucosal and acquired immunity has expanded greatly in the last decade. The embryology of the eye is complex and includes formation of the passive barriers of the blood:retinal and blood:aqueous partitions, which are involved in regulation of exposure to systemic immunity and in ocular pharmacokinetics. Uniquely, the eye is a prototypical site of immune privilege, which is not immunological ignorance, but a process of regulated tolerance. Local cellular and secretory activity of immunoregulatory cells in the eye provides an active barrier that minimizes destructive inflammatory outcomes through immunosuppression and anterior chamber-associated immune dysfunction. If released to systemic circulation from an injured eye, ocular antigens interacting with the systemic immune system may lead to sympathetic ophthalmitis, a destructive bilateral auto-immune response. Similarly, neoplastic cells that manage to evade barriers in tissues with immune privilege are also more likely to be progressive. Intraocular uveal melanomas arising within the eye also harness the techniques of ocular immune privilege to avoid destruction upon systemic metastasis. An understanding of ocular passive and active barrier function is important to toxicologists as intraocular injection of drugs or implants, trauma, infections, chemical injuries, paracentesis, surgery, and experimental injection of antigens can result in highly destructive inflammatory responses that threaten vision. This presentation will overview ocular structures, and passive and active barriers of the eye and their relationship to immune privilege, immunopathology, and dysfunctional states that distort the visual axis or result in ocular immunotoxicology.

**742** Innate and Adaptive Immune Responses to Ocular Insult

This presentation will provide an overview of the recent developments in the understanding of ocular surface and intraocular innate and adaptive immune response. Understanding the ocular immune response is essential for specific ocular and systemic general toxicology when assessing biological responses to therapies (small molecule, biologics, gene therapies) given topically, intraocularly, or systemically, their time course, and their implications for preclinical development. The innate or non-antigen specific immune response represents the first line of defense against many pathogens in the eye. The cellular effectors in the innate immune response include neutrophils, eosinophils, mast cells, macrophages, and natural killer cells. While activation of these cells is not antigen specific, innate immunity is based on the recognition of specific pathogen associated molecules through a variety of cell surface receptors. It has long been noted that certain bacterial or fungal molecules, particularly cell wall products such as lipopolysaccharides (LPS) and endotoxins, as well as certain plant-based molecules, can elicit rapid and robust inflammation and immune responses in the eye. These common contaminates of test articles and thus they may confound ocular toxicity results. The antigen specific immune response, also termed the acquired or adaptive immune response, involves a variety of effector mechanisms involving both T cell directed cellular effectors as well as humoral or antibody driven responses to eliminate more complex pathogens. It also provides for a memory response, which is responsible for providing immunity to subsequent infections. It is also responsible for most autoimmune diseases. The antigen specific immune response is dependent on inflammation and the innate immune response for activation and direction. Routine and specialized techniques for evaluating ocular immune responses will also be described.

**743** Complement As a Target for Ocular Disease

Complement pathways have been implicated in human disease for many years and more recently there has been a focus on their role in ocular diseases, including uveitis, macular degeneration and diabetic retinopathy. Complement is a component of innate and acquired immunity and its activity is tightly regulated within the eye. Control of complement activation through the use of inhibitors is an active area of ocular therapeutics. An antigen-binding fragment (Fab) was developed to intervene in the alternative complement pathway for treatment of acute macular degeneration by intravitreal administration. In a pilot safety study in cynomolgous monkeys, adverse effects, particularly in one animal, were characterized by severe inflammation, hemorrhaging, and blindness after a single dose. Investigations into the cause of the toxicities implicated the presence of high levels of anti-drug antibodies in the eye and surface bound Fab. Potential mechanisms for these adverse effects will be discussed.
Gene therapy for ocular diseases is an exciting prospect and recent success in treating Leber’s Congenital Amaurosis with AAV based vectors is encouraging. AAV, Lentivirus, Adenovirus, Herpes simplex virus, and Baculovirus vectors have all been used experimentally to deliver genes to ocular tissues. AAV vectors generally do not trigger ocular immunotoxicity but they have a small carrying capacity. In rodents, these viral vectors do not seem to trigger inflammation; however, a single injection of Lentivirus, Herpes simplex virus, and Adenovirus vectors into non-human primate eyes triggers a transient uveitis. This “toxic” response is an issue in determining whether to proceed with clinical development and with regulatory agencies that approve therapeutics. Vector-induced uveitis develops within a few days of injection, suggesting innate, and not adaptive immune mechanisms are involved. The uveitis does not appear to be due to endotoxin contamination of vector preparations. Cells in the retina express several Toll-like receptors and some of these are up-regulated in the presence of viral vectors. Preliminary array studies suggest that specific changes in host cell innate immunity genes are also occurring. This talk will discuss our efforts to characterize the components of innate immune responses to viruses that are present in the primate eye and how they respond to the presence of these viral gene delivery vectors in order to develop ways to inhibit the responses.

Preclinical models may not predict manifestations of ocular immunotoxicity and this may result in unexpected ocular disease in clinical trials and marketed therapeutics. This presentation will report on clinically relevant immunotoxicity associated with ocular therapeutics. Case reports from spontaneous reporting systems and the world literature were mined for ocular immunological reactions related to medications. The reports come from the FDA spontaneous reporting database, the World Health Organization’s Uppsala Monitoring Center, and the National Registry of Drug Induced Ocular Side Effects (Casey Eye Institute, Portland, Oregon). Multiple drugs were associated with immunologic related pathophysiology. Off target effects of topical ocular chloramphenicol induced aplastic anemia, bisphosphonate related ocular inflammation, and post vaccination uveitis are of particular clinical importance. A working knowledge of some of the most common immunotoxicity adverse effects in ocular tissue is important for toxicologists and clinicians as rapid recognition and drug withdrawal is often curative.

An adverse outcome pathway (AOP) describes a sequence of key measurable events, starting by a molecular initiating event in which a chemical interacts with a biological target, followed by a sequential series of key cellular events, leading to anatomical and functional changes in biological processes and ultimately resulting in an adverse outcome relevant to the human organism and the human population. Thereby, AOP characterization could provide information on the development of structure-activity relationships, i.e., using effect information from one chemical to predict effects for other structurally similar chemicals. Finally, AOPs provide evidence important for qualitative and quantitative predictive models of the adverse outcome that result from triggering molecular initiating or other key events for which high-throughput testing methods can be developed. There are a large number of cellular and molecular processes known to be critical to proper function of the central nervous system (CNS) and peripheral nervous systems (PNS). However, comprehensive understanding of pathways leading from chemical exposure to an adverse outcome in the CNS or PNS is sparse. In this session, five AOPs with relevance for human neurotoxicity will be presented, and common key events across these AOPs will be determined, increasing the possibility to identify potential neurotoxins, even if toxicity is mediated by various pathways. Moreover, vulnerable windows of susceptibility to chemical exposure during brain development and aging will be discussed.

Glutamate is the major excitatory neurotransmitter in the central nervous system (CNS). It mediates key aspects of normal brain function such as sensory information, motor coordination, emotions and cognition. However, it has neurotoxic effects when it is present in excess causing neuronal dysfunction and degeneration (excitotoxicity hypothesis). Most neurons have the ionotropic glutamatergic N-methyl-D-aspartate (NMDA) and α-amino-3-hydroxy-5-methyl-4-isoxazolpropionic acid and kainic acid receptors (NMDAR, AMPAR, KAR), and glutamate-induced neurotoxicity occurs due to their over activation, mainly the NMDAR, which allows the influx of cations, most notably calcium. The activation of NMDAR requires not only binding of various ligands but also cellular depolarization that can be triggered by the activation of AMPAR and KAR. NMDAR are predominantly distributed in the hippocampus, cortex and basal ganglia, where they play a major role in the processes of learning and memory that occur in the hippocampus. The Adverse Outcome Pathway (AOP) methodology is designed to provide a causative link between a Molecular Initiating Event (MIE) and an adverse health effect due to exposure to toxicants. An AOP is proposed that links domoic acid (DA) neurotoxicity (manifested by seizures and loss of memory and histopathological hallmarks like cell death in the hippocampus and other brain areas) with the activation of KAR as the Molecular Initiating Event. Key events in this process are the high affinity of DA to bind KAR, the influx of Na+ and Ca2+ leading to cell depolarization, the release of glutamate from hippocampal neurons, which in turns over activates NMDAR that leads to hippocampal cell death. Data gathered from the bibliography related to the effects of domoic acid-contaminated mussels on human
health, as well as the effects of domoic acid on animal status, on glutamate receptors in vitro preparations and on cultured neuronal cells allow to get a picture of this pathway of neurotoxicity. Supported by the Spanish Grant FIS PI10/0453 cofinanced with European Social Funds

750 SH-Group Binding-Induced (Developmental) Neurotoxicity

C. van Thiel1, IFADe-Leibnitz Research Center for Working Environment and Human Factors, Dortmund, Germany.

The adverse effects of methylmercury (MeHg) on the nervous system have been observed in humans, experimentally studied in animals, and MeHg serves as a test compound in many alternative in vitro NT and DNT methods. Like other electrophilic neurotoxins MeHg binds to sulphydryl groups on macromolecules in cells and body fluids. Such interactions might be the molecular initial event (MIE) in the AOP of several neurotoxins sharing the feature of electrophilicity. In case of MeHg the formation of a methylmercury cysteine complex (MeHgCys2), mimicking methionine, enables the compound to cross membranes (e.g. blood brain barrier) via specific amino acid transporters. Due to this event, and in contrast to inorganic mercury, MeHg becomes a potent neurotoxin that causes disturbances of glutamate uptake by astrocytes or induces ROS by affecting the mitochondrial electron transfer chain. Like other electrophilic neurotoxins MeHg might bind to glutathione (GSH) reducing the antioxidant capacity of neurons. Thus, in case of MeHg one key event of the AOP is reinforced by another. Such multiple and sometimes interactive molecular and cellular events might cause disturbance in brain physiology (e.g. reduce activity-dependent neuronal plasticity) resulting in the neurobehavioral phenotype of MeHg poisoning.

751 Adverse Outcome Pathway (AOP) for Neuroinflammation

F. Tschudi-Monnet1 and A. K. Price1. 1Department of Physiology, University of Lausanne and Swiss Center for Applied Human Toxicology (SCAHT), Lausanne, Switzerland and 2Joint Research Centre, European Commission, Institute for Health and Consumer Protection, Ispra, Italy. Sponsor: E. Fritsche.

Neuroinflammation implies the reactivity of microglial cells and astrocytes. It can be triggered following neuronal stress, injury, or death, following demyelination, or direct activation of microglia and astrocytes. Several classes of toxic molecules initiating events leading to oxidative stress, calcium overload, cytokine instability, synapse impairment, or apoptosis, can trigger a neuroinflammatory response. Therefore, neuroinflammation is a common key event.

Depending on the pathogenic context and/or on the duration of neuroinflammation, glial cells can acquire a neurodegenerative phenotype, which will cause neurodegeneration. Neurodegeneration, the adverse outcome, will exacerbate the neuroinflammatory response and lead to a self-sustained neurodegenerative loop. It is generally accepted that neuroinflammation is involved in several neurodegenerative diseases, playing an important and early role in the disease process. Therefore the detection of neurotoxicant-induced increased expression of the markers of the microglial neurodegenerative phenotype (Igta2, CD86), of some pro-inflammatory cytokines (TNF-alpha; IL-1beta; IL-6), of the reactive oxygen species production (i-NOS, hsp32) and of the astrocyte reactivity (GFAP) associated to a decrease of the markers of the microglial reparative phenotype (Arg1, MRC1) and of some anti-inflammatory cytokines (IL-4, IL-13), completed with morphological observations of an increased number of microglial cells and of markers of their macrophagic state (ED1) will provide early alert for neurotoxicants that may be considered as risk factors for the development of neurodegenerative diseases. The use of in vitro models for screening strategies is possible providing cultures contain all types of brain cells, since cell-cell interactions are crucial for the neuroinflammatory process.

752 Oxidative Attack of the Neural Progenitor Cell Niche As an AOP for Neurotoxicity of the Elderly

E. Fritsche1, IFADe-Leibnitz Research Institute for Environmental Medicine, Düsseldorf, Germany.

Hippocampal neurogenesis accompanied by neural progenitor cell (NPC) proliferation and differentiation takes place in the adult human and rodent brain. Thereby, loss in regenerative (functional) capacities of NPC, i.e. decline in NPC proliferation and neuronal differentiation, causes the steady process of ‘Normal Brain Aging’ with increasing cognitive decline over time. Loss of antioxidative response is one cause for brain aging and decreasing amounts of the major antioxidative transcription factor Nrf2 are found in brains/NPCs of aged rodents in vivo. Just as in vivo, in vitro aged NPCs also loose Nrf2 function. Applying a lentiviral shRNA approach, we identified Nrf2 as a critical pathway contributing to decline in hNPC proliferation and neuronal differentiation thus proving its causal role in declined hNPC function during aging. Shifting the cellular redox balance towards the oxidative side produces accumulation of intracellular NAD+ (molecular initiating event). NAD+ serves as a co-factor for the HDAC Sirt1, which is involved in inhibition of pro-neuronal gene transcription like Mash1 by association with Hes1. On the contrary, reducing conditions supported by decline in Nrf2 leads to decreased neuronal differentiation in adult brains by activation of the HDAC Sirt1 (Key event). This diminished neuronal regeneration causes cognitive decline on the individual and therefore also on the population level (adverse outcome).

753 Idiosyncrasies of Cells in Culture: Lessons from Genetic Toxicology

M. M. Moore1, J. Clements1, M. J. LeBaron1, P. White1 and S. Phuhler1. 1ENVIRON International Corporation, Little Rock, AR, 2Cavus Laboratories, Harrrogate, North Yorkshire, United Kingdom, 3The Dow Chemical Company, Midland, MI, 4Health Canada, Ottawa, ON, Canada and 5Proctor & Gamble, Mason, OH.

Because of a desire to reduce laboratory animal use and a goal to provide information using human cells in culture, rather than rodents, there is an international focus on developing in vitro predictive toxicity assays for chemical hazard assessment. These factors, coupled with the new molecular ‘omics technologies, have provided the major impetus behind the Tox21, ToxCast, and other efforts to move toward an all in vitro hazard test battery. The genetic toxicology community began developing in vitro assays to predict both cancer and human heritable genetic disease in the early 1970s. Ultimately, a regulatory test battery was established and is used by the majority of international regulatory agencies. Over the decades there has been substantial knowledge gained concerning the strengths and weaknesses as well as the important issues involved in using in vitro assays for hazard assessment. In addition, major improvements to the genetic toxicity assays and the interpretation of data have been accomplished over this time period. Currently, there is a multi-sector international effort with a focus on better understanding the issues around cell stewardship, cell line characteristics, and the appropriate strategies for providing/assuring the required metabolic activation for in vitro systems. This effort, coupled with other genetic toxicology community, including the use of 2D vs. 3D cell cultures, and the selection of endpoints and correlations with apical health outcomes, provide extensive information that should inform the current efforts to establish all in vitro approaches for chemical hazard assessment.

754 Overview and Perspective Based on Lessons Learned from the Evolution of In Vitro Genetic Toxicology

M. M. Moore. ENVIRON International Corporation, Little Rock, AR.

The discipline of genetic toxicology began more than four decades ago with the development of a large number of assays in a large number of different organisms and in cell culture. Early on, the postulate was an in vitro assay system was “better” than animal tests. Unfortunately, over time, with the testing of more chemicals and the addition of more in vitro assays, it became clear that the Ames Test and other assays were not completely satisfactory for reliable and accurate carcinogen prediction. The fact that the apical health outcome (the induction of tumors) is not the result of a single biological effect (mutation) that leads, in every case, to a tumor, adds complexity to the situation. Generally, when regulatory agencies selected their preferred genetic toxicity test battery, assays were chosen based on the type of genetic damage that they detect rather than correlation with rodent cancer bioassays. There are currently many parallels between the emerging field of all in vitro toxicology testing and the evolution of in vitro genetic toxicology tests. Many major issues were identified and tackled for in vitro genetic toxicology assays that are just now being recognized as important for the new 21st century in vitro assays. The experiences and lessons learned from the evolution of genetic toxicology will be put into a perspective to provide insight into optimal development, validation and ultimate utilization of new in vitro systems to predict toxicological outcomes.
Good cell culture practices are of critical importance for the reliability and reproducibility of results obtained from in vitro cell systems. In addition to quality standards applied to any cell system, cell cultures used for toxicity testing should demonstrate their ability to accurately detect the endpoint of interest. Experience with genetic toxicology testing emphasizes the importance of avoiding "genetic drift" and minimizing selective pressure that could potentially interfere with the system used to detect the event of interest. Although cell culture based genetic toxicology tests have been in use for several decades, it is only recently that experts in the field have embarked on a mission to provide well characterized, documented, and continuously available stocks of the most common cell lines used in genotoxicity testing. One of the first tasks was to identify the cell line isolate as close as possible to those described in the original publications and characterize these cells on their performance and, where possible, spectral karyotype analysis. These well characterized cells were deposited at multiple locations globally (European Collection of Cell Cultures – U.K., Sigma – U.S., and Japanese Collection of Research Bioresources - Japan) to ensure the continuous availability of certified cells for use in genotoxicity testing. This experience from genetic toxicology should be extended to other toxicity test systems in view of the growing interest in the application of in vitro test systems for high throughput (e.g. ToxCast/Tox21) and other regulatory-mandated safety assessment studies (e.g., Endocrine Disruptor Screening Program of the U.S. EPA). It is imperative that consistent performance and reliability of all aspects of these in vitro test systems are critical elements of realizing the U.S. National Academy of Sciences vision of "Toxicity Testing in the 21st Century."

In vitro genetic toxicology assays have been reported to have a high rate of positive results that are not confirmed in in vivo studies and raising the question of relevance to human risk assessment. This observation led to several studies in which initial observations appeared to indicate that there might be a difference between cells with normal and impaired p53 function, altered DNA repair capacity and/or human versus rodent origin. As part of an on-going collaborative programme of work looking to improve existing in vitro assays (reducing the rate of so called "false positive" results) commonly used mammalian cell types of different species origin, with differing p53 status have been investigated. This present study compared human versus mouse and p53 competent versus p53 mutated function. Nine reproducibly 'false positive' chemicals were tested in a microumulus study using mouse lymphoma L5178Y-3,7,24' mutagenesis (mutated p53), human TK6 (functional p53) and WI2-NS (TK6 related with mutated p53). Although p53 function does not seem to be the overriding factor impacting the generation of positive responses, rodent versus human origin and apoptosis (measured via Caspase-3/7 activity) may have a role to play. This experience emphasizes that differences in qualitative and quantitative responses among cell lines is generally not based on one or perhaps a small number of cell line specific characteristics. Rather, it indicates the importance of understanding the individual cell lines used in toxicological evaluations and accepting the fact that there will be differences in the responses and that proper test interpretation requires that cell line characteristics be factored into test interpretation.

Ames and colleagues later established a standard in vitro metabolic activation mixture containing hepatic microsomes from male rats exposed to AhR agonists (e.g., PCBs). Indeed, rat liver microsomal preparations (i.e., S9) have become the standard for in vitro assessment of chemical mutagenicity. The system is not without its problems however, and researchers have investigated the utility of S9 preparations from a wide range of tissues and animals, as well as a host of alternative approaches for simulating mammalian metabolism in vitro. Fast forward to 2007, and the launch of the ToxCast program for rapid, high-throughput in vitro assessment of chemical toxicity. The ToxCast and Tox21 programs are employing a wide range of in vitro assessment tools, capable of monitoring a vast array of endpoints, to screen over 10,000 substances. However, incorporation of mammalian xenobiotic metabolism into the quantitative high-throughput screening (qHTS) paradigm has proved difficult. Several options are being explored (e.g., metabolically competent cells, coculture, etc), some of which were initially developed for in vitro assessment of genetic toxicity. The presentation will provide an overview of the technical challenges underscoring effective in vitro simulation of mammalian xenobiotic metabolism, and highlight promising avenues for effective qHTS.
For a chemical to demonstrate phototoxity and/or photoulage, the following characteristics are critical: Absorbs light within the range of natural sunlight (290-700 nm); generates a reactive species following absorption of UV/visible light (UV/VIS); and distributes sufficiently to light-exposed tissues. UV/VIS absorption by chemicals alone may not always directly correlate with phototoxic potential and may provide false photoreactivity predictions; however, when UV/VIS absorption is associated with a molar extinction coefficient (MEC) of less than 1,000 M-1 cm-1, there is little phototoxic risk since this low level of light absorption is unlikely to be harmful. Reactive oxygen species (ROS) are generated via energy transfer mechanisms following UV/VIS excitation, including superoxide and singlet oxygen. The ROS assay has been designed to assess photoreactivity of pharmaceuticals, of which the principle is to monitor types I and II photochemical reactions of the test chemicals when exposed to simulated sunlight. This simple analytical test could be used to screen potential chemical scaffolds, leads, and candidate drugs to identify and/or select away from those having phototoxic potential. The validation study for the ROS assay has been carried out by the Japanese Pharmaceutical Manufacturers Association (JPMA), supervised by the Japanese Center for the Validation of Alternative Methods (JaCVAM). Although several false positives appeared, the ROS assay on 42 coded chemicals has provided no false negative predictions. The validation study tentatively indicates satisfactory outcomes in terms of transferability, intra- and inter-laboratory variability, and predictive capacity. Thus, a negative result in this ROS assay would indicate a very low probability of phototoxicity, whereas a positive result would be a flag for follow-up assessment. In conclusion, UV/VIS analysis, MEC, and the ROS assay are non-biological assessments useful for the prediction of the photoreactive property, and their strategic use may minimize animal use in photoreactivity testing of pharmaceuticals.

Clinical development of therapeutic products may encounter issues related to photosafety. This can be due to photoirritation or to a photoallergic reaction, both broadly covered under the indiscriminate term “photosensitivity.” Over 300 therapeutic products are reported to have given photosensitivity reactions, including a variety of pharmacologic classes and biologic agents. Lack of an accurately defined population base makes it difficult to estimate the real incidence of photosensitivity associated with pharmaceutical use. Of the implicated medications, only a minor proportion is of sufficient frequency to be studied in greater detail. Clinical manifestations of adverse drug reactions upon light exposure depend on the interaction between the host, the agent, and the radiation. They range from an acute inflammatory skin reaction, unusual clinical patterns, to photocarcinogenicity. Thus, prediction of the potential for photo-reactions in humans is challenging, both for frequency and severity, and standardized conditions for studies intended to compare pharmaceuticals for photosafety are important. Current approaches to the evaluation of photosafety in clinical trials are primarily based on adverse event reporting or active solicitation of anticipated events, as well as for five possible findings when there is suspicion from nonclinical studies. Issues concerning this strategy include bias introduction, limitation of sample size, and variability in usage in postmarket studies. For topical products, drug development necessitates predictive testing under standard conditions when the to-be-marketed formulation contains ingredient(s) absorbing visible or ultraviolet light. Such testing for photoirritation and photocontact allergy is informative for the design of precautions and safety monitoring in later-phase clinical trials as well as for product labeling. As there are advances in vitro studies for photo-reactions and the development of human biomarkers for adverse experiences, it is likely that these will impact future approaches to the clinical evaluation of photosafety.

Reconstructed human skin models, with the presence of a stratum corneum and lipid barrier, permit testing of various types of topically applied materials ranging from neat chemicals to final clinical formulations. To date, the methods developed have been based on measuring cell viability in the tissue with and without irradiation. The release of cytokines/chemokines into the medium can be informative as well. In the 1990’s, an ECVAM pre-validation phototoxicity study on the EpiDerm™ model (Liebisch et al., 1999) showed that reconstructed human epidermis (RhE) models are capable of correct detection of the acute human phototoxins and non-phototoxins. Several studies with other commercially available reconstructed tissue models (EPISKIN®, SkinEthic™) confirmed these findings. The sensitivity and specificity of assays developed with RhE models for prediction of acute skin phototoxicity are close to 100%. Use of RhE-based phototoxicity assays for prediction of the topological phototoxicity testing was recently implemented into the Draft ICH Guidance Document on Phototoxicity Testing (S10) and As shown in a feasibility study with EpiDerm sponsored by ECVAM between 2002-2005 (contract No. 19868:2002-09 FIED ISP DE), these models can also be used to assess photo-potency, i.e., to assess the phototoxic strength of a topical phototoxin and to estimate the non-phototoxic concentrations that can be safely used in human (e.g., for therapeutic use). Based on comparison between in vitro and in vivo human studies, a safety factor of 10 fold is recommended when extrapolating the in vitro results to man. This presentation will focus on current 3-D skin models for the assessment of the phototoxicity potential of dermal formulations. The presentation will provide an overview of RhE-based phototoxicity assays and discuss their strengths and weaknesses for photo-safety assessment in toxicology and pharmacology.

Stem Cell-Derived Cardiomyocytes: An Alternative Cardiac Toxicity Model for Assessing Drug Safety and Chemical Health Risk

Cardiac safety is a major cause of attrition, withdrawal, and adverse reactions in drug development. It is estimated that adverse cardiac and/or vascular reactions account for greater than 20% of drug attrition over the preclinical, clinical trials, and post-market phases. Effective chemical safety evaluations are also critical for protecting public health. Significant adverse cardiac effects following exposure to a variety of chemicals present in the environment have been reported by the World Health Organization and other researchers. Cardiac safety associated with pharmaceutical drugs and chemical exposures are a mutual focus of keen interest for clinical and public health researchers, academic scientists, government regulators, and industrial scientists worldwide. The development of alternative testing methods of predictive drug and/or chemical toxicity could impact drug discovery and safety evaluations as well as chemical health risk assessment. This workshop brings together a trans-sector and multidisciplinary group of experts to present and discuss
the use of stem cell-derived cardiomyocytes as an alternative model to determine alterations in cardiac electrophysiology, contractility, and structural and developmental toxicity following drug or chemical exposure. Presenters and discussions will address the sensitivity, reproducibility, and biological relevance or ‘fit for purpose’ of stem cell-derived cardiomyocytes and how these factors relate to the use of such data in a screening, risk, or safety evaluation for drugs and chemicals.

**W 765** Transitioning Cardiac Stem Cells from Research Platforms to Predictive Tools
S. D. Pettit. ILSI, Health and Environmental Sciences Institute, Washington, DC.

The availability and use of induced, stem-cell derived cardiac myocytes has grown exponentially in the last 10 years. With this growth has come a concurrent diversification of the potential applications for these assays – for structural, functional, and toxicity based assessments as well as direct clinical translation. This presentation will highlight key areas that could benefit from greater consensus and weight of evidence. These include the sensitivity, reproducibility, and biological relevance of these cell lines and how these factors relate to the use of such data in a screening, risk, or safety evaluation context.

**W 766** Stem Cell-Derived “Cardiomyocytes” and Their Application to Cardiac Safety Assessment: Ready for Primetime?

Human stem cell-derived cardiomyocytes (SC-CM) are an emerging model for the study of drug safety, in particular drug-induced changes in cardiac electrophysiology and contractility. The potential for SC-CM to be used for proarrhythmia assessment is also being considered. An advantage of this test system is that safety pharmacology studies can be performed in human embryonic progenitor cells or adult fibroblasts transformed to resemble mature cardiac myocytes, which could assist translation of nonclinical to clinical findings, and risk assessment. The utilization of an in vitro human SC-CM system to de-risk candidates during preclinical drug development could improve our ability to bring forward novel and safe drug candidates for clinical evaluation. However, the application of SC-CM for drug safety requires robust validation of these cells, to understand how closely they resemble authentic mature ventricular myocytes, and their performance relative to conventional assays used in cardiovascular safety testing. What are the limitations of the human SC-CM model? This presentation will explore the electrophysiologically evaluation of SC-CM, their response to a variety of ion channel blockers known to alter cardiac conduction and repolarization, and discuss some of the challenges that need to be overcome to validate the use of SC-CM for cardiovascular safety assessment.

**W 767** Stem Cell-Derived Cardiomyocytes in High-Throughput Screens for Modulators of Contractility
M. Mercola. Department of Bioengineering, University of California San Diego, San Diego, CA. Sponsor: S. Pettit.

Human stem cell-derived cardiomyocytes (SCCM) are an emerging model for the study of drug safety, in particular drug-induced changes in cardiac function. The application of SCC in drug safety evaluation requires robust validation of these cells, to understand their performance relative to other pharmacological assays used in cardiovascular safety testing. To facilitate high throughput analyses of cardiomyocyte physiology, we developed kinetic imaging cytometry, a high content screening technology capable of measuring cardiomyocyte contractile calcium transients and voltage action potential kinetics and morphology. The instrument and dedicated software are now commercially available, and function by optically recording and analyzing the fluorescence changes of small molecule calcium and voltage sensing probes in response to electrical field stimulation and exposure to ion channel blockers known to alter cardiac conduction and repolarization. We have begun to evaluate the technology using a panel of safe and arhythmicogenic drugs, revealing EC50 values similar to the reported EC50 and/or IC50 values obtained by biochemical and traditional electrophysiological studies. The presentation will discuss current progress and limitations in the optical, high throughput measurements of electrophysiological parameters to assess arhythmicogenic risk. Furthermore, we have used kinetic imaging cytometry in screening campaigns to identify molecules and targets to sustain cardiomyocyte contractility in heart failure, leading to the development of a potential RNA therapeutic that shows efficacy in halting the progression of established heart failure in a mouse pressure overload model.

**W 768** High-Content Screening of Bioenergetic Modulation of Kinase Inhibitor Mitochondrial Toxicity in Human Stem Cell-Derived Cardiomyocytes
N. Thomas. GE Healthcare, Whitchurch, Cardiff, United Kingdom. Sponsor: S. Hunter.

Cardiotoxicity is a significant issue in the development of new drugs targeting key cellular kinases. Human embryonic stem cell (hESC) derived cardiomyocytes cultured in glucose and galactose media were used to examine the cardiotoxicity of twenty six kinase inhibitors and other drugs using high content screening (HCS) to examine a number of key mitochondrial and cellular parameters indicative of toxicity. Analysis of HCS data revealed a number of compounds with increased toxicity under conditions of mitochondrial oxidative phosphorylation. The tyrosine kinase inhibitor Mubritinib, was non-toxic in cells cultured in glucose but exhibited very significant mitochondrial toxicity in galactose media which correlated with the direct impact of the compound on mitochondrial activity measured by respirometry. HCS is a sensitive and efficient approach to surveillance of drug cardiotoxicity in hESC derived cardiomyocytes with multi-parameter analysis providing insight into toxicity mechanisms and that cellular bioenergetics can significantly influence drug cardiotoxicity.

**W 769** Evaluating Chemical Safety, Molecular Targets, and Toxicity Pathways in Mouse Embryonic Stem Cell Differentiation to Cardiomyocytes
E. S. Hunter. US EPA, Research Triangle Park, NC.

As one of the earliest systems to develop and function, evaluation of the cardiovascular system as a critical target for chemical safety and risk assessment in cardiogenic anlagen are established with formation of cardiac plate mesoderm, cardiomyocyte differentiation and establishment of a beating heart tube. The embryonic stem cell test examines compound effects on differentiation of pluripotent mouse ESC to beating cardiomyocytes. Our modified Adherent Cell Differentiation and Cytotoxicity assay evaluates differentiation to cardiomyocytes using myosin heavy chain (MHC) or gastrulation using goosecoid (GSC) as biomarker proteins (In-Cell Western analysis). Additionally, differentiation to multiple cell lineages is assessed using mRNA biomarkers (quantitative nucleic acid assays). Cell number was determined to account for induction of excess cell death or altered proliferation. We evaluated 276 chemicals of the ToxCast phase I library for effects on MHC and GSC. Twenty six chemicals produced a >50% change in the cardiomyocyte differentiation biomarker and 80 chemicals produced more than a 20% change. Two predominant ‘targets’ were identified for chemicals that decreased cardiomyocyte formation, BMP signaling and altered redox potential. Cardiomyocyte differentiation requires normal development and function of the lineages that precede its specification. A comparison of chemical effects indicated that 45% of chemicals that perturb cardiomyocyte differentiation also affect gas-trulation, raising questions of selectivity and specificity of targets and pathways. Thus, ESC can be used to evaluate compound effects on cardiomyocyte formation. Studies that characterize the cell lineage ontology are needed to determine the target cell population and define molecular targets for an assessment of the specificity of effects on cardiomyocyte differentiation. This abstract does not represent EPA policy.

**W 770** The Doorway between Exposure and Response: How Biologically-Based Inhalation Dosimetry Models Enhance Human Health Risk Assessment
I. A. Hatchett1 and J. B. Morris2. 1The Dow Chemical Company, Midland, MI and 2University of Connecticut, Storrs, CT.

The respiratory tract is the portal of entry for inhaled gases, vapors, and particles, providing a route of entry for systemic exposure and a potential target for toxic agents. The inhaled dose is dependent on the physical state, solubility, reactivity and concentration of the material, the structural and functional characteristics of the respiratory tract, and the types and metabolic capability of the surface epithelial cells. It is also contextual and dependent on the dose metric used, whether it is the systemic blood or tissue concentration or the regional dose to specific anatomic sites or target cell populations in the respiratory tract. Human risk assessments are often based on inhalation toxicity studies in rodents, yet a number of vapors, including hydrogen fluoride and diacetyl, have been shown to produce nasal and large airway injury in rodents but small bronchiolar airway injury in humans. Computational modeling has confirmed significant differences in regional vapor absorption patterns between rats and humans that provide a rational framework to explain the observed differences in site-specific injury between species. Multiscale
computational models of the respiratory system that incorporate species-specific anatomical details and data derived from in vivo measurement of particle deposition/clearance and vapor absorption have been developed to improve estimates of material transport and regional dosimetry. Model accuracy is greatly improved by incorporating regional morphologic characteristics of the mucosa and exposure-response data to validate model predictions of site- and species-specific dosimetry. The goal of this workshop is to provide participants with a working knowledge of the state-of-the-art computational tools available to predict regional deposition, absorption and dose of inhaled materials in laboratory rodents, the essential data needed to validate these predictions, and the use of biologically-based computational modeling in human health risk assessment applications and related research.

**W 771 Site-Specific Airway Pathology and Dosimetry of Inhaled Toxicants**
J. R. Harkema, Department of Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI.

Injury caused by acute and chronic inhalation exposures to airborne toxicants (gases and particles) is site specific in the respiratory tract, and dependent on airway dosimetry and cell/tissue sensitivity. Airway dosimetry and injury of inhaled toxicants are further determined by many additional factors such as the physicochemical character of the inhaled toxicant, exposure regimen, host species/strain, age, gender, diet and overall health. In this talk, the speaker will briefly review comparative anatomy and physiology of the respiratory tract in laboratory animals (rodents and nonhuman primates) and humans. He will further provide examples of site-specific nasal and pulmonary pathology caused by exposures to various gaseous and particulate toxicants (e.g., aldehydes, chlorine, ozone, nanoparticles). In addition, examples of state-of-the-art, yet practical, approaches to unbiased determination of exposure-related morphometric, molecular, and biochemical alterations (i.e., computational toxicologic pathology) will be discussed. The talk will conclude with a description of methods to correlate site-specific pathology with estimated 3D-airway dosimetry and modeling of both the upper and lower respiratory tract in laboratory animals that can be used in predictive toxicology to estimate human risk to toxicant exposure.

**W 772 In Vivo Measurements of Dosimetry: What Do the Data Say?**
J. B. Morris, Pharmaceutical Sciences Toxicology Program, University of Connecticut, Storrs, CT.

This presentation will discuss in vivo measurements of regional vapor absorption and integration of that data into computational models of inhaled dose of absorbed vapors for purposes of human health risk assessment. In rodents a large dataset exists on vapor uptake in the isolated upper respiratory tract (URT). Data are also available on whole respiratory tract uptake. Data on URT uptake reveal the critical importance of solubility (as measured by tissue/cair partition coefficient), local metabolism, and direct reactivity in influencing vapor absorption in that site. Physiologically based pharmacokinetic (PBPK) model structures accurately predict the importance of these parameters in controlling uptake, thus providing validation of the PBPK-based approach. Extension of this modeling approach to the whole respiratory tract also provides accurate prediction of total vapor uptake in the rodent. A rich data set from mouth-breathing experiments is available on lower respiratory tract (LRT) vapor uptake in humans. As for the rodent, vapor solubility, local metabolism and direct reactivity are important factors influencing vapor uptake and PBPK-based model structures accurately predict the data that has been obtained. Diacetyl is a vapor that causes nasal and large airway injury in rodents but is associated with bronchiolar injury in man. Application of the PBPK-based modeling approach to diacetyl vapor predicts that the delivery of diacetyl to the lower airways in the human is much greater than in the rat particularly in mouth breathing humans undergoing light exercise. This difference is greatest at lower exposure concentrations at which local airway metabolic pathways are not saturated. The rodent-human difference in airway delivered dose likely reflects a general pattern rather than one specific to diacetyl. Thus, modern validated modeling approaches provide key insights that can be incorporated in quantitative inhalation risk assessments.

**W 773 Interspecies Differences in Respiratory Dosimetry of Volatile and Aerosol Materials Using Multiscale Computational Models**
B. A. Corley, Exposure Science & Systems Toxicology, Pacific Northwest National Laboratory, Richland, WA.

Computational models are often used to link exposures to target tissue doses and responses to inhaled gases, vapors and aerosols. Models have ranged from empirical to compartmental, or mechanistic approaches, depending upon the application and available data. For materials that target specific sites or cell types within the respiratory tract, computational fluid dynamics (CFD) airflow-based models that explicitly incorporate 3D anatomy and physiology have emerged as a leading choice for predicting species- and site-specific exposure-dose-response relationships. In the past, development of such models was expensive, time-consuming, and limited to highly specialized applications. Using modern 3D and 4D imaging and computational methods, CFD models have become more widely available for use in chemical, pharmaceutical, and biological exposure assessments in multiple species including mice, rats, rabbits, monkeys, and humans. These models can extend from the nose/mouth to the bronchiolar airways of the lung. Lower dimensional models can be added to 3D models to address tissue mechanics and the impact of disease on airflows and tissue dosimetry in the deep lung. Likewise, physiologically based pharmacokinetic (PBPK) models have been utilized as airway boundary conditions in CFD models for material transport, uptake, metabolism, and clearance by respiratory tissues along conducting airways. This talk will emphasize the experimental foundation for the development, evaluation, and refinement of these multiscale models, including 3D and 4D CT imaging of normal and diseased animals and humans; MR imaging of hyperpolarized 3He gas flows; airway extraction studies with volatile chemicals; and particle deposition using breath analysis, SPECT/CT imaging; and post-mortem tissue analysis. The potential impacts these multiscale computational models have on relating exposures to site-specific “doses” that are critical for toxic responses and potential risk assessments will be demonstrated for several volatiles and aerosolized materials.

**W 774 Material Transport, Deposition, and Clearance in the Respiratory Tracts of Humans and Animals**

Assessment of the dose and site of deposition of inhaled materials in the lung aids in the interpretation of biological response. The deposited dose provides the link between external exposure and potential adverse effects. While high fidelity computations of the dose are only feasible for the proximal regions of the lung which fall within the resolution of scanned images, anatomically accurate and physiologically relevant mathematical models of material transport and deposition in the entire respiratory tract are developed for humans and a few selected animals to predict site-specific dose and tissue uptake, and allow interspecies extrapolation based on various dose metrics. Mathematical models have been formulated for insoluble, hygroscopic, nonspherical (fibers and nanotubes) particles as well as for vapors and mixtures. Modeling approach and application to a few specific scenarios will be discussed and a few examples will be presented.

**W 775 The Role of Inhalation Dosimetry Models in Multiscale Support to a Range of Risk Assessment Applications**
A. M. Jarabek, National Center for Environmental Assessment, US EPA, Research Triangle Park, NC.

Inhalation dosimetry models afford the flexibility and versatility to support a range of potential applications in human health risk assessment that spans aiding in vitro experimental design, through translation of dose across various test species, to facilitating inferences regarding pathogenesis processes typically represented by endpoints that may also span a scale from genomic profiling in specific target tissues to population biomonitoring. Understanding how the various model structures discussed in the previous presentations can aid these various applications in risk assessment is critical to advancing the accuracy of it as a science-based discipline. This presentation addresses how to best marry available model structure to risk assessment application with examples for both particles and gases. Impact of model applications illustrated include in vitro dosimetry for the design of nanoparticle experiments, translation of fiber dose across species, inferring exposure from biomonitoring of solvents, and using models to inform the plausible mode of action for reactive gases. Opportunities for refining current default inhalation dosimetry algorithms used in dose-response analysis, originally already based on fuller model forms, will be highlighted to show how risk assessment applications continue to evolve as more sophisticated computational structures emerge. Ultimately such
computational models of inhalation dosimetry will serve as the bridge to virtual tissues and systems biology descriptions of the cardiopulmonary system, and link models of multi-pollutant exposures in a given aired to a multi-dimensional description of mode of action and resultant disease. (The views expressed in this abstract are those of the author and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.)

**PL 776 Adverse Outcome Pathways As a Method to Characterize Potential Sources of Increased Risk of Health Effects Attributed to Inorganic Arsenic**

Inorganic arsenic is associated with a number of human health effects including the development of tumors and other diseases. These health effects can be organized into collections of biological responses, i.e., key events that represent adverse outcome pathways (AOPs). An analysis of AOPs may be useful in characterizing the potential impact of sources of variability for health effects, such as the increased risk for particular key events or adverse outcomes. A literature review was conducted to identify the factors that may increase risk for an arsenic-induced adverse outcome, transitional cell tumors of the urinary bladder. Using an AOP framework, we characterized potential impacts of individual-level factors (e.g., sex, genetic polymorphisms, nutritional status, and cigarette smoking status) and life stages (e.g., childhood and in utero) on the risk of bladder cancer. Preliminary results support the hypothesis that factors associated with reduced secondary methylation (i.e., the conversion of monomethylarsonic acid (MMA) to dimethylarsinic acid (DMA)); may also correlate with increased risk of bladder cancer, including sex, genetic polymorphisms, nutrition, and smoking. Our results demonstrate the utility of an AOP analysis in identifying events to which certain human populations may be at increased risk to arsenic-induced bladder cancer.

Disclaimer: The views expressed are those of the authors and do not necessarily represent the views or policies of the US EPA.

**PL 777 Evaluation of an Arsenic Reference Dose for Potential Neurobehavioral Effects in Children**

M. R. Garry1, J. S. Tsui2, V. Perez3 and D. D. Alexander4. 1Exponent, Bellevue, WA, 2Exponent, Chicago, IL and 3Exponent, Boulder, CO.

Health effects associated with low-dose exposures typically occur only after long-term, repeated exposures. However, a health-protective dose based on neurobehavioral effects in children has the potential to be lower than a lifetime-average dose that is protective of chronic health effects. Since an earlier review finding skin lesions as the most sensitive endpoint for populations of arsenic-exposed children, more recent studies have examined cognitive effects in populations exposed to lower arsenic levels in drinking water (<100–200 μg/L). Based on a systematic review of the epidemiological literature (reported separately), we identified critical studies to assess a point of departure (POD) for evaluation of a reference dose (RfD) for neurobehavioral effects. Data from a population-based longitudinal cohort study in Bangladesh provided the strongest evidence for quantifying an association between low-level arsenic exposure and neurobehavioral effects in children. Based on the specific test, gender, and age with the highest positive association between cognitive results (verbal IQ in girls at age 5) and specified urinary arsenic level, a 38 μg/L specified urinary arsenic level is a POD, assuming a decrease of 1 IQ point. This urinary arsenic level is well above the distribution in U.S. children. Using an age-specific urinary excretion rate and population-specific body weight, the POD was converted to an absorbed dose of 0.001 mg/kg/day. Uncertainty factor selection considered study population sensitivity and potential bias toward overestimation (highest dose-response used, malnutrition, incomplete correction for maternal IQ and other socioeconomic factors). Application of an uncertainty factor of 1 to 3 would result in RfDs in the range of 0.001 to 0.0003 mg/kg/day. The existing RfD for chronic exposure in adults (0.0003 mg/kg/day) is thus also protective of potential neurobehavioral effects in children.

**PL 778 Characterization of Blood Lead Levels for Children in a Community Affected by Historical Mining Activities**

R. School1, D. I. Johnson1, A. Feldpausch2, E. R. McConnell3, C. Van Ladingham2, L. Dell1, M. Das3 and A. Gallagher2. 1ENVIRON, Seattle, WA, 2ENVIRON, Monroe, LA and 3ENVIRON, Ambler, PA.

Numerous studies of child blood lead levels (BLLs) were conducted during the 1980s and 1990s in former mining communities in the western U.S.; however, data characterizing contemporary BLLs in such communities are not readily available. For the past decade, blood lead samples have been analyzed for children ages 1-5 in Butte, MT where mining and mineral processing activities have occurred for more than a century within the community. Additional samples were also collected for some children outside the area most affected by mining, and for infants and pregnant women. An electronic database has been compiled from the Silver Bow County Health Department paper records that includes over 6600 records for infants, children and pregnant women. Our study focuses on over 3,500 records for Butte children 12 to 60 months old for the period from 2002 through 2011. Each record includes gender, birthdate, sample date, and a blood lead result. House age data were obtained from the Montana Cadastral online land survey repository. Consistent with nationwide trends, average Butte BLLs have declined by more than 50% from 2002 through 2011. BLLs are higher in 1-2 year olds compared with 3-5 year olds. Strong seasonal variation in BLLs is evident with peak levels in late summer. More than 55% of the children resided in homes built before 1950 and BLLs correlated with house age. A reference population was created by considering the comparability of prominent risk factors between the Butte dataset and the NHANES blood lead database. Weighting factors are applied to adjust for differences in gender balance, child age distribution, and house age distribution. Additional adjustments considered differences in distributions for race/gender and poverty level. Comparisons with the reference population and assessment of variations in BLLs across neighborhoods will guide assessment of ongoing remediation and lead abatement activities.

**PL 779 Variation Analysis of PBPK Model Parameters for Describing the Delivery of Cr(VI) to the Small Intestines of Humans**

C. R. Kirman1, D. Proctor1, M. Suh1, C. M. Thompson1, M. A. Harris1, L. C. Hawe2 and S. M. Hays5. 1ToxStrategies, Rancho Santa Margarita, CA, 2ToxStrategies, Katy, TX, 3ToxStrategies, Austin, TX and 5Summit Toxicology, Lyons, CO.

Sensitivity analyses were used to identify PBPK model parameters that are important for predicting the delivered dose of Cr(VI) to the small intestines in humans. These include physiological parameters (GI lumen pH, transit rates, reduction capacities, and volumes), chemical-specific parameters (pH-dependent reduction rate, absorption rates), and exposure parameters (number of drinking events, event duration). Monte Carlo methods were used to characterize the impact of parameter variation on PBPK model predictions for Cr(VI) internal dose. Coefficients of variation for the key model parameters ranged from approximately 25% to 120%. The impact of correlations between model parameters was assessed. Monte Carlo simulations were conducted for neonates, infants/children, youths, adults, and elderly, using two exposure levels, and two measures of internal dose to the small intestines. Model parameters contributing to greater than 10% of the variance in the predictions for both dose measures include the reduction rate constant and gastric transit rate. Stomach lumen volume was an important contributor to gastric flux, and the absorption rate constant was an important contributor to SI flux. At high doses, the number of drinking water events per day and exposure event time (during fed or fasted states) also become an important variables. The results of the initial analyses were used to calculate data-derived extrapolation factors to account for inter-individual variation. The ratios of the predicted 95th percentile to predicted mean lifetime average dose of Cr(VI) delivered to the small intestines, ranged from approximately 2 to 4. These results indicates the default value of 3 (USEPA) or 4 (IPCS) for intraspecies variation in toxicokinetic processes sufficiently characterizes variability in Cr(VI) SI tissue dose.
It is important for the Texas Commission on Environmental Quality (TCEQ) to conduct up-to-date assessments of all carcinogens (e.g., hexavalent chromium) emitted in Texas based on the latest scientific data and analyses. Consequently, TCEQ has developed an inhalation unit risk factor (URF) for hexavalent chromium (CrVI) based on excess lung cancer mortality in two key epidemiological studies of chromate production plant workers. One of the studies (Crump et al. 2003) concerns the Painesville, OH worker cohort and is an update to an earlier study (Mancuso 1975) used by USEPA (1984) to derive a URF, while the other (Gibb et al. 2000) regards a Baltimore, MD worker cohort used previously to calculate occupational URFs. A cohort of workers from four low-dose chromate plants (Corpus Christi, TX, Castle Hayne, NC, two in Germany) was used for a supporting quantitative dose-response assessment (URFs for other studies also calculated). For the Painesville cohort (Crump et al. 2003), grouped observed and expected number of lung cancer mortalities along with the cumulative exposures to CrVI were used to obtain the maximum likelihood estimate and asymptotic variance of the slope ($\beta$) for the linear multiplicative relative risk model using Poisson regression modeling. For the Baltimore cohort (Gibb et al. 2000), Cox proportional hazards modeling was performed with optimal exposure lag and adjusting for the effect of covariates (e.g., smoking) to estimate $\beta$ values as more detailed, individual, data were available. Life-table analyses were used to develop URFs for each of the two key studies, which were then combined using weighting factors relevant to confidences. For the Baltimore cohort (Gibb et al. 2000), the TCEQ will use this value to protect the general public in Texas against the potential carcinogenic effects from chronic exposure to CrVI in ambient air.

Quantifying the risk of chronic beryllium disease (CBD) from occupational beryllium (Be) exposure is challenging because of limitations in the exposure characterization and interindividual variability in sensitivity. Using worker-specific average exposures and prevalence data for beryllium sensitization (BeS) and CBD for 264 workers at a primary manufacturing facility investigated by NIOSH, the risk of CBD was quantified using logistic, log-logistic and log-logistic transformed regression models. Several modeling approaches and assumptions regarding background risk were explored to estimate the added risk of CBD using models of CBD and bifurcated models of BeS and CBD. Bifurcated models assume two populations with different sensitivities. For both approaches, the average Be concentration associated with a 1/1000 added risk of CBD (RSACs) ranged from 0.02 to 0.22 $\mu$g/m$^3$, with median values of 0.05-0.13 $\mu$g/m$^3$. Bifurcated models estimate that approximately 16% of the cohort was more sensitive, with the remaining members being highly insensitive. These data may be used to inform an Occupational Exposure Limit (OEL) protective of CBD; however, OELs are limits that are not to be exceeded on a day-to-day basis, whereas the RSACs are measures of average exposure. To determine an OEL consistent with these data, 4,016 total Be-labeled samples from the same facility that were used in the exposure reconstruction were further analyzed. Cluster analysis and homogeneity testing was conducted to group the data by job codes with airborne concentrations fitting the same distribution. Of eight statistically distinct groups found, two had mean concentrations of 0.05 and 0.12 $\mu$g/m$^3$, consistent with the estimated range of median RSACs. For these groups, 0.2 $\mu$g/ m$^3$ occurs at the 99th and 84th percentiles, respectively. Thus, setting an upper limit of exposure at 0.2 $\mu$g/m$^3$ is associated with average exposures consistent with a 1/1000-increased risk of CBD.
Introduction: The Antarctic moss *Saxonia uncinita* has presented high contents of chromophores after exposition to high levels of natural ultraviolet B radiation and can be an important source of antioxidants. The photoprotective activity of this moss has been observed. However, there is no data in the literature about toxicological research.

Objective: To investigate the mutagenic, genotoxic and cytotoxic activities of the *S. uncinita*.

Material and Methods: The *Salmonella* microsome assay was performed using the pre-incubation protocol. The mixture of 100 μL of the stationary culture of *Salmonella enterica* serovar Typhimurium strains TA97, TA98, TA100, TA104 and 500 μL of the 59 mix was incubated for 20 min with 100 μL of different concentrations of the hydroethanolic (HE) and ethanol (EE) extracts. Top-agar was added and poured into a Petri dish containing minimal agar medium. After 72h the number of revertants was counted. In MN assay HepG2 cells were exposed to HE and EE for 3 hours, fixed and stained with DAPI. To determine the mitotic index and the number of cells with micronuclei, 6000 cells/dish were counted. The percentage of cells with micronuclei and the mitotic index was calculated. After 72h the number of revertants was counted. In MN assay HepG2 cells were exposed to HE and EE for 3, 24 and 72 hours, it was added WST dye and the absorbance was measured in 440nm.

Results and Discussion: The extracts did not show mutagenic activity in the *Salmonella* strains and did not induce genotoxicity in HepG2 cells, moreover, it was not observed apoptosis or necrosis cell death in these cells. Besides, the cell viability evaluated by WST assay was not affected by HE and EE. Our results showed that in metabolically competent cells, the HE and EE did not induce mutagenic, genotoxic and cytotoxic effects.

Conclusion: The HE and EE should be of interest to further explore the possibility of using it as potential photoprotective.

**Cytotoxicity of Extracts of Three Medicinal Plant Species Used to Treat Inflammation-Related Conditions in South Africa**

S. A. Adebajo1−2, I. L. Shi1 and K. A. Ello2.

Biomedical Sciences, Tulane University of Technology, Pretoria, South Africa and 2Phytochemical Programme, Department of Paracultural Sciences, University of Pretoria, Pretoria, South Africa.

Extracts of medicinal plants are widely used in developing countries for the treatment and management of many diseases. The safety or hazards presented by the consumption of these substances is scarce in literature. There are many cases of fatal intoxication from plants in hospitals. The aim of this study was to assess the safety of oral consumption of extracts derived from the selected medicinal plant species used in vitro cytotoxicity tests.

Dried leaves portion of *Acacia sieberiana*, *Erythrophleum laisanthum* and *Teckovaria capensis* were ground into a fine powder. The ground materials were extracted with cold and hot distilled water, as well as ethanol, representing traditional methods of extraction. The dried extracts were re-constituted in dimethyl sulfoxide at a concentration of 20 mg/ml. These extracts were tested against isolated mononuclear leukocytes, U937 macrophage, vero kidney and liver cell lines maintained in Dubeclo’s Minimum Essential Medium (DMEM) for 72 hours. The assessment of cytotoxic effects were done using both the reduction of yellow tetrazolium salt (3-(4, 5-dimethylthiazol-2)-2, 5-diphenyltetrazolium bromide (MTT) and Excellence RTCA assay systems.

Overall, the results indicated that all the extracts tested were not cytotoxic to the cell lines used when compared with hydrogen peroxide (1 mM) and Doxorubicin hydrochloride (2 mg/ml) positive controls. The vero kidney cell lines grew at optimal rate when cultured in the presence of ethanolic extracts of *A. sieberiana*, while the least growth was observed when the same cell lines were cultured in the presence of cold water extracts of *E. laisanthum*. The cold water extracts of *E. laisanthum* had the least effects on mononuclear leukocytes using the MTT assay among the extracts tested. This indicated that the choice of evaluation method is critical for results interpretation. However, there is a need for *in vivo* study using a model animal to validate these results.

**Amelioration of Sodium Arsenite and Potassium Chromate Toxicities by Methanolic Extract of *Rauvolfia vomitoria***

K. A. Akinwumi1,2, O. A. Odunola1, A. N. Dosunmu2, O. B. Owolabi2, A. Songonuga1, O. A. Aboyeji2, O. O. Olawuni1 and O. O. Osise1.

1Dept. of Biochemistry, University of Ibadan, Ibadan, Oyo, Nigeria and 2Dept. of Chemical Sciences, Bells University of Technology, Ota, Ogun, Nigeria. Sponsor: D. Landolph.

Exposure to arsenic and hexavalent chromium is a major public health concern especially in the developing part of the world and there is still no reliable treatment. This study therefore evaluates the effect of methanolic leaf extracts of *Rauvolfia vomitoria* (MRV) on mice exposed to sodium arsenite (NaAsO2) and potassium hexaarsenate (VI) (K2Cr2O7). Test and control mice were pre-treated with 20mg/kg body weight MRV before being challenged with either NaAsO2 and K2Cr2O7 on the seventh day. The negative control animals were exposed to distilled water, while the positive control mice were exposed to a single dose of either 2.5 mg/kg body weight NaAsO2 and 12mg/kg of K2Cr2O7 a day before the animals were sacrificed. The frequency of micronucleated polychromatic erythrocytes (mPCEs) was monitored in bone marrow cells, while aspartate aminotransferase (AST) and alanine aminotransferase (ALT) activities were assessed in the plasma. Hepatic glutathione (GSH) and malondialdehyde (MDA) levels as well as catalase (CAT) and glutathione-S-transferase (GST) activities were also monitored.

**The Effect of Eukaryotic Initiation Factors on the Activity of Pokeweed Antiviral Protein**

S. Cheng, A. Domashkevsky and L. Kobelinsky.

Science, John Jay College of Criminal Justice, New York, NY.

Ribosome-inactivating proteins (RIPs) are found in numerous plant, fungi and bacterial species, and are recognized to have a broad spectrum of anti-viral activity. RIP function is characterized by depurination, the N-glycosidase activity, of the conserved sarnic/rin loop of the large ribosomal subunit. PAP is also able to depurinate mRNA at specific nucleotide locations, by binding to the m7G cap at the 5’-end of the mRNA, and interaction with eukaryotic initiation factors (eIFs).

These biological functions suggest that the mechanism of PAP action is complex, yet information about the molecular mechanism of how this toxin causes apoptosis or the basis for its selection of RNA for depurination scores. In order to determine the role of multiple protein-protein interactions (PAP, eIF3, eIF4 and eIF4G) in PAP function, the pull-down assay and the fluorescent-resonate energy transfer assay (FRET) have been investigated here. Our results indicate that eIF3 and eIF4 bound together as the eIF3/eIF4 complex to m7GpppG cap analog and this binding cannot be overcompeted by PAP. eIF4G repressed the competition of PAP with eIF3 and eIF4 bound analog binding. FRET energy transfer study revealed that eIF3 and eIF4 bound in close proximity as PAP and eIF4 and eIF4G bound closely to each other to increase FRET energy transfer. PAP and eIF4 bound to each other; this interaction produces only low level of FRET energy transfer. PAP, eIF4 and eIF4G bound closely to each other to increase FRET energy transfer dramatically. This triple protein interaction demonstrated eIF4G plays a key role in regulation of PAP binding.

**Effect of Sesamin on Endothelial Nitric Oxide Synthase Activation via Multiple Pathways**

Endothelial nitric oxide synthase (eNOS) is the key regulator of vascular functions in the vascular endothelium. While many pathways are involved in the regulation of eNOS activity, phosphorylation at the most thoroughly studied site at Ser1177 is generally found to be a critical requirement for eNOS activation. Sesamin, one of the major lignans in sesame seeds and oil, has been reported to have many benefits and medicinal properties including anti-hypertensive effect, but its influence on intracellular pathways underlying eNOS remains unclear. Sesamin increased the phosphorylation of eNOS in a concentration-dependent manner in human endothelial cells. In addition, sesamin increased the phosphorylation of Akt, ERK1/2, JNK1/2, and p38 MAPK in cells. Furthermore, sesamin increased the phosphorylation of AMP-activated protein kinase (AMPK) and calmodulin-dependent protein kinase II (CaMKII). eNOS phosphorylation was inhibited by specific upstream inhibitor of ERK1/2 (PD98059), p38 (SB203580), AMPK (compound C), and CaMKII (BAPTA, W7). These results indicate that sesamin stimulates eNOS phosphorylation via the activation of ERK1/2, p38, AMPK, and CaMKII.

**Amelioration of Sodium Arsenite and Potassium Chromate Toxicities by Methanolic Extract of *Rauvolfia vomitoria***

K. A. Akinwumi1,2, O. A. Odunola1, A. N. Dosunmu2, O. B. Owolabi2, A. Songonuga1, O. A. Aboyeji2, O. O. Olawuni1 and O. O. Osise1.

NaAsO2 and K2C2O7 significantly (p<0.05) increased the frequency of mPCE formation. AST, ALT, CAT and GST activities when compared with the control. Simultaneous exposure to NaAsO2 and K2C2O7 further increased (p<0.05) the levels of the markers. In addition, GSH and GST were significantly (p<0.05) reduced in mice exposed to NaAsO2 or K2C2O7 or their combination. However, pre-treatment with MRV restored the markers towards that of the control. Our study therefore suggests that MRV ameliorates NaAsO2 and K2C2O7 induced toxicities via reduction of oxidative stress and fortification of anti-oxidant system.

**789** Cytoxic and Genotoxic Assessments of the Natural Dye Erythrostominone

F. R. Abe and D. P. Oliveira, University of São Paulo, Ribeirão Preto, São Paulo, Brazil.

Introduction: Synthetic dyes are used extensively for pharmaceutical, cosmetic or food industries. These industrial sectors are affected by the low cost, easy availability and high diversity of colors and shades of synthetic dyes, however, several of these compounds present inherent toxicity, and can be precursors of toxic intermediates and/or mutagens produced during metabolism. Thus, natural dyes obtained by the fermentation processes of micro-organisms are alternatives for the substitution of synthetic dyes in some applications. Additionally, they have low cost, and require little space for the large-scale production, increasing the economic viability for industrial use. Objectives: The present work aimed to evaluate the cytoxicity and genotoxicity of the natural dye erythrostominone extracted from micro-organism. Methodology: Cultures of HepG2 cells were exposed to erythrostominone at concentrations of 35, 87, 174, 261, 348, 522, 696 and 870 mg/ml and to negative (NC-DMSO) and positive controls (PC-CCCP) and cytoxicity was evaluated after 24 hours using MTT assay. After exposure, cell viability was analyzed by spectrophotometry. The comet assay verified the genotoxicity of the dye at concentrations of 35, 87, 174, 261, 435 and 522 mg/l NC (DMSO) and PC (MMS). The DNA tail formation was analyzed with fluorescence optic microscopy. The values of cell viability and tail moment were analyzed statistically by the software GraphPad Prism 5.01. Results: Erythrostominone dye at 522, 696 and 870 mg/ml presented statistically significant difference in cell viability, when compared to the NC. No statistically significant difference was observed in tail moment. Discussion: Erythrostominone dye is cytoxic at higher concentrations, however it does not induce genotoxicity in tested concentrations. Conclusion: According to our data, erythrostominone dye can be used in industrial sectors as a substitute of synthetic dyes, since it has no citotoxicity and genotoxicity at concentrations lower than 522 mg/l. Others toxicological studies are necessary to investigate possible damage to human and environmental health.

**790** Comparison of the Estrogenic Modulating Activities of Dong Quai with Hops and Red Clover

Many women use dong quai (Angelica sinensis, (Oliv.)) dietary supplements as over-the-counter medication to relief menstrual irregularities and menopausal symptoms in a natural and safe way. However, despite the widespread use of dong quai in the US, its efficacy and safety has not been demonstrated. Data in the literature about dong quai’s estrogenic/antiestrogenic activities are contradictory. To analyze this controversy, a lipophilic (CO2) and hydrophilic (EtOH 75%) dong quai extract was systematically analyzed for its estrogen receptor (ER) modulating activities in a natural and safe way. However, despite the widespread use of dong quai in the over-the-counter medication to relief menstrual irregularities and menopausal symptoms, (Oliv.)) dietary supplements as over-the-counter medication to relief menstrual irregularities and menopausal symptoms. Erythrostominone dye is cytotoxic at higher concentrations, however it does not exhibit genotoxicity in tested concentrations. Consequently, our data suggest that the dong quai extract displays cell-specific cytoxicity toward PCa cells, with no toxicity towards breast (MCF-7), lymphocyte (THP-1) or neuronal (GT1-7) cancer cells. Furthermore, our current data show that low doses of Biz-2 kill PCa cells, but show no apparent effect on normal, transformed prostate cells, or display any in vivo toxicity in mice. Next, we examined the mechanism of action of Biz-2-induced cytoxicity by examining LNCaP and DU145 cells exposed to Biz-2 for morphological signs of apoptosis, along with the expression of several apoptotic markers. In those experiments, we found that Biz-2 was able to induce apoptotic cell death in PCa cells. Biz-2 was twice as potent in inducing apoptosis in AR- DU145 cells as in the AR+ LNCaP cells. This study has demonstrated that Biz-2 can modulate prostate cancer cell function. (Work was supported by a NIH grant, Grant No. 5P20RR016456-08S1)

**791** Extracts of Protea cynaroides Are Cytotoxic toward Hormone-Resistant Breast and Prostate Cancer Cells

P. Gwava, F. Imhoff-White, B. Bridge, S. Taurin and R. J. Rosengren, Pharmacology & Toxicology, University of Otago, Dunedin, New Zealand.

This study was designed to determine the optimal extraction method for extracting phenolic compounds from the plant Protea cynaroides. In all extraction methods, 1 g of leaves were thoroughly washed and submerged in 0.1 N HCl prior to extraction preparation. Immediate freezing and grinding in LN2 followed by freeze drying produced the freeze dried extract. Leaves that were oven dried were subjected to water, alcohol and alcohol/water extraction methods. All stock solutions were sterilised using a 0.22 μm filter. Cytotoxicity was determined using the sulforhodamine B assay. Phenolic content of the extracts was determined using the Folin-Ciocalteu method. The results showed that the alcohol/water extraction method produced a 2-fold greater amount of phenolic compounds compared to water extraction (100 vs 50 μg/ml, respectively). This correlated with more potent cytotoxicity of the alcohol/water extract toward both cell lines. Specifically, 92, 94 and 97% of MDA-MB-231 cells were killed by the alcohol/water extract compared to 47, 55 and 55% for the water extract at concentrations of 0.9, 1.8 and 9 mg/ml, respectively. A similar trend was seen in PC3 cells as 83, 93 and 99% of cells were killed following treatment with the alcohol/water extract compared to 55, 76 and 86% for identical concentrations of the water extract. However, freeze-dried extracts were equally cytotoxic at 9 mg/ml concentrations, as > 94% of PC3 and MDA-MB-231 cells were killed at this concentration by both freeze-dried and alcohol/water extracts. However, alcohol/water extracts were more potent than freeze-dried extracts at the lower concentrations of 0.9 and 1.8 mg/ml. The results of this study show that water, alcohol/water and freeze drying are all viable methods of extracting phenolic compounds from Protea cynaroides. However, alcohol/water extraction is the preferred method as it produces a more potent extract that is cytotoxic toward >90% of MDA-MB-231 and PC3 cells at concentrations of 0.9 mg/ml.

**792** Differential Effects of Biz-2 in Cancer Cells

O. S. Phillips1, K. Harris2 and W. G. Gray2,1, 1Environmental Toxicology, Southern University and A&M College, Baton Rouge, LA and 2Department of Chemistry, Southern University and A&M College, Baton Rouge, LA.

Prostate cancer (PCa) is the leading cause of cancer death in men in the USA, making it a major problem with a socio-economic burden in the millions of dollars. Despite rapid advancements in the early detection and treatment of PCa over the past fifty years, there are no effective cures for this disease. It is of paramount importance to develop new, effective ways of addressing PCa. Our laboratory has been studying the mechanism of the bioactive chemicals present in the Kola acuminata, a "cure-all" herbal medicine known to the Ettu people of Jamaica as bizzy nut. Based on the ethnoveterinarian and anecdotal data available on this natural product, we hypothesized that bizzy nut contains one or more bioactive compounds that can modulate prostate biology. Using cell cytotoxicity, androgen receptor (AR) binding and AR gene expression as indices of androgenicity, we found that the ether extract of bizzy (Biz-2) contains compounds with potent anti-androgenic potential in both AR+ and AR- prostate cells. Biz-2 was able to inhibit the proliferation of prostate cells (DU145 and LNCaP) in a concentration-dependent manner. We observed that the Biz-2 extract displays cell-specific cytoxicity toward PCa cells, with no toxicity towards breast (MCF-7), lymphocyte (THP-1) or neuronal (GT1-7) cancer cells. Furthermore, our current data show that low doses of Biz-2 kill PCa cells, but show no apparent effect on normal, transformed prostate cells, or display any in vivo toxicity in mice. Next, we examined the mechanism of action of Biz-2-induced cytoxicity by examining LNCaP and DU145 cells exposed to Biz-2 for morphological signs of apoptosis, along with the expression of several apoptotic markers. In those experiments, we found that Biz-2 was able to induce apoptotic cell death in PCa cells. Biz-2 was twice as potent in inducing apoptosis in AR- DU145 cells as in the AR+ LNCaP cells. This study has demonstrated that Biz-2 can modulate prostate cancer cell function. (Work was supported by a NHF grant, Grant No. 5P20RR016456-08S1)

**793** Antioxidant Activity of Extracts of Stem Bark of Enantia chlorantha (Oliv)

O. E. Adebiyi and O. M. Abatan,

Department of Veterinary Physiology, Biochemistry and Pharmacology, University of Ibadan, Nigeria, Ibadan, Oyo, Nigeria.

Enantia chlorantha is an ornamental tree that has been reported to posses hae-mostatic antimalarial, antibacterial, antiviral and hepatoprotective properties. The hexane, chloroform, ethyl acetate and methanol extracts of stem bark from Enantia chlorantha stem bark were assessed for in vitro antioxidant activity using Ferric
Curcumin, a phytochemical found in Tumeric, has been widely studied for its potential in the prevention of different types of cancer. However, it only has limited clinical applicability because of its low oral bioavailability. One of the approaches to improve curcumin’s bioavailability is to develop curcumin prodrugs. Ester prodrugs are the most common type that can be easily converted back to the active agent by esterases found in the body. A series of aminoacylsulphonyl esters of curcumin was designed and synthesized involving amino acids such as leucine, isoleucine, and valine. Mono-conjugated (only one phenol group in curcumin was conjugated with an amino acid moiety) and di-conjugated (both phenols were modified) products were observed. The conjugates were then evaluated in cytotoxicity assays using different prostate cell lines and in cancer prevention screening assays using sphere formation in gastric cancer cells. Overall, valine conjugates were less cytotoxic than curcumin while mono-isoleucine conjugates had comparable cytotoxicity to curcumin. Two mono-conjugates were screened for their cancer preventive effects. The results showed that curcumin and both amino acid conjugates significantly reduced sphere formation. This indicates that curcumin analogs, which are expected to have better aqueous solubility and improved oral bioavailability, have similar chemopreventive effects to curcumin, possibly at reduced cytotoxicity.

Kahweol, the coffee-specific diterpene, has been reported to have anti-carcinogenic properties. Animal data support such a chemopreventive effect of coffee. However, the precise underlying chemopreventive mechanism is poorly understood. This study examined the inhibitory effect of kahweol on phorbol myristate acetate (PMA)-induced MMP-9 expression in HT-1080 human fibrosarcoma cells. Results showed that kahweol suppressed PMA-induced phosphorylation of Akt and the tissue inhibitor of metalloproteinase (TIMP)-1, while the amount of 4-hydroxylated products remained unaffected by kahweol. Cytochrome P450 1A1 (CYP1A1) and 1B1 (CYP1B1) catalyze 2- and 4-hydroxylation of estradiol into precursors of carcinogenic quinones. Modulation of mRNA levels and activity of CYP1A1 and CYP1B1 were measured to assess possible mechanisms of actions. The results correlated with the 4-hydroxylation metabolism data. 8- and 12- hydroxyestradiol, and IX were differentially induced. CYP1B1 activity was evaluated independently of CYP1A1 activity. Analysis of the influence of an IX-rich (57.6% w/w) hops extract on 2- and 4-hydroxylation of estradiol by LC-MS/MS revealed that the extract reduced the carcinogenic 4-hydroxylation pathway similar to pure IX. These data suggest that hops constituents differentially modulate estradiol carcinogenesis and underscore that analysis of hops extract is essential for the reproducibility of biological outcome.

Support for this work was provided by P50 AT00155.
Stimulates eNOS phosphorylation via the activation of Akt, ERK1/2, AMPK, and CaMKII. These results demonstrate that CAPE might be useful for the treatment or prevention of endothelial dysfunction associated with atherosclerosis and cardiovascular disease.

797b Kahweol Induces Apoptosis in HER2-Overexpressing Breast Cancer Cells through a Down-Regulation of HER2/SREBP-1/FAS Pathway
S. Oh, M. Do and H. Jeong, Pharmacy, Chungnam National University, Daejeon, Republic of Korea.

Breast cancer is the leading cause of cancer-related death among women worldwide. Kahweol, natural diterpenes from coffee, has been reported to exhibit anti-cancer activities. This study investigated molecular mechanisms by which kahweol induced apoptosis in HER2-overexpressing breast cancer cells. Results showed that kahweol strongly inhibited cell growth and induced apoptosis in SKBR3 breast cancer cells through caspase-3 activation and induction of FAS cleavage. Kahweol markedly reduced HER2 protein levels in a concentration-dependent manner. Kahweol significantly suppressed fatty acid synthase (FAS) mRNA and protein levels in SKBR3 cells. Kahweol inhibited Akt activation, leading to reduction of mature sterol regulatory element-binding protein (SREBP)-1 protein levels. Furthermore, using specific PI3K inhibitor LY294002 confirmed that the blockade of Akt/SREBP-1 signaling pathway caused FAS reduction in SKBR3 cells. These results demonstrate that kahweol down-regulates HER2/SREBP-1/FAS pathway and induces apoptosis in breast cancer cells, suggesting a potential role in prevention and treatment of human breast cancer.

797c Antiproliferative and Apoptotic Effect of Rhus trilobata Extracts on SKOV-3 Ovarian Cancer Cells
B. E. Sánchez Ramírez1, E. Saénz-Pardo-Reyes1, C. González-Horta1, R. Infante-Ramírez1 and P. Talamás-Rohana2. 1Graduate Program in Biotechnology, Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, Mexico and 2Basic Pharmaceutical Science, Univ LA-Monroe, Monroe, LA.

Rhus trilobata, known as Skunk brush, is a plant from northern Mexico frequently used in traditional medicine for different types of cancer. The aim of this work was to analyze the effect of extracts of Rhus trilobata on proliferation and apoptosis of SKOV-3 ovarian cancer cells. Extracts were prepared by equilibrium in distilled water (AE) or with 70% methanol (ME) using stems of the plant recollected in November 2012. Sub-fractions of both extracts were obtained using Sep-Pak C18 cartridges and different solvents. Crude extracts and sub-fractions were tested on SKOV-3 ovarian cancer cells; viability and cytotoxicity or apoptosis were determined in cultures using the ApoToxGlo kit, and mitotic index was calculated for all treatments. Cultures without treatment or incubated with Vinoversine or Curcumine, were used as controls. Results showed that both extracts, AE and ME, significantly decreased proliferation (mitotic index < 1) and cell viability at concentrations < 20 μg/mL at 24 and 72 h, compared with untreated cultures (p <0.05); no significant differences were found with cultures treated with 20 μg/mL of Vinoversine. Fractionation of crude extracts produced seven fractions that were evaporated to dryness prior to their use. The fractions that showed greater antiproliferative effect were 3, 4, 5 and 7 from the AE, and 2, 5 and 7 from ME at a concentration of 5 μg/mL (p <0.05). Apoptosis assays showed that antiproliferative effect was associated with an increase in caspase activity in cells treated with 5 μg/mL of AE, ME, or active sub-fractions. No cytotoxic effect was detected at any of the concentrations tested. Results presented here demonstrate that Rhus trilobata stems contain active compounds with an important antiproliferative effect on SKOV-3 ovarian cancer cells, which is related to the induction of apoptosis rather than a cytotoxic effect. Supported by FOMIX CHIH-2010-C01-147532.

798 Comparison of Myelostimulation by Echinacea purpurea Extracts with Analytical Fingerprint to Identify Active Constituents
S. A. Meyer1, H. F. Husin1 and K. A. El Sayed2. 1Toxicology, Univ LA-Monroe, Monroe, LA and 2Basic Pharmaceutical Science, Univ LA-Monroe, Monroe, LA.

We have previously described a myelostimulatory activity of Echinacea herbal supplement (Spring Valley Natural Whole Herb, Ida Sphere Inc., American Fork, UT) (Ramasahayam et al. 2011. Planta Med. 77:1883-9). Product label described the encapsulated material as Echinacea purpurea (aerial part) with gelatin and medium-chain triglycerides. A 7.5% ethanol extract administered orally for 7d at 50-100 mg dried extract/kg/d, as recommended for human intake, to female Sprague-Dawley rats yielded a 70% increase in femur myeloid progenitors, i.e., CFU-GMs, from nucleated bone marrow cells upon culture in methylocellose with csf2, IL-3 and SCF (HALO assay, Hemogenix, Colorado Springs, CO). To determine that bioactivity was due to plant-derived material, we obtained an HPLC fraction enriched in the natural source (Ray Jaglowksi, Twinlab Corp., Grand Rapids, MI), extracted with ethanol (EtCP) and tested for CFU-GMs. Since Echinacea aerial part contains lipophilic N-alkylamides as a primary constituent class, we also determined myelostimulatory activity of n-hexane-washed EtCP (HexEtCP). Analytical fingerprints of EtCP and HexEtCP were acquired with HPLC and 1HNMR (400 MHz, 20 mg/700 μl MeOH-d4). Increase in CFU-GMs of EtCP was comparable to that previously determined for herbal supplement and HexEtCP activity, normalized to source EtCP (~95% yield), was 2 times more potent than EtCP. Hexane wash fraction of CP did not affect CFU-GMs. Proton NMR spectra of hexane wash contained prominent peaks from β-sitosterol, as verified from spectra of pure standard (ChromDox, Irvine, CA). Similarly, 1HNMR spectral peaks with shifts equivalent to those of dodeca-2,4,8,10-tetraenoic acid isobutylamide (PhytoLab, Vestenbergsgreuth, Germany) were evident in hexane wash. HPTLC confirmed that these lipophilic constituents were removed from EtCP by washing with n-hexane. In conclusion, these studies demonstrated that myelostimulation of supplement Echinacea was due to phytochemical other than lipophilic constituents.

800 Inhibitory Effects of Platycodon grandiflorum Root-Derived Saponins on DNBC-Induced Atopic Dermatitis-Like Skin Lesions in Mice and the Possible Mechanisms in Cells
J. Choi1, S. Jin1, B. Park1, H. Kim1, Y. Chung2 and H. Jeong1. 1Pharmacy, Chungnam National University, Daejeon, Republic of Korea and 2Department of Food and Medicine, International University of Korea, Jinju, Republic of Korea.

Platycodon grandiflorum root-derived saponins (Changkil saponins, CKS) have many biological and pharmacological effects, including anti-inflammatory, anti-oxidative, and anti-obesity effects, but its influence on contacted allergens-induced atopic dermatitis (AD) remains unclear. The consequences of precipitously rising allergic skin inflammation rates worldwide have accelerated the risk of AD. AD is a major health problem all age in globally. This study investigated the inhibitory effect of CKS on AD-like skin lesions in mice and the possible mechanisms in cells. DNCB treatment for 9 weeks led to marked AD-like skin lesions as assessed by AD severity, ear thickness, serum level, and histopathological examination in mice. DNCB-induced AD severity, serum level of IgE and TARC and mRNA expression of TARC, TNF-alpha, IFN-gamma, IL-4, IL-5, and IL-13 attenuated by CKS treatment in NC/Nga mice. Histopathological examination showed that DNCB-induced thickness of the epidermis/dermis and dermal infiltration of inflammatory cells and mast cells reduced by CKS treatment in the ear lesions. Also, CKS suppressed TNF-alpha/IFN-gamma-induced TARC expression in HaCaT cells. CKS inhibited TNF-alpha/IFN-gamma-induced NF-kB activation as well as STAT1 activation. Furthermore, CKS increased Nr2f2/ARE-mediated HO-1 expression. These results indicate that CKS suppressed DNCB-induced AD-like skin lesions by regulating cytokine mediators in NC/Nga mice and TNF-alpha/IFN-gamma-induced TARC expression through the suppression of NF-kB and STAT1 and induction of Nr2f2/ARE-mediated HO-1 expression in HaCaT cells, which may be an effective alternative therapy for AD-like skin symptoms.
metalloproteinase-13 (MMP-13), tissue inhibitor of metalloproteinase-1 (TIMP-1), tumor necrosis factor-alpha (TNF-a), alpha-smooth muscle actin (SMA), and collagen type 1 inhibited by CKS treatment. Moreover, CKS inhibited HDF-induced cyclooxygenase-2 (COX-2) protein expression, NF-kB p65 nuclear translocation, and TNF-alpha degradation. These results indicated that CKS manifests hepatocellular protective action and ameliorative effects against chronic liver injury and developing NASH induced by HDF treatment.

**801 Inhibitory Effects of Platycodon grandiflorum Root-Derived Saponins on Ovalbumin-Induced Airway Hyper-responsiveness in Mice**

Y. Lee1, J. Choi1, S. Jin1, H. Kim1, Y. Chung2 and H. Jeong3, 1Pharmacy, Chungnam National University, Daejeon, Republic of Korea, 2Jangsaeng Doraji Research Institute of Biotechnology, Jangsaeng Doraji Co., Ltd., Jinju, Republic of Korea and 3Department of Food and Medicine, International University of Korea, Jinju, Republic of Korea.

Platycodon grandiflorum root-derived saponins (Changkil saponins, CKS) have many biological and pharmacological effects, including anti-inflammatory, antioxidant, and anti-obesity effects, but its influence on inhaled allergens-induced airway hyperresponsiveness remains unclear. Allergic asthma is a chronic respiratory disease caused by inappropriate responses to inhaled allergens and is characterized by reversible obstruction of airway hyperresponsiveness. Inflammation in the airway results from an influx of inflammatory cells, mucus overproduction, and the overexpression of inflammatory cytokines and chemokines. This study investigated the inhibitory effects of CKS on ovalbumin (OVA)-induced airway inflammation in mice and PMA-induced MUC5AC expression in A549 cells. Mice were sensitized and challenged with OVA developed inflammation and remodeling in airway. The inhibitory effect of CKS on OVA-induced airway inflammation was evaluated by number of total and differential leukocytes, level of IgE, MCP-1 chemokine, and cytokines, and histopathological study. CKS attenuated OVA-induced number of total cells, eosinophils, basophils, lymphocytes, and macrophages, level of TNF-alpha, IFN-gamma, IL-4, IL-5, IL-13, MCP-1, and IgE in bronchoalveolar lavage (BAL) fluid. CKS suppressed OVA-increased mRNA expression of MMP-2/9 and MUC5AC in mice. Additionally, CKS attenuated airway hyperresponsiveness, inflammatory cells and goblet cells hyperplasia in lung tissue. CKS blocked NF-kB p65 nuclear translocation from lung tissues of OVA-sensitized/challenged mice. Furthermore, CKS suppressed PMA-induced MUC5AC mRNA expression and luciferase activity in cells. These results indicate that CKS suppressed the development of the airway inflammation-like symptoms and MUC5AC expression by suppressing of NF-kB activation in mice, and so may be a useful tool in the therapy of airway inflammation-like symptoms.

**802 Inhibitory Effects of Platycodon grandiflorum Root-Derived Saponins on Estrogen Deficiency-Induced Osteoporosis in Mice**

H. Jeong1, J. Choi1, B. Park1, K. Lee2 and Y. Chung1, 1Pharmacy, Chungnam National University, Daejeon, Republic of Korea, 2College of Pharmacy, Chonnam National University, Gwangju, Republic of Korea and 3Department of Food and Medicine, International University of Korea, Jinju, Republic of Korea.

Platycodon grandiflorum root-derived saponins (Changkil saponins, CKS) have many biological and pharmacological effects, including anti-inflammatory, antioxidant, and anti-obesity effects, but its influence on estrogen deficiency-induced osteoporosis remains unclear. Osteoporosis is a reduction in bone mass and the micro-architectural weakening of bone tissue, with a resultant increase in bone fragility and vulnerability to fracture. Osteoporosis is a major health problem in postmenopausal and aged women in the world. This study investigated the inhibitory effect of CKS on osteoporosis induced by ovarioectomy (O VX) in mice. O VX animal model has been widely used to evaluate for postmenopausal osteoporosis with estrogen insufficiency. The inhibitory effect of CKS on O VX-induced osteoporosis was evaluated by body weight, plasma parameters, and micro-computed tomography for bone turnover in mice. After 4 weeks of recovery from surgery, the O VX mice were randomly divided into three groups and orally treated with saline or CKS for 3 weeks. CKS attenuated O VX-induced body weight. CKS improved O VX-reduced plasma levels of alkaline phosphatase, phosphorus, and calcium. Also, CKS restored the bone deterioration of trabecular microarchitecture. These results indicate that CKS attenuate O VX-induced bone turnover and lower the risk of osteoporosis.

**803 Toxicological Evaluation of Methanol Leaf Extract of Alchornea cordifolia**

T. O. Aibade and F. O. Olayemi, Department of Veterinary Physiology, Biochemistry and Pharmacology, University of Ibadan, Nigeria, University of Ibadan, Nigeria, Ibadan, Oyo, Nigeria.

Alchornea cordifolia is commonly used as a medicinal plant and widely distributed throughout Africa including Nigeria and Democratic Republic of Congo (DRC). The leaves are traditionally used for the treatment of venereal diseases. Thirty six male Wistar albino rats were randomly divided into six groups of six rats each. The toxic effects of the methanol extract of Alchornea cordifolia leaves were investigated on reproductive and hematological parameters of male rats at 0, 100, 200, 400, 800 and 1600 mg/kg-1. The Red Blood Cell (RBC) count, packed cell volume (PCV), hemoglobin concentration (Hb) and hematric indices except mean corpuscular volume decreased (p<0.05) significantly at the 1600 mg/kg-1 dose compared to the control. Markers of hepatic damage alanine and aspartate aminotransferases (ALT and AST) and renal damage (Urea and Creatinine) were significantly elevated (p<0.05) at 800 and 1600 mg/kg-1. Similarly, significant increases were observed in testicular weight, spermatozoa count and motility with concomitant increase in serum testosterone levels in all treatment groups. Severe deleterious effects were not recorded at doses below 400 mg/kg-1. However, the leave extract of Alchornea cordifolia at 800 and 1600 mg/kg-1 has hematotoxic, hepatotoxic and nephrotoxic effects. In conclusion, caution is therefore required for the medicinal usage of this plant because of its potential toxic effects on the liver, kidney and blood cells.

**804 Elucidation of the Mechanisms of Teratogenicity of Some Commonly Used Medicinal Plants**

G. O. Alolayan1, M. L. Carvan1, O. Awodele2 and E. O. Agbaje2, 1School of Freshwater Sciences, University of Wisconsin-Milwaukee, Milwaukie, WI and 2Department of Pharmacology, University of Lagos, Lagos, Nigeria.

An array of studies has proven the efficacy of numerous medicinal plants against ailments ranging from pain to microbial infection. However, their teratogenic potentials have not been well elucidated. One such ethnobotanical survey was used to determine the types of medicinal plants used by pregnant women in Lagos, Nigeria. The aim of this study is to determine the possible teratogenic effects on the cardiovascular and nervous systems and the mechanism of teratogenicity of these commonly used medicinal plants. The aqueous extracts of some of the most commonly used plants (Enantia chlorantha, Morinda lucida and Moringa oleifera) were prepared. Pregnant Wistar rats were treated with several doses (150-600 mg/kg) of these extracts at gestational day six and the litters were examined for any defects at gestational day 20. There was no significant change in the number of litters and their gross morphology. However, there was a significant increase in fetal resorptions, and the overall body weight and crown to rump length of the litters was affected in a dose dependent manner of which the direction is dependent on the plant species. Zebradish embryos were also exposed to several concentrations (0-1.28 mg/ml) of the extracts between 4-144 hours post-fertilization. A dose dependent effect was observed in the developmental processes of the zebrafish resulting in embryo lethality, skeletal dysmorphogenesis and pericardial edema leading to the formation of a tubular heart. However, there was no significant change in locomotor activity of the cleemothroembryo by six days post-fertilization when there was no overt teratogenicity. These research findings offer a basis for further investigation of the cellular and molecular mechanisms by which these extracts cause developmental defects in both zebrafish and rat whole embryo culture. These approaches remove the influence of maternal metabolism and other influences, and will provide valuable endpoints for exploration in pregnant mammals and newborns.

**805 Effect of α7 Nicotinic Acetylcholine Receptor Agonists and Antagonists on Motor Function in Mice**

K. Welch1, J. A. Pfister1, F. Lima2, K. E. Pantel1, B. T. Green1 and D. R. Gardiner1, 1Poisonous Plant Research Laboratory, USDA-ARS, Logan, UT and 2Federal University of Goias, School of Veterinary Medicine, Goiania, Goias, Brazil.

Nicotinic acetylcholine receptors (nAChRs) are ligand-gated cation channels found throughout the body, and serve to mediate diverse physiological functions. Muscle-type nAChR located in the motor endplate region of muscle fibers play an integral role in muscle contraction and thus motor function. The toxicity and teratogenicity of many plants are due to various toxins that bind to nAChRs including deltaline and methyllycaconitine (MLA) from larkspur (Delphinium) species, and nicotine and anabasine from tobacco (Nicotiana) species. The primary result of the actions of these alkaloids at nAChRs is neuromuscular paralysis and respiratory failure. The objective of this study was to further characterize the motor coordination deficien-
cies that occur upon exposure to a non-lethal dose of nAChR antagonists MLA and deltaline as well as nAChR agonists nicotine and anabasine. We evaluated the effect of nAChR agonists and antagonists on the motor function and coordination in mice using a balance beam, grip strength meter, rotarod, open field analysis and tremor monitor. These analyses demonstrated that, within seconds after treatment, the mice had significant loss of motor function and coordination that lasted up to one minute, followed by a short period of quiescence. Recovery to normal muscle coordination was rapid, typically within approximately 10 min post-dosing. Additional studies were conducted to determine if the c7 nAChR subunit plays a role in these motor coordination deficiencies by comparing the motor function and coordination in wild-type mice to mice lacking the c7 subunit of the nAChR, after treating them with a non-lethal dose of MLA or anabasine. The results from this study suggest that the c7 nAChR subunit does not play an integral role in the acute effects of MLA or anabasine on motor function/coordination.

806 Toxic Effects of Root Extract of Caestis ferruginea (de Candolle) on the Blood Profiles of Male Rats

Caestis ferruginea belongs to the family Convolvulaceae and it possesses antibiotic activities. It has alkaloid as its main bioactive constituent and our preliminary investigation revealed that it has antifertility property. The toxic effects of methanolic root extract of Caestis ferruginea on the blood profiles were studied in male albino rats. The rats were treated with daily oral administration of 500mg kg−1bw of Caestis ferruginea for 5, 30 and 60 days. The erythrocyte values (red blood cell (RBC), packed cell volume (PCV), haemoglobin (Hb), mean corpuscular haemoglobin (MCH), mean corpuscular haemoglobin concentration (MCHC) and mean corpuscular volume (MCV) and leucocyte values (total white blood cell (WBC), lymphocyte, eosinophil and monocyte counts) and plasma concentrations of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were not affected by the treatment after the 30days treatment period. However, there were significant reductions in the values of RBC (P<0.001) and PCV (P<0.02) on the 60th day of treatment. The rats were treated with daily oral administration of 500mg kg−1bw of Caestis ferruginea for 5, 30 and 60 days. The erythrocyte values (red blood cell (RBC), packed cell volume (PCV), haemoglobin (Hb), mean corpuscular haemoglobin (MCH), mean corpuscular haemoglobin concentration (MCHC) and mean corpuscular volume (MCV) and leucocyte values (total white blood cell (WBC), lymphocyte, eosinophil and monocyte counts) and plasma concentrations of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were not affected by the treatment after the 30days treatment period. However, there were significant reductions in the values of RBC (P<0.001) and PCV (P<0.02) on the 60th day of treatment. The values of Hb and MCV were not affected while those of MCH and MCHC were increased (P<0.001) after 60 days of treatment. Furthermore, the total WBC, neutrophil, eosinophil and monocyte counts were not affected by prolonged treatment. The plasma level of AST was not affected by prolonged treatment, but the plasma levels of ALT increased (P<0.01) on the 60th day of treatment. In the recovery experiment, the values of PCV, MCH, MCHC and plasma ALT were also restored to the pre-treatment values. This study revealed that prolonged administration of the crude root extract of Caestis ferruginea may induce anaemia.

807 Acute and Subchronic Oral Toxicity Studies of Stem Bark Extract of Syzygium guineense (Myrtaceae) in Rats

O. A. Salawu1, M. Hafeez2 and A. Y. Tijani1. Veterinary Physiology, Biochemistry and Pharmacology, University of Ibadan, Ibadan, Nigeria.

Introduction/Objective: Syzygium guineense, widely used in African Traditional Medicine, has been evaluated for its effect on diabetes mellitus, Herpes zoster in combination with other medicinal plants, malaria, bacterial infections, diarrhoea and hypertension. To confirm its safe use, the present study evaluated the potential toxicity of a methanol extract of Syzygium guineense stem bark after acute and subchronic administration in Wistar rats.

Materials and Methods: The oral acute toxicity of the extract was studied using the modified Lorke’s method, and the rats were then monitored for 14 days. In the subchronic toxicity study, the extract was administered orally to groups of rats (6 rats/dose/sex) at doses of 250, 500 and 1000 mg/kg/day for 90 consecutive days. Measurements included clinical observations, water and food consumption, body weight, haematology, blood chemistry, urinalysis, gross necropsy, organ weight and histopathology.

Results: There was no mortality or signs of acute or subchronic toxicity. There was no significant difference in body weight, relative organ weight or haematological, liver function monitoring parameters, urea, creatinin and electrolytes at 42 and 90 days respectively in the subchronic toxicity study. No abnormality of internal organs was observed in both gross and histopathological examinations between treatment and control groups.

Conclusion: These results suggest that the lethal oral dose of the stem bark extract of Syzygium guineense is more than 5000 mg/kg in both male and female rats and the no-observed-adverse-effect level (NOAEL) of the extract for both male and female rats is considered to be 1000 mg/kg per day for 90 days.

808 Enzymic and Nonenzymic Antioxidant Status in Wistar Rats Administered Aqueous Leaf Extract of Morinda morindoides

D. I. Akinloye1, E. A. Balogun2,1, T. O. Sunmonu2 and S. O. Omotainse2.

Morinda morindoides is a medicinal plant in some African countries where its leaves are used for treating malaria. Information on biochemical changes induced following oral administration of this plant is scarce in the literature. Hence, this study was designed to investigate the enzymic and non-enzymic antioxidant status in Wistar rats administered aqueous leaf extract of Morinda morindoides using activities of catalase (CAT), glutathione peroxidase (GPOX), glutathione reductase (GSH.RD), superoxide dismutase (SOD), glutathione-S-transferase (GST), gamma glutamyl transferase (GGT) and levels of reduced glutathione (GSH), total-thiol (T.SH), vitamin C and E as indices.

In vivo antioxidant activity of the extract and its in vivo effects on malondialdehyde (MDA) concentration and histology of liver and kidney were also investigated. Thirtty rats grouped into five (A, B, C, D, and E) were used for the study. Group A served as control and was administered distilled water while groups B, C, D and E were given 100, 200, 400 and 800 mg/kg body wt of the extract for 28 days. Pyrochrome analysis revealed that the plant is rich in phenolic and flavonoid compounds. Plasma vitamins C and E, T.SH and GSH were significantly (P<0.05) increased while a significant (P<0.05) reduction in plasma concentration of MDA and activities of glutathox yse GPOX, GSH.RD as well as liver activities of SOD and CAT occurred when compared with control. These are indications of antioxidant property of Morinda morindoides. The extract showed significant scavenging effects on hydrogen peroxide, nitric oxide, ABTS radical cation and DPPH radical. Histological investigations revealed mild vacuolar degeneration of hepatocytes and moderate tubular degeneration of the kidney. These findings indicate that Morinda morindoides possesses in vivo and in vitro antioxidant activities but may be slightly injurious to the tissues studied.

809 The Antioxidant, Anti-Inflammatory, and Antinociceptive Activities of the Ethanolic Leaf Extract of Andrographis paniculata Nees (Family Acanthaceae)

A. A. Adedapo1, B. O. Adeoye1, A. A. Ovaghemi1 and M. O. Sofidiya1,2.

1Veterinary Physiology, Biochemistry and Pharmacology, University of Ibadan, Ibadan, Oyo, Nigeria and 2Pharmacognosy, University of Lagos, Lagos, Lagos, Nigeria.

Introduction

Andrographis paniculata Nees commonly known as king of bitters is well-known medicinal properties (Sandberg 1994, Samir & Amrit 2002, Adedapo et al 2009). This study is to evaluate the medicinal property of this plant obtained in the wild in Nigeria.

Materials and Methods

Ethanol extract (EE) was prepared by dried ground leaf material (200g) in absolute 1 L ethanol for 48 h, filtered, dried and then used for the pharmacological investigations. Standard phytochemical methods were used to test for the presence of phytoactive compounds in the plant. Acute toxicity was carried out in mice to determine safe doses for this plant extract. Anti-oxidant activities of the plant were assessed using ABTS, DPPH, FRAP and total phenolics test. The anti-inflammatory activities were conducted using carrageenan and histamine-induced tests while antinociceptive activities were carried out using writhes and formalin licking tests.

Results

Acute toxicity test showed that no animals died at the doses even at 1600mg/kg dose. The extract at 50, 100 and 200mg/kg body weight caused a significant reduction in the anti-inflammatory and analgesic activities though not in the same magnitude as indomethacin, the reference drug used in this study. In the case of anti-oxidant activities, the extract caused 82.7% ABTS inhibitory activity i.e. 6.21±0.003 gallic acid equivalent; 76.61% DPPH inhibitory activity (12.91±0.007 ascorbic acid equivalent); 50.37±0.23 (42%) ascorbic acid equivalent for FRAP and 78.56±0.04 (58.43%) gallic acid equivalent for total phenolics.

Conclusion

The results from this study may have validated the traditional basis for the use of Andrographis paniculata as medicinal agent. The pharmacological activities noted in this study may be attributed to the presence of flavonoids and other phenolics contained in this plant.
Green tea polyphenols (GTP) are found to protect against many chronic diseases in animal models and human studies. There are four major GTP: EC, ECG, EGC, and EGC2 in green tea. They mainly undergo phase 2 metabolism, including glucuronidation, sulfation, and methylation. In addition, there was significant metabolism by gut microbiota in the colon. The lack of sufficient information on the biotransformation of GTP has limited our understanding of its possible beneficial health effects. In this study we determined the metabolic fate of GTP in humans with particular emphasis on their methylated forms and microbial metabolites. After feeding 600 mL of green tea (5 g tea leaves), human urine samples were collected that showed by HPLC with a multi-channel coulometric electrochemical detector (HPLC-ECD) and liquid chromatography-mass spectrometry (LC-MS).

The major methylated metabolites appeared in human urine as 4'-O-methyl(-)-epigallocatechin (4'-ME-EGC), 4'-O-methyl(-)-epigallocatechin-3-gallate (4'-ME-EGCG) and 4,3'-di-O-methyl(-)-epigallocatechin-3-gallate (4,3'-DiME-EGCG). Only trace amounts of 4'-O-methyl(-)-epigallocatechin-3-gallate (4'-ME-EGC) were found. These methylated metabolites were mostly in glucuronidated form (50-75%) in human subjects and the renal excretion peaked 4.5-5.5 h after the dose. The cumulative excretion of 4'-ME-EGC, 4'-ME-EGCG and 4,3'-DiME-EGCG during a 8 h period ranged from 4 to 100 µg, 15 to 18 µg, and 5.9 to 300 µg, respectively. The amount of 4'-ME-EGC excreted in urine was about 20% of total excreted GEC and accounted for about 1% of EGCG ingested, whereas excreted 4,3'-DiME-EGCG accounted for about 0.1% of ingested EGCG. Microbial metabolites such as (-)-5-(3',4',5'-trihydroxyphenyl)-γ-valerolactone (M4), (-)-5-(3',4'-dihydroxyphenyl)-γ-valerolactone (M6), and (-)-5-(3',5'-dihydroxyphenyl)-γ-valerolactone (M8) also were detectable and predominantly in glucuronidated and sulfated forms in the urine. These results will enhance our understanding of protective characteristics of green tea constituents against human diseases.

A common amino acid, β-alanine (BA) is frequently used as a nutritional supplement to enhance workout capacity in athletes and delay fatigue; effects potentially attributable to enhanced buffering in muscle resulting from increased carnosine content. The present study in rats was designed to assess the safety of BA exposure against human diseases.

**811 Subchronic Oral Gavage Safety of Beta-Alanine in Rats**

D. W. Pouge1, B. Frantez2, P. Hanlon2 and H. Ferguson2. 1MPI Research, Matthews, NC and 2Abbott Nutrition, Columbus, OH.

A common amino acid, β-alanine (BA) is frequently used as a nutritional supplement to enhance workout capacity in athletes and delay fatigue; effects potentially attributable to enhanced buffering in muscle resulting from increased carnosine content. The present study in rats was designed to assess the safety of BA exposure against human diseases. The present study in rats was designed to assess the safety of BA exposure against human diseases.

The control group received saline and each treated group received the EEZA in dose of 500, 1000, 2000 and 4000 mg/kg through gastric intubation for 15 days (once a day in the morning). At the end of the experiment, blood was collected from the orbital sinus under ether anesthesia for biochemical and hematological analysis. The animals were sacrificed by cervical displacement and selected organs (liver, heart, spleen, left kidney and left lung) were removed for macroscopic analysis. Oral administration of the alcoholic extract of Z. armatum in a dose from 100 to 4000 mg/kg did not produce any significant changes in behavior, breathing, cutaneous effects, sensory nervous system responses and gastrointestinal tract effect in mice. In conclusion these results showed that in subacute dose, there is no adverse effect of Z. armatum indicating that the medium lethal dose (LD50) is higher than 4000 mg/kg for both male and female mice. The macroscopic analysis of the target organs of the treated animals (liver, lungs, heart, spleen and left kidney) did not show any significant changes in colour and texture when compared with control group.

**813 Investigation on the Toxicity of Aconitum brachypodum Diels In vitro and In vivo**

To investigate the toxicities of four active extracts from Aconitum brachypodum Diels in vitro and in vivo. LD50 was detected to estimate the toxicity of the extracts after intragastric administration to Kunming mice. The results showed that the extracts from Aconitum brachypodum Diels have different degrees of toxic effects on mice. The toxic symptom included reduced activity amount, retching, abdominal breathing, diaphoresis, exorbitism and convulsion. The chloroform extract even lead to fatality of some mice at doses above 25 mg/kg. LD50 of chloroform extract, petroleum benzine extract and n-butanol extract were 38.0 mg/kg, 6766.9 mg/kg and 5492.3 mg/kg respectively. The rank of their toxicity was: chloroform extract > petroleum benzine extract > acetic ether > n-butanol extract. The present study compared the toxic fractions of Aconitum brachypodum Diels in vitro and in vivo.

**813a Toxicity in Mice and Rats Associated with Inhalation of the Flavor and Fragrance Ingredient Alpha-Pinene**

C. V. Rider, M. D. Stout and R. A. Herbert. NTP/NIEHS, Research Triangle Park, NC.

α-Pinene is the main component in turpentine and is used as a fragrance and flavoring ingredient. Due to widespread exposure potential and a lack of available toxicity data, the National Toxicology Program conducted 2-week and 3-month inhalation studies in male and female F344/N rats and B6C3F1/N mice. In the 2 week studies, groups of 5 male and 5 female rats and mice were exposed to α-pinene by whole body inhalation at concentrations of 0, 100, 200, 400, 800, or 1,600 ppm, 6 hours plus T90 (12 minutes) per day, 5 days per week for 16 (rats) or 17 (mice) days. There was significantly decreased survival in the 800 and 1,600 ppm male and female rats and mice, clinical signs of toxicity in rats (400 ppm and greater) and mice (800 and 1600 ppm), and increased liver weights in both species. In the 3-month studies, groups of 10 male and 10 female rats and mice were exposed to α-pinene at concentrations of 0, 25, 50, 100, 200, or 400 ppm, 6 hours plus T90 (10 minutes) per day, 5 days per week for 14 weeks. All exposed male rats and male and female mice survived to the end of the studies, while six 400 ppm female rats died before the end of the study. The major targets for α-pinene toxicity were the urinary system and the male reproductive system. Increased kidney weights in male (100 ppm and greater) and female (50 and 200 ppm) rats were accompanied by histopathological lesions (i.e., granular casts and hyaline droplet accumulation) in all dosed groups of male rats only. A dose-dependent increase in the incidence of transitional epithelium hyperplasia in the urinary bladders was observed in male (70%, 100%, and 100%) and female (60%, 100%, and 100%) mice exposed to 100, 200, and 400 ppm α-pinene, respectively. Finally, there were significantly decreased numbers of cauda sperm in 200 ppm and above male rats and 100 ppm and above male mice, reaching a maximum of 50% decrease in 400 ppm male mice. Based on these toxicity findings, chronic inhalation studies with α-pinene are warranted. This research was supported by the NIH, National Institute of Environmental Health Sciences.
Arsenic toxicity has been associated with diverse ailments including cancer in both experimental animals and humans. Hence, the search for agents that can protect/reduce arsenic-induced toxicities. In the present study, the anticlastogenic and hepatoprotective abilities of aqueous leaf extract of *Andrographis paniculata* (Ap) against sodium arsenite (NaAsO2)-induced toxicities were examined in male albino rats. The *in vitro* antioxidant activity of the extract was also determined as compared with standard antioxidants. Test and control rats were exposed to 200, 500 and 1000 mg/Kg body weight of Ap for 28 days. Simultaneously, the animals were treated with 5mg/kg body wt of NaAsO2 on the 7th, 14th, 21st and 28th day of the experiment before they were sacrificed. The frequency of micronucleated polychromatic erythrocytes (mPCEs) as monitored in bone marrow cells while aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP) and gamma glutamyl transferase activities were assessed in the serum. NaAsO2 induced significantly (p<0.05) mPCEs formation and the activities of all the hepatic enzyme markers. Pre-treatment with Ap significantly reduced the mPCEs and enzyme activities observed. Our study suggests that aqueous leaf extract of Ap may be useful in the management of arsenic toxicity.

Epigallocatechin gallate (EGCG), the major flavonoid in green tea, has been associated with cases of hepatotoxicity in humans and animals. Here the EGCG effect on rat liver mitochondria was examined as a useful model of xenobiotic hepatotoxicity. Though EGCG showed negligible effects on oxidative phosphorylation at 7.5-100 μM in normal mitochondria, respiratory chain complexes (RCCs) were profoundly inhibited in mitochondria undergoing calcium overload-induced mitochondrial permeability transition (MPT). At RCCs are located in mitochondrial inner membranes (IM) and matrix, it was reasoned that EGCG could not readily pass through IM to affect RCCs in normal mitochondria but may do so when IM integrity is compromised. This speculation was substantiated in three ways. (1) Purified EGCG-bound proteins were barely detectable in normal mitochondria and contained no RCCs as determined by Western blotting, but swelling mitochondria contained about 1.5-fold more EGCG-bound proteins which included four RCC subunits together with cyclophilin D that locates in mitochondrial matrix. (2) Swelling mitochondria consumed more EGCG than normal ones as determined by HPLC. (3) MPT blocker cyclosporine A diminished the above-mentioned difference. Among four subunits of RCC II, only SDHA and SDHB that locate in mitochondrial matrix, but not SDHC or SDHD that insert into the IM, were found to be EGCG targets. Interestingly, EGCG promoted calcium overload-induced MPT only when moderate MPT already commenced. The data suggest EGCG could be detrimental in MPT-associated diseases and toxicities by causing synergistic or additional mitochondrial damages.
Physiologically Based Pharmacokinetic Modeling of Cerium Oxide Nanoparticles by Pulmonary Exposure in Rats

D. Li1, J. Barres1, U. Carlander2, E. Eagle3, C. Emound4, G. Johanson1, M. Morishita1, J. G. Wagner2, M. Woolridge3 and O. Jolliet1.

Environmental Health Science, University of Michigan, Ann Arbor, MI, 1Environmental Medicine, Karolinska Institutet, Stockholm, Stockholm, Sweden, 2Mechanical Engineering, University of Michigan, Ann Arbor, MI, 3BioSimulation Consulting Inc, Newark, DE and 4Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

In vitro studies have reported toxic effects of cerium oxide nanoparticles (CeO2 NPs) which can be used as a diesel fuel additive, thus it is important to understand the biodistribution of CeO2 NPs in the body via pulmonary exposure. The aim of this study was to measure this biodistribution and to develop a physiologically based pharmacokinetic model of CeO2 NPs using a compartmental analysis approach. A one-compartment model was fit to CeO2 intratracheal instillation data in rats. The resulting CeO2 biodistribution model was then applied to predict CeO2 concentrations in different organs after intratracheal instillation of the nanomaterials. The model was validated using CeO2 NPs (-80nm) for 5 hours and measured concentrations in different organs over 14 days. These results were then compared to the CeO2 concentrations after intratracheal delivery of 200µg CeO2 NPs (-6.6nm) over 28 days measured by He et al. (2010). High concentrations of CeO2 NPs were found in the lungs and feces about 2mg/g and 12mg/g of NPs were found respectively in the lungs and feces 1 day post inhalation exposure. Concentrations in other organs were 3-4 orders of magnitude lower at this time. By comparison, the intratracheal instillation study had similar tendencies in the concentrations among organs but captured a higher fraction of the total administrated CeO2 NPs in the lungs compared to the nasal exposure study (78% vs 4%). The simulated time courses of NPs biodistribution agreed well with experimental data, yielding R2 of 0.73 for the inhalation exposure study and 0.99 for the intratracheal instillation study. Further investigations are ongoing to study the sensitivity of the model parameters and to support the most critical parameters.

Comparative Analysis of Predictive Models Used to Identify Drivers of Nanomaterial Toxicity

B. Harper1, R. Liu1, Y. Cohen2 and S. L. Harper1,2. 1Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR, 2Center for Environmental Implications of Nanotechnology, University of California, Los Angeles, Los Angeles, CA.

Understanding the inherent and conditional factors associated with nanomaterial toxicity is critical to the development of nanotechnologies that pose minimal threats to humans and the environment over the life cycle of the nanomaterial. We compared the results of several different models built to predict toxicity from the open-source data on nanomaterial toxicity to embryonic zebrafish (Danio rerio) found in the Nanomaterial-Biological Interactions (NBI) knowledgebase at Oregon State University. Model comparisons included the ABMiner predictive models, MATLAB clustering analysis and the use of Self-Organizing Map (SOM) based consensus clustering conducted on the data in the NBI knowledgebase (nbi.oregonstate.edu). Overall results suggest that exposure concentration and surface area to volume ratio should be considered in conjunction with the core composition of nanomaterials when trying to develop predictive models for predicting zebrafish toxicity. Core composition was found to be a significant contributor to the ABMinor predictive model. MATLAB clustering grouped materials into two clusters with outermost surface chemistry being the primary determinant. The SOM modeling identified five significant clusters (clustering index = 0.89); while no core materials occurred in all 5 clusters, 4 material types (based on core composition) occurred in 4/5 clusters and 15 material types occurred in 3/5 clusters. In addition, over half of the materials appeared in multiple clusters depending on the dose applied. Thus, classification of nanomaterials by simple descriptors such as core composition may not be sufficient for predicting nanomaterial toxicity or managing nanomaterial risks.

Development and Validation of a Dosimetric Platform for In Vitro Nanotoxicology

J. Cohen and P. Demokritou. Harvard School of Public Health, Boston, MA.

Sponsor: J. Brain.

There is a great need for developing screening tools capable of rapidly and accurately assessing engineered nanomaterial (ENM) toxicity. One impediment to the development of reliable in vitro screening methods is the need for accurate dosimetry. In a typical in vitro cytotoxicity study ENM powders are suspended in liquid media for application to cells. ENMs in liquid suspension can form large fractal aggregates thereby altering (1) the total number of free particles, (2) the total surface area available for biointeractions, and (3) the effective size and density of the particles. While these two properties influence their fate and transport and determine the effective dose actually delivered to cells in culture over the duration of exposure, the present here a methodology for in vitro nanotoxicology that takes into consideration factors that influence their fate and transport and determine the effective dose actually delivered to cells in culture over the duration of exposure. We present here a methodology for in vitro nanotoxicology that takes into consideration factors that influence their fate and transport and determine the effective dose actually delivered to cells in culture over the duration of exposure. This multi-step methodology includes: (1) standardization of ENM liquid suspension preparation; (2) sample characterization using transmission electron microscopy to determine the ENM transformations in exposure media; and (3) numeric calculation of the effective dose as a function of exposure time.

The described methodology was then used to derive simple mathematical equations that are applicable to determine the effective dose delivered to cells as a function of exposure time, or to perform meta-analyses on previously reported toxicity datasets taking dosimetry into consideration.

A Pharmacokinetic Modeling Framework for Interspecies Extrapolations of Nanoparticle Biodistribution Taking into Account Biocorona Dynamics Independent of Species-Specific Disposition Processes

J. E. Riviere1,2, F. D. Sahneh1, C. Scooglio1 and N. A. Monteiro-Riviere1.

1Institute of Computational Comparative Medicine, Kansas State University, Manhattan, KS and 2Nanotechnology Innovation Innovation Center of Kansas State, Kansas State University, Manhattan, KS.

Formation of a corona complex around engineered nanoparticles (NP) dramatically alters their biodistribution. A common practice in nanotoxicology and nanomedicine is to extrapolate results from in vitro cell culture or in vivo rodent models to humans. There are concerns about the reliability of these predictions about whether the fate of NP in rodent models with high basal metabolic rates (BMR) and short blood circulation times can predict the fate of the NP in large mammals that have a lower metabolic rate and a greater circulation time? The interaction between two major processes determines the NP biodistribution: delivery to target cells with an allometrically scalable rate across species and an independent process of NP corona formation. Long circulation times in humans allows for the formation of a mature hard corona complex potentially masking the NP originally engineered with specific surfaces for target cell receptors. A simple and descriptive compartmental model is proposed to compare the potential fate of NP in rodent models versus humans by allometrically scaling those components dependent upon BMR and separately describing the potential fate of NP in large mammals that have a lower metabolic rate and a greater circulation time. Our model has 10 compartments and 15 material types (based on core composition) occurred in 4/5 clusters and 15 material types occurred in 3/5 clusters. In addition, over half of the materials appeared in multiple clusters depending on the dose applied. Thus, classification of nanomaterials by simple descriptors such as core composition may not be sufficient for predicting nanomaterial toxicity or managing nanomaterial risks.

Understanding the Dynamic Behavior of the Protein Corona and Its Influence on the Physicochemical Composition of Silver Nanoparticles

A. Sadhihar1, R. Chen1,2, S. Oldenburg3, J. E. Riviere1,2 and N. A. Monteiro-Riviere1.

1Nanotechnology Innovation Innovation Center of Kansas State, Kansas State University, Manhattan, KS, 2Institute of Computational Comparative Medicine, Kansas State University, Manhattan, KS and 3nanoComposix Inc, San Diego, CA.

The health effects and safety of nanoparticles (NP) are of a great concern due to their increasing availability and use in consumer products and biomedical applications. It has been established that NP tend to interact with proteins to form a protein corona upon entering biological fluids. The dynamic interactions of the protein corona with NP may significantly influence the bio-identity of NP, leading to diverse biological outcomes, especially at the cellular level. Since NP-protein interactions are poorly understood, a fundamental understanding of the complexity and dynamic interactions of the protein corona with NP is crucial. A systematic investigation on time dependent adsorption kinetics of the protein corona formation was conducted with citrate or lipoic acid coated silver NP (AgNP) of 40nm. AgNP were exposed to human albumin (HSA) and fibrinogen at their in vivo physiological concentrations. Dynamic light scattering, zeta potential, NP tracking analysis and transmission electron microscopy were used to monitor kinetics of the
AgNP protein corona formation. Data on time evolution revealed that irrespective of the surface chemistry, rapid and prominent binding of HSA at 40μg/ml formed coronas with both citrate and lipopolysaccharide coated AgNP and caused an increase in size to 60nm which was stable. In contrast, AgNP in fibrinogen at 2mg/ml showed a time dependent decrease in stability with aggregation within 1 to 4h with a significant reduction in NP concentration and size (24.8nm) over 12h at 37°C. These results showed that the corona proteins at their physiological concentrations interacted rather differently with AgNP; whereby HSA prevented NP dissolution and aggregation, while fibrinogen caused a significant size reduction and aggregation.

**Toxicity Assessment of Six Titanium Dioxide Nanoparticles in Human Epidermal Keratinocytes**

N. A. Monteiro-Riviere 1, L. W. Zhang 1 and B. Veronesi 2, 1 NanoTechnology Innovation Center of Kansas State, Kansas State University, Manhattan, KS and 2United States Environmental Protection Agency, Research Triangle Park, NC.

Nanoparticle uptake in cells may be an important determinant of their potential cytotoxic and inflammatory effects. Six TiO2 NP (A=Alfa Aesar, 10nm, A*=Alfa Aesar, 32nm, B=P25, 27.5nm, C=Aeros, 200nm, C*=NanoAmor, 30-40nm, and D*=Mkano 200-400nm) and controls were assessed for their size, effect on cell viability, agglomeration, cytokine release, and cellular uptake in human epidermal keratinocytes (HEK). TiO2 NP were suspended in water or in culture medium, and characterized by transmission electron microscopy (TEM) and dynamic light scattering (DLS). TiO2 NP did not change shape with any NP type in medium by TEM but DLS showed an increase in size and in aggregations. TiO2 NP were assessed for viability with CellTiter 96 AQueous One (96AQ), MTT and alamar Blue assay was selected to assess all NP in serial dilutions ranging from 25ng/ml to 2μg/ml coated with a complex PC and differences in PC formation. The PC alters the interaction of AgNPs with keratinocytes (HEK). PC alters the interaction of AgNPs with keratinocytes (HEK). The PC alters the interaction of AgNPs with keratinocytes (HEK). The PC alters the interaction of AgNPs with keratinocytes (HEK). The PC alters the interaction of AgNPs with keratinocytes (HEK).

**Characterization of a Complex Protein Corona on Silver Nanoparticles and Its Influence on Cellular Interactions**

L. Shannahma 1, F. A. Wietmann 1 and L. M. Brown 1, 1 University of Colorado, Aurora, CO and 2Indiana University, Indianapolis, IN.

Silver nanoparticles (AgNP) have been incorporated in biomedical and consumer products as antimicrobial agents. Upon introduction into physiological environments NP associate proteins forming a protein corona (PC). The PC alters the NP-cell interface resulting in modified uptake, activity, clearance, and toxicity. Here we characterized the formation of a complex PC (consisting of multiple proteins) on AgNPs and examined its alterations in cellular interactions. To characterize the formation of the PC, PVP- or citrate-suspended AgNPs of 20 or 110 nm were incubated in DMEM containing 10% FBS. PC formation was indicated by alterations in the hyperspectral image of AgNPs such as a broadening of peaks and a red shift in the spectra. Spectral profiles were altered due to the size and surface coating of the AgNPs suggesting dissimilar PC formation. Individual PC components were identified and quantified via label-free mass spectroscopy. All AgNPs associated with the same complex PC that included different amounts of a common subset of 11 proteins including albumin and certain apolipoproteins. 110 nm AgNPs were found to associate the greatest number of proteins compared to 20 nm AgNPs, suggesting differences in PC formation based on surface curvature, whereas the PC on 20 nm AgNPs consisted of more hydrophobic proteins. These findings demonstrate the importance of electrostatic and hydrophobic interactions in the formation of the PC. To assess how the PC influences cellular interactions, macrophages were exposed to AgNPs (25 μg/ml) coated with a complex PC and differences in uptake were analyzed by hyperspectral dark field microscopy and flow cytometry. Addition of the PC was observed to increase uptake for all AgNPs (110 nm > 20 nm) by flow cytometry. By using spectral libraries we were able to intraclinically observe AgNPs and qualitatively determine differences in uptake by image analysis. These findings demonstrate the influence of variations in NP size and surface coatings, on the formation of the PC and modifications of cellular interactions.

**Acute and Subchronic Exposure to Inhaled Silver Nanoparticles Results in Alterations in Gene Expression, Gene-Specific Promoter Methylation, and Mitochondrial Integrity**

M. A. Popovech, E. L. Saunders, K. Galdanes, J. M. Vaughan, L. Chen and T. Gordon, Environmental Medicine, New York University School of Medicine, Twcisco, NY.

The use of silver nanoparticles (AgNPs) is ubiquitous. Legitimate toxicology concerns exist and a number of recent studies suggest that AgNPs pose a threat to human health. This study was conducted to examine the effects of acute and subchronic exposure to inhaled AgNPs. Male FVB/NJ mice were exposed to AgNPs generated using a Palas spark generator, via nose only inhalation, at either a single 4 hr exposure of 1 mg/m3, or at an exposure of 0.25 mg/m3 for 30 days. At 24 hr, 48hr, and 7d post-exposure, animals were euthanized and blood, lung and tissue were collected. Lavage was analyzed for total cell counts, differentially cell analysis, and protein levels. Fifty-four samples, isolated from lung and liver tissue, were used in Affymetrix Mouse Gene 2.0 ST Array Analysis. Microarrays were analyzed using Agilent GeneSpring and results verified by real-time qPCR. DNA isolated from lung and liver tissue was used in the analysis of gene-specific promoter methylation using Epitect Methyl II arrays. Inner mitochondrial membrane integrity was quantified using JC-1 staining and fluorescence microscopy. Outer mitochondrial membrane integrity was examined by measuring cytochrome c oxidase activity in the presence and absence of n-dodecyl beta-D-maltoside. Highly significant alterations in gene expression were observed in response to both acute and subchronic AgNP exposure, in both lung and liver tissues, in a time dependent manner. In addition, AgNP exposure resulted in significant decreases in both inner and outer mitochondrial membrane integrity. These experiments suggest that exposure to inhaled AgNPs results in gene expression alterations, which may be regulated by alterations in promoter methylation, in a time dependent manner. Further, cellular uptake of inhaled AgNPs, in lung and extra-pulmonary organs results in detrimental effects on mitochondrial membrane integrity.
The use of silver nanoparticles (AgNPs) in consumer products has vastly increased due to their antimicrobial activity. However, recent reports suggest the inhalation of AgNPs can lead to neurodegeneration due to translocation via olfactory nerves. Previous studies fail to evaluate biologically relevant exposure routes and concentrations. Therefore, this study evaluated the effects of inhaled AgNPs on gene expression within distinct subregions of the brain under diverse exposure terms. Adult male FVB/J mice were exposed via nasal inhalation to AgNPs produced by a Palas spark generator. Animals were assigned to 3 exposure groups: 1) single exposure (1mg/m3), 2) subacute repeated dose (30d, 0.25mg/m3), or 3) subchronic repeated dose (90d, 0.25mg/m3). Tissues were taken at 24hr, 48hr, and 7d post-exposure for the single exposure group, and repeated group animals at 24 hr. Animals were euthanized and brains removed and dissected into three portions: olfactory bulbs (OB), cerebellum (CB), and midbrain (MB). Isolated total RNA was analyzed by real-time RT-PCR using various oxidative stress-associated gene primers. Overall a variety of gene expression alterations were found for each neural subregion. Most interesting, the single exposure resulted in gene expression alterations for amyloid beta (Aβ) precursor protein (APP), which is associated with Alzheimer’s, a detrimental neurodegenerative disease. APP upregulation was segregated to the OB, where it remained high 7d post-exposure suggesting possible long-term neurotoxic effects from a single exposure to AgNPs. Conversely, Amyothrophic Lateral Sclerosis (ALS) associated gene was only mildly changed in all sub-regions, suggesting a specific mechanism of toxicity. Additionally, oxidative stress related genes were upregulated within the MB and CB at 48 and 72 hr and returned to control levels by 7d post-exposure. Together these results demonstrate that inhalation of AgNPs can result in oxidative stress and gene expression alterations which could contribute to neurotoxicity and potentially neurodegeneration.

Silver nanoparticles (AgNPs) have been increasingly used in manufactured goods for their bactericidal properties. Previous work has shown these particles to be toxic to the nervous and immune systems under various dosing regimens. A previous study from our lab demonstrated localization of AgNPs in the brain following a one-time intranasal (IN) administration of 50 mg/kg AgNPs. We also found increased Hmox1 gene expression, a marker of oxidative stress, in the hippocampus of the silver-treated mice. To examine possible functional consequences of AgNP accumulation and increased Hmox1 gene expression, behavioral experiments were performed to characterize changes in learning and memory following IN AgNP exposure. Adult male C57BL/6 mice were housed with 7 consecutive days with uncoated AgNPs (0 or 50 mg/kg; average diameter 35.7 nm) to mimic repeated workplace exposure in adult humans. One week after the end of AgNP administration, the behavior of the mice was assessed via novel object recognition and Morris Water Maze. AgNP-treated mice exhibited no significant difference in exploration of the novel object during testing. No significant difference was observed between the control and treated groups during the acquisition, reversal, or cued phases of Morris Water Maze testing. Blood cell counts were similarly unaffected between the control and AgNP-treated mice, with the exception of a significant increase in the number of eosinophils. In addition, weight differences were observed, with thymus weights being affected across groups. Further studies into the localization of silver following repeated doses and exposure of animals at different life stages will lead to a greater understanding of the effects of repeated exposure to these toxic particles. This work was funded in part by NIEHS T32ES016646-01 and NIEHS P30ES006096.

Silver nanoparticles (AgNPs) have antimicrobial activity and unique electrical properties, resulting in increasing use. While biological effects of AgNPs have been studied, there has not been a comparison of particle size on aerosol-delivered AgNPs persistence. We investigated lung deposition and retention of 20 and 110nm citrate-coated AgNPs. Aerosol of AgNPs was generated using a nebulizer. Adult male rats were exposed nose-only for 6 to either 20min or 110min AgNPs (8mg/m3 and 6.2mg/m3) or 2mM citrate buffer vehicle control. Tissues were collected immediately following exposure (T0) and 1, 7 and 21 days post-exposure (DPE). Ag was quantified using inductively-coupled plasma mass spectrometry and tissue distribution was determined using autoradiography (ARG). Each lung lobe and the trachea were measured to determine differences between lobes at T0. At T0 the mean Ag concentration of 110nm AgNPs ranged from 11.89 -18.95µg/g tissue with no significant difference between lobes. 20nm AgNPs T0 lobes were significantly different from each other and ranged from 2.05-9.28µg/g by macrophages and has been reported to play a role in recognition of negatively charged particles. We therefore hypothesized that SR-B1 contributes to macrophage uptake of AgNPs and subsequent cellular activation. To test this hypothesis, we exposed a mouse macrophage cell line (RAW 264.7) and bone marrow-derived macrophages (MDM) to 20 nm citrate-suspended AgNPs. To verify the role of the SR-B1 receptor, we utilized B2-1, an SR-B1 pharmacological inhibitor. Flow cytometry was used to evaluate cellular uptake following exposure to AgNPs (50 ng/ml). Exposure to AgNPs led to increases in the side scatter of macrophages indicating cellular uptake. Inhibition of SR-B1 with B2-1 reduced RAW and BMDM uptake of AgNPs. To further examine the role of SR-B1 in macrophage uptake of AgNPs, BMDMs were derived from SR-B1-/- mice. Following AgNP exposure, SR-B1-/- BMDMs demonstrated decreased uptake by flow cytometry. To confirm flow cytometry findings, cells were imaged following AgNP exposure with hyperspectral dark field microscopy and quantitatively assessed by ICP-MS. In vivo studies confirmed the role of SR-B1 in AgNP-induced toxicity. C57BL/6 mice receiving a single intranasal instillation of AgNPs demonstrated increases in lung inflammatory cells, and lung tissue IL-6 and IL-1β gene expression. In comparison, SR-B1-/- mice showed a significant decrease in AgNP-induced inflammatory cell recruitment and gene expression. In conclusion, macrophage SR-B1 activation contributes to the inflammatory response induced by AgNPs.
829 Inhaled Nano-TiO2 Size Distribution along with Mass Concentration Define Lung Responses
A. Noel1, 4, Y. Cloutier2, M. Charbonneau3, K. Maghni1, R. Tard1 and G. Truchon1. 1School of Public Health, University of Montreal, Montreal, QC, Canada, 2Institut de Recherche en Santé et en Sécurité du Travail, Montréal, QC, Canada, 3INRS-Université du Québec, Laval, QC, Canada and 4SVM, Louisiana State University, Baton Rouge, LA.
Currently, there is no consensus regarding the exposure metric that best expresses the nanoparticle (NP) dose. Although the surface area was extensively studied for the inflammatory reaction, it has not been validated for cytotoxicity or oxidative stress. Since inhaled NP deposit and interact with lung cells according to their agglomerates size, we hypothesized that the mass concentration combined to the aerosol’s size distribution is suitable for NP risk assessment. The objective of this study was to evaluate different exposure metrics for TiO2 aerosols composed of small (SA) (<100 nm) or large (LA) (>100 nm) agglomerates at 2.7 and 20 mg/m3 on rat lungs inflammatory, cytotoxicity and oxidative stress responses. Six groups of male F344 rats (n=6) were nose-only exposed for 6 hr to the different 5 nm TiO2 aerosols. The control group was exposed to air. Exposures were characterized by weight measurement for mass concentration and with an electrical low pressure impactor for number concentration and size distribution. Bronchoalveolar lavages (BAL) were analyzed 16 hr after exposure. Our results showed that the 7 mg/m3 LA and the 20 mg/m3, both LA and SA aerosols, increased the number of neutrophils compared to controls. The 20 mg/m3 SA significantly (p<0.05) increased LDH activity and 8-isoprostane concentration compared to controls. When the size distribution of NP was considered with the mass as an exposure metric, we found a strong correlation (r=0.97) with the number of neutrophils for SA and LA. For LDH and 8-isoperoxide, we observed a high correlation (r=0.89) only with SA. These data show that the mass concentration alone is not sufficient to adequately predict oxidant and cytotoxic pulmonary effects. Overall, our study indicates that considering the NP size distribution along with the mass concentration contribute to a more mechanistic discrimination of respiratory effects.

830 Cell Transformation Potential of Nano-Cerium Oxide (nCeO2), Nano-Ferric Oxide (nFe2O3) Compared to Multiwalled Carbon Nanotubes (MWCNT)
L. Wang1, T. A. Sneedke1, P. Demokritou1, M. Chen1, R. Derk1, S. Luanpitpong1, T. Y. Ma1, Y. Castranova1 and Y. Rojanasakul1. 1School of Public Health, University of Montreal, Montreal, QC, Canada.
Unique physicochemical properties of engineered nanomaterials (ENMs), including CNTs and metal oxides, are distinct from their micron-sized counterparts evidenced by their unique biological effects. Previous studies have suggested potential lung disorders induced by these ENMs. Recent animal study indicated cancer promotion by MWCNT. Our previous in vitro work showed subchronic single walled CNT or MWCNT exposure can cause human lung epithelial cell transformation which formed tumors when subcutaneously injected into mice. These findings raise ENM-induced carcinogenicity concerns due to rapid growth in ENM applications, including widely used nCeO2, nFe2O3 and MWCNT. The present work tested cell transformation potential of nCeO2 and nFe2O3 compared to MWCNT as a positive tumorigenic control. Primary human small airway epithelial cells were treated with a sub- toxic, low dose of ENMs (62.5 ng/cm2 of nCeO2 and nFe2O3 or 60 ng/cm2 of MWCNT), with albumin and saline as dispanser and no treatment controls, respectively. Cells were continuously exposed to ENM containing medium for 6 weeks. Following exposure, cells were assayed for cell transformation and cancer hallmark analysis. Increased cell proliferation suggested significant cell stimulation by nCeO2 and MWCNT. Next, nFe2O3 and MWCNT-treated cells formed soft agar colonies and significantly enhanced cell invasion which suggests their potential cell transformative effect. These results will guide future in vivo studies to confirm the observation and to assess the relevancy of our subchronic in vitro exposure model. Such an in vitro model may serve as a simple/fast/high throughput tool to screen countless ENM to predict cell transformation/carcinogenic potential and addresses a critical need in ENM risk assessment.

831 Evaluation of Pulmonary Response to Tungsten Oxide (WO3) Nanoparticles in Golden Syrian Hamsters
M. V. Prajapati and J. M. Carreta. PHS, St. Johns University, Queens, NY.
Tungsten oxide (WO3) nanoparticles possess excellent photochromic, electrochromic, thermochromic and catalytic properties. Extensive industrial and military uses have raised the possibilities of human occupational and environmental exposure with concomitant health concerns. To evaluate the effects of such particles in the lung, Golden Syrian Hamsters were exposed by inhalation to aerosols of WO3 nanoparticles (Nanostructured and Amorphous Materials, Inc., TX). Hamsters were divided into four groups – a control group that was exposed to distilled water and 3 treatment groups that were exposed to 5, 10 or 20 mg/m3 WO3 nanoparticles (4 hrs/day, for 4 days). Animals were euthanized 24 hours post-exposure and bronchoalveolar lavage fluid (BALF) was collected. Lungs were then fixed by instillations of 10% formalin. Tissue sections were analyzed using bright and dark field microscopy. The average size of WO3 nanoparticles, 71 ±34 nm, was confirmed using TEM. There was a significant increase (p<0.05) in total cell counts 22.3 ±0.1, 21.6 ±2.5, and 29.3 ±0.1 x10^6 cells/ml of BALF from treated groups (5, 10 or 20 mg/m3 respectively), as compared to controls (15.6 ±1.4 x10^6 cells/ml). BALF protein levels increased in treated groups (106.1, 110.7 and 124.1 µg/ ml) as compared to controls (97.9 µg/ml). The number of macrophages increased in the BALF treated group (76.8, 65.6 and 145.3 cells/field at X400) as compared to controls (29.2 cells/field at X400) without increase in the number of PMN’s. Dark field micrographs of tissue sections revealed WO3 nanoparticles present in alveolar macrophages that were dispersed in large numbers throughout the lung. Nanoparticles were also identified on airway epithelium, within airway epithelial cells and in interstitial areas of alveolar structures. Results from these experiments indicate that WO3 nanoparticles can reach alveolar space, enter epithelial layers and penetrate to interstitial structures.

832 Evaluating Metallic NP-Induced Stress Using a Neuronal Coculture Model
M. Grogg, L. K. Braydich-Stolle and S. M. Hussain. Molecular Bioeffects Branch, Bioeffects Division, 711HW/AFRL, Wright Patterson AFB, OH.
To date nanotoxicity studies on the central nervous system are limited and conflicting with discrepancies between animal models and humans adding to the complexity. A previous study focused on establishing a neuronal co-culture model which included neurons and their microglia, to evaluate the phagocytic response effects of nanoparticles (NPs). As a continuation, the present study examined the toxicity of different nanometals which included silver (Ag) and gold (Au) as well as known neurotoxictants manganese (Mn), aluminum (Al), and copper (Cu); and while all of the metallic NPs had an initial size of 80 nm, dispersion resulted in varying degrees of aggregation. The cells were dosed with realistic exposure levels of the different metallic NPs to represent a daily or weekly exposure based on the current limits reported for the bulk metals by OSHA. In addition to viability and reactive oxygen species (ROS) production, key stress genes (NF-kB, TNFα, IL-6) were selected to examine changes following varying times of exposure (4, 8, and 24 h) to metallic NP. The Mn-NPs induced significant toxicity at daily and weekly exposure levels, while Cu-NP showed toxicity only at the weekly exposure level. Furthermore, the Mn-NP treatment demonstrated concentration dependent increases in ROS production and TNFα and IL-6 expression over time while NfKβ remained unchanged. Surprisingly, while the Cu-NP treatment induced toxicity, and increased ROS production, the stress response profiles showed no changes at 4 h, and decreased expression for IL-6 and TNFα following 8 and 24 h. In comparison, the Ag-, Au-, and Al-NP treatments did not induce toxicity or significant increases in ROS and showed no changes in gene expression at either treatment concentration or time point. Taken together, the results demonstrated that the co-culture model provides enhanced sensitivity for studying NP induced stress responses and the nanometals displayed differential toxicity with Mn>Cu>Al/Au/Ag.
833 Unique Mode of Toxicity of Cu Nanoparticles Compared to Their Micron and Ionic Analogs in E. coli and L. brevis

C. Kawesterauwa1, A. Ivaske2, C. Chang2, P. Holden1,3 and H. Goodwin1,2.
1Molecular Toxicology, UCLA, Los Angeles, CA, 2UC Center for Environmental Impact of Nanotechnology, UCLA, Los Angeles, CA and 3Donald Bren School of Environmental Science and Management, UCSB, Santa Barbara, CA.

Nanotechnology has grown rapidly over the past decade, promising benefits in diverse areas of society. However, the rate of toxicological analysis of nanoparticles (NPs) has not kept pace with the rate of development, leading to concerns over the potential biological toxicity and environmental contamination of NPs. Here, we report toxicity ranking as well as mechanisms of toxicity for a series of Cu particles, including nano Cu, nano CuO, nano Cu(OH)2, micro Cu and micro CuO as well as ionic Cu (CuCl2 and CuSO4) in bacteria (Escherichia coli and Lactobacillus brevis). Fluorescent assays such as PI/STYO, XTDT, DIBAC, and H2DCFDA were used to measure viability, respiration rate, membrane potential, and ROS production, respectively. IC50 values were calculated from growth inhibition curves, revealing that Cu and CuO NPs are more toxic than their micro-sized counterparts, with toxicities approaching that of ionic Cu. Strikingly, the NPs showed distinct differences in their mode of toxicity when compared to the Cu ions, highlighting the unique toxicological properties of materials at the nanoscale. Moreover, cells treated with nano Cu showed higher levels of bioavailable Cu+ than cells treated with ionic Cu. 3D tomography from electron microscopy of cells exposed to the NPs revealed the presence of intact NPs inside the cells.

834 Physicochemical Characterization and Ecotoxicological Evaluation of TiO2 Nanoparticles in Earthworm Eisenia fetida

B. Siva Prasad, S. Ashwini and P. Sankar Ganesh. Biological Sciences, Birla Institute of Technology and Science Pilani, Hyderabad Campus, Hyderabad, India.

Wide spread application and use of nanoparticles such as TiO2, confers their release into various compartments of environment thereby raising concerns about their health impacts. It is essential to assess the ecotoxicity and implications of TiO2 on the flora, fauna and ecosystem as a whole. Although there are studies reporting toxicity of TiO2, but specific findings on its effect and underlying toxicity mechanisms in terrestrial organisms such as earthworms remain poorly understood and documented. Hence in this study, ecotoxicological evaluation of the rutile form (10-100nm) of TiO2 nanoparticles on earthworm, Eisenia fetida was conducted as per the modified filter paper test of OECD-207 guidelines. Physicochemical characterization of TiO2 nanoparticles was carried out using zeta sizer and scanning electron microscope. Earthworms were exposed to a series of concentrations (0.05, 0.1, 0.15, 0.2 and 0.25 mg/cm3) of TiO2 nanoparticles on earthworms. Eisenia fetida was conducted as per the modified filter paper test of OECD-207 guidelines. Physicochemical characterization of TiO2 nanoparticles was carried out using zeta sizer and scanning electron microscope. Earthworms were exposed to a series of concentrations (0.05, 0.1, 0.15, 0.2 and 0.25 mg/cm3) of TiO2 nanoparticles. Mortality of earthworms was determined after 48h exposure to TiO2. Activity of the enzymes, catalase, superoxide dismutase and glutathione reductase was assessed in whole body homogenate of the worms surviving after exposure. Lipid peroxidation was measured to define the levels of oxidative stress during toxicity assessment. Perturbations caused by TiO2, nanoparticle resulted in the oozing of coelomic fluid and pale coloration of earthworm body. Mortality rate, activity of antioxidant enzymes and lipid peroxidation were influenced by size and charge of TiO2, nano particles rather than concentration. Results of the study showed that agglomeration of TiO2 nanoparticles is responsible for the variation in their size and charge. The finding is first of its kind to establish a toxicological profile of TiO2 nanoparticles on earthworms. Similar studies will eventually help in developing strategies to predict ecotoxicity of TiO2 in the soil environment.

835 Gene Expression Changes in Secondary Organs of Rats Intratracheally Exposed to Silver Nanoparticles

T. Coccini1, R. Gornati2, I. Vanetti3, E. Signoreetto3, F. Rossil1, G. Bernardini2 and L. Manzo2,3. Toxicology Division, Manager Foundation IRCCS, Institute of Pativa, Pavia, Italy, 1University of Pavia, Pavia, Italy and 2Department of Biotechnology and Life Sciences, University of Insubria, Varese, Italy.

Studies in rats have demonstrated the ability of silver nanoparticles (AgNP) to translocate to secondary target organs (e.g. liver or kidney) after administration by respiratory route (Takenaka et al, Environ Health Perspect, 2001). In this study, the expression profile of genes involved in oxidative stress (Gpx1, SOD, Gss, FMO2, Gsr, Tnrd1), metal toxicity (mt1), apoptosis/cell cycle (Casp3, p53), and protein folding (Hsp70) was investigated in liver and testis of rats at different time intervals after i.t. instillation of AgNP. AgNO3 was used as a positive control. Groups of adult male Sprague-Dawley rats received 50 μg/rat of AgNP (20 nm), 7 μg/rat of AgNO3 or 100 μL aqueous solution/rat (control). At days 7 and 28 post-administration, the transcriptional profile of selected genes was examined in tissues by cDNA microarray analysis coupled with bioinformatics and functional gene annotation studies. Semiquantitative followed by Real Time PCR was performed to quantify gene expression changes. At day 7, changes in gene expression that selectively involved antioxidant enzymes were observed in both liver and testes. In particular, Gpx1, FMO2 and SOD genes were upregulated. No changes were seen for the other genes. At day 28 the AgNP-treated animals exhibited a tissue gene expression profile similar to control. None of the investigated genes was shown to be affected by treatment with AgNO3 at both time points considered. The results suggest the potential of AgNPs to cause, at low doses, subtle molecular changes in secondary target organs, in contrast with Ag ions, possibly reflecting the strong tendency of Ag ions to form inert complexes with cellular or blood components or be neutralized by defense mechanisms. (Grants: Italian Ministries of Health, Research & Education; & CARIPLO foundation-Rif. 2011-2096).

836 The Influence of UV Light on the Genotoxicity of Engineered Nanoparticles

D. Cupi and A. Baum. Environmental Engineering, DTU (Technical University of Denmark), Kongens Lyngby, Denmark.

TiO2 nanoparticles (NPs) are one of the most commonly used engineered nanomaterials due to their use in a large variety of applications as photocatalytic agent. The inherent properties of TiO2 might however, lead to photo-induced toxicity in human and animal tissue. Under UV irradiation, TiO2 NPs can produce ROS which is damaging to DNA and other biomolecules. In this study we used a chemical test for quantifying ROS generation in combination with the umu-test which is a short-term genotoxicity assay providing high throughput screening (96-well plates). Various nanoparticles (SiO2, CeO2, ZnO, and TiO2) were screened using concentrations of 0.0125-0.1 mg/mL with a 2 hour incubation/exposure time and no metabolic activation. No genotoxicity was induced for any of the NPs in the absence of UV light in the concentration range tested.

The next set of experiments involved the use of full spectrum UV light. Methylen blue dye decomposition was used for assessing the photocatalytic activity of TiO2 for an exposure period of 5-80 minutes. Maximal degradation of methylene blue occurred after 60 minutes. In order to investigate the effect of UV on Salmonella typhimurium bacteria, growth rate was investigated at 10, 20, 30, 40, 50, 70 min of exposure. Less than 15% decrease was observed for all the exposed bacteria compared to control. Therefore, an exposure period of 60 minutes was chosen to observe the ability of OECD reference hydrophilic (NM-104) and hydrophobic (NM-105) TiO2 NPs to induce genotoxic effects in the presence of UV light compared to absence of UV light. Concentrations of 0.25, 0.5, 1 mg/mL (45, 90, 180 μg/mL) increased the β-galactosidase activity indicating a possible genotoxic effect in the presence of UV light.

837 Monocyte Activation by Particulate Matter and Reactive Oxygen Species Formation

K. L. Tran1, P. Pakbin2, A. Kim1, C. Soutras2 and A. Campbell1. 1Department of Pharmaceutical Sciences, Western University of Health Sciences, Montclair, CA and 2Southern California, Los Angeles, CA.

Acute as well as chronic exposure to ambient air particulate matter (PM) has been implicated in playing a part in adverse health outcomes. Formation of reactive oxygen species (ROS) is one pathway by which PM exposure may disrupt normal physiological balance leading to disease pathogenesis. This study used human mononcytic (THP-1) cells to assess potential activation and subsequent production of reactive oxygen species. THP-1 cells were seeded in 96-well plates and then exposed for 24 hrs to particulate matter collected from a site in Los Angeles. The particles were smaller than 100 nm in aerodynamic diameter and were collected in an urban site of downtown Los Angeles. Two different doses 2 or 20 μg/m3 were used. Levels of ROS were measured by a fluorescent method. After exposure, there was a dose-dependent increase in the amount of ROS formation. Mitochondrial activity, measured by the MTS assay, was increased at both doses. This increase was not due to changes in cell number. Instead at the highest dose, we noted a decrease in cell number which may reflect decreased cell proliferation or viability. The data shows that THP-1 cells may be activated by PM leading to ROS formation. Further co-culture studies are needed to determine how activation of monocytes may affect normal human cells. This is the current focus of our laboratory.
Uptake and biodistribution of nanomaterials in an in vivo model system are important considerations for nanotoxicology. The use of fluorescent labeling can help with identifying particle location within a specimen and enable particle tracking. This study aimed to quantify the uptake of rhodamine labeled carbonylated nanocrystalline cellulose (NCC) throughout development in the model vertebrate, Danio rerio. NCC was selected for initial investigation because it elicits low toxicity in zebrafish embryos and is increasingly important in commerce. Similar to unlabeled NCC, no significant mortality or developmental abnormalities were observed at the highest dose tested. Fluorescent microscopy images of control embryos and embryos exposed to 500ppm rhodamine labeled NCC were taken on days 1-5. Integrated density (ID) was used as a surrogate measure for uptake. The experiment was repeated using embryos with and without intact chorions. On day 1, embryos exposed without a chorion had an ID value 3 times higher than those with the chorion intact. On day 2, the chorion off embryos had an ID value 1.43 times that of the chorion on embryos. After hatching, the ID values were not significantly different. There was a linear increase in uptake over the first 4 days, and then an exponential increase on day 5, possibly due to the onset of mouth gaping. From this data, dermal and oral uptake rates were calculated. Confocal microscopy was used to identify heavily concentrated locations within the embryos that seemed to be associated with the integumentary system. Our data demonstrates that carbonylated NCC was taken up both dermally and orally by the embryos depending on the stage of development. In addition, the chorion does pose a barrier for these particles prior to hatching which is important when assessing toxicity within the first 72 hours of development.

Gold nanoparticles (AuNPs) have unique properties for been considered as transfection vectors for gene delivery. Using gold nanoparticles for gene therapy brings a new opportunity for enhance the level of transfection and protect the genetic sequence to be delivered. However, the AuNPs application for biomedical topics could be limited for cytotoxicity. In order to decrease the cytotoxicity and enhance the gene delivery efficiency we synthesized AuNPs using polyethylenimine (PEI) as reducing agent with 25 kDa polyacrylamid branched polymer, which is actually used in DNA transfection protocols. The nucleotide si-miR-148a sequence were grafted to the AuNPs and labeled with carboxyfluoresceine (CFSE). Optical feature, shape and size distribution of AuNPs were examined using UV-Vis spectroscopy, transmission electron microscopy (TEM) and dynamic light scattering (DLS). The results showed the absorbance plasmon centered at 430 ± 5 nm usually attributed to AuNPs spheres, the size of particle-size was at 5 nm with narrow distribution. Zeta potential measurements indicate that PEI produced more stable NPs (-35 mV) compared with those synthesized by using other reducing agents (citric acid (-10 mV)). We evaluated the cell viability (HeLa cells) through the resazurin assay and follow the nanoparticles distribution into cells using fluorescence microscopy and flow cytometry. We found that the HeLa cells viability was up to 95%, and the interaction between AuNPs vector and HeLa cells was evident through positive fluorescence of CFSE by microscopy and flow cytometry as cells complexity augmented due to AuNPs intake. These results suggest that AuNPs transfection system brings stability and is biocompatible for be used in mammalian cells.
silver nitrate (AgNO3) as a positive control in the same soils. Soil exposures lasted for 14 days, after which surviving earthworms were counted and the median lethal concentration for 50% of the population (LC50) was calculated according to the trimmed Spearman–Karber method. PVP–AgNP LC50 in the Memphis Silt soil was 2828.43 mg/kg; in contrast, AgNO3 was much more toxic than PVP–AgNP in the same soil (LC50 = 223.31 mg/kg). The PVP coating did not contribute to PVP–AgNP soil toxicity (PVP LC50 > 40,000 mg/kg). PVP–AgNP LC50 in Suney, Camp Shelby, and Big Black soil were all >1000 mg/kg. These data demonstrate that PVP–AgNP is less toxic in a soil environment than the ionic form (AgNO3).

Furthermore, by utilizing four soils that cover over 50% of the soil in the contiguous U.S., these data provide quantitative soil toxicity values to better evaluate the effects of PVP–AgNP in soil environments.

841b Transmission Electron Microscopic (TEM) Evaluation of Silver Nanoparticles (AgNP) or Silver Acetate (AgOAc) Deposition in Selected Tissues of Sprague-Dawley (SD) Rats

M. S. Imam1, M. D. Bougourd1, G. Olson1 and A. Paredes1. 1National Center for Toxicological Research, Jefferson, AR and 2Toxicologic Pathology Associates, Jefferson, AR.

This study investigated the deposition of silver (Ag) in selected tissues (ileum, jejunum, colon, kidney, liver, spleen and mesenteric lymph nodes) of SD rats administered either AgNP or AgOAc. A subtle surface difference between AgNP and AgOAc deposition were observed in the colons and kidneys of rats. Rats treated with AgNP showed fine, spherical, and measurable Ag granules, whereas AgOAc showed irregular, flower-shaped surface depositions. The majority of Ag granules were located within the lamina propria and basement membrane of the intestinal epithelial cells. The localization and distribution of Ag varied in the other tissues, including the kidneys, livers, and mesenteric lymph nodes. Ag granules were entrapped by the macrophages in the mesenteric lymph nodes, whereas in the kidneys, the Ag deposition was observed in the basal lamina of the glomeruli involving podocytes and endothelia cells. In particular, the 10 nm AgNP had greater deposition in mesenteric lymph nodes, kidneys, and colons of both male and female rats suggesting size-dependent bio-distribution. Furthermore, the energy-dispersive X-ray spectral analysis revealed that Ag deposition is in the kidneys, colons, and mesenteric lymph nodes consisted of silver and often coexisted with selenium, silicon and sulphur containing granules. A gender-related difference in Ag deposition was noted in the kidneys and colons, with greater Ag deposition in females compared to males. This study provides new insights into the bio-distribution patterns of AgNP or AgOAc in the major tissues and proposes a need for further research. This study is supported by interagency agreements 224-12-0003 and AES12013 between the NCTR/FDA and NIEHS/NTP.

841c Toxicity and Allergy Responses in the Lung following Pulmonary Exposure to Nanoparticle Silver in Mice

Silver nanoparticles (AgNP), due to antimicrobial properties, are widely used in medical applications and consumer products. Expansive use of AgNP in manufacturing raises the concern of effects following respiratory exposure in workers. Previous work in the laboratory has shown dose-dependent lung toxicity with inflammation and alterations in lung immune parameters in rodents. The goal of the current study is to characterize effects of AgNP for potential exacerbation/attenuation of respiratory allergy in an ovalbumin (OVA)-induced allergy model in BALB/c mice. For range-finding (RF) studies, mice were exposed to physiological dispersion medium (DM), 6.1μg (LO), 18.2μg (ME), or 73.4μg (HI) AgNP. AgNP were 20 nm diameter with 0.3% wt polyvinylpovidone coating (NanoAmor, Inc.), were suspended and sonicated before exposures by pharyngeal aspiration (PA) on day 0. For RF studies assays were conducted on days 1, 10, and 29 post exposure—time points chosen to correspond with the allergy paradigm time course. Airway hyperreactivity was measured as PenH, bronchoalveolar lavage (BAL) was performed on the whole lung, cells and fluid were retained for analysis of lung-associated injury and inflammation and phenotyping by flow cytometry, lymph nodes (LN) were harvested for enumeration and phenotyping. Changes in PenH did not occur with AgNP alone at any time point. Results indicated a dose-dependent injury and inflammation by day 10 which began to resolve by day 29. For the allergy model, DM and OVA served as controls and ME and HI were chosen for study. Animals received i.p. injections of OVA + aluminum hydroxide gel (alum) during the sensitization phase on days 1 and 10. To elicit an OVA-specific response, 2 PA challenges of OVA were given on days 19 and 29. Dose dependent increases in PenH, BAL and LN cell number were observed in mice exposed to AgNP over OVA controls. Results indicate potential for AgNP to exacerbate allergic response in the lung.

841d Differential Genomic Effects on Signaling Pathways by Two Different CeO2 Nanoparticles in HepG2 Cells

Nanoparticles composed of CeO2 are of particular interest in toxicological studies due to their growing use in pharmaceuticals, biomedical products, cosmetics, polishing materials and as automotive fuel additives. Human liver HepG2 cells were exposed for these three days to two different forms of nanoparticles both composed of CeO2 (0.3, 3 and 30 μg/mL) and a genomic study performed. The two CeO2 nanoparticles have dry primary particle sizes of 8 nanometers ([M] made from NanoAmor) and 58 nanometers ([L] made by Alfa Aesar) and differ in various other physical-chemical properties as well. This systems biological genomics study showed that the major altered pathways were protein synthesis, stress response, proliferation/cell cycle, cytoketone remodeling/actin polymerization and cellular metabolism. Some of the canonical pathways affected were mTOR signaling, EIF2 signaling, fatty acid activation, G2/M DNA damage checkpoint regulation, glycolysis and ubiquitination. Nanoparticle M showed a normal dose-response pattern with 363, 633 and 1273 differentially expressed genes (DEGs) at 0.3, 3 and 30 μg/mL, respectively. M is more active than L in respect to altering the pathways of mitochondrial dysfunction, acute phase response, apoptosis, 14-3-3 mediated signaling, remodeling of epithelial adherents junction signaling, actin nucleation by ARF-WASP complex, and altered TCA cycle. However, L is more active than M in respect to the pathways of NRF2-mediated stress response and hepatic fibrosis/hepatic stellate cell activation. In summary, these two CeO2 nanoparticles exerted both many shared and some differing toxicity pathways. Disclaimer: This is an abstract or a proposed presentation and does not necessarily reflect EPA policy. 841e Aggregation of Gold Nanoparticles with Thioether-Containing Amino Acids

S. Babu1, F. Jaeche Seo2, R. M. Uppu2, and M. O. Claville2. 1School of Science, Hampson University, Hampson, VA and 2Department of Environmental Toxicology and the Health Research Center, Southern University and A&M College, Baton Rouge, LA.

Gold nanoparticles (Au NPs) have vast applications in drug therapy because of their unique optical, electronic and molecular properties. The toxicity of the Au NPs varies in cellular environment, depending on the physiochemical properties such as size, shape, surface chemistry, and the molecules with which they interact. When blue mussels, Mytilus edulis, are exposed to Au NPs of particle size < 5 nm, they exhibit an increase in oxidative stress and decrease in thiol-containing proteins. These organisms also contain methionyl peptides that are hypothetically subject to oxidation due to Au NP exposure. In this present study, we present preliminary findings regarding the interaction of Au NPs with methionyl compounds, L-Methionine(Met), D/L-Met, N-Acetyl-L-Met, L-Met Ethyl Ester, and Met-Glycine. The average sizes of the eight Au NPs used in the study are ~5, 10, 15, ~20, ~30, ~35, and ~40 nm diameters. The UV-Vis spectral studies showed that Au NPs exhibit a strong plasmon at ~530 nm while the methionyl compounds displayed an additional plasmon band at ~785 nm, indicating the formation of Au NPs aggregates. Methionine was found to aggregate Au NPs (conc. 3.487E+10 M) with size ~35 nm at higher concentration (final 0.125 M) with the color change from red to blue. While lower concentration of L-Met and D/L-Met did not aggregate immediately, N-terminal (N-Acetyl-L-Met) and C-terminal protected Met (Met Ethyl Ester) readily formed Au NPs aggregates. Methionine-Glycine dipeptide was only slightly better than D/L-Met at inducing aggregation of Au NPs. The results provide insight into the impact of NP size, peptide sequence, and concentration of NPs on aggregation. We strongly believe aggregation size and kinetics may have a role in the etiology of cellular response which needs to be systematically evaluated. Young children are exposed to substantial amounts of low dose radiation (LDR) during diagnostic imaging. The long term carcinogenic effects of LDR are not known, especially when prior exposure to environmental chemicals could sensitize to LDR. We previously reported in adult mouse models, in which lung cancer was induced by either transgene expression or chemical carcinogen treatment, that whole-body CT doses approximating clinical screening doses significantly increased tumor multiplicity by 40 to 100%. Pregnant C57BL-6BALB/c mice were treated in utero with a vehicle or a single 45 mg/kg dose of 3-methylcholanthrene (MC). Half of the male and female offspring in each group were exposed to a single dose of 50 mGy of LDR from a clinical CT scanner 4½ weeks after birth. RNA was isolated 10 min post-exposure. Affymetrix gene chip expression profiling followed by gene ontology analysis identified 32 differentially expressed genes that were altered in utero exposure to MC but were not altered in response to neonatal LDR. Using DAVID, we identified clusters of genes under the categories response to stimulus and immune system process that were significantly altered following neonatal exposure to LDR, with network centers in the p38 MAPK pathway. When male and female responses to LDR were determined, significant gender related differences were identified. For females, the top network was related to cardiovascular disease, cardiovascular system development and function, and cell morphology. In males, differentially expressed genes were enriched in two networks. The first was related to connective tissue development and function, tissue morphology, and lymphoid tissue structure & development, and the second to functions in cancer, involving cell-cell signaling & interaction and cellular growth & proliferation. Our data demonstrate gender related differences in LDR-induced differential gene expression following neonatal exposure in gene pathways related to disease pathogenesis that may be responsible for the long term toxic responses to radiation. (NIH grant CA136910)

842 Toxicogenomic Analysis of Low-Dose CT Exposure in Neonatal Mouse Lungs

843 Lead Pollution in Soil, Domestic Animals, and Children from Townships near a Lead-Zinc Mine in Kabwe, Zambia

Bacterial lead resistance (BLLs) in children exposed to Pb pollution. The concentrations of Pb in tissues of Kabwe cattle were higher than those in other Zambian rural districts (9-51188 mg/kg) in Kabwe soil (n=101) were much higher than benchmark values. Moreover, upregulation of HBG2 and AHSP genes may imply the role of hypoxia in asthma development. Taken together, our results demonstrated the existence of distinct phenotype of asthma in children living in polluted Ostrava region compared to children living in rural district of Prachatice.

844 Gene Expression Profiles in Asmatic Children Living in Localities with Different Extent of the Air Pollution

This study is a part of the broader molecular epidemiology study dealing with health effects of the air pollution in children living in the heavily polluted industrial area of the Czech Republic, Ostrava region, where the incidence of asthma bronchiolitis in children is extremely high (30-40%). We hypothesized that high level of the air pollution by polycyclic aromatic hydrocarbons (mostly bound on PM10) is associated with increased asthma morbidity in children from Ostrava region. We compared gene expression profiles in leukocytes of asthmatic children (aged 6 -10 years) with profiles of healthy children without asthma using Illumina HumanHT-12 BeadChip in a group of 200 children living in Ostrava-Radvanice and Ostrava-Bartovice (100 asthmatic and 100 healthy children) and a control group of 200 children living in rural district of Prachatice (100 asthmatic and 100 healthy children). Our results indicated completely different gene expression profiles among localities. We identified significantly deregulated genes specific for Ostrava or Prachatice, however, no gene was found to be commonly deregulated in both localities. Gene expression data of astmatic children from Prachatice showed increased expression of SIGLEC8, CLC, CCL23 and CACNG6, genes related to the presence of bronchial eosinophilic inflammation suggesting allergic phenotype of asthma. Skin tests also confirmed the diagnosis of allergy in most cases. In contrast, children living in industrial Ostrava region exhibited upregulation of genes associated with neutrophilic inflammation and non-atopic asthma phenotype (which could be triggered by air pollution). Moreover, upregulation of HBG2 and AHSP genes may imply the role of hypoxia in asthma development. Methods were developed to evaluate immunotoxicity effects of chemicals in preweaning piglets using immunophenotyping (IP), circulating cytokine evaluation & immunohistochemistry (IHC) of the gastrointestinal tract (GIT). Yorkshire crossbred piglets were offered ProNurse® formula 6x/day at 500 mL/kg/day for 4 weeks. Groups were Formula Control; Phosphate Buffered Saline (PBS) Control (im injection); Lipopolysaccharide (LPS) Positive Control (im injection); PBS Control by percutaneous endoscopic gastrostomy (PEG) tube & Dextran Sodium Sulfate (DSS) (as positive control). Piglet tissue & blood were used for evaluations.

In Africa, major sources of childhood Pb poisoning include Pb mining and smelting. In Kabwe, the capital of Zambia’s Central Province, extensive Pb contamination of township soils in the vicinity of a Pb-Zn mine has been reported and poses a serious health risk to children in these townships. Therefore, this study investigated Pb levels in soil, edible tissues of cattle and chickens as well as blood lead levels (BLLs) in children exposed to Pb pollution. The concentrations of Pb (9-51188 mg/kg) in Kabwe soil (n=101) were much higher than benchmark values. Pb levels in tissues of Kabwe cattle were higher than those in other Zambian towns. Moreover, mean concentrations of Pb exceeded maximum levels for human consumption in some organs including muscle in free-range chickens, in contrast to low levels in broiler chickens. Given these results of Pb pollution in soil and domestic animals, we investigated BLLs in children (n = 246), under the age of 7 years, in townships around the Pb-Zn mine in Kabwe and to identify children in Kabwe with BLLs that require medical intervention. Almost all of the sampled children had BLLs exceeding 10 µg/dL. Children in these areas could be at serious risk of Pb toxicity as 18% of the sampled children in Chowa, 57% (Kasanda) and 25% (Makulukulu) had BLLs exceeding 65 µg/dL; the threshold widely considered to result in Pb toxicity. A total of 8 children had BLLs exceeding 150 µg/dL. These levels were markedly high, especially that concentrations of up to 427 µg/dL were recorded. Therefore, it is recommended that medical intervention be commenced in the children with BLLs exceeding 45 µg/dL and other interventions to reduce Pb exposure in the affected townships.

845 The Development and Validation of Methods for Evaluating the Immune System in Preweaning Pigs

B. A. Thorsrud1, M. J. Cameron2, B. Zeigler3, K. G. Nelson1, J. M. McKeim1, M. L. Weiner1, H. Ferguson1, B. Frantz2 and W. Blakemore3.

1Hokkaido Univ, Sapporo, Japan, 2Pathology, MPI, Mattawan, MI, 3CeeTox, Kalamazoo, MI.

Methods were developed to evaluate immunotoxicity effects of chemicals in preweaning piglets using immunophenotyping (IP), circulating cytokine evaluation & immunohistochemistry (IHC) of the gastrointestinal tract (GIT). Yorkshire crossbred piglets were offered ProNurse® formula 6x/day at 500 mL/kg/day for 4 weeks. Groups were Formula Control; Phosphate Buffered Saline (PBS) Control (im injection); Lipopolysaccharide (LPS) Positive Control (im injection); PBS Control by percutaneous endoscopic gastrostomy (PEG) tube & Dextran Sodium Sulfate (DSS) (as positive control). Piglet tissue & blood were used for evaluations. The IP method used whole blood from control animals on Days 13, 14, 28, and 29 to evaluate peripheral blood leukocytes by flow cytometry. The cytokine method used blood from PBS control & LPS groups collected to evaluate IL-1β, IL-6, IL-8, and TNF-α. ELISA kits were used to detect cytokines. The ICH method used tissues obtained from the stomach, duodenum, jejunum, ileum, proximal & distal colon & cecum on for IL-6, IL-8 and TNF-α staining. These tissues were collected from PBS controls & DSS animals. H&E staining was used to confirm ICH changes. Results of the IP evaluation confirmed that it was a precise assay for evaluating lymphocytes, mature T-cells, helper T-cells, cytotoxic T-cells, B-cells & monocytes in preweaning piglet blood. Cytokine evaluations confirmed an increase in cytokine levels in LPS-treated animals. Immunohistochemistry evaluation confirmed increased IL-8 & TNF-α staining in the proximal &/or distal colon in DSS animals. H&E staining was associated with colonic inflammation/edema in tissues of DSS animals. In conclusion, these three methods were confirmed to be robust assays to evaluate the immune system of preweaning piglets. Funded by EMC Corp. & the International Formula Council.

846 Increased Prevalence of Asthma in Children Exposed to Pyrethroid Pesticides

S. L. Shalat1, M. Ramagopal1, B. Buckley2, K. Black2 and G. Mainelis2.

The household environment is recognized as a potentially important factor in the early childhood development and exacerbation of asthma and allergies. In recent years pyrethroid pesticides have become widely used for control of household pests, based upon the widespread acceptance of their safety for use in and around children. A study was conducted in households in New Jersey to examine the nature of the relationship between household and its common contaminants and the prevalence of asthma and allergies in young children (ages 6 months to 5 years). A total of 75 children and households were enrolled in the study. Health endpoints were assessed by a technician-administered questionnaire. The parents of the study subject were asked a questionnaire based upon that employed in the International Study of Asthma and Allergies in Children (ISAAC). Environmental sampling was carried out with vacuum sampling for dust, and aerosol (inhaalable) sampling for particulate matter. House dust was analyzed for the presence of a panel of 10 pyrethroid pesticides.
throid pesticides by GC/MS. A multivariate logistic regression analysis was carried out to total pyrethroids in house dust. All non-detects (N=9) were included at half the limit of quantitation and log transformations of the data carried out. Additional variables in the final model included age (years), gender, and family history of asthma (yes/no first degree relative). The model for prediction reporting of the child having had a physician diagnosis of asthma was statistically significant at the 0.003 level with log total pyrethroids OR = 1.25 (95% 1.03-1.51). When pyrethroid exposure was examined as quartiles the results for the top three quartiles with the bottom quartile as reference was OR = 1.05, 2.55, and 5.77 respectively, with the top quartile statistically significant (P < 0.027). The presence of a dose response increase in reporting of asthma in young children is suggestive that pyrethroid pesticides may play a role in early childhood asthma.

**847** Femoral Growth Plate Dysplasia in Juvenile Rabbits Dosed with a Spleen-Like Kinase (Syk) Inhibitor

P. Duffy1, T. Mitchard1, G. R. Clemence2 and P. A. Hall3. 1Drug Safety and Metabolism, AstraZeneca, Macclesfield, United Kingdom and 2Rigel Pharmaceuticals Inc, South San Francisco, CA.

Tyrosine Kinase inhibitors with inhibitory activity at the VEGF receptor have been associated with effects on the epiphyseal growth plates in rodents. This has potential impact for clinical trials and therapy in paediatric patients. This study was designed to investigate the potential for off target effects of a syk inhibitor in juvenile rabbits. Three groups of juvenile New Zealand White rabbits, each consisting of 10 males and 10 females, were given the test syk inhibitor orally, twice daily, for 1 month. The control group consisted of 11 males and 9 females and was similarly treated with vehicle. The dose levels were 5, 15 or 30 mg/kg/bid. The animals were 9 weeks old at the start of dosing. After dosing with 15 or 30 mg/kg bid, histopathological changes were evident in the proximal femur (growth plate dysplasia; reduced bone marrow cellularity), femoro-tibial joint (growth plate dysplasia; reduced bone marrow cellularity) and sternum (reduced bone marrow cellularity). The treatment-related dysplasia noted in the growth plate of the proximal femur was characterised by the thickening, fusating and in some animals, fracturing of the growth plate due to the accumulation of hypertrophic chondrocytes. In conclusion, the syk inhibitor produced growth plate dysplasia in the proximal femur and femoro-tibial joint and reduced bone marrow cellularity in the femur and sternum at 30 and 60 mg/kg/day. These findings were consistent with those seen in toxicity studies in rodents. The chondrodysplasia/growth plate dysplasia in rat and rabbit at 30 and 60 mg/kg/day. These findings were consistent with those seen in toxicity studies in rodents. The presence of a dose response increase in reporting of asthma in young children is suggestive that pyrethroid pesticides may play a role in early childhood asthma.

**848** Persistent Mitochondrial Damage in Offspring of Patas Monkeys Exposed In Utero to Antiretroviral Nucleoside Reverse Transcriptase Inhibitors (NRTIs)

Y. Liu1, A. T. Gibbons1, E. Shim1, P. Nguyen1, R. L. Dici2, R. A. Woodward3, M. J. Sowers4 and M. C. Poitier5. 1Carcinogen and DNA Interactions Section, LCBG, CCR, National Cancer Institute, NIH, Bethesda, MD, 2DCPC, National Cancer Institute, NIH, Bethesda, MD and 3Animal Center, NIH, Dickson, MD.

Combination antiretroviral therapy containing NRTIs is highly successful in controlling HIV-1 infection, and reducing mother-to-child HIV-1 transmission. However, NRTI exposure may cause mitochondrial dysfunction in infants born to mothers receiving NRTIs during pregnancy. To model NRTI use in human pregnancy, patas dams received human-equivalent protocols of antiretroviral drug combinations, and the offspring were examined for mitochondrial integrity. Dams were given combinations of 3 NRTIs, zidovudine (AZT)/lamivudine (3TC)/abacavir (ABC), or 2 NRTIs, AZT/3TC, plus a non-NRTI, Nevirapine (NVP), for the last 10 wk (50%) of gestation. Heart and brain tissues, collected from offspring at birth, 1 and 3 yrs of age, were examined by electron microscopy (EM) to evaluate mitochondrial morphology. The EM photomicrographs of heart and brain from drug-exposed offspring revealed damaged mitochondrial membranes with mitochondrial swelling, loss of cristae, and increased lucenty. Scoring of coded EM photomicrographs, by 3 independent investigators, revealed significantly higher damage in 1 yr old patas exposed to both drug combinations in utero, compared to 1 yr old unexposed patas (P<0.05). In addition, the 3 yr old drug-exposed patas had levels of heart and brain mitochondrial damage similar in magnitude to the 1 yr old drug-exposed animals, and significantly higher than the unexposed 1 yr old patas. Additional evaluations, including mtDNA levels, and mitochondrial oxidative phosphorylation assays are in progress. Because the drug-induced damage was persistent in 3 yr old patas, an age equivalent to 14 years in human life, this study provides powerful evidence for the persistence of NRTI-induced mitochondrial damage, and helps to explain the mitochondrial dysfunction observed in NRTI-exposed children.

**848a** Isotopic Analyses of Lead in Blood of Children to Identify Sources and Routes of Pollution in a Mexican Mining Site

P. R. Rebeca Yasmin1, C. L. Javier2, G. T. Arturo2 and P. A. Olívia2. 1Universidad Autonoma de San Luis Potosi, San Luis Potosi, Mexico and 2Universidad Autonoma de Mexico, Queretaro, Mexico. Sponsor: M. Gonzmart.

Lead (Pb) is a highly toxic element to the human body and even at low concentrations (<10 µg/L) it will have severe physiological or neurological effects particularly for children; it is well known that can be provided by different sources such as paint, ceramic, mining residues, etc.

In semiarid Mexican mining and metallurgical centers such Cedral San Luis Potosi, Mexico, the residues of these activities containing high concentrations of heavy metals (Pb, As, Cd, Hg) are generally deposited in uncovered piles, which constitute a source of contamination due to the wind dispersion. Human population can be exposed to these particles by different routes through inhalation, ingestion, and this source of pollution could be the cause of adverse effects associated to Pb. Some health affections in this community have been reported, but it has not been identified the source or sources of Pb to which the children are exposed.

The aim of this study is to trace the origin of Pb pollution and identify the principal source of environmental and human Pb contamination, using isotopic methods.

Pb concentrations and isotopic compositions in blood samples of children (4–8 years old) were determined by MC-ICPMS and compared to those of associated environmental samples (soil, residues, outdoor and indoor dust). Pb concentrations of soil, residues and dust ranged between 73-2460, 1736-6700, 144-3550 µg/kg, respectively. Blood Pb concentrations levels (11.0 ± 5.3 µg/ml) in children ranged between 2.7-36 µg/ml, which is 3-14 times higher than the current average (1.9 µg/ml) of children in the US. We find that blood Pb isotopic ratios (206Pb/204Pb 18.787±0.0003) strongly correlates with those values determined in atmospheric particles (206Pb/204Pb 18.775±0.0003) and the latter correlates with the isotopic value of samples coming from residues (206Pb/204Pb 18.774±0.0003). The results indicate that the main source of Pb in this site is mining residues, which are dispersed through wind.

**848b** Impulsivity and Attention in Fluoxetine-Treated Juvenile Monkeys

M. Golub1, C. Hogrefe2 and E. Hackett2. 1Environmental Toxicology, University of California Davis, Davis, CA and 2California National Primate Research Center, University of California Davis, Davis, CA.

The psychopharmacological agent fluoxetine is approved by FDA for use in children and is widely prescribed for a variety of developmental disorders. Possible adverse consequences of chronic fluoxetine treatment during brain development are being investigated in a rhesus monkey model. PK/PD studies were first conducted to select a dose with serum concentrations of active agent comparable to therapeutic use in children. Fluoxetine (2.2 mg/kg/d) or vehicle control was then administered orally to male rhesus monkeys (N=15,16 per group) daily between 1 and 2 years of age (equivalent to 4-8 years of age in humans). A reward delay (impulsivity) test and an automated Continuous Performance Test (CPT) were administered. Fluoxetine-treated monkeys demonstrated shorter average response latencies during the reward delay test and more immediate responses to presentation of the test. During CPT sessions conducted in the home cage room, fluoxetine-treated monkeys showed more omission errors taking into account cage location, which also influenced this measure. The study suggests that response inhibition and attention, two executive functions important to daily life in children, can be influenced by fluoxetine at therapeutic dose levels. Supported by HD065826.

**848c** Perinatal BispHENol A Exposure Changes Expression of Airway Secretory Products in the Developing Mouse Lung

BispHENol A (BPA) is a component of plastics. Recent work has shown that BPA exposure alters mucous cell development in fetal rhesus monkeys. While perinatal BPA exposure has been shown in a mouse model to increase airways hyperresponsiveness and alter immunity, the ability of BPA to change normal growth and development of secretory cells, including mucous cells, in the airways of mice, has not been studied. To address this, we exposed timed pregnant NIH Swiss mice to 10ug/ml BPA in drinking water beginning on gestational day 14 (GD14) and continuing for the length of the study. We examined the proximal (extrapulmonary trachea/bronchi) and distal (intrapulmonary bronchioles) conducting airways of both male and female offspring using histopathology and gene expression approaches at 1d, 3 weeks and 8 weeks of age to span birth, weaning and young adulthood. Mucous cell abundance was defined using AB/PAS histologic staining approaches at 1d, 3 weeks and 8 weeks of age to span birth, weaning and young adulthood.
and muc5B/muc2 gene expression. Club (Clara) cell abundance was defined using immunohistochemistry and gene expression of secretoglobin 1A1 (sgb1A1). We found that continual BPA exposure beginning in the third trimester and extending to 3 weeks postnatal resulted in site-specific changes in Muc5B expression. Proximal extrapulmonary airways had a 2-fold decrease in Muc5B gene expression in males and females, which achieved statistical significance in males. In contrast, the more distal, intrapulmonary airways of both males and females had a greater than 2-fold increase in Muc5B expression. This was mimicked by Muc2 gene expression but only in male mice and an increase in sgb1A1 gene expression only in female mice. When the abundance of sgb1A1 protein was assessed, the amount per cell was diminished in the distal airways of BPA-treated mice suggesting a mismatch between mRNA expression and protein expression which might be explained by accelerated secretion. We conclude that BPA exposure during lung development changes secretory product expression, even in species with limited mucous cells such as mice. Supported by NIEHS R21 ES021600

849 BMS-986094: Nonclinical Investigative Studies on a Nucleoside Analog Intended for Treatment of Hepatitis C Virus Infection

BMS-986094 (formerly INX-08189), a 2’-C-methylguanosine prodrug with pivalate and 1-naphthol moieties, was withdrawn from clinical trials because of a serious safety issue. Events included decreased left ventricular ejection fraction, electrocardiogram changes, and acute kidney injury. In prior animal studies, tolerated doses associated with minimal and reversible skeletal muscle degeneration were established. Since skeletal muscle degeneration correlated with increases in standard serum analytes (e.g., transaminases), it was expected that clinical dosing could proceed safely with careful monitoring prior to onset of more severe events.

Because the onset and severity of clinical adverse events (heart and kidney) were unexpected, Bristol-Myers Squibb Company conducted a robust series of in vitro and in vivo investigative studies including innovative, and in some cases newly developed, mechanistic and diagnostic methodologies, to further characterize BMS-986094 toxicity. These studies focused on several potential mechanisms including: 1) reactive metabolites and cytotoxicity of BMS-986094 and its prodrug moieties, 2) mitochondrial toxicity, 3) pivalate involvement in tissue energy status, 4) plasma and tissue metabolomic changes, 5) tissue transcriptional changes, and 6) levels of BMS-986094 and its metabolites in plasma and tissues.

Although these studies extended the understanding of the nonclinical toxicities of BMS-986094, they did not identify a specific underlying mechanism. Observations included possible novel kidney injury biomarkers; an apparent correlation of tissue nucleoside triphosphate levels to toxicity; that predominate BMS 986094 metabolites were not associated with reactive metabolites or oxidative stress; and preliminary evidence that, although some potential secondary energy utilization changes were observed, BMS 986094 does not appear to be a direct mitochondrial toxicant.

To characterize any CV changes, BMS-986094 was given to 5 telemetered monkeys/group at 0 or 15 mg/kg/day (45 days) or 30 mg/kg/day (30 days) with recovery for 29 days. Key criteria included toxicokinetics, serum cardiac troponin (cTnI) and N-terminal brain natriuretic peptide (BNP), echocardiography, arterial and left ventricular (LV) pressure, LV dP/dt (terminal), and electrocardiography (ECC). The predominant plasma analyte (74-89% total AUC) was INX 08032 (initial nucleoside, 534 and 3400 ng·h/mL at 15 and 30 mg/kg/day, respectively). There were no LV ejection fraction [EF], % fractional shortening [%FS], or stroke volume [SV] changes at 15 mg/kg/day. Beginning Day 32, ventricular dilatation occurred at 15 (2.1x pretest) and 30 mg/kg/day (4.0x). Day 32 changes (vs. pretest) at 30 mg/kg/day were decreased mean LV EF (0.43x), % FS (0.35x), and SV (0.62x), with recovery by Day 39. Absolute LV EF ranged from 12 to 43%. Dose-related LV dP/dt decreases at 15 (0.78x) and 30 mg/kg/day (0.45x) occurred with nadirs on Days 33-47 at 15 and Days 26-53 at 30 mg/kg/day. Potential cardiac biomarkers (cTnI, BNP) did not correlate in individual monkeys. ECC changes were prolonged QT interval at both doses, and flat and inverted T waves and ST-segment depression at 30 mg/kg/day. Two 30 mg/kg/day monkeys were euthanized on Day 32; with their hemodynamic and anatomic pathology changes suggesting heart involvement. CV changes in survivors exhibited partial to complete recovery.

In summary, BMS-986094 was not tolerated at 30 mg/kg/day, and partial-to-complete reversible, dose- and time-related ventricular dilatation, decreased ventricular function, and ECC interval and morphologic changes were observed at both doses.

850 BMS-986094: Investigation of Potential Biomarkers and Mechanisms of Toxicity in Cynomolgus Monkeys

K. Horn1, T. Sanderson1, R. White1, E. Renshaw1, D. Nelson1, S. Clark1, T. R. Van Vleet1, D. Simic1, B. Baumgart1, B. Wang3, J. Lute5, E. Janovitz4, S. Davies2 and M. J. Graziano2. Drug Safety Evaluation, Bristol-Myers Squibb (BMS), Mt. Vernon, IN, 2DSE, BMS, Lawrenceville, NJ and 3DSE, BMS, New Brunswick, NJ.

BMS-986094 (formerly INX-08189), a 2’-C-methylguanosine prodrug, was withdrawn from clinical trials because of a serious safety issue. Events included decreased left ventricular ejection fraction, electrocardiogram changes, and acute kidney injury. BMS-986094 was dosed orally at 0, 15, or 30 mg/kg/day to cynomolgus monkeys for 3 weeks + a 3-week treatment-free period. BMS-986094, INX-09054 (prodrug less naphthol), INX-08032 (initial nucleoside), INX-08144 (O-methyl nucleoside), and INX-09114 (triphosphorylated nucleoside) were measured by LC/MS in plasma and peripheral blood mononuclear cells (PBMCs) in Weeks 1, 3, and 6; and in tissues in Weeks 3 and 6. INX-08032 was the major circulating analyte (66-68% of total AUC) followed by INX-08144 (<16%). BMS-986094, INX-09054, and INX-09114 levels (<22%) in plasma were low and INX-09114 levels in PBMCs could not be quantified. In Week 3, INX-09114 (± 4280 ng/mL) was high in heart and kidney, and males had higher (3.3x) heart levels than females at 30 mg/kg/day. Other analytes increased dose dependently in target and non-target tissues with BMS-986094 highest in heart and kidney. BMS-986094 and selected BMS-986094 metabolites were measured in target (heart, kidney, diaphragm, and liver) and non-target (lung) tissues under optimal stabilization to determine any associations between analyze levels and toxicity. Consistent with companion studies, BMS-986094 was dosed orally at 0, 15, or 30 mg/kg/day to cynomolgus monkeys for 3 weeks + a 3-week treatment-free period. BMS-986094, INX-09054 (prodrug less naphthol), INX-08032 (initial nucleoside), INX-08144 (O-methyl nucleoside), and INX-09114 (triphosphorylated nucleoside) were measured by LC/MS in plasma and peripheral blood mononuclear cells (PBMCs) in Weeks 1, 3, and 6; and in tissues in Weeks 3 and 6. INX-08032 was the major circulating analyte (66-68% of total AUC) followed by INX-08144 (<16%). BMS-986094, INX-09054, and INX-09114 levels (<22%) in plasma were low and INX-09114 levels in PBMCs could not be quantified. In Week 3, INX-09114 (± 4280 ng/mL) was high in heart and kidney, and males had higher (3.3x) heart levels than females at 30 mg/kg/day. Other analytes increased dose dependently in target and non-target tissues with BMS-986094 highest in diaphragm (± 4400 ng/mL) followed by INX-08032 in liver and kidney (± 1360 ng/mL) and low INX-08144 and INX-09054 levels (± 124 ng/mL) in other tissues. After the treatment-free period (Week 6), heart and kidney INX-09114 remained high (± 1870 ng/mL). Tissues and plasma had low INX-08032 levels (± 37 ng/mL), and other analytes were not detected. Persistent INX-09114 in heart and...
kidney appeared to correlate with toxicities in these tissues in companion studies; however, higher tissue INX-09114 in males did not translate to increased toxicity in this sex. There were no other correlations between analytes and target organ toxicity.

853 BMS-986094: Metabolomic Assessment of Cardiotoxicity in Monkeys and Mice

BMS-986094 (formerly INX-08189), a 2'-C-methylguanosine prodrug, was withdrawn from clinical trials because of a serious safety issue. Events included decreased left ventricular ejection fraction, electrocardiogram changes, and acute kidney injury. Pivatate prodrugs, as is BMS-986094, can be metabolized to pivaloylcarnitine (PVC) which is not further metabolized, and is eliminated in urine potentially leading to systemic carnitine depletion and, after prolonged high doses, secondary cardiomyopathy. Some monkeys and mice given BMS-986094 develop cardiomyocyte degeneration and to a lesser extent skeletal muscle degeneration. During mechanistic evaluation of potential BMS 986094 cardiotoxicity, metabolomics in monkey plasma and tissue (0, 15, or 30 mg/kg/day, 3-4 weeks) and in mouse heart (0 or 150 mg/kg/day, 2 weeks) were conducted. In monkey plasma, a dose-proportional, novel MS peak, isobaric with valeryl and isovaleryl carnitine, was identified as PVC. PVC was not evident in control or recovery monkeys. In monkey heart, there were no decreases in free carnitine or acetylcarnitine in diaphragm despite having PVC levels similar to heart, suggesting tissue specificity. In mouse heart, there were no decreases in free carnitine or acetylcarinetein on Day 2, with only modest reduction (0.7x control) subsequently. Tissue acetylcarinetein changes, a reflection of acetyl CoA status, were disparate across species suggesting acetylcarinetein changes are likely secondary, and not indicative of a cardiac toxicity mechanism.

854 BMS-986094: Transcriptional Profiling in Monkeys and Mice

BMS-986094 (formerly INX-08189), a 2'-C-methylguanosine prodrug, was withdrawn from clinical trials because of a serious safety issue. Events included decreased left ventricular ejection fraction, electrocardiogram changes, and acute kidney injury. Transcriptional changes (TC) associated with potential BMS 986094 toxicities were evaluated in monkeys dosed (0, 15, or 30 mg/kg/d) for 1 month and mice dosed (0, 25, or 150 mg/kg/d) for 2 weeks. For gene expression analysis, tissues were collected after the last dose (monkey) or on Days 1 (6 and 24 h), 3, 8, and 15 (mouse, course-study). In both species, the primary target tissues were heart, kidney, and skeletal muscle, and in these tissues TC generally separated from control in PCA space. No consistent pattern of TC (up- or down-regulated) was apparent. In monkeys, heart TC was greatest (≥ 16% total genes) with much fewer kidney TC and still fewer in skeletal muscle. Heart TC suggested cytoskeleton/myofilaments/sarcomeres, GTPase (Rho, Rab, Rac, and Ras), Ca2+ and redox signaling, mitochon-dria, and purine synthesis involvement. Kidney TC suggested altered transport/endocytosis. Skeletal muscle TC was similar to heart, but at lower magnitude. In mice, kidney TC was greatest (≥ 13% total genes) with fewer skeletal muscle and heart TC. Early gene expression changes in kidney were associated with GTPase signaling (Rho and Rab), the cytoskeleton, Ca2+-related genes, and endocyto-sis-related genes. Early TC in heart was associated with cytoskeleton/myofilaments/sarcomeres and GTPase and Ca2+ signaling. Most mitochondrial gene expres-sion changes were in kidney (mostly tRNA and ribosomal genes). Gene expression changes in skeletal muscle were similar to those in heart, but lower in magnitude and delayed in onset. Overall, TC timing and magnitudes were generally associated with the level of toxicity in target tissues. The earliest TC appeared related to cytoskeleton/myofilament/sarcomere, and GTPase and Ca2+ signaling with other TC (e.g., mitochondrial changes) likely secondary.

855 BMS-986094: Investigations of In Vitro Metabolism, Reactive Metabolite Formation, and Oxidative Stress in Human Liver Microsomes, Hepatocytes, and Cardiomyocytes

W. Li1, L. Ma1, W. Zhao1, J. Kwagh2, C. Storck3, Y. Zhu1, A. Liu1, O. Flint4 and R. G. Humphreys3. “Bristol-Myers Squibb, Lawrenceville, NJ and 3Bristol-Myers Squibb, Pennington, NJ.

BMS-986094 (formerly INX-08189), a 2'-C-methylguanosine prodrug, was withdrawn from clinical trials because of a serious safety issue. Events included decreased left ventricular ejection fraction, electrocardiogram changes, and acute kidney injury. These experiments evaluated in vitro metabolism and reactive metabolite formation of BMS-986094 (non-labeled) or single BMS-986094 diastereomers (14C- or 3H-labeled BMS-986095 and BMS-986096) in human liver microsomes (HLM), hepatocytes (HH) and cardiomyocytes (HCM). Incubates were analyzed by LC-MS/radioactive detection or targeted LC-MS/MS assays. Protein covariant binding (PCB) in HLM, and intracellular glutathione (GSH), adenosine triphosphate (ATP), and reactive oxygen species (ROS) in HH or HCM were measured. BMS-986095 and BMS-986096 were extensively metabolized in HLM, but via different oxidative pathways. Substantial PCB was detected in HLM with both diastereomers, with higher levels of PCB being produced by BMS-986095 than BMS-986096. PCB derived from the 14C-labeled naphthyl moiety was higher than that from the 14C-labeled guanine moiety for both diastereomers. GSH conjugates derived from the naphthyl moiety were detected. In human hepatocytes and cardiomyocytes, hydrolysis was the predominant metabolism pathway for both diastereomers, which led to the formation of the pharmacologically active triphosphate metabolite. Oxidative metabolites were minor in these cells. BMS-986094 was not associated with reduced intracellular GSH in either HH or HCM, or with ROS induction in HH.

These data suggest that reactive metabolite formation by BMS-986094 in HLM was mainly associated with oxidative metabolism at the naphthyl moiety, but the predominant metabolism pathway (hydrolysis) of BMS-986094 in HH and HCM was not associated with the formation of reactive metabolites or oxidative stress.

856 BMS-986094: Potential Cytotoxicity in Differentiated Human Cardiomyocytes

BMS-986094 (formerly INX-08189), a 2'-C-methylguanosine (2CMG) prodrug with pivalate and 1-naphthol moieties, was withdrawn from clinical trials because of a serious safety issue. Events included decreased left ventricular ejection fraction, electrocardiogram changes, and acute kidney injury. 2CMG-triphosphate (2CMG-TP), pivalate and 1-naphthol are formed by cellular metabolism of BMS-986094. The objective of these studies was to assess potential cytotoxicity of these 3 metabolites in cultures of differentiated human cardiomyocytes (hCM). hCM, derived from induced pluripotent stem cells, were cultured up to 10 days. Cell viability and function endpoints included total ATP, caspase 3/7 activity, beat rate, and contractility by impedance (eXCELLiGenic). Glucose- and fatty acid-driven mitochondrial respirations were assessed using the Seahorse XF-96 analyzer and acylcarnitine formation was measured by HPLC. Based upon ATP depletion, BMS-986094 IC50 values on Days 3, 6, and 10 were >50, 17.3, 2.1 and 0.6 μM, respectively. Caspase 3/7 activity, a measure of apoptosis activation, was increased on Days 3, 6 and 10. Decreased hCM contractility (amplitude) was associated with reduced cell viability. Other changes associated with BMS-986094 (10 μM) included, (1) inhibition of mitochondrial respiration as early as Day 1 (IC50: 7.7 μM); (2) inhibition of palmate-fueled oxygen consumption after 4 days; and (3) reduced glucose-driven basal cell oxygen consumption on Days 6 and 10. In contrast, 1-naphthol (100 μM) and pivalate (10 μM), when added directly to cultures, were not associated with reduce cell viability when tested up to 10 days. BMS-986094 was associated with concentration- and time-related cytotoxicity and altered energy utilization in hCM cells. However, the relevance of these observations to in vivo findings remains unclear. Pivalate and 1-naphthol, principal BMS-986094 produg metabolites, were not cytotoxic.
BMS-986094 (formerly INX-08189), a 2′-C-methylguanosine prodrug, was withdrawn from clinical trials because of a serious safety issue. Events included decreased left ventricular ejection fraction, electrocardiogram changes, and acute kidney injury.

The objective was to assess any changes on mitochondrial DNA (mtDNA) replication, transcription, or mRNA translation in HepG2 cells and in differentiated human cardiomyocytes (hCM), derived from induced pluripotent stem cells, exposed to BMS-986094. HepG2 and hCM were exposed to BMS-986094 (0.22-2 μM) for ≥19 days. The mitochondrial genes ATP8 and COXIXI total cell number, protein, ATP, and lactate were assayed by qPCR. In separate experiments (0.1, 1, and 10 μM: 24 hours), transcripts of the mitochondrial genes ND1 and ND5 were assayed by Northern blot in Huh7 cells and the respiratory chain proteins ND1 and COXII were assayed in hCM by in-cell Western.

BMS-986094 at >1 μM was associated with concentration- and time-related cytotoxicity after 3 days. Non-cytotoxic concentrations (<1 μM), BMS 986094 was not associated with HepG2 or hCM mtDNA reductions after 19 or 10 days, respectively. BMS 986094 at high concentrations (9-10 μM) was associated with reduced ND1 and ND5 transcription in Huh7 cells and ND1 and COXI proteins in hCM within 24 h. Other observations at 10 μM were inhibition of mtRNA-poly-merase-driven mRNA transcription (POLRMT) and reduced expression (transla-
tion) of respiratory chain proteins. These latter observations are consistent with a recent report [Arnold et al, PLoS Pathog 8(11): 2012] that 2′-C-methylguanosine is a terminator of POLRMT-driven mRNA strand elongation. In summary, BMS-986094 was not associated with mtDNA replication inhibition, but was associated with POLRTM inhibition and reduced respiratory chain protein expression. However, the relevance of these in vitro observations to in vivo findings remains unclear.

Human and rabbit response to drug effects on corneal wound healing was evaluated in an anterior chamber model. New Zealand white rabbit eye globes were obtained and placed in Optisol. Human eyes were procured with donor consent through Midwest Eye-Banks (Ann Arbor, MI) and The Lions Eye Institute for Transplant and Research (Tampa, FL). Wounding, anterior keratectomy (AK), was induced by scoring the cornea (rabbit 2.5 mm, human 8 mm), and removing the epithelium using a gill knife. The anterior segment of the eye was dissected and cultured in complete medium on a rotating platform to maintain tissue differentiation for several days. The initial wound and progression of wound closure was visualized with fluorescein (0.015%), and the area recorded with a digital photo and quantified with ImageJ. Wound closure in untreated AK cornea occurred at different rates, rabbit (75% at 2 h) compared to human (24 h). Diclofenac (DCF) a nonsteroidal anti-inflammatory agent often used post-surgery and dosed topically (0.1%), impaired wound healing in both species. Rabbit AK cornea treated with DCF showed no change in immune/inflammation, cell adhesion/chemo-
patogenesis of vascular conditions including diabetes (T2DM). Exposure to traf-
fic-related air pollution (TRAP) has been implicated in the pathogenesis of vascular conditions including diabetes (T2DM). Exposure to traf-
ic-related air pollution (TRAP) has been found to negatively impact clinical vascu-
lar outcomes, possibly through loss of endothelial function. Reactive hyperemia (RH), a potent inducer of EDNO, is reduced in T2DM and following exposure to TRAP. In this study we examined impact of an acute 2 hour highway TRAP exposure on NO metabolism in 20 type II diabetic and 20 control subjects. Plasma nitrite (NO2-), a proximal measure of EDNO, and nitrate (NO3-), a further ox-
idized metabolite, were measured prior to and following RH, before and after pollution exposure. Diabetics displayed a higher resting NO2- level than controls at baseline (230 vs. 182.6 μM, p<0.06). Resting NO2- in diabetics decreased by 18.3% following the car ride (p<0.06), while controls decreased by 2.9% (p=0.08). Controls responded with a significant increase in NO2- following RH (15.9%, p<0.02) that was blunted by TRAP exposure (5.0%, ns). Diabetics showed no change in NO2- due to RH (1.8%, p=0.8) that was unaffected by TRAP. The ratio of NO2- to NO3- showed no change in controls due to TRAP. This ratio shifted toward NO3- in diabetics. Therefore, TRAP appears to lower the RH response in EDNO production, a property that is already lost in T2DM. Meanwhile TRAP strongly impacts the handling of NO within T2DM, favoring oxidation. Oxidative metabolization of NO in T2DM, leading to loss of endothelial function, appears to be further increased following TRAP exposures, implying this population may be more susceptible to adverse clinical events from traffic.
using micro-bioanalysis and/or reduced blood volume techniques for clinical pathology (CP) assessments. These study designs were created using recommended guidelines for weekly blood volume collections (7.5% of total blood volume/week). Study designs included a 4 week dosing period with a 4 week recovery period using a large molecule test article and included toxicokinetic (TK) and anti-drug antibody (ADA) endpoints, one pharmacodynamic marker (PD) and clinical pathology (CP) assessments. In rat studies, we were able to reduce the total blood volume that was collected on a weekly basis by up to 15 fold using micro-bioanalysis. This resulted in a 1 to 2 fold decrease in number of animals for the study. Additionally, we demonstrated that by combining micro-bioanalysis with reduced blood volume for CP assessments it would be possible to perform a rat study with no satellite groups and collect all required samples from the same animals (TK, ADA, PD and CP). In mouse study designs, the difference was greater, by incorporating micro-bioanalysis and reduced CP volume, we could not only reduce the number of animals by 4 fold, but also perform some study endpoints using the same animal; increasing the reliability of the data from each animal. Toxicology rodent studies can be greatly improved by incorporating reduce blood volume assays into their designs, allowing reduction in animal and improving data interpretation. These practices all support and incorporate the principles of the 3Rs.

862 Exploration for Mitochondrial Toxic Oxidative Stress in Pregnant Women on Iron Supplements in a Population with High Maternal Mortality Rate

J. L. Aneter1, E. I. Dia1, A. Arowojolu1, L. B. Amo1 and G. O. Anetor2.
1Departments of Chemical Pathology & Obstetrics/Gynecology, University of Ibadan, Ibadan, Oyo, Nigeria and 2Health Education, University of Ibadan, Ibadan, Oyo, Nigeria.

Although Iron (Fe) is a common supplement in pregnancy, it generates toxic oxygen species (TOS). Manganese(Mn) is vital for mitochondrial function; key component of the mitochondrial antioxidant, MnSOD which scavenges TOS. Fe competes with Mn for a common transporter, transferrin (Tf). The contribution of this interaction to mitochondrial toxic oxidative stress in at risk populations has received little attention. Sixty-three pregnant women on Fe supplements (FeSO4) covering the 3 trimesters, and 63 non-pregnant women, were investigated. Fe and indices of Fe homeostasis, Mn and key components of the antioxidant system were evaluated in serum in all groups and sub-groups. The levels of Mn, SOD, and Tf were raised in pregnant subjects vs control (p < 0.05). In contrast, levels of Fe, ferritin, Cu, uric acid, TIBC, % saturation, and Zn were significantly reduced in the same group (p<0.05). The first trimester demonstrated significant elevations in Mn and Tf compared to control (p <0.05), while Fe, Cu, Zn, Hct, ferritin were decreased. The second trimester exhibited significant elevations in the levels of Mn, Tf and SOD. In contrast, Fe, Cu, Zn, ferritin & TIBC were significantly reduced; as for the first trimester (p < 0.05). In the third trimester, Mn and Tf were again significantly elevated like the previous trimesters. The levels of other bioidicators were identical with those of earlier trimesters. The consistent increase in Mn and Tf levels in the pregnant compared to non-pregnant states, and the 3 trimesters, with inverse patterns in Fe level and key components of the antioxidant system may in addition to increased demand for Fe, reflect antioxidant dynamics consist with oxidative stress, including toxic mitochondrial oxidative perturbation. Mild to moderate mitochondrial impairment contributes to many pathologies. Understanding these interactions may improve strategies for addressing the refractory high maternal mortality rate in this high risk population.

863 ELISA Detection of Zilpaterol in Retinal Tissue

C. Wilson1,2, M. Mengel1 and J. Butz1.
1Indiana Animal Disease Diagnostic Laboratory, Purdue University, West Lafayette, IN and 2Comparative Pathobiology, Purdue University, West Lafayette, IN.

Zilpaterol is a β-adrenergic agonist feed ingredient intended for livestock animals in order to enhance lean muscle mass and increase feed efficiency. Unfortunately, due to zilpaterol’s anabolic properties, it can be abused as a performance enhancing drug in livestock show and racing animals. Illicit abuse of the drug also extends into animal health and medicine with the drug being abused or being used off-label. Drug testing in livestock show and racing animals. Illicit abuse of the drug also extends into animal health and medicine with the drug being abused or being used off-label.

1) homogenizing approximately 0.40 g retinal tissue with acetonitrile/isopropanol (4:1) and 0.24 g NaCl, 2) drying the extract with 0.10 g MgSO4 and 0.80 g Na2SO4, 3) N2 evaporating the extract to dryness, reconstituting with 0.4 mL PBS, and 4) analyzing 50 µL of the reconstituted sample by ELISA. Sample optical densities less than or equal to the optical density of the 10 ppb positive control were considered positive. Using this protocol, zilpaterol was detected in the retinal tissue of 2 steers fed 96 mg zilpa- terol/head/day for 26 days. The average optical density in the 2 samples was 0.050, while the 10 ppb positive control average optical density was 0.280. This study shows that zilpaterol can be detected in retinal tissue from animals being fed the drug and provides a means by which the presence of zilpaterol can be monitored in animals for which the drug is being abused or being used off-label.

864 Monitoring GI Liability of EGFR Inhibitors with a Scratch Wound Assay in Intestinal Epithelial Cells

J. Harvey1, M. Hendek2 and G. Yanochok1.
1Drug Safety Research and Development, Pfizer, Inc., Groton, CT and 2Pfizer, La Jolla, CA.

Clinically, the use of epithelial growth factor receptor (EGFR) inhibitors for oncol- ogic indications is known for gastrointestinal (GI) toxicity and is dose limiting. EGFR is a member of the ErbB receptor tyrosine kinase family. In normal cells, EGFR signaling is important for migration, survival, and proliferation and promotes epithelial restitution after normal GI mucosal damage. In cancer cells, activating EGFR mutations drive the development of a specific subset of non-small-cell lung cancers and in 50% of these patients the use of wild type (WT) EGFR inhibitors such as erlotinib and gefitinib is limited by the development of a T790M secondary mutation. To target patients who harbor both primary and secondary mutations, selective EGFR double mutant (DM) inhibitors are in development. We sought to determine if DM compounds would have a better GI safety profile over WT inhibitors. We used a rat intestinal epithelial cell line (IEC-6) in a scratch-wound assay (SWA) as a model for restitution of the GI epithelium. The ability of WT or DM com- pounds to prevent TGF-β-induced repair of wounded IEC-6 cell monolayers was measured using the IncuCyte to monitor real time wound closure (WC) (Essen BioScience). Seven WT and five DM targeted compounds were tested. WT inhibi- tors prevented TGF-β-induced WC. The IC50 for the rate of WC from 0-6 hours was 0.009±0.001 to 1.15±1.38 µM with a mean of 0.19±0.56 µM and was not due to cytotoxicity as IC50 values for cytotoxicity were ≥30 µM (Promega). Inhibition of WC was associated with the WT inhibitor potency at EGFR; R2 = 0.60. In contrast to WT inhibitors, the IC50 range for the rate of WC from 0-6 hours was 5046±1.6 to 34,32±12.32 µM with a mean of 11.41±15.52 µM and was significantly greater than that for WT inhibitors (p<0.0001). There was some overlap between inhibition of WC and cytotoxicity in this group of compounds: IC50 values for cytotoxicity ranged from 20-100 µM. Collectively, these data suggest that the DM EGFR inhibitors should have reduced GI liability in vivo compared to WT inhibitors.

865 The Protective Effects of Short-Term Fasting against 60Co-γ Ray Radiation

L. Li1,2.
1Soochow University, Suzhou, China and 2RIRBM, Hiroshima University, Hiroshima, Japan.

To investigate the antagonistic effects and mechanism of short-term fasting against 60Co-γ ray radiation in vivo and in vitro. ICR mice were randomly divided into control, 12h, 48h, and 72h fasting groups and were irradiated 7.5 Gy. General symptoms, organ ratio, WBC, ROS, SOD, MDA, T-AOC and eNOS were detected. To observe the differential effects and mechanism on glucose restriction against 60Co-γ ray radiation to normal and tumor cell. V79 and A549 cells were irradiated 12Gy. V79 and A549 cells were di- vided into 9 groups, including high glucose of 3.0g/l with 10% serum group (3.0g/ l+10%), 0.5g/l+10%, 3.0g/l+5%, 1.0g/l+5%, 0.5g/l+5%, 3.0g/l+1%, 1.0g/l+1% and 0.5g/l+1% group. In vivo, the survival rates of ICR mice were 0 for the control and 12 h group, 12.5% for the 48h group and 50% for the 72h group respectively. Compared with 0 group, ROS content and eNOS activity of 72h group were reduced and increased respectively. SOD, T-AOC activity of 72h group was less than 0 group. The viability of V79 and A549 cell was related to the dose level of γ ray, when the dose was 12Gy. Toxic effects and differential stress resistance (DSR) could be observed. As a result of interaction between serum restriction and radiation, the concentration of glucose in the media was reduced to mimic STS. After 60Co-γ ray radiation, V79 cell viability of the high, normal, low glucose group was reduced to 46%, 23% and 1% respectively, and A549 cell was reduced to 37%, 50% and 48%; The apoptosis rate of V79 cell of low glucose contents was reduced significantly, but A549 cell had no significant difference among groups. ROS production of V79 cell with low glucose was reduced, SOD activity was increased significantly, in contrast, ROS production of A549 cell was increased and SOD reduced significantly.
PI3 kinase inhibitors are being developed for several clinical indications including metastatic breast cancer in women overexpressing HER2. GDC-0941 is a potent pan PI3K inhibitor, which when given in combination with trastuzumab emtansine (T-DM1) showed >Grade 3 thrombocytopenia. The purpose of the present study was to examine the potential of GDC-0941 alone and in combination with T-DM1 to effect megakaryocyte production and proliferation in vitro. We utilized human in vitro model for the study which consisted of deriving the human hematopoietic stem cells (CD34+) from healthy donor bone marrow and differentiating them into megakaryocytes, during which cells were collected for cytotoxicity, cell number and CD41/CD61 expression. We evaluated the cytotoxic effect of GDC-0941 treatment on human megakaryocyte formation from CD34+ HSCs. We further co-treated GDC-0941 with T-DM1 to evaluate whether effects on human megakaryocyte formation are additive/synergistic. The data showed that GDC-0941 treatment caused a decrease in megakaryocyte production from hematopoietic stem cells and cell proliferation over a period of 14 days. Further, the treatment of GDC-0941 in combination with T-DM1 showed an enhanced cytotoxicity leading to a decrease in production of megakaryocytes over a period of 14 days when compared to GDC-0941 alone. The results show consistency when tested in additional donors. Thus, the human in vitro bone marrow model is very useful to evaluate the potential of a drug candidate to cause thrombocytopenia or bone marrow toxicity.

866 Effect of GDC-0941 Treatment in Combination with T-DM1 on Formation of Megakaryocytes

M. R. McGill1, W. M. Lee2, 3 and H. Jaeschke1. 1Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS. 2Dietive and Liver Diseases, University of Texas Southwestern Medical Center, Dallas, TX and 3Acute Liver Failure Study Group, Dallas, TX.

Acetaminophen (APAP) overdose is a major problem. Although most patients survive, the volume of cases makes it the most common cause of acute liver failure (ALF) and ALF-related deaths in the US. We are only beginning to translate the mechanisms of hepatotoxicity from rodents to humans. Our group recently reported evidence of mitochondrial dysfunction in APAP overdose patients using biomarkers of mitochondrial damage (mitochondrial DNA [mtDNA], glutamate dehydrogenase [GDH], and nuclear DNA [nDNA] fragments). In this study, we wanted to determine if these markers correlate with death or survival. We measured mtDNA by qPCR, GDH activity by kinetic assay, and nDNA fragments by ELISA in serum from APAP-induced ALF patients who did (n = 35) and did not (n = 34) survive. All three parameters were elevated at or near the time of peak ALT in patients with APAP-induced liver injury. Unlike ALT, peak levels of both GDH and nDNA fragments were higher in serum from non-survivors than survivors (1.08±0.22 vs. 1.34±0.77 U/L and 259±2 vs. 209±4 % of control, respectively). GDH and nDNA fragments also exhibited weak but significant correlations with ALT, prothrombin time, and with each other. Importantly, receptor operating characteristic (ROC) curve analysis revealed that higher peak levels of both GDH and nDNA fragments better associated with non-survival (AUC=0.68 and 0.65 for GDH and nDNA, respectively; p<0.03) than ALT (AUC=0.60; p=0.11). Limited data suggest similar results for mtDNA. Conclusions: Biomarkers of mitochondrial damage are higher in non-survivors with APAP-induced ALF. This indicates that patients with more mitochondrial damage are less likely to survive. Mitochondrial biomarkers could be useful as part of a panel for patient prognosis. (NIDDK U-01 DK58369 to the Acute Liver Failure Study Group)

867 Serum Biomarkers of Mitochondrial Damage in Survivors and Nonsurvivors of Acetaminophen-Induced Acute Liver Failure: Implications for the Mechanism of Hepatotoxicity in Humans

868 A Labor of HERCULES: Curation of the Environmental Metabolome for Exposome Research

D. P. Jones1, E. Uppal1, D. J. Walker2, Y. Tran1, Y. Liang1, Y. Ge2, E. Voit3, D. B. Bart3, P. Tolbert4, K. D. Pemmel5 and G. W. Miller2, 1Dept of Medicine, Emory University, Atlanta, GA, 2Civil and Environmental Engineering, Tsai University, Medford, MA and 3Georgia Technology Institute, Atlanta, GA.

Liquid-chromatography high-resolution mass spectrometry with advanced algorithms for data extraction, termed “high-resolution metabolomics” (HRM), now enables routine measurement of >20,000 chemicals in biologic samples. As part of the new NIEHS-funded P30 Center at Emory University and Georgia Tech called the Health and Exposome Research Center: Understanding Lifetime Exposures (HERCULES), we have initiated systematic curation of the environmental metabolome through cross-platform statistical tests of results from validated, targeted analyses of environmental chemicals and HRM analyses of the same samples. The principles of the approach were validated using quantitative results obtained commercially (Metabolon) and compared to HRM using “targeted” MWAS (Metabolome-Wide Association Study). In this validation, the values for specific chemical targets in a series of 50 samples were regressed against the intensities for all ions [mass/charge (m/z) features] detected by HRM. The cross-platform targeted MWAS for >100 metabolites were performed, with each displayed as Manhattan plots of log2(p value for t-test) as a function of m/z, along with false discovery rate correction. Co-elution of authentic standards and MS6 confirm metabolic identity from HRM. Results with internal standards and calibration against pooled reference samples demonstrate that HRM can be used for absolute quantification, with initial cureation results also verifying the detection of environmental agents (e.g., dibutylphthalate, triphenylphosphate, pirimicar, atrazine metabolites) and associated physiological metabolites. As part of the NIEHS Center program, HERCULES provides a robust foundation for exposome research, applying this methodology to develop a knowledgebase of environmental chemicals and their distribution among human populations and ecologic systems.

867 Serum Biomarkers of Mitochondrial Damage in Survivors and Nonsurvivors of Acetaminophen-Induced Acute Liver Failure: Implications for the Mechanism of Hepatotoxicity in Humans

869 Pathogenic Mechanisms in Highly Active Antiretroviral Therapy (HAART)-Induced Hepatotoxicity: Role Phosphodiesterase 4 (PDE4) and ER-Stress

H. Donde1, P. Barve1, D. Barker1, S. Joshi-Barve1, L. Gobejishvili1, C. McClain1, 2 and S. Barve1, 1Department of Medicine/GI, University of Louisville, Louisville, KY and 2Robley Rex VAMC, Louisville, KY.

HIV protease inhibitors (HIV-Pis) are the major components of the highly active anti-retroviral therapy (HAART) and have been successfully used in the treatment of HIV-1 infection in the past two decades. However, it has been shown that HIV-Pis induce endoplasmic reticulum (ER) stress response and subsequent activation of unfolded protein response (UPR) leading to dys-regulation of hepatic lipid metabolism and hepatotoxicity. Our recent work shows that PDE4/cAMP metabolism plays a significant role in alcohol-induced hepatic steatosis and injury. Hence in the present study, we examined the potential mechanisms underlying HIV-PI induced hepatic ER stress and toxicity with a particular emphasis on the pathogenic role of PDE4 family of enzymes. The effects of clinically used HIV-PIs (ritonavir (RT) and lopinavir (LOP)) were examined both in a rat hepatoma cell line (H4IIE) as well as rat primary hepatocytes. The data obtained from these studies demonstrated that RT+LOP led to a significant loss of hepatocyte survival. Notably, inhibition of PDE4 by a specific PDE4-inhibitor, rolipram, markedly attenuated hepatotoxicity induced by PI treatments. Examination of the mechanistic role of PDE4 showed that PDE4 inhibition significantly decreases the expression of the ER stress related proteins CHOP, ATF-4 and -3 induced by PIs. Furthermore, examination of the PDE4/cAMP regulated downstream signaling demonstrated the involvement of Exchange proteins activated by cAMP (EPAC). Specifically, similar to rolipram, EPAC CAM analogue (8-pCPT'-2'-O-Me-cAMP) downregulated the expression of the PI-induced ER-stress genes. These data strongly support and identify a pathogenic/mechanistic role for PDE4 regulated cAMP-EPAC in the development of HIV-PI induced ER-stress leading to hepatic steatosis and injury.

870 Dual Regulation of Calcineurin Activity following Lymphocyte Activation: Contribution to Cyclosporine-Induced Toxicity

S. Sanquer1, C. Lena1, L. Herry1, M. Stern2 and R. Barouki1. 1INSERM UMR-S 747, Paris Descartes University, Paris, France and 2Hôpital Foch, Suresnes, France.

Introduction: The standard for rejection prevention in transplantation includes a calcineurin (CN) inhibitor, such as cyclosporine (CsA). It was thought that high CN activity (CN-a) reflected inadequate immunosuppression (IS) with insufficient
therapy that may lead to rejection, whereas low CN activity reflected excessive IS that would facilitate the development of adverse events. We have recently found that in several transplanted patients, both rejection and CSa-related adverse events were paradoxically accompanied by a decreased CN-a. The aim of this study was to provide a molecular explanation for such discrepancies.

Methods: We measured CN-a in human lymphocytes up to 48 h following stimulation by PMA/ionomycin. The induction of lymphocyte activation was verified by assessing the gene expression of Ile6, IL2RA and IL17 by qPCR. The effect of CSa was measured in both resting and activated lymphocytes. CN-a was quantified by using tandem mass spectrometry.

Results: In resting lymphocytes, CSa led to a dose-dependent decrease in CN-a. In stimulated lymphocytes, CN-a was increased at short time-points after stimulation but was gradually decreased at later time-points. In addition, this down-regulation was even more dramatic in the presence of CSa. The transient activation of CN-a was accompanied by a lasting effect on other markers of lymphocyte activation. Furthermore, we found that lymphocyte activation in vitro triggers a dual regulation of CN-a. The fact that the addition of CSa led to a more potent inhibition of CN-a when cells were activated suggests that two distinct mechanisms might concomitantly decrease CN-a: one mediated by CSa itself and another one mediated by an endogenous down-regulation of the CN/NFAT signalling pathway. We anticipate that the activation of such mechanisms following lymphocyte activation could contribute to the toxicity induced by CNIs, especially as the CNI dosage is generally increased when rejection is suspected.

871 Derivation of Induced Pluripotent Stem Cells and Their Potential Application for Cardiac Regeneration in a Porcine Model

B. Kumar1, 2, T. Kim1, W. Lee1, Y. Lee1, R. Joon1, S. Jang1, S. Lee1, S. J. Peng1, H. Kim2, S. L. Park2 and G. Rho1.
1. Department of Theriogenology and Biotechnology, College of Veterinary Medicine, Gyeongsang National University, Jinju, Republic of Korea, 2. Centre for Stem Cell Research & Regenerative Medicine, and Biotechnology, College of Veterinary Medicine, Gyeongsang National University, Jinju, Republic of Korea.

Porcine induced pluripotent stem cells (iPSCs) offer a great promise to advance the strategies for cardiac therapy using a large animal model. Therefore, the present study investigated the derivation of iPSCs and their potential application for the treatment of myocardial infarction in a porcine model. Porcine bone marrow derived mesenchymal stem cells (BMSCs) were reprogrammed to iPSCs by the lentiviral transduction of transcription factors Oe4, Klf4, Sox2 and c-Myc. Generated iPSCs exhibited alkaline phosphatase activity and expressed pluripotent markers. Porcine iPSCs differentiated well into three germ layer-derived cells in vitro. Further, they efficiently formed teratomas in immunodeficient mice and the tumor tissues revealed the tissues of three germ layers. The efficiency of iPSCs to differentiate in vitro into cardiomyocytes was greatly enhanced in the presence of 5-azacytidine. To demonstrate the therapeutic potential, porcine iPSCs labeled with a membrane dye PKH26 were transplanted into miniature pigs with myocardial infarction generated by coronary artery ligation and reperfusion. Four weeks after transplantation, compared with control, animals injected with porcine iPSCs showed significant functional improvement measured by echocardiography. PKH26 labeled cells were detected in iPSCs transplanted groups, and showed the expression of cardiac specific markers in ischemic microenvironment. No inflammation or teratoma formation was observed in pigs that received iPSCs. The findings revealed the potential of porcine iPSCs as ideal cellular models for cardiac cell therapy and preclinical assessments.

872 Engineered Nanomaterial Exposure and the Mitochondrial Syndrome

Physiology and Pharmacology, WWU, Morgantown, WV.

Mitochondrial disease (MS) is a diagnosable condition, affecting the microcirculation, represented by a set of cardiovascular risk factors. Engineered nanomaterial exposure (ENM) has been shown to lead to a variety of cardiovascular effects. In this study, we evaluated coronary microvascular reactivity within the Zucker rat model of MS after ENM exposure, to determine if exposure would exacerbate microvascular dysfunction. Nine and 17-weeks old lean control (LZ) and obese MS (OZR) male Zucker rats were exposed to filtered air or a single inhalation exposure (count median aerodynamic diameter of 152±22 nm, 11±0.2 mg/m3, 5hrs/day) to nano-titanium dioxide aerosols 24h before sacrifice producing calculated pulmonary deposition of 15±0.5%, respectively. Coronary arteriolar (1.5–6.0μm) were evaluated within an isolated microvasculature preparation. Vascular reactivity analysis was performed based on responses to endothelium-dependent (acetylcholine, ACh, 10–9–10–4 M and adenosine, ADO, 10–4 M) and –independent stimuli (spermine-NONOate, SRT, 10–9–10–4 M and serotonin, 5-HT, 10–9–10–4 M). Within the control, the LZR exhibits reduced dilator reactivity (ACH and SRT) after ENM exposure at 17w. With respect to ADO, a profound vasodilator, ENM exposure led to a 28% reduction in dilation at 9w, limiting reactivity to aged levels. This response was elobed, although not significant, at 17w. Additionally, reactivity to the vasoconstrictor 5-HT, is abolished at 17w, after ENM exposure. Within the MS, ENM exposure further reduced (to significance) impaired endothelium-dependent vasodilation at 9w (ACH [>10%] and ADO [21.7%]). ENM exposure within the aged group also significantly reduced ADO stimulated dilation. SER reactivity was significantly impaired with aging; however there were no additive differences associated with ENM exposure. While microscopic dysfunction was evident after ENM exposure in both age groups, there was a greater decline associated with metabolic syndrome progression than an additive effect stemming from ENM exposure. NIH-R01-ES0435 (PAS) NIH-R01-ES051022 (TRN) NSF-1003907 (VCM)

873 Cyclophilin Inhibitor Alisporivir (DEB025) Is Not Toxic to Mitochondria: A Comprehensive In vitro and In vivo Assessment

E. Papian1, K. Balavenkatraman1, P. Couttet1, R. Kreutzer1, S. B. Hellidwell2, D. Brees2, A. Cordier1, S. Chibount2, N. Naoumou2, A. Wolf2 and M. Uetrecht1.
1. NIBR, Novartis, Basel, Switzerland and 2. Pharma, Novartis, Basel, Switzerland.

Some pancreatic cell lines were reported in clinical studies with alisporivir (ALV) in combination with peg-interferon/ribavirin treatment of hepatitis C patients. The potential of ALV to affect mitochondrial function or morphology was assessed both in vitro and in vivo.

In vitro, a dose range of ALV and Zalcitabine (ddC - mitochondrial toxin) were tested in proliferating cell lines HepG2, Panc-1 and Capan-1 after 7 and 14 days of continuous treatment. Viability, ATP content, mitochondrial mass, mitochondrial DNA (mtDNA) and oxygen consumption rates (OCR) were measured as endpoints. With ALV, OCR paralleled cytotoxicity, reflecting cell death; however with ddC, OCR decreased even at non-cytotoxic concentrations, demonstrating mitochondrial specific impairments. At cytotoxic concentrations of either agent only ddC provoked a decrease of mtDNA content. To further assess potential mitochondrial toxicity, similar readouts were assessed in galactose-adapted HepG2 and Mol74 cells (T-cell line sensitive to mitochondrial toxins). Galactose forces metabolism via OxPhos and thus reveals mitochondrial toxin effects not detectable in glucose. Galactose grown HepG2 and Mol74 cells were more susceptible to ddC after 14 and 25 days treatment compared to glucose, but no differential cytotoxicity or mitotoxicity was observed with ALV compared to glucose grown cells. Hence, ALV was shown to be devoid of mitotoxicity in these in vitro assays.

In vivo, the morphology of mitochondria in pancreas, heart and skeletal muscle from mice treated daily with DEB025 at an oral dose of 300mg/kg for 26 weeks and rats treated daily for 2-weeks at an oral dose of 100 mg/kg were examined by electron microscopy. No differences in the ultrastructure of mitochondria in either species. In conclusion, the results demonstrate that alisporivir is not a mitochondrial toxin.

874 Sulforaphane Protects against Influenza Virus Infection in the Nasal Mucosa of Smokers

E. Glista-Baker1, L. Muller1, B. N. Barse3, M. Meyer4, S. Z. Jones1, H. Zhang1, H. Zhou1, 2, T. Noah1, 2 and L. Jasper1, 2, 3, 4.

School of Medicine, University of North Carolina, Chapel Hill, NC, 4. Department of Biostatistics, University of North Carolina, Chapel Hill, NC.

Influenza continues to affect approximately 5-20% of people in the United States. Moreover, studies show that exposure to cigarette smoke increases the susceptibility to and severity of respiratory virus infections. Researchers have explored nutritional antioxidants as a preventative therapy for viral infection. In the current study, we evaluated whether the antioxidant sulforaphane (SFN), an isothiocyanate found in cruciferous vegetables, could modify viral replication in the nasal mucosa of smokers and non-smokers in vitro. Separate cohorts of smokers and non-smokers were randomized to receive either a SFN-rich broccoli sprout homogenate or placebo (alfalfa sprout homogenate) once daily for four consecutive days. On day two, all subjects were inoculated with a standard dose of live attenuated influenza virus (LAIV) vaccine. Markers of viral replication, hemagglutinin-1 (HO-1), and...
were cloned and expressed. These reagents provide valuable tools to explore factors involved in regulation of sEH and its role in health and disease. (This work was supported by the NIEHS Superfund Basic Research P42 ES04699.)

876b Clinical Toxicology and Community Health Education: National Poison Prevention Week in the United States

M. Broderick Pritty1 and T. Dodd-Butera2. 1San Diego Division, California Poison Control System, San Diego, CA and 2Nursing, CSU San Bernardino, College of Natural Sciences, San Bernardino, CA.

Unintentional poisoning deaths increased by 160% from 1999 to 2009 in the United States (CDC, 2012). Approximately 4 million calls were reported by regional centers in 2010, to the American Association of Poison Control Centers. Unintentional poisonings occur primarily in the home, in children under six years of age. However, poisonings are also one of the leading causes of death among adults. Thus, educational outreach in communities, across the lifespan, fulfills a significant need for mitigating acute toxicological exposures. In 1961, the U.S. Congress established National Poison Prevention Week - held annually in the third week of March and organized by the Poison Prevention Week Council. The focus is on raising awareness and providing education and prevention efforts to the public and public health community. In addition, resources are provided to assist in prevention and treatment of intentional and unintentional poisonings throughout the year. Examples include offering the toll-free number to the PoisonHelp Line from the American Association of Poison Control Centers (AAPCC); and websites, such as PoisonPrevention.org (http://www.poisonprevention.org/index.htm); and resources about poisoning from the Centers for Disease Control (http://www.cdc.gov/features/poisonprevention/), along with educational materials developed by the AAPCC in multiple languages. Annual data from the National Poison Data System (NPDS) is reported to identify numbers and severity of exposures in human poisonings, and it is used to assess the risk to public health. Select topics of concern are chosen as the focus of National Poison Prevention Week. National Poison Prevention Week continues to be a source of community health education after more than 50 years, and supports the efforts of AAPCC to inform, advocate, and educate about acute toxicology incidents.
Textile contact dermatitis results when a patient develops skin manifestations due to clothing or other fabrics that contact the skin, commonly from the chemical additives used in processing the fabric, such as textile dyes, tanning agents, and finishing resins. In this study the authors provide a framework for working up and counseling a patient with suspected textile dermatitis, focusing on identifying which textile materials are most likely to be the cause of the eczematicous lesions, the current clinical guidelines, the utility and appropriateness of patch testing, the limitations of these guidelines, and our pro tempore recommendations. Although there are many challenges to correctly identifying and counseling patients on how to avoid the offending textile products in a patient with suspected textile dye dermatitis, there is value in following the guidelines set forth to help identify the textile dermatitis source.

Clinicians should instruct patients to categorize and list all colored-fabric textile products that contacted the affected skin areas. The fiber composition, corresponding colorant class, and dye fastness of each suspected garment should then be noted. Lastly, fabrics should be prioritized based on color darkness. While patch tests can be useful, dermatologists should understand the limitations of standardized patch testing for patients with suspected textile dye induced dermatitis. These guidelines are expected to increase the likelihood of identifying the causative textile(s) so that patch testing can be supplemented with swatch testing and chemical dye extraction to help discover the allergenic dye.

The cardiovascular effects of two common pollutants, diesel exhaust (DE) and ozone (O3), were examined alone and in combination in an IRB approved clinical study. Consenting healthy subjects (n=15) were exposed for 2 hrs with intermittent, moderate exercise on Day 1 to 0.3 ppm O3, 300 µg/m3 DE, both O3 and DE, or filtered air (FA). On Day 2, subjects were exposed to 0.3 ppm O3. Cardiac electrophysiology and venipuncture were performed pre and post exposure. In addition, blood pressure (BP) was measured pre, post, and every hour up through 4 hrs post on days 1 and 2. Relative to air exposure values, maximum heat rate decreased -12% immediately post DE exposure, and the cardiac QTc interval (QTcDYN) increased 2% immediately post O3 and DE+O3 exposure. Systolic BP was significantly decreased immediately post DE+O3 exposure compared to air. Plasma lipid profiles were altered significantly immediately after day 1 exposure. Specifically, after DE+O3 exposure triglycerides were decreased (vs O3), and VLDL increased compared to O3 and DE+O3. LDL and HDL levels increased exposure. Evidence was found for independent effects of acute O3 and DE exposures alone and in combination on some outcomes. These data suggest that either interactions of ambient air pollutants or individual pollutants themselves may play a role in inducing adverse health outcomes. [Disclaimer: The views expressed are those of the authors and do not necessarily reflect the official views or policies of the US EPA.]
Development of LC-MS method more sensitive than LBA for challenging quantification of Glucagon at low pg/mL level in new formulation which is easier to administer than the currently available formulations. A bioanalytical method for glucagon in human plasma was validated on API5000. However, the LLOQ (100pg/mL) was not adequate to cover the pharmacokinetic profile of a novel formulation. Therefore, the method was re-developed on two different instruments to reach higher level of selectivity and sensitivity. TripleTOF5600 was tested in full scan TOFMS (30K resolution). The 3 most abundant isotopomers of +5 charge state of glucagon were summed. Moreover, MRMHS (15K resolution targeted approach), was also evaluated and the 3 most abundant isotopomers of the +5 charge state product ion (neutral loss of NH3) were summed. This experiment revealed that using a targeted quantification approach (MRMHS) led to a 10-fold increase in sensitivity over TOFMS. Hence, it was possible to have on a TripleTOF5600 the same sensitivity of a API5000. QTRAP6500 was able to reach the LLOQ of 10pg/mL (10-time lower than validated LLOQ on API5000). The calibration curve was linear (weighted 1/x2) for the concentration range 10-10000pg/mL with a coefficient of correlation of 0.9990. The accuracy for the LLOQ was 88% with 16% precision. The accuracy for quality control samples ranged between 91-101% while the precision between 5-9%. The outcome of this showed that it possible the development an LC-MS method more sensitive than LBA for the challenging quantification of Glucagon at low pg/mL level for a novel formulation.

881 Advanced Use of High-Resolution Mass Spectrometry (HRMS) to Overcome Triple Quadrupole Limitations in Large Molecules Quantification

The use of HRMS (QTOF) to overcome limitation of triple quadrupole for development of Large Molecule bioanalytical assays. To achieve the lowest LLOQ possible during the method development of somatostatin and enfurvirtide, the use of HRMS was preferred over triple quadrupole. For somatostatin, a large cyclic peptide known for ineffective fragmentation, a parent-to-parent approach was selected to limit loss of sensitivity during the fragmentation process. This approach is practically impossible with a triple quadrupole due to high chemical noise generated. The LLOQ achieved on HRMS with the summation of the two most intense isotopomers was 12pg/mL (S/N 22 vs. 9 on triple quadrupole). For enfurvirtide, the product ion used was 1343, which is outside the normal mass range of the quadrupole (m/z 1200). When compared to the most sensitive fragment obtained with the triple quadrupole (465,1m/z) the LLOQ was easily decreased from 100 to 50pg/mL with S/N>15. Calibration curves were found linear (weighted 1/x2) and coefficients of correlation were 0.9995 for somatostatin and 0.9987 for enfurvirtide. The CV% calculated from five replicate injections of QCLOQ was 6% for somatostatin and 9% for enfurvirtide. For both compounds, the precision of the QC samples were all within 15% and accuracy between 96-102%. This study demonstrated that HRMS instrument is more adapted and suitable than the regular triple quadrupole for overcoming of complex analytical challenges as in the case of Large Molecule quantitation. The HRMS was able in both case studies to allow more flexibility in the quantification to increase selectivity and sensitivity of the assays.

882 Human Metabolism Studies of High-Molecular Weight Polycyclic Aromatic Hydrocarbons Utilizing UPLC-Moving Wire Solid Sample Feed-Accelerator Mass Spectrometry

E. Madsen1, R. A. Corley2, M. A. Malfatti3, T. Ognibene1, K. W. Turreltaub4, T. McQuistan and D. E. Williams1. 1OSU, Corvallis, OR, 2Pacific Northwest National Laboratories, Richland, WA and 3Lawrence Livermore National Laboratory, Livermore, CA.

High molecular weight polycyclic aromatic hydrocarbon (PAH) exposure occurs from atmospheric deposition of incomplete combustion products to food crops and from flavoring during cooking food smoking processes. High molecular weight PAHs are carcinogenic to laboratory animals and are probable human carcinogens. Human PAH studies was previously not possible due to exposure occurring as mixtures and ethical concerns of administrating the PAHs in detectable quantities to human volunteers. The application of the traditional carbon dating instrument, the accelerator mass spectrometer, to biological sample analysis is now possible with defeminum health risk due to the improved sensitivity (one 14C molecule per 1024 molecules of 12C) and efficiency (100% transfer from UPLC eluent to AMS). We were able to detect parent and metabolites of our model PAH, dibenzo(def,p)chry-sene (DBC), in the urine and plasma of human volunteers from an oral microdose of 29ng/SmCi. Volunteers, n=9, were selected to be non-homogeneous of age, sex, BMI, and ethnicity to represent the variability of human metabolism. Total 14C-PC in 19% of DBC resulted in pharmacokinetic parameters of plasma Cmax = 61.5 ± 42.9 fg DBC eq, Tmax = 2.25 ± 0.95 hr, α-phase T1/2 = 5.3 ± 3.28 hr, while α-Kels = 0.19 ± 0.01 fg/hr, followed by a prolonged β-phase parameters. Current work is focused on UPLC separation of urine and plasma metabolites and detection using the moving wire solid sample interface as well as upcoming studies of human metabolism with PAHs phanthrene and benz[a]pyrene microdosing. This meta is used to validate physiologically based pharmacokinetic models of human PAH metabolism with the goal of future mixture modeling.

883 Development and Characterization of a LC-MS/MS Method for Antifolate Compounds for the Treatment of Bacillus anthracis Infections

P. J. Kaechl1, C. Bourne2, K. Berlim3, R. A. Bunc4, J. Laczk1, J. Marsters1, B. C. Moeller1, M. Valderas5 and W. Barrow. 1Lovelace Respiratory Research Institute, Albuquerque, NM, 2Department of Veterinary Pathobiology, Oklahoma State University, Stillwater, OK and 3Department of Chemistry, Oklahoma State University, Stillwater, OK.

Bacillus anthracis is a category A priority pathogen as classified by the National Institute of Allergy and Infectious Disease division of the National Institutes of Health. Exposure to Bacillus anthracis is currently treated by antibiotics (ciprofloxacin, doxycycline, penicillin, etc.), however antibiotic resistance has been produced in the laboratory. Therefore a medicinal chemistry program has been created to synthesize compounds that overcome the trimethoprim resistance observed in B. anthracis. This program has selected two early lead compounds, RAB1 and #53. In order to support preclinical development programs, a liquid chromatography-tandem mass spectrometry method was developed for quantification of these leads in mouse biological matrices (plasma, urine and GI content). The bioanalytical assay achieves separation via a reversed phase method and by detection multiple reaction monitoring. The extraction procedure uses a two-step protein precipitation method (MeOH and ACN) to prepare samples for analysis. This extraction procedure was selected as it provides sample stabilization prior to analysis, which is required for sample analysis from B. anthracis challenged animals. The assay was found to be specific and selective for both lead compounds with an LLOQ of 1 ng/mL in mouse plasma. The linear range was shown to be 1.0 to 200 ng/mL with dilutional linearity up to 6,000 ng/mL. Additionally, the mass spectrometer was selectively tuned to screen for phase I metabolites (mono- and di-hydroxylation; and mono- and di-demethylation). Application of the assay to plasma protein binding studies (using rapid equilibrium dialysis) indicated that both compounds are highly protein bound (99%) in mouse plasma. This method allows for quantification of both lead compounds in preclinical pharmacokinetic and efficacy studies.

884 Differential Pharmacokinetics of Tetracycline and Sulfamethoxazole in Brassica chinensis L. Grown Hydroponically

C. Chung, Y. Wu, P. Chen and H. Chen. Veterinary Medicine, National Cheng-Hsing University, Taichung, Taiwan.

Veterinary antibiotics in edible vegetables have quietly become an increasing food safety concern as these antibiotic-containing vegetables may find their way back to the human food chain. Although much has been studied on the deposit levels of antibiotics in plants, relatively little is known regarding the fate of antibiotics with time once they got entry to the plant. The pharmacokinetics (uptake, distribution, metabolism and elimination) of two most commonly detected antibiotics in soil and river, tetracycline (TC) and sulfamethoxazole (SMX) in edible vegetable Brassica chinensis L. were investigated. The vegetable was exposed to 100 µg/mL of drugs in cultivation fluid for 24 hrs, drug concentrations in roots, petioles and leaves at 0.5, 3, 6, 12 and 24 hrs were quantified by HPLC-UV method and the bioaccumulation factors (BAF) were calculated. The results suggested significant differential uptake and distribution of the two antibiotics evidenced by a BAF of 21/0.4 in the roots and 1.3/0.2 in the leaves for TC/SMX, respectively and by a concentration ranking of roots>petioles>leaves for TC versus roots>petioles>leaves for SMX. The Cmax and Tmax in the roots are 948±132 µg/mL at 6 hrs for TC and 334±44 µg/mL at 24 hrs for SMX, whereas in the leaves they are 92±4 µg/mL at 12 hrs (TC) versus 7±1 µg/mL at 24 hrs (SMX). The percentage uptake of drugs by the vegetable were similar at 3 concentration levels (100, 10 and 1 µg/mL) indicating the appropriateness of the current model and the ability of Brassica chinensis L. to uptake high amount of TC. Possible biotransformation of TC (but not SMX) was detected only in the leaves. Elimination of drugs from the vegetable was most noted in the roots mainly in the first 0.5 hr (30% reduction for TC and...
15% for SMX); refreshing the cultivation fluids maximized the reduction to 50%. In conclusion, it appeared that the pharmacokinetic behaviors of TC in *Brassica chinensis* L. acted in a controlled manner while SMX followed the passive water transport in xylem.

### 885 Comparative Metabolism and Pharmacokinetics of Diisobutyl Ketone and Diisobutyl Carbinol in Male SD Rats

F. Zhang, M. J. Bartels, A. J. Clark, J. J. Staley, T. S. Lardie, D. A. Markham, B. J. Hughes and N. N. Ball. TERG, The Dow Chemical Company, Midland, MI.

Diisobutyl ketone (DIBK) and diisobutyl carbinol (DIBC) are important organic solvents widely used as industrial intermediates. It was hypothesized that DIBK and DIBC have common metabolic pathways and metabolites and as such toxicological data on DIBK could be used to characterize the hazards of DIBC. To confirm or refute this hypothesis a comparative metabolism and pharmacokinetics assessment of DIBK and DIBC was conducted via single oral gavage dosing in male SD rats, followed by blood collection, metabolite identification, major biomarker quantitation, and pharmacokinetics analysis. Overall, the major metabolites of both DIBK and DIBC in blood were their corresponding monohydroxylated metabolites (DIBC alcohol and DIBC alcohol) with the site of hydroxylation at the α and α-1 positions, respectively. Quantitative analysis of DIBK, DIBC, DIBC- alcohol, and DIBC-alcohol in blood samples collected from 5 min to 120 hr after single dosing indicated the following: 1) DIBK and DIBC are both well absorbed following oral gavage with substantial evidence of enterohepatic recycling of DIBK, DIBC, DIBC-alcohol, and DIBC-alcohol; 2) DIBK and DIBC are also inter-converted in rats; 3) DIBK and DIBC have similar bioavailability (AUC) after oral administration; 4) higher bioavailability (AUC) was found for DIBC-alcohol than DIBC-alcohol, implying that DIBC-alcohol may be more easily conjugated and eliminated in bile, thus leading to lower systemic exposure than from DIBC- alcohol. In summary, the metabolic similarities and the metabolite bioavailability difference between these substances observed in the current study support the hypothesis that DIBC will have a low potential toxicity similar to that of DIBK.

### 886 Short-Acting and Long-Acting Buprenorphine Therapeutic Drug Levels following Single Subcutaneous Administration in Diabetic Yucatan Miniswine

B. C. Hanks¹, S. Schlink¹, L. Brown¹, M. Luna², Y. Liu¹, J. Liu¹, A. Stricker-Krongrad¹ and G. Bouchard¹. ¹Sinclair Research, Axouace, MO and ²KCAS, LLC, Shawnee, KS.

Sustained and controlled analgesia for animals involved in potentially painful procedures is required for animal welfare and ethical considerations. We designed a study to assess the PK for buprenorphine (BUP) analgesics in diabetic Yucatan miniswine. Four castrated male allaconic diabetic animals weighing approximately 30 kg were used in a complete cross-over design. For BUP, animals were dosed subcutaneously (left flank fold) with either 0.01 mg/kg (low-dose) or 0.02 mg/kg (high-dose), while for BUP SR (sustained release) the dose was either 0.12 mg/kg (low-dose) or 0.24 mg/kg (high-dose) for 240 min. Results for BUP SR plasma drug profile showed peaks at 1795.5 pg/mL at 240 min (high-dose) and at 1531.8 pg/mL (low-dose) at 30 min. Sustained release drug was present in plasma for 96 hrs for both high- & low-dose (above 0.1 ng/mL). In conclusion, these data show that these dose levels provide sufficient plasma levels of drug for analgesia (>0.1 ng/mL) for at least 8 hr (short-acting BUP) or 96 hr (long-acting BUP SR).

### 887 Oxycyte®, a Perfluorocarbon Emulsion Drug Candidate for the Treatment of Ischemic Brain Injury, Has Similar Pharmacokinetic Characteristics across Rodent and Nonrodent Species, Including Humans

T. B. Grizzle¹, T. Bradshaw¹ and S. Anderson¹. ¹Oxygen Biotherapeutics Inc, Morrisville, NC and ²Toxicology Services Inc, Chapel Hill, NC.

Oxycyte is a 60% w/v perfluorooctylbicyclohexyl (PFOB) intravenous emulsion being developed as a novel treatment for a variety of ischemic conditions, including traumatic brain injury. The pharmacokinetics (PK) of Oxycyte’s perfluorocarbon, FbBu, across two rodent species, two nonhuman primate species, and humans were compared with the objective of using exposure ratios to assist in the selection of clinically relevant dose for future nonclinical studies. Following intravenous administration of Oxycyte in BALB/c mice and Sprague Dawley rats (3, 6, 12 mL/kg), cynomolgus monkeys (4 and 10 mL/kg), olive baboons (3 and 12 mL/kg) and humans (0.5, 1.5 and 3 mL/kg), concentrations of FbBu in whole blood generally decreased over time in a monoeXponential manner. In all species, while peak exposures were roughly dose proportional, overall exposure (AUC) more than doubled with each doubling of Oxycyte dose (e.g., 3 to 6 mL/kg; 6 to 12 mL/kg). In addition, FbBu half-life (T1/2) increased with increasing Oxycyte dose, whereas values for systemic clearance (Cl) decreased. Oxycyte emulsion particles are removed from circulation via phagocytic cells of the reticuloendothelial system with the metabolically inert perfluorocarbon eventually exhaled during respiration. The nonlinearity between the systemic exposure and elimination data reflect, at least partially, saturation of this clearance mechanism with increasing dose levels. By comparing FbBu systemic exposures (AUC), it was determined that in previous animal safety studies Oxycyte dose levels provided systemic exposures up to 25-fold higher than those expected at the highest clinical Oxycyte dose (3 mL/kg). Based on the comparison of PK parameters, the pharmacokinetics of FbBu are similar across species, including humans. Therefore, exposure estimates can be used to determine appropriate, clinically relevant, Oxycyte doses for use in future animal and pharmacology studies.

### 888 Iron Sucrose Nanoparticles: Effects on Tissue Iron Levels and Hepatic Gene Expression in the Rat

N. J. Pearson¹, R. Forster¹, J. Bouchard¹, L. Jaillet¹, A. Rogue¹ and P. Elford². ¹GiToxLab, Evreux, France and ²Azad Pharma AG, Toffen, Switzerland.

The generic Iron Sucrose Azad (ISA) or reference iron sucrose drug Venofer® were administered intravenously to (non-anemic) male rats at 15 mg/kg, a supratherapeutic dose level. Tissue iron levels in plasma and selected tissues were determined over 28 days using an ICP-MS method. Hepatic gene expression was evaluated by microarray analysis of mRNA from samples taken 24 hours after drug administration. Iron concentration/time profiles for plasma and tissues were quantitatively similar; circulating iron levels briefly exceeded transferring binding capacity and there was a transient increase in hepatic iron. Iron levels remained elevated in the bone marrow. No increases in tissue iron were observed in the heart, stomach or lungs of treated rats and small transient increases were recorded in the kidney. Spleen iron levels increased over the 28 day period in treated and control rats. The effects of ISA and Venofer® on hepatic gene transcription were similar. There was no systematic effect of either treatment on transcriptional profiles. Only a small number of genes showed significant modulation of expression. No transcriptional pattern matches with toxicity pathways were found in the ToxFX database for either treatment. No modulation of key genes in apoptosis, inflammation or oxidative stress pathways was detected. The biodistribution of administered iron is essentially similar for Iron Sucrose Azad and Venofer® and iron sucrose paritions predominantly into the liver, spleen and bone marrow. Hepatic gene expression studies did not provide any evidence of hepatic toxicity.

### 889 Comparative Metabolism and Pharmacokinetics of Pterostilbene in Rhesus Macaques, Cynomolgus Macaques, and Common Marmosets

M. Muzzio, T. G. Ooms, W. D. Johnson and D. L. McCormick. Life Sciences, IIT Research Institute, Chicago, IL.

Resveratrol (3,5,4′-trihydroxy-trans-stilbene) is a natural polyphenol that demonstrates cancer chemopreventive, antiinflammatory, and cardioprotective activities in animal models. Although resveratrol has a number of desirable biological effects, its activity may be limited by poor oral bioavailability and rapid metabolism. Pterostilbene (3,5-dimethoxy-4′-hydroxy-trans-stilbene) is the dimethyl ether analog of resveratrol. Like resveratrol, pterostilbene is found in grapes and other foods, and has antiinflammatory and cancer chemopreventive activities in a comparative...
PK and metabolism study in rats, we found that total absorption (AUC) and peak plasma levels (Cmax) of pretosilbene (parent) are 10 to 40-fold higher than those of resveratrol (parent) after oral dosing. Plasma levels of resveratrol glucuronide and resveratrol sulfate are comparable after a single oral dose, whereas metabolism of pretosilbene is overestimated by 22-fold. The present study was performed to compare the PK and metabolism of pretosilbene in three species of non-human primates. Although common marmosets (Callithrix jacchus) are used much less often in preclinical development studies than are cynomolgus macaques (Macaca fascicularis) or thusus macaques (Macaca mulatta), their smaller body size may offer important benefits, particularly when drug supply is limited or synthesis costs are high. Groups of 3 to 4 animals per species received a single gavage dose of pretosilbene (50 or 100 mg/kg); the 100 mg/kg dose is an interspecies extrapolation of the rat NOAEL for resveratrol. Timed blood collections were performed over 24 hours after dosing. No evidence of pretosilbene toxicity was seen in any animal. Plasma levels of pretosilbene (parent) were generally comparable in common marmosets and in the two species of macaques over the 24 hour collection period. These data suggest that common marmosets may provide a useful model for preclinical drug development, particularly in situations when test article availability is limited.

**890** Toxicokinetics of Combined Treatment with Melamine and Cyanuric Acid in Male Sprague-Dawley Rats

T. Jeong1, G. Kim1, Y. Um1, C. Seo1, K. Noh1, W. Kang1, H. Kim2 and M. Kang1. 1College of Pharmacy, Yeungnam University, Gyeongsan, Republic of Korea and 2College of Pharmacy, Sungkyunkwan University, Suwon, Republic of Korea.

When melamine is combined with cyanuric acid, melamine-cyanuric acid crystals can easily be formed, by which nephrotoxicity of melamine would be aggravated. In the present study, toxicokinetics of melamine and cyanuric acid was studied in male SD rats orally received either melamine or cyanuric acid alone and combination of melamine and cyanuric acid for 7 consecutive days. Melamine and cyanuric acid in serum, urine and kidney were determined by liquid chromatography-mass spectroscopy. In the groups of both melamine and cyanuric acid alone, they reached the maximal serum concentration at 1 hr after dosing. Melamine and cyanuric acid were eliminated almost completely within 24 hr without a sign of accumulation. On the other hand, they were not rapidly eliminated when combined. In sera, they were increased in dose- and time-dependent manners with the sign of accumulation. The sign was also seen in kidney. In addition, the combined treatment could induce severe nephrotoxicity when compared to the group of either melamine or cyanuric acid alone. Taken together, the toxicokinetic characteristics suggested that the combination of melamine and cyanuric acid might be responsible for the severe nephrotoxicity which was not seen in either melamine or cyanuric acid alone. Supported by the grant from KFDA (09162KFDA542).

**891** An Updated PBPK Model for RDX (Hexahydro-1, 3, 5-Trinitro-1, 3, 5-Triazine) and Its Metabolites in Mice

RDX is a military explosive that has been detected at or near military bases and munitions plants and storage facilities in air, soil, and ground water. Mice, but not rats, exposed to RDX in the diet for 2 years show an increasing trend in the combined incidence of hepaticellular adenomas and carcinomas (Lish et al. 1984). Physiologically-based pharmacokinetic (PBPK) models can aid in interpreting toxicological data and extrapolations across dose, species and exposure routes, and a PBPK model for RDX has previously been developed for mice based on oral absorption of RDX from single gavage doses (Sweeney et al. 2012 Regul. Toxicol. Pharmacol., 2012 v. 66, p. 205-224). Recently the absorption, distribution, and biotransformation of RDX administered to mice in feed for 28 days has been measured by Pan et al. (Environ. Toxicol. Chem., 2013 v. 32, p. 1295-1303). These new toxicokinetic data were used to evaluate the PBPK model of RDX in mice. The PBPK model was modified to account for absorption of RDX from feed and the metabolism of RDX to N-nitroso compounds in the GI tract. The resulting model simulations are consistent with experimental measurements of RDX concentrations in plasma, liver and brain tissues, reported by Pan et al. (2013). The model is used to evaluate correlations between the internal dose metrics of RDX and its metabolites with tumor incidence in mice. The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. Environmental Protection Agency or other affiliations.

**892** Scoping the Need for PBPK Modeling of Child-Adult Metabolism Differences: Case Studies Applying an Enzyme Ontogeny Database

Knowledge of the ontogeny of Phase I and Phase II metabolizing enzymes could be essential in determining internal dose and risk of xenobiotic exposure to children in comparison to adults. Early life ontogeny of metabolizing systems has been considered in therapeutic drug monitoring, animal toxicology, gene expression studies, and physiologically-based pharmacokinetic (PBPK) modeling; however, this body of literature has not previously been organized into a single database. We created an Enzyme Ontogeny Database (EOD) for selected Phase I and Phase II enzymes commonly encountered in xenobiotic metabolism. This EOD can be used to screen child-adult metabolism differences and whether such differences should be the focus of PBPK modeling. This scoping function was exemplified with case studies of 5 chemicals, 3 of them (acetaminophen, tolenule, and chlorpyrifos) were proof of concept examples because they have sufficient data to know whether enzyme ontogeny affects risk and two (trichloroethylene and aromatic amines) demonstrate how to prioritize with limited data. This analysis demonstrated that early life stages are likely to be more vulnerable to tolenule and chlorpyrifos, but not to acetaminophen. Scoping for both trichloroethylene and aromatic amines indicates immaturities in cytochrome P450 enzymes (2E1 & 1A2) and conjugation systems (glutatione and N-acetylation) that may tend to offset one another. However, these predictions need to be further explored with PBPK modeling. The EOD combined with knowledge of chemical metabolism and mechanism of action may provide the basis for scoping as well as any PBPK analyses needed to determine whether children are at heightened risk due to metabolic factors.

**893** Distribution of Capceitabine and Its Metabolites 5’-Deoxy-5-Fluorocytidine, 5’-Deoxy-5-Fluorouridine, and 5-Fluorouracil in a Preclinical Mouse Model of Brain Metastases of Breast Cancer

Capceitabine is an oral triple prodrug of 5-fluorouracil (5-FU), which is successful against many types of systemic tumors. Capceitabine itself is approved for treatment of breast and colorectal cancer. However, there is no information on the distribution or uptake of capceitabine and its metabolites in brain metastases of breast cancer (BMBC). We investigated conversion and extent of exposure of capceitabine and its metabolites in brain metastasis and peripheral tumors in a mouse preclinical model. Dose levels that produce plasma levels matching those in humans were selected. Xeloda (capceitabine, 150 mg/kg) was administered orally to athymic NuNu mice bearing intracranial MDA-MB-231BR human breast cancer tumors. Tissue and plasma samples were collected from 0.5-8 h and compound levels were measured by LC-MS/MS. Enzymatic biotransformation of capceitabine and its metabolites in brain and tumor was also assayed in vitro. Improved uptake and conversion of capceitabine and its produg metabolites was observed in brain metastases compared to healthy brain. Integrated exposure of capceitabine and its nucleoside prodrugs in brain metastases were 12-39% of plasma level and 3.5-fold higher than healthy brain (P<0.05). The 5-FU levels in brain metastases were 6.7 times higher than in brain (P<0.05) with Cmax approaching values associated with antitumor activity in vitro. Cytidine deaminase and thymidine phosphorylase enzymes activities were higher in intra-cranial tumor than healthy brain. The results demonstrate that capceitabine and each of its produg metabolites exhibit improved uptake and distribution in BMBC relative to normal brain.

**894** Disposition of the Actinide Chelating Agent 3, 4, 3-LI(1, 2-HOPO) in Swiss-Webster Mice Using C-14 As a Radio- Tracer

In a continuing effort to remediate the harmful effects of internally deposited radioactive actinides, our research group is investigating a linear octadentate spherand based ligand, 3,4,3-LI(1,2-HOPO), for clinical application. In order to
comprehensively evaluate the disposition and tissue pharmacokinetics of this compound, 3,4,3-Li(1,2-HOPO) labeled with C-14 was administered to healthy, male and female Swiss-Webster mice by oral, intraperitoneal or intravenous route (dose level = 100 μmol/kg; C-14 activity = 100 μCi/kg). Plasma, kidney, liver, urine, and feces were collected over a course of 24 hours post single administration and analyzed using liquid scintillation counting (LSC). The study demonstrated that the ligand was rapidly distributed and cleared from tissues and was predominantly excreted through the biliary route. In order to improve the oral bioavailability of the ligand, the compound was formulated with a permeability enhancer and was administered by oral route. The maximum concentration (Cmax) of the ligand in plasma improved by 3-fold when administered with a permeability enhancer.

Additional toxicity studies were performed; no toxic effects were observed in mice at the highest administered oral dose (1800 μmol/kg). The results clearly show that 3,4,3-Li(1,2-HOPO) exhibits promising activity and merits further investigation.

**895 Effect of Altitude on Tissue Distribution of Toluene in S-D Rats**

D. A. Mahle¹, P. R. Eden¹, P. Shiyano¹,², E. Hack¹,², L. Qi¹,², B. A. Wong⁴, W. R. Howard³ and A. James³,⁴, ²Henry Jackson Foundation, WPAFB, OH, ³Camris International, WPAFB, OH, ⁴, W. R. Howard⁴ and A. James³,⁴.

Extreme altitude is one of the unique stressors experienced by pilots of high performance combat aircraft. Under conditions associated with the operation of high performance combat aircraft, children ages 1 to 3 years generally have greater exposure to pyrethroids due to their higher hand-to-mouth behavior. Differences in the pharmacokinetics between children and adults may influence their relative sensitivity to pyrethroids. The tissue to blood partition coefficients (Krb) for pyrethroids in adults rats have been reported, there are no studies reporting Krb in humans. Thus, we determined the Krb of the commonly used pyrethroids, DLM, CIS and TRANS in adults and 21-day old pups. Krb values for DLM in 21-day old pups at 72 hr ranged from 0.4 to 0.7 for brain, liver and muscle, and were 4.6 for skin. The Krb values for adults were similar to those in pups, with the exception that the Krb for adult skin was 29.0, and that a Krb for fat was determined, which was 102.3. Krb values for CIS in 21-day old pups were 2.8 for brain, 1.4 for liver, 2.8 for muscle and 8.2 for skin. This was in contrast to 1.8 for brain, 0.8 for liver, 8.9 for muscle, 140.0 for fat and 47.3 for skin in adults. The Krb values for TRANS in brains of 21-day old pups were lower than adults (0.4 Vs. 2.9), as were the Krb values for the liver (0.4 Vs. 6.5). In contrast, the Krb for TRANS for muscle (7.6) and skin (43.5) in 21-day old pups were higher than adults (1.8 for muscle and 11.7 for skin). The fat Krb in adults for TRANS was 67.0. Krb values for fat in 21-day old pups were not able to be calculated for any pyrethroid due to the small amount of this tissue in this age group. These data show the novel finding that the Krb for several common pyrethroids differ between adults rats and 21-day old pups. It is unknown if such differences contribute to age-dependent differences in the toxicokinetics of these pesticides.

**896 Airborne PCB11 Does Not Bioaccumulate: The Fate of 14C-Labelled PCB11 and Its Metabolites In Vivo**

K. Khichi¹, A. H. Nguyen¹, S. L. Wild¹, W. Sohn¹, N. Chirmule¹, M. B. Hook¹, M. L. Horner¹, F. M. Lewis¹, G. J. Molloy¹ and L. L. Bussiere¹.

Backgound: The production ban of polychlorinated biphenyl (PCB) technical mixtures has left the erroneous impression that PCBs exist only as legacy pollutants. Some lower-chlorinated PCBs are still being produced and contaminate both mixtures has left the erroneous impression that PCBs exist only as legacy pollutants.

Recent advancements in understanding the pharmacokinetics of pyrethroids have provided new insights into the tissue distribution of these compounds. These data show the novel finding that the Krb for several common pyrethroids differ between adults rats and 21-day old pups. It is unknown if such differences contribute to age-dependent differences in the toxicokinetics of these pesticides. Background: This embryofetal development studies in mice with Fc-containing biopharmaceuticals revealed lower drug exposure in pregnant mice than nonpregnant mice, lower maternal exposure in late gestation than early gestation and higher fetal exposure than maternal exposure at gestation day [GD]18. Methods: Pregnant mice received subcutaneous injections of one of two murine surrogate monoclonal antibodies (mAb A [IgG2] 30 or 300 mg/kg or mAb B [IgG1] 300 mg/kg) on GD6 and GD13. PK profiles for mAb A was compared to nonpregnant mouse. PK profiles were also compared between GD6 and GD13 doses. At GD18, fetal and maternal (F/M) exposure ratio was assessed. Results: mAb A exposure (AUC) after GD6 dose was 48-54% lower in pregnant mice compared to nonpregnant mice, which was primarily attributed to more rapid clearance. For both mAb A and mAb B, clearance was also enhanced in late gestation compared to early pregnancy (AUC[GD13-18] for mAb A and mAb B was 39-65% and 52% lower than AUC[GD6-12], respectively). Anti-drug antibody development did not impact exposure. At GD18, fetal exposure was higher than maternal exposure (F/M ratio was 8.2-29 for mAb A and 29 for mAb B). Fetal plasma concentrations on GD18 for mAb A and mAb B were 51.5-258 and 111 μg/mL, respectively, which were within the pharmacologically relevant range for both mAbs. Conclusion: Clearance of murine IgG1 and IgG2 mAbs was more rapid in pregnant mice than nonpregnant mice. The rapid clearance is further enhanced in late gestation compared to early stage, leading to high F/M exposure ratios in late gestation. However, for conclusions related to placental transfer of mAbs in mice and pharmacological relevance to the fetus, it is more important to consider the absolute fetal plasma concentration.
First, the inhibition of P-glycoprotein (Pgp/ABC1), Breast Cancer Resistance Protein (BCRP/ABCG2) and Multidrug-Resistance Associated Protein 2 (MRP2/ABCC2) was investigated in inverted membrane vesicles from HEK293 cells over-expressing each of the ABC proteins. Inhibition profiles of prototypic substrate transport were obtained for 24 compounds and compared with results obtained in alternative expression systems. A good correlation between the HEK-MRP2 and S9-MRP2 vesicle data was observed. However, up to 40-fold lower IC50 values were obtained for Pgp and BCRP in the HEK vesicles compared to those in cellular expression systems. Next, estradiol 17β-glucuronide (E17G) was found to be a substrate for all three transporters. The contribution of each transporter to the E17G biliary efflux was investigated in HEK vesicles and in sandwich-cultured human hepatocytes (SCHH), using nine inhibitors with different specificities for the three ABC-proteins. The SCHH identified ABC inhibitors from the HEK vesicles that lost their inhibition in this physiologically more relevant model. Finally, the maximal transport activity (MTA) of each transporter was calculated and their contribution to the biliary clearance of E17G was predicted, using transport kinetics and protein expression. The canalicul efflux of E17G in SCHH was predicted with an accuracy of 90%.

**901a Toxicokinetics: Role in Improving Guideline Toxicological Studies for Agrochemicals**

S. A. Saghir, Intrinsik Environmental Sciences Inc., Mississauga, ON, Canada.

Dose is central to our understanding of biological responses and used in developing toxicity criteria and ADI. In guideline toxicity studies, top dose is selected based on MTD to provide a adequate margin of safety for human exposure. Responses at such high doses likely overwhelm physiological parameters (e.g., ADI) which, for low-risk chemicals, are not reached in human or MOE (animal = mg/kg vs human = μg or ng). Ideally, the top dose in animal studies would be selected based on the POD from linear kinetics of biomarker(s) in blood to obtain a kinetically-derived maximum dose (KMD). KMD ensures the use of appropriate doses, eliminates the generation of data at irrelevantly high doses and additional MOA studies, reduces animal use, and avoids unnecessary classification (e.g., carcinogen or developmental toxicant). Sulforaflo (an insecticide) doses for a 13-week dietary mouse study were based on the MTD of a 4-week study that showed nonlinear TK responses. Systemic dose (plasma AUC24h) became supra-linear in males and remained sublinear in females between the mid and the high doses with only producing the MTD. The KMD was used to select the top dose (which was 1.1x10 fold higher than expected human exposure) for the chronic mouse study resulting in TK linearity across doses, avoiding possible nonspecific toxicity. The plasma AUC24h of 2,4-D (a herbicide) became nonlinear at doses ≥25 mg/kg/day in F0 female rats after 28 days of dietary exposure with higher nonlinearity during pregnancy and lactation due to increased dietary intake. In pups of both genders, TK became nonlinear at maternal doses of ≥40 mg/kg/day. Based on these data, the top dose was selected slightly above the KMD (~50 mg/kg/day; 8×10 fold higher than expected human exposure) for the subsequent extended one-generation reproductive toxicity study. This dose was 1/2 of the MTD and accepted by EPA and PMRA. Use of the KMD-derived MOE avoided the identification of a NOEL, which would have resulted from the saturation of OAT1-dependent elimination at MTD-derived doses. Additionally, this procedure allowed the removal of 3X safety factor.

**901b Fates of Two Emerging Brominated Flame Retardants, 2-Ethylhexyl Tetrabromobenzene and Bis(2-ethylhexyl) Tetrabromophthalate, in Female Sprague-Dawley Rats**

2-ethylhexyl tetrabromobenzene (TBB; MW 550 g/mol) and bis(2-ethylhexyl) tetrabromophthalate (TBBP; MW 700 g/mol) comprise the brominated components used in several ‘alternative’ flame retardant mixtures (Firemaster 550, BZ-54, DP-45) introduced after the phase-out of lower-brominated polybrominated diphenyl ether (PBDE) mixtures. As replacements for ‘Penta’ PBDE flame retardants, TBB & TBBP are used in a wide variety of consumer products, most notably in polyurethane foams. TBB & TBBP have been detected in household dust, surface waters, adsorbed to sediment, and air samples. [14C]-labeled TBB was administered to female Sprague Dawley rats by gavage at 0.1, 1, 10, or 100 μmol/kg (6 or 25 μCi/kg). [14C]-TBBP was administered at 0.1 or 10 μmol/kg. TBB is extensively absorbed, readily metabolized, and eliminated by both urinary and fecal routes. More than 80% of administered radioactivity was recovered after 24 h at doses up to 10 μmol/kg, with fecal recoveries increasing with dose (24 h: 33±5→350%; 72h: 39±5→81±6%). Urinary recovery peaked between 8 and 24 h at these doses. Administration of 100 μmol/kg TBB resulted in a clear delay in both urinary and fecal recoveries, indicating saturation of elimination pathways. [14C]-radioactivity recovery exceeded 93% by 72 h after all doses and
retention of [14C]-radioactivity in tissues was minimal. HPLC analyses of urinary [14C]-radioactivity detected up to 6 metabolite peaks. The number and relative proportion of each metabolite present in urine were time and dose-dependent. The principal moieties present in fecal extracts corresponded to parent TBB and tetrabromobenzoic acid (TBPH). TBPH was poorly absorbed and was primarily eliminated as parent compound in the feces at both doses tested. These findings indicate that while TBB & TBPH are structurally similar, they have very different disposition. This work was supported by the Intramural Research Program of the National Cancer Institute at the National Institutes of Health (Project ZIA BC 011476).

**901c Durable Pharmacological Responses from the Peptide ShK-186, a Specific Kv1.3 Channel Inhibitor That Suppresses T Cell Mediators of Autoimmune Diseases**

E. J. Tarcha1, E. J. Munoz-Elias2, D. Bailey1, G. W. Ruppert1, S. E. Boley1, R. Slauter1, B. Knapp1, D. Kentala1, M. W. Pennington1, C. Becton3, K. Chandy3, S. P. Iadonato1 and S. W. Frantz4.  

The Kv1.3 channel is a recognized target for drug development to treat autoimmune diseases and organ rejection. ShK-186, a specific peptide inhibitor of Kv1.3, has shown promise in animal models of both multiple sclerosis and rheumatoid arthritis. Here, we describe the pharmacokinetic/pharmacodynamic (PK/ PD) relationship for ShK-186 in rats and monkeys. The PK profile was evaluated with a validated high-performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS) method to measure the peptide’s concentration in plasma. These PK results were compared with the single-photon emission computed tomography/computed tomography data for ShK-186 that were collected with an 111In-1,4,7,10-tetrazacyclododecane-1,4,7,10-tetraacetic-acid-conjugate of ShK-186 to assess whole-blood PK parameters as well as the peptide’s absorption, distribution, and excretion profiles. Analysis of these data support a model wherein ShK-186 is absorbed slowly from the injection site, resulting in blood concentrations above the Kv1.3 channel blocking IC50 value for up to 7 days in monkeys. PD studies on human peripheral blood mononuclear cells showed that brief exposure to ShK-186 resulted in sustained suppression of cytokine responses and may contribute to prolonged drug effects. Delayed-type hypersensitivity, chronic relapsing-remitting experimental autoimmune encephalomyelitis, and pristane-induced arthritis rat models all show that single doses of ShK-186 every 2 to 5 days are as effective as a daily administration. ShK-186’s slow distribution from injection sites and its long Kv1.3 channel residence time contribute to the prolonged therapeutic effects of ShK-186 in animal models of autoimmune disease.

**901d Comparison of the Disposition and Pharmacokinetics of 14C-Octamethylcyclotetrasiloxane (D4) following a Single Low Dose in Rodent Liquid Diet or a High Dose in Corn Oil via Oral Gavage to Fischer 344 Rats**

The absorption, distribution, metabolism and excretion of D4 in Fischer 344 rats following a single oral gavage administration of a low dose, 30 mg 14C-D4/kg, in a rodent liquid diet or a high dose, 300 mg 14C-D4/kg, in corn oil were evaluated. Parent D4 and total radioactivity were measured in blood through 168 h post-dosing and in various tissues. Animals were housed in metabolism cages for collection of urine, feces, expired volatiles (EV) and CO2. Blood AUCs were not proportional to dose. About 25% more of the dose was absorbed following the low dose administration with a greater % of radioactivity compared to parent than in the high dose study. Parent D4 and radioactivity were measurable in all tissues with the highest concentration found in fat and majority of the recovered radioactivity being eliminated by 24 h post-dosing following either dose. Following a high dose in corn oil (females), 41% of the recovered dose was found in feces, 26% in urine, 14% in EV, 4% in CO2 and 8% in carcass. Following a low dose in rodent liquid diet (females), 23% of the dose was found in feces, 32% in urine, 30% in EV, 3% in CO2 and 11% in carcass. An increase in the % of dose in EV and a decrease in the % of dose in feces was noted in the low dose study with metabolites being present in both feces and EV. Urinary elimination consisted entirely of polar metabolites for either dose. Metabolism appeared to be increased following low dose administration driving a greater absorption. Since an earlier PBPK model based on the high dose study did not adequately describe the parent’s concentration and was primarily used as parent compound in the feces at both doses tested. These findings indicate that while TBB & TBPH are structurally similar, they have very different disposition. This work was supported by the Intramural Research Program of the National Cancer Institute at the National Institutes of Health (Project ZIA BC 011476).

**901e Mass Spectrometry Imaging in Toxicology Study: Biodistribution of Unlabeled Bleomycin in Induced Interstitial Pulmonary Fibrosis (IPF) Model**

D. Bonnel1, M. McEllroy2, S. Madden3 and J. Stauber2.  

One of the main difficulties in toxicology study is to identify the potential causes of the histopathologic/functional tissue changes. Mass spectrometry imaging (MSI) technology has been used to address these crucial issues. The main advantage of this label free imaging technique is the detection of all molecules of interest directly on-tissues with high specificity. Indeed the molecular distribution of some unlabeled targeted molecules could be directly correlated with some histopathologic and functional tissue changes. MSI was used to identify the cause and to improve the understanding of the Bleomycin interstitial pulmonary fibrosis rat model. Experimental procedures: Rats were administered seven doses of bleomycin delivered to lung by the oropharyngeal aspiration route and followed for 7 days. Control animals received seven doses of saline. Three control and three treated animals were sacrificed and lungs were collected. Several fresh sections were prepared and then the distribution of the Bleomycin was determined by high resolution mass spectrometry imaging with a MALDI-FITCR. The images were generated by Quantinetix software.

Results: This work illustrates a technique for identifying the causes of some histopathologic and functional tissue changes correlated with a drug administration in toxicology study. We describe a process which combines MSI and classical staining approach directly on tissue to follow the distribution of targeted molecules implicated in a fibrosis model generation, and allows a better understanding of the toxicity model. Conclusions: We have demonstrated the use of Mass Spectrometry Imaging to follow the distribution of a non-labeled drug and to understand its application in interstitial pulmonary fibrosis model generation. Mass Spectrometry Imaging could also allow the detection of other important endogenous molecules in the same or adjacent tissue section, such as specific disease or toxicity markers, thus allowing further understanding of PK-Tox relationships.

**901f A Simplified and Reliable Capillary Microsampling Procedure to Support Preclinical Regulatory Studies in Rodents**

1Debiopharm International SA, Lausanne, Switzerland and 2Covance Laboratories Ltd, Harrogate, United Kingdom. Sponsor: A. Jackson.

Until recently, blood sampling in rodents for toxicokinetic (TK) assessment required separate satellite groups in order to obtain complete TK profiles. Due to blood volume limitations, especially so in mice, these profiles, composed of samples taken from different animals at each time point, resulted in an apparent average systemic exposure not reflecting individual exposure. Serial sampling from toxicity animals is preferable over the use of separate satellite groups, not only to correlate individual animal exposure to observed toxicity but also to reduce the overall number of animals. The recent introduction of highly sensitive mass spectrometry into routine sample analysis has enabled drug concentrations to be measured from a significantly reduced plasma volume allowing the move towards low volume blood sampling (<100 μL).

The new technique proposed involved, at the initial blood sample processing stage, that the plasma remaining within the original sampling capillary after centrifugation is placed directly into a labeled holding tube for storage and transportation. At the bioanalytical laboratory, the sample is thawed and a measured volume (currently 10 μL) removed by pipette and subsequently diluted as part of the pre-analysis procedure. This removes the need for the error-prone original capillary to volumetric micro-capillary plasma transfer, thereby reducing the sample processing time and allowing all the plasma harvested to be available for analysis. The data presented demonstrate the feasibility of this approach in the frame of a 4 week GLP toxicity study in mice from which good TK profiles were obtained by taking serial samples (5 time points, blood volume ≤60 μL) from 4 mice/group/sex only. Moreover, the addition of a single blood sample from the toxicity animals at Cmax allowed observed toxicity in individual animals to be correlated directly with exposure. In addition to producing good quality data, the method also follows the principles of 3Rs by importantly reducing the number of mice required for TK.
The AhR hydrocarbon receptor (AhR) is involved in the regulation of immune responses, T-cell differentiation and immunity. Here we show that inflammatory stimuli such as lipopolysaccharide (LPS) induce the expression of AhR in human dendritic cells (DC) associated with an AhR-dependent increase of Cytochrome P450 1A1 (CYPIA1). In vivo data confirmed the induction of AhR by LPS and the LPS-enhanced 2,3,7,8-tetrachlorodibenzodioxin (TCDD)-mediated induction of CYPIA1 in thymus of B6 mice. Inhibition of nuclear factor-kappa B (NF-kB) repressed both normal and LPS-enhanced, TCDD-inducible, AhR-dependent gene expression and canonical pathway control of RelA regulated AhR-responsive gene expression. LPS-mediated induction of AhR was NF-kB-dependent as shown in mouse embryonic fibroblasts (MEFs) derived from Rel null mice. AhR expression and TCDD-mediated induction of CYPIA1 was significantly reduced in RelA deficient MEF compared to wildtype MEF cells and ectopic expression of RelA restored the expression of AhR and induction of CYPIA1 in MEF RelA null cells. Promoter analysis of the human AhR gene identified the putative NF-κB-binding elements upstream of the transcription start site. Mutation analysis of the AhR promoter identified one NF-kB site as responsible for mediating the induction of AhR expression by LPS and electrophoretic shift assays demonstrated that this NF-kB motif is recognized by RelA/p50 heterodimer. Our results show for the first time that NF-kB RelA is a critical component regulating the expression of AhR and the induction of AhR dependent gene expression in immune cells illustrating the interaction of AhR and NF-kB signaling.

**903 Toxicogenomic Evaluation of Dose-Derpendent TCDD-Elicited Effects in the Jejunal Epithelium of C57BL/6 Mice**

K. A. Fader¹, R. Nault²,³ and T. R. Zacharewski⁴,⁵. ¹BioMolecular Sciences, Michigan State University, East Lansing, MI, ²Department of Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, and ³Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

2,3,7,8-Tetrachlorodibenzodioxin (TCDD) exerts its effects primarily through activation of the aryl hydrocarbon receptor (AhR). We have previously demonstrated that dietary fat rather than de novo synthesis is the primary lipid source in TCDD-elicited hepatic steatosis in C57BL/6 mice. This study examined the dose-dependent effects of TCDD (0.01, 0.03, 0.1, 0.3, 1, 3, 10 or 30 μg/kg body weight [bw]) on gene expression in the jejunum of mice orally gavageyed every 4 days for 28 days. Agilent 4 x 44K microarray analysis of jejunal epithelium identified 439 genes differentially expressed (fold change ≥ 1.5, P(1) ≥ 0.099) across one or more doses. Dose-response modeling (ToxResponse Modeler) identified 264 for 28 days. Agilent 4 x 44K microarray analysis of jejunal epithelium identified dose-dependent effects of TCDD (0.01, 0.03, 0.1, 0.3, 1, 3, 10 or 30 μg/kg body weight [bw]) on gene expression in the jejunum of mice orally gavageyed every 4 days for 28 days. Agilent 4 x 44K microarray analysis of jejunal epithelium identified 439 genes differentially expressed (fold change ≥ 1.5, P(1) ≥ 0.099) across one or more doses. Dose-response modeling (ToxResponse Modeler) identified 264 for 28 days. Agilent 4 x 44K microarray analysis of jejunal epithelium identified dose-dependent effects of TCDD (0.01, 0.03, 0.1, 0.3, 1, 3, 10 or 30 μg/kg body weight [bw]) on gene expression in the jejunum of mice orally gavageyed every 4 days for 28 days. Agilent 4 x 44K microarray analysis of jejunal epithelium identified 439 genes differentially expressed (fold change ≥ 1.5, P(1) ≥ 0.099) across one or more doses. Dose-response modeling (ToxResponse Modeler) identified 264 for 28 days. Agilent 4 x 44K microarray analysis of jejunal epithelium identified dose-dependent effects of TCDD (0.01, 0.03, 0.1, 0.3, 1, 3, 10 or 30 μg/kg body weight [bw]) on gene expression in the jejunum of mice orally gavageyed every 4 days for 28 days. Agilent 4 x 44K microarray analysis of jejunal epithelium identified 439 genes differentially expressed (fold change ≥ 1.5, P(1) ≥ 0.099) across one or more doses. 196a which has been shown to control proliferation associated with the expression of p27kip1. Hence, we propose that AhR-dependent regulation of miR-196a promotes proliferation by inhibiting the p27kip1 expression. Methods: AhR+/+ and AhR−/− mouse lung fibroblasts were treated with B[a]P (1μM) with or without the AhR antagonist CH-223191 (10 μM) and miR-196a assessed by qRT-PCR. miR-196a was also assessed in A549 cells where AhR expression was knocked-out using zinc finger nuclease technology. p27kip1 and AhR protein levels were assessed by western blot. Proliferation was evaluated by thymidine incorporation. Human lung fibroblasts (HFLs) derived from smoker or COPD individuals were used for AhR knockdown and miR-196a analyses. Results: AhR−/− cells (lung fibroblast and A549 cells) have a significant decrease in basal miR-196a expression compared to control cells. Both B[a]P and CH-223191 decreased miR-196a and AhR protein expression. AhR expression promoted proliferation concurrent with a reduction in p27kip1 protein. Finally, AhR protein levels in HFLs were significantly less in COPD cells as was miR-196a.

Conclusions: We report miR-196a regulation as a potential novel endogenous role for the AhR. The regulation of p27kip1 could also be how the AhR controls cell proliferation. Elucidating the role of the AhR in cell cycle progression may provide novel therapeutic options for lung diseases which have significant alterations in proliferation, such as COPD.

907 Ligand Promiscuity of Aryl Hydrocarbon Receptor Agonists and Antagonists Revealed by Site-Directed Mutagenesis

A. Soshilov and M. Denison, Environmental Toxicology, University of California Davis, Davis, CA.

The aryl hydrocarbon receptor (AhR) is a ligand-dependent transcription factor that can be activated by structurally diverse chemicals. Although AhR ligand-binding promiscuity appears to be determined by distinct binding mechanisms within the ligand-binding pocket, direct experimental evidence is lacking. To examine the mechanisms responsible for the promiscuity in AhR ligand binding, we determined the effects of mutations within the mouse AhR ligand-binding domain (LBD) on the activity of diverse AhR ligands. AhR point mutations were generated using site-directed mutagenesis. Mutant AhR proteins were expressed in vitro and their ligand-dependent DNA binding was analyzed by gel retardation assay and functional activity confirmed by analysis of reporter gene expression in transfected cells. Site-directed mutagenesis identified Ile319, and to a lesser extent Phe318, as residues involved in ligand promiscuity and specificity of ligand binding, agonist or antagonist mode of ligand binding and hsp90 binding and provide further insights into molecular determinants of ligand activation of the AhR. Supported by the NIHES (R01ES07685).

908 The Ah Receptor Recruits IKK-alpha to Phosphorylate Ser10 in Histone H3 of the Cyp1a1 Promoter Chromatin

H. Kurita and A. Pugl, Environmental Health, University of Cincinnati, Cincinnati, OH.

Halogenated aromatic hydrocarbons such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) cause many types of toxicity via the aryl hydrocarbon receptor (AhR). One of the best known proteins induced by TCDD is the cytochrome P450 Cyp1a1. Induction of this enzyme requires AhR ligand-dependent activation, followed by binding of the activated AhR to AHR responsive elements (AhRE) in the promoter region of the Cyp1a1 gene. Histone modifications are well-known epigenetic markers modulating the activity of transcription factors by alteration of chromatin states. Among histone modifications, phosphorylation of serine-10 in histone H3 (H3S10ph) by various kinases has been reported to play a role in mitosis. Prior work from this lab has shown that the level of H3S10ph in the AhRE enhancer region of the Cyp1a1 promoter was elevated by AhR activation, which led us to search for responsible kinases that would be recruited by the ligand-activated AhR. To search for candidate kinases that phosphorylate H3S10ph in an AhR dependent manner, we performed chromatin immunoprecipitation (ChIP) assays for the enhancer region of Cyp1a1 in TCDD-treated Hepa-1 cells and C35 (AhR mutant) cells by using antibodies for AhR, H3S10ph and various kinases previously reported to phosphorylate this site. We found that binding of a subset of kinases, including Ikkα, MSK1 and MSK2, to the Cyp1a1 enhancer region was absent in control cells and significantly increased by TCDD treatment in an AhR dependent manner. In addition, Cyp1a1, Ahldh3a1 and Nqo1 mRNA induction, and the level of H3S10ph in the Cyp1a1 enhancer region of in TCDD-treated cells transfected with IKKα-shRNA was significantly decreased in comparison to TCDD-treated cells transfected with a scrambled-shRNA. We conclude that IKKα is recruited by AhR to the Cyp1a1 enhancer region and that phosphorylation of H3S10 is a main requirement for Cyp1a1 induction. Supported by Nih grant R01 ES 06273

909 RNA-Seq Analysis Reveals Roles for Aryl Hydrocarbon Receptor in Endogenous Lipid Synthesis and TNF Signaling

T. B. Salisbury1, I. K. Tomlin1, D. Primerano2, G. Boskovic2, J. Fan2, A. R. Chaudhry1, G. Morris2 and J. Denison1, 1Pharmacology, Physiology and Toxicology, Joan C Edwards School of Medicine, Marshall University, Huntington, WV, 2Biochemistry and Microbiology, Joan C Edwards School of Medicine, Marshall University, Huntington, WV and 3Department of Science and Mathematics, Glennville State College, Glennville, WV.

Aryl hydrocarbon receptor is a major xenobiotic sensing transcription factor involved in the metabolism of toxicants. This study uses RNA-seq analysis to further characterize endogenous AhR roles in the absence of xenobiotics in human MCF-7 breast cancer cells. Reducing AHR with short interfering RNA significantly reduced AHR levels compared to control cells. AHR knockdown induced CYP1A1. Induction of this enzyme requires AHR ligand-dependent activation statistically (false discovery rate < 10%) significant changes in the expression of 634 genes compared to controls. Ingenuity pathway analysis identified that differentially expressed genes in AHR knockdown cells were significantly associated with several processes that are important for endogenous lipid processing including: conjugation of lipid, conjugation of 12-hydroxyicosatetraenoic acid, glucuronidation of leukotriene B4, synthesis of lipid, fatty acid metabolism, metabolism of eicosanoids, metabolism of prostaglandins, synthesis of fatty acid, synthesis of prostaglandins and synthesis of eicosanoids. Based on the patterns of expression of differentially expressed genes, the activity of tumor necrosis factor (TNF) was predicted to be inhibited in AHR knockdown cells. TNF responsiveness was further investigated by treating cells with TNF and measuring the induction of TNF targets p53, p21 and the antioxidant manganese superoxide dismutase (MNSOD). AHR knockdown significantly compromised TNF induction of MNSOD protein. Collectively, these results suggest that AHR (1) is active in the absence of exogenous AhR ligands (2) could play a role in signaling by controlling the expression of genes that generate bioactive intracellular lipids and (3) modulate cellular responses to intracellular reactive oxygen species (ROS).
Using Three-Dimensional Cell Culture to Understand Ethanol Toxicity in Mammary Cells

R. David and N. J. Gooderham, Imperial College London, London, United Kingdom.

Mechanistic studies are best performed in highly controlled experimental models such as cell culture. Yet cell monolayers (2D) are generally only useful for acute exposure to toxicants and are not representative of the cellular environment found within an organism as most physiological parameters are lost. Three-dimensional (3D) cell culture is reported to better represent the in vivo structure of tissues and tumours regarding cell shape and their environment, thus culturing in 3D is suggested to decrease the gap between cell culture and physiological tissue.

The current study aimed to determine whether 3D cell culture provides a more in vivo-like model of ethanol-induced toxicity to mammary cells. MCF-7 cells in 2D or 3D (spheroid) culture were exposed to a dose range (1-100mM) of ethanol for an acute (24-72h) or chronic repeat dose (10 cycles of 72h treatment, 3D only) study following which proliferation, migration, spheroid size, signal transduction and gene expression were measured.

Acute exposure of 2D MCF-7 cells to ethanol increased proliferation dose and time-dependently over 72 h. Cell migration was also increased at 100mM compared to control. Acute exposure of 3D MCF-7 spheroids to ethanol (up to 100mM) showed a trend for increased signal transduction (p-ERK ratio) consistent with increased proliferation.

Chronic repeated exposure of spheroids to ethanol dose-dependently decreased spheroid size by cycle 5. With continued exposure to low doses of ethanol (1-100mM) the decrease in size was reversed. Total cell number, however, was unaffected by treatment. At cycle 10 signal transduction (p-ERK ratio) was reduced for all treatments in line with rat in vivo data, where continuous/intermittent alcohol exposure (Sanna et al. Brain Res 948 P186 2002) and chronic ethanol exposure (45 days) (Sampere et al. J Biol Chem 282 P1925 2010) decreased levels of p-ERK. In contrast there was a trend for induction of the oncogenic microRNA miR-21 (anti-apoptotic) at cycle 10. These data indicate that chronic ethanol exposure induces phenotypic change in 3D cultured mammary cells that has similarities to ethanol exposure in vivo.

Transcriptome Analysis of PXR-Regulated Gene Expression in HepG2 Cells

G. Wang1, E. Yang1, S. Ke2, J. Ca2 and Y. Tian1. 1Department of Veterinary Integrative Biosciences, College of Veterinary Medicine, Texas A&M University, College Station, TX and 2Department of Physiology and Pharmacology, College of Veterinary Medicine, Texas A&M University, College Station, TX.

Pregnane X receptor (PXR, NR1I2) is a ligand-dependent nuclear receptor (NR) that functions as a xenobiotic sensor and effector in coordinately regulating expression of genes of the xenobiotic detoxification network. PXR exerts its transcriptional regulatory functions by dimerization with retinoic X receptor (RXR), and PXR-RXR complex binds to specific DNA sequences for regulating gene expression. Whole-genome transcriptome analysis based on next generation sequencing technology (RNA-Seq) provides unprecedented opportunity to study the PXR-regulated gene expression. PXR-HeptG2 cells were generated by stable transfection of PXR gene in human liver cell line HepG2 and treated with PXR ligand rifampicin (10 μM, 48 hr). PolyA RNA was isolated and the samples were subjected to RNA-Seq analysis. We have found around 2000 genes were significantly up-regulated by ligand treatment in PXR in a PXR-dependent manner, including classic PXR-regulated phase I enzymes such as CYP3A family, phase II enzymes UGT1A family and GST1As. Interestingly, we have identified PXR-regulated novel intergenic noncoding RNAs that were significantly regulated by ligand-activated PXR. In addition, we have identified alternative RNA splicing process in certain genes appears to be regulated by PXR. Our results suggest that RNA-seq through next-generation sequencing technology (RNA-Seq) provides unprecedented opportunity to study the PXR-regulated phase II enzymes UGT1A family and GST1As. Interestingly, we have identified PXR-regulated novel intergenic noncoding RNAs that were significantly regulated by ligand-activated PXR. In addition, we have identified alternative RNA splicing process in certain genes appears to be regulated by PXR. Our results suggest that RNA-seq through next-generation sequencing technology (RNA-Seq) provides unprecedented opportunity to study the PXR-regulated gene expression which may lead to a predisposition to carcinogenesis in the lung. F0 female C57BL/6 mice (Mus musculus) were exposed to 0, 10, 50 or 500 ppb sodium arsenite in their drinking water throughout mating, gestation and nursing. F1 generation mice were exposed to arsenic only during gestation and nursing. F2 mice were not directly exposed to arsenic. The expression of three cell cycle regulatory genes, Foxm1, Cdc25s and Cdc6, from the lung tissue of F1 and F2 mice was evaluated using quantitative real time PCR (qRT-PCR). Preliminary findings showed a significant change in expression of Foxm1 and Cdc6 at doses as low as 10 ppb. Histological findings suggest arsenic exposure induce inflammation in lung tissues. These results suggest low-dose transplacental arsenic exposure alters the transcription levels of several genes involved in cell cycle regulation. Our findings contribute an important insight toward the identification of a mechanism for cell cycle deregulation, following exposure to low doses of arsenic.

Low-Dose Transplacental Arsenic Exposure Alters Expression of Cell Cycle Genes in Lung Tissues of C57BL/6 Mice

D. J. Udawatte1, X. Li2, P. Carlson3 and R. J. Van Beneden1, 4, 4. Molecular and Biomedical Sciences, University of Maine, Orono, ME, 2Center for Molecular Medicine, Central South University, Changsha, Hunan, China, 3Graduate School of Biomedical Sciences and Engineering, University of Maine, Orono, ME and 4School of Marine Sciences, University of Maine, Orono, ME. Sponsor: J. Goss.

Arsenic is an environmental toxicant associated with several human diseases including cancer. The current EPA and WHO maximum allowable level for arsenic in drinking water is 10 ppb. This level is often exceeded in private wells in the state of Maine and many places world-wide, and poses a potential health concern. Molecular mechanisms of arsenic-induced carcinogenesis are still not well defined. In this study, we hypothesized that transplacental arsenic exposure alters cell cycle regulatory gene expression which may lead to a predisposition to carcinogenesis in the lung. F0 female C57BL/6 mice (Mus musculus) were exposed to 0, 10, 50 or 500 ppb sodium arsenite in their drinking water throughout mating, gestation and nursing. F1 generation mice were exposed to arsenic only during gestation and nursing. F2 mice were not directly exposed to arsenic. The expression of three cell cycle regulatory genes, Foxm1, Cdc25s and Cdc6, from the lung tissue of F1 and F2 mice was evaluated using quantitative real time PCR (qRT-PCR). Preliminary findings showed a significant change in expression of Foxm1 and Cdc6 at doses as low as 10 ppb. Histological findings suggest arsenic exposure induce inflammation in lung tissues. These results suggest low-dose transplacental arsenic exposure alters the transcription levels of several genes involved in cell cycle regulation. Our findings contribute an important insight toward the identification of a mechanism for cell cycle deregulation, following exposure to low doses of arsenic.

913 Development of a Nanoparticle Platform for the Targeted Delivery of siRNA to HER2-Positive Breast Cancers

D. Castro1, 2, W. Ngamchentrakul3, J. Marr2, T. Svangavich3, S. Gu2, S. Goodyear2 and W. Yantasee1, 2. 1PDX Pharmaceuticals, Portland, OR and 2Biomedical Engineering, Oregon Health and Science University, Portland, OR.

Successful siRNA based therapy has the potential to revolutionize cancer therapy by mediating the silencing of any gene deemed important for disease progression. We are developing an effective siRNA based nanoparticle platform that would overcome traditional shortcomings of siRNA based therapies such as poor bioavailability and off-target effects. The platform utilizes a mesoporous silica nanoparticle electrostatically loaded with siRNA and conjugated with an antibody for target homing. The human epidermal growth receptor type 2 (HER2) is a highly validated therapeutic target in breast cancer due to its prognostic role in cancer aggressiveness and drug resistance when overexpressed in tumors. Suppression of HER2

914 Hormonal Changes and Gene Signaling Pathways in Female Rat Thyroids Exposed to Acrylamide

R. C. Colli-Dula1, N. D. Danslow1 and M. A. Friedman2. 1CEHT, University of Florida, Gaineville, FL and 2Kennesaw State University, Kennesaw, GA.

In this study, we used biological endpoints and transcriptomics to identify molecular events associated with acrylamide (AA) exposure. Pregnant female RccHan Wistar rats were treated with 3 mg AA/kg in drinking water from gestational day 6 to postnatal day 30. Thyroid glands were collected from female pups at 10 AM and at 10 PM. While control animals showed no statistical difference in serum levels of TSH, T3 and T4 between AM and PM, animals exposed to AA and collected in the AM showed significant increase in serum levels of TSH and PM animals showed significant increases in levels of T4 and T3, compared to controls. In terms of gene expression changes, there were fewer changes in the AM animals compared to PM animals, consistent with their increased activity and dietary patterns at night. PM animals treated with AA showed decreases in transcripts involved in metabolic activity such as insulin-like growth factor 2, transforming growth factor beta, and glucose-6-phosphate transporter compared to controls, while these same transcripts were not altered in AM animals. In addition, the PM animals showed up-regulation of transcripts involved in detoxification, oxidative stress, apoptosis, neurotoxicity, tumorigenesis, among others. But, there were also changes seen in morning animals that were specific to that time point such as up regulation of branched chain amino acid metabolism and aspartate metabolism. There were commonalities among both morning and night animals which included up-regulation of transcripts related to the checkpoint pathways, DNA replication and sister chromatid cohesion, among others. This analysis indicates that the time of collection of animals is important in assessing how acrylamide affects gene expression in the thyroids of treated animals.
with siRNA based therapy (siHER2) offers a new treatment modality and provides a testable system for the development of our nanoparticle platform. Incorporation of Herceptin, a monoclonal antibody which binds to HER2, will serve to selectively target HER2-positive cancer cells. We first evaluated our nanoconstruct loaded with a highly optimized siHER2 directed against a portion of HER2, specifically in a mouse tumor model. The siHER2 loading efficiently inhibited growth in HER2-positive cell lines resistant to Herceptin and lapatinib. In vivo success translated well to tumor growth inhibition in a HCC1954 mouse tumor model following i.v. injection of our siHER2–nanoconstruct. Current efforts are directed toward immune cell function and hematology assays to generate an immunological safety profile of the nanoconstruct.

916 Pentoxifylline Induces GSK-3β-Independent Proteasomal Degradation of Cyclin D1 and Arrests Renal Cancer Cells in the G1 Phase

W. Cai, N. Mastrandrea, K. Y. Tham, S. L. Lau and T. J. Monks. Pharmacology and Toxicology, University of Arizona, Tucson, AZ.

Cyclin D1 is required for progression from the G1 phase into the S phase of the cell cycle. Over-expression of cyclin D1 causes an increase in cell cycle progression and proliferation, implicating it in a variety of tumors. Canonical cyclin D1 degradation is initiated by phosphorylation of Thr286 by GSK-3β. Pentoxifylline (PTX), a non-specific phosphodiesterase inhibitor, is used as an adjunct in chemotherapy to treat cachexia. We report that PTX causes a time- and dose-dependent decrease in cyclin D1 protein levels and G1 cell cycle arrest in QTRE-R and ACHN cells. RT-PCR analysis showed no significant changes in cyclin D1 mRNA. However, PTX’s ability to decrease cyclin D1 protein was prevented in the presence of a proteasome inhibitor, MG-132. Inhibition of GSK-3β with LiCl in the presence of PTX failed to rescue cyclin D1 levels. PTX increases the phosphorylation of Ser9 on GSK-3β, indicative of an inhibition of GSK-3β activity. Following siRNA knockdown of GSK-3β, PTX retains the ability to decrease cyclin D1 levels. Moreover, PTX treatment in the presence of MG-132 revealed no increase in phospho-Thr286 compared to control. Our data indicate that PTX initiates GSK-3β- and phospho-Thr286-independent proteasomal degradation of cyclin D1 and arrests the RCC cell models in the G1 phase. Because our findings demonstrate a novel anti-cancer property of PTX, its use as an adjuvant therapy in RCC treatment should be further explored.

917 Regulation of Intestinal Drug-Processing Genes in Germ-Free Mice

L. Cai, F. Selwyn and C. D. Klaassen. Pharmacology and Toxicology, University of Arizona, Tucson, AZ.

Little is known regarding how the gut microbiome regulates the drug-processing genes (DPGs) in various sections of the intestine, which is an important metabolic organ for orally administered drugs. The goal of this study was to determine the regulation of DPGs in intestine of germ free (GF) mice. Total RNAs from duodenum, jejunum, ileum, and colon of adult male GF and Conventional mice (n=3 per group) were isolated, and the transcriptome was quantified using RNA-Seq (50 cycles paired end). Over 35 million reads were generated per sample, of which >96% were mapped to the mouse mm10 genome (TopHat). Among 23,846 genes in mice, jejunum had the largest number of differentially regulated genes (2514, FDR-BH<0.05), followed by colon (835), duodenum (435), and ileum (368). In duodenum, drug metabolism was among the top most differentially regulated networks in GF mice. In all 3 sections of the small intestine, Cyp1a1 was among the top most down-regulated genes within the transcriptome, suggesting that the aryl hydrocarbon receptor signaling is attenuated in the small intestine of GF mice. In duodenum and ileum, many of the Cyp2b, 2c and 3a mRNAs were down-regulated in GF mice, suggesting attenuated transcription of the pregnane X receptor and constitutive androstane receptor. In duodenum, there was a decrease in the mRNAs of glutathione-S-transferases, which are responsible for detoxifying electrophiles and oxidative stress. In jejunum, many alcohol dehydrogenases, aldo-keto reductases (Akrs), aldehyde dehydrogenases, and the Cyp4 family members, were up-regulated. In ileum, the apical sodium-dependent bile acid transporter (Asbt) and Akt1c19 were among the top most up-regulated genes in the transcriptome. In colon, most differentially regulated DPGs were up-regulated, exemplified by increased mRNAs of Asbt and organic solute transporter ct. In conclusion, our study was the first to quantitatively determine the regulation of all DPGs in GF mice, and identified that distinct sections of intestine respond differently to the absence of the gut microbiome.

918 Caudal-Related Homeodomian Protein 2 (Cdx2) and the Hepatocyte Nuclear Factor 4α (HNF4α) Synergize to Regulate UDP-Glucuronosyltransferase (UGT) 1A8 Gene Expression

S. N. Muhoro et al. Pharmacology, Flinders University, Adelaide, SA, Australia, University of Islam failed to deduce HER2 from the full-length transcriptome, and identified that distinct sections of intestine respond differently to the absence of the gut microbiome.

919 CYP251 Depletion Promotes Cell Growth in Human Lung Cells

T. Madanayake and A. M. Bowland. New Mexico State University, Las Cruces, NM.

Cytochrome P450 251 (CYP251) expression is elevated in several epithelial derived cancers including squamous cell carcinoma. Although the expression pattern of CYP251 suggests an important physiological function, it is still considered as an orphan enzyme with unknown endogenous substrate. We reasoned that changes in CYP251 expression would initiate metabolic shifts in pathways linked to CYP251-mediated metabolism of endogenous substrates, and that these pathways can be identified through transcriptional alterations. CYP251 expression was depleted in human BEAS-2B cells, using RNA-interference targeting the 3′UTR (759) and exon 3 (984) of the CYP251 gene, and compared with a non-targeting shRNA control (SCRAM). Transcriptome analysis was performed on CYP251 depleted (759) and scrambled control (SCRAM) BEAS-2B cells using RNA-sequencing (RNA-seq). Pathway analysis of differentially expressed genes, using the Database for Annotation, Visualization, and Integrated Discovery (DAVID) analysis, revealed pathways consistent with previously published endogenous substrates and phenotypes. Additionally, analysis also revealed significant changes within mTOR signaling in response to CYP251 depletion. mTOR signaling is involved in regulating cell growth. Consistent with changes in cell growth, both CYP251 depleted cell lines, 759 & 984, exhibited an approximate 10% increase in cell diameter and 50% increase in cell volume. Western analysis reveals post-translational modifications within the mTOR signaling cascade consistent with increased cell size in CYP251 depleted cells (759 & 984) compared with control (SCRAM). CYP251 depleted cells specifically exhibit increased phosphorylation of mTOR, and its downstream target 56 kinase. These data suggest that alterations in CYP251 expression, and presumably CYP251-mediated endogenous metabolism, influence cell size through regulation of mTOR signaling. We are currently pursuing the mechanistic link between CYP251-mediated metabolism of endogenous substrates and mTOR signaling.

SOT 2014 Annual Meeting 237
920 Functional Genetic Screen in Human Haploid Cells to Identify Genes Involved in Susceptibility to Chemical Exposure

H. Shen, M. T. Smith and L. Zhang, Environmental Health Sciences, University of California Berkeley, Berkeley, CA.

Functional genetic screening systems have been successfully applied to study susceptibility to chemical toxicity. However, some approaches have certain limitations, such as lack of relevance to humans of yeast mutant screen findings and incomplete gene knock-out and off-target effects of RNA interference. Human haploid cell models are advantageous as an induced gene mutation can result in a clear phenotype due to the absence of a second gene copy. We recently developed a more efficient semi-solid medium based screening platform that employs a human haploid cell mutant library (KB7-Mu) to identify genes that modulate sensitivity to chemical exposures. Compared to the liquid medium-based approach, our method allows for simultaneously screening and generating mutant colonies from cells resistant to the chemical of interest. This shortens the entire screening process by approximately 3 weeks and decreases the rate of false positives. Using this new approach, we identified eleven human genes that confer the resistance to formaldehyde (FA), a known human leukemogen. Among these genes, LPR5 (Low-density lipoprotein receptor-related protein 5), GOT1 (Glutamic-oxaloacetic transaminase 1) and M1AP (Meiosis 1 Associated Protein) were confirmed in two independent screening experiments. LPR5, GOT1 and M1AP mutant KB7 cells showed significant resistance to FA-induced toxicity compared to wild type cells (KB7-Wt). Further studies on LPR5 mutant KB7 cells using quantitative RT-PCR and western blotting confirmed the knockdown of transcription and knockout translation of the LPR5 gene. These findings suggest that LPR5, GOT1, M1AP and other genes are involved in susceptibility to FA toxicity. They further demonstrate the broad applicability of this optimized approach to screen genetic susceptibility to toxic chemicals, identify novel susceptibility genes, and gain insight into potential mechanisms of toxicity of chemical exposures.

921 Carbon Monoxide Modulation of mRNA in Human Airway Smooth Muscle Cells

B. A. Rolls1, L. Aguila-Aguirre1, L. M. Hallberg4, I. Boldogh1, A. J. Halayko1 and B. T. Ameredes1, 2

1University of Texas Medical Branch, Galveston, TX and 2Bren School of Environmental Science & Management, UC Santa Barbara, Santa Barbara, CA.

Rationale: Asthma is a chronic inflammatory airway disease involving disregulation of human airway smooth muscle cell (HASMc) function; subsequently, asthma may be more susceptible to the adverse effects of inhaled pollutants, such as carbon monoxide (CO). CO is toxic at high concentrations due to asphyxia resulting from carboxyhemoglobin formation, but may also have non-hemoglobin related effects. Thus, we investigated the effect of CO exposure in HASMC, to determine its effect on intracellular message regulation.

Methods: Cultures of primary HASMC at passage 6 were serum-starved for 24hr, refed, and stimulated with 1ng/ml IL-1β for 2-10hr, or exposed to 500ppm CO for 8hr, following the 2hr stimulation period. Inflammatory cytokine and receptor mRNA levels were assayed by q-PCR; the significant modulation threshold was taken as ≥2.5-fold over controls. Results: CO was upregulated from 24- to over 2300-fold. Of the 84 messages we assayed in controls (IL-1β alone), Tnfβ was the main upregulated early message (2hr), while IL-1β receptor antagonist (IL1RN) was the primary upregulated late (10 hr). IL-8, CXCL1, CXCL2, CXCL3 and CCL20 were upregulated to 2 hr, and maintained at 10hr, while CXCL5 and CXCL6 were further upregulated by 10 hr. At 10hrs, exposure to 500ppm CO upregulated SPP1, TNPβ, IL-10, TNFβ, and IL-13 (7 - to 32-fold), while downregulating CXCL5, IL-1β, CXCL2, CXCL6 and IL1RN (5 - to 24-fold).

Conclusions: We conclude that CO exposure can upregulate specific messages in HASM to a greater extent than IL-1β alone. Conversely, CO exposure can also downregulate specific messages, at least two of which are involved in the IL-1β pathway, namely, IL-1β and IL1RN. These results show that CO exposure can have direct effects on the intracellular mRNA levels in HASMC, an airway cell relevant to environmentally-associated asthma.

922 Role of microRNA in the Induction of Immunosuppressive MDSC by Δ⁹-THC. In Vivo Regulation of Transcription Factor C/EBPβ by miR-690

1Pathology, Microbiology & Immunology, University of South Carolina, Columbia, SC.

Δ⁹-tetrahydrocannabinol (THC), the major psychotropic component of marijuana has been shown to induce potent myeloid-derived suppressor cells (MDSC) in vivo. We investigated the role of miRNA in this process. C11b+Gr-1+ MDSCs were purified from peritoneal cavities of BL/6 mice injected with THC. Genome-wide profiling of 690 mouse miRNA by microarray analysis showed significantly altered expression in THC-MDSCs vs control BM precursors, with 13 miRNA identified as differentially expressed (≥2-fold). We used a robust combination of TargetScan, RNAhybrid and miranda algorithms (Poisson P0.05, predicted by at least 2) to identify the targets. Ingenuity pathway analysis revealed that cell growth, proliferation, differentiation, and myeloid differentiation were the top significantly enriched canonical pathways. Several specific, potentially important miRNA-target interactions were identified. MIR-690 was the highly overexpressed miRNA in THC-MDSC (~16 fold). Transcription factor C/EBPβ involved in myeloid differentiation was identified as the potential functional target of miR-690 with a good seed binding site within its mRNA 3'UTR. C/EBPβ expression was found to be higher in BM precursors with a significant decrease in THC-MDSC, while showing inverse correlation with miR-690 expression. Knock-down of miR-690 in THC-MDSC following transfection with stable, peptide nucleic acid (PNA) antagonist resulted in unblocking, and significant increase in C/EBPβ levels. Further, FACS sorted, THC-induced C11b+Ly6G-Ly6C+ granulocytic and C11b+Ly6G-Ly6C+ monocytic MDSC subtypes showed similar levels of miR-690 and attenuated C/EBPβ suggesting that miR-690 is a pan MDSC marker, and miR-690-C/EBPβ is a common pathway in MDSCs. Select miRNA and their targets play a key role in the induction of immunosuppressive MDSC following cannabinoid exposure, and hence, in cannabinoid-induced immune suppression. 922a Profile of Six Hepatic Insulin Signaling Pathway Genes in Response to 2-Aminoanthracene Dietary Ingestion

J. W. Jay, G. W. Barnett1, L. C. Means2 and W. E. Gatto1, 1Chemistry, Georgia Southern University, Statesboro, GA and 2Bren School of Environmental Science & Management, UC Santa Barbara, Santa Barbara, CA.

Six genes that regulate various processes in the insulin signaling pathway were profiled. These transcripts were reported to regulate other genes that are essential for glucose metabolism, fatty acid and lipid biosynthesis. In a previous hepatic global gene expression analysis followed by DAVID bioinformatics analysis showed upregulated, g6pc, gck, ppi, srebp-1c and socs2 to be likely modulated by 2-aminoanthracene (2AA) dietary consumption. The goal of the current study is to evaluate the responses of these proteins in the liver of Fisher-344 (F344) rats exposed to 2AA. 2AA belongs to a class of compounds referred to as polycyclic aromatic hydrocarbons (PAHs). This compound has been detected in broiled food exposed to 2AA. 2AA belongs to a class of compounds referred to as polycyclic aromatic hydrocarbons (PAHs). This compound has been detected in broiled food. F344 rats were fed 2AA adulterated diets of 0 mg/kg, 50 mg/kg, 100 mg/kg and 100 mg/kg for 14- and 28-days. Differential gene expression of ampk (Pik3b), g6pc, gck, ppi, srebp-1c and socs2 was carried out by qRT-PCR. Results seem to suggest 2AA modulates different genes related to energy metabolism in the liver. Relative quantification of these products indicated an up-regulation of the ampk and socs in animals treated to 100 mg/kg-diet and 50 mg/kg-diet respectively during 14 days of feeding. The rest of the mRNA transcripts were downregulated in the treated rats relative to the control group. G6pc gene was highly up-regulated in all animals that ingested 2AA for 28 days. Ppi protein was also up-regulated in the 75 mg/kg-diet group. The rest of the genes tested were not differentially altered. This result will be followed by a protein immunoblot assay to examine the expression of g6pc and ampk.

922b Effects 2-Aminoanthracene Exposure on Insr, Irs, Akt and Glut4 Expression

N. D. Mattis1, J. J. Rosaldo1, L. C. Means2 and W. E. Gatto1, 1Chemistry, Georgia Southern University, Statesboro, GA and 2Bren School of Environmental Science & Management, UC Santa Barbara, Santa Barbara, CA.

The modulation of the toxic effects of 2-aminoanthracene (2AA) on the expression of insulin receptor (Insr), insulin receptor substrate (Irs1), α-ket urate thymoma viral oncogene homolog 1 (Akt1) and solute carrier family2, facilitated glucose transporter member 4 (Glut4) liver is being investigated. These genes play vital
roles including regulatory activity in insulin signaling and glucose metabolism (Akt1), important glucose transporter essential for the development of type 2 diabetes (Glut4) and activation and processing of insulin signaling transduction (Insr, Irs).

In a previous study to assess the toxic effects of 2AA using global gene expression coupled with DAVID bioinformatic tools, it was found that several genes that regulate the insulin signaling pathway may be altered by 2AA toxicity. The objective of the current investigation is to examine the mRNA expression of four specific genes that mediate insulin signaling due to 2AA toxicity. Polynuclear aromatic amine, 2AA is a by-product of cigarette smoke and broiled meat. Twenty four post-weaning 3-4 week old F-344 male rats were exposed to the test compound (low dose group was 40 mg/kg-diet, low dose - LD), 75 mg/kg/diet (medium dose - MD) and 100 mg/kg-diet (high dose - HD) 2AA for 2weeks and 4weeks. The mRNA expression of Insr, Irs1, Akt1 and Glut4 was determined by quantitative time PCR followed by the quantification of Akt1 via enzyme-linked immunosorbent assay (ELISA) assay. Transcripts Glut4 and Insr were not expressed at all in all treatment groups. Akt1 gene was up-regulated in animals treated to 2AA for both two and four weeks. Similarly, Irs1 mRNA was only up-regulated in rats that ingested 2AA for four weeks. It appears Akt1 and Irs1 proteins were targets of 2AA intoxication. This study is still ongoing to quantify the level of protein expression of Akt1 in the livers of rats exposed to 2AA.

**Functional Analysis of the Dioxin Response Elements (DREs) of the Murine Cyp1A1 Gene Promoter: Beyond the Core DRE Sequence**

L. S. Birnbaum1.

TBBPA treatment resulted in a statistically significant increase in the synthesis, oxidative stress, and perturbations of lipid and endogenous estrogen metabolism. The present work investigated modes-of-action of TBBPA-mediated toxicity in Wistar Han rats and hepatoblastoma in male B6C3F1 mice. The mechanisms of TBBPA, a widely used brominated flame retardant, is an endocrine disruptor in mouse, human and rat. Deletion analysis showed that a single DRE at -488 was sufficient to induce CYP1A1 transcription in response to TCDD and the core DRE (5'-TNGCGTG-3') tends to show higher transcriptional level than that of the adjacent sequences of DRE. The core sequences of seven DREs did reduce the transcriptional efficiency, which illustrated that the adjacent sequences of DRE played a vital role in activating transcription. The reversed 25bp core sequences including DREs showed that the core DRE sequence (5'-TNGCGTG-3') tends to show higher transcriptional level than that of the core DRE sequence (5'-CAGCGCA-3') which processed the core DRE. Furthermore, in the core DRE (5'-TNGCGTG-3') sequence, when N is Thymine or Cytidine (T, C), the transcription efficiency was stronger compared with that of the other nucleotides. This study not only systematically the effects of DRE orientation, DRE adjacent sequences, and the nucleotide N in the core DRE (5'-TNGCGTG-3') sequence on the AhR-regulated CYP1A1 transcription in response to TCDD and laid a good foundation for further investigation into the AhR-dependent transcription regulation triggered by dioxin and dioxin-like compounds.
with SYN, and on subsequent aggregation reactions. Redox modulation of SYN PTMs and of SYN aggregation suggests potential interventions to alleviate SYN-dependent cytotoxicity. (P30ES006694 & T32-ES016652)

**925** Linking Nicotinamide Nucleotide Transhydrogenase (Nnt) Activity and Respiratory-Dependent H2O2 Consumption through the Mitochondrial Thioredoxin/Peroxiredoxin System in Cell-Based Model of Parkinson’s Disease

P. Lopert¹, L. Liang² and M. N. Patel³. ¹Neuroscience, University of Colorado Anschutz Medical Campus, Aurora, CO and ²Pharmaceutical Sciences, University of Colorado Anschutz Medical Campus, Aurora, CO.

Mitochondrial reactive oxygen species (ROS), such as hydrogen peroxide (H2O2) are implicated in neurodegenerative diseases such as Parkinson’s disease (PD). Epidemiological studies have shown pesticide exposure can increase the risk of developing PD and many pesticides/herbicides, such as Paraquat (PQ) work through redox cycling or inhibiting the electron transport chain. Mitochondria are thought to be net producers of ROS but recently it was shown brain mitochondria can consume H2O2 in a respiratory-dependent manner by the thioredoxin/peroxiredoxin (Trx/Ptx) system (Drechsel, 2010). This study wanted to determine the mechanism linking mitochondrial respiration with H2O2 consumption in a cellular model of PD. We examined the role of Nicotinamide Nucleotide Transhydrogenase (Nnt), which uses the proton gradient to generate NADPH from NADH and NADP⁺, to detoxify H2O2 by the Trx/Ptx system. Pharmacological inhibition of Nnt in isolated brain mitochondria significantly decreased their ability to consume H2O2 in the presence, but not absence, of respiration substrates. Nnt inhibition in liver mitochondria, which do not need substrates to detoxify H2O2, had no effect. Pharmacological inhibition or siRNA knockdown of Nnt in N27 cells a) decreased H2O2 consumption b) decreased TrxR activity c) decreased NADPH and increased NADP⁺ levels and d) decreased basal, spare and maximal mitochondrial H2O2 consumption b) decreased TrxR activity c) decreased NADPH and increased NADP⁺ levels and d) decreased basal, spare and maximal mitochondrial oxygen consumption rates. Nnt deficient cells where more susceptible to ROS production and cell death following exposure to subtoxic levels of PQ. This data implicates Nnt as a critical link between the metabolic and antioxidant functions in brain mitochondria and suggest Nnt as a potential therapeutic target to improve the redox balance in conditions of oxidative stress associated with neurodegenerative diseases. Funding: RO1NS45748

**926** Environmental/Mitochondrial Toxicity Induced by Paraquat and MPP+ Is Associated with a Decrease in Ubiquitination-and p62/Autophagy-Mediated Clearance of Oxidized Proteins

L. Navarro-Yepes¹, A. Anandhan¹, B. Quintanilla-Vega² and R. Franco¹. ¹School of Veterinary Medicine and Biomedical Sciences, University of Nebraska-Lincoln, Lincoln, NE and ²Toxicology, CINVESTAV, IJPN, Mexico City, D.F., Mexico.

A hallmark of neurodegenerative diseases is the accumulation/aggregation of misfolded or damaged proteins, which has been associated with increased oxidative stress and dysfunction in protein degradation pathways (ubiquitin-proteasome system and autophagy). α-Synuclein, ubiquitin and p62 are major components of Lewy body inclusions in Parkinson’s disease. In this work, we aimed to study the effect of environmental/mitochondrial toxins in the ubiquitin-proteasome and autophagy-mediated degradation pathways in human neuroblastoma and dopaminergic mesencephalic cell cultures. Using the ubiquitin-proteasome and the autophagy-only reporters, GFP and GFP-ODC, and western blot analysis of ubiquitin-bound proteins and changes in the autophagy flux, we observed that paraquat- and 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPP⁺)-induced cell death was associated with a decrease in protein ubiquitination. Decreased protein ubiquitination induced by paraquat or MPP⁺ was paralleled by a decrease in the autophagic flux (LC3-II accumulation in the presence of chloroquine) and an increase in p62 accumulation. Paraquat-induced oxidative stress was paralleled by the accumulation of oxidized (sulfenylated) proteins. Neither paraquat nor MPP⁺ toxicity was increased by the presence of the proteasomal inhibitor MG132. However, overexpression of a dominant-negative form of the autophagy protein 5 (dnAtg5) increased both paraquat and MPP⁺ toxicity. We hypothesize that impairment of protein ubiquitination by paraquat or MPP⁺ is compensated by autophagic clearance of p62-bound oxidized protein aggregates, and that inhibition of autophagy potentiates the toxicity of these environmental/mitochondrial toxicants.

**927** Evidence for the Involvement of Protein Kinase C Delta (PKCδ)-Mediated Epigenetic Deregulation in the Histone Deacetylase Inhibitor Trichostatin-A-Mediated Neurotoxicity in N27 Dopaminergic Neuronal Cells

V. I. Lawang, N. Singh, V. Anantharam, H. Jin, A. Kothasamy and A. Kothasamy. Interdepartmental Toxicology, Iowa State University, Ames, IA.

Acetylation and deacetylation of histones has been shown to be a critical regulator of gene transcription and chromatin remodeling. We have previously demonstrated that NF-kB activation is critically linked to trichostatin A (TSA)-induced apoptotic cell death in N27 dopaminergic cells. However, the influence of protein kinase c delta (PKCd), a redox sensitive kinase, on histone hyperacetylation and its impact on dopaminergic neuronal survival remains to be established. Therefore in the present study we sought to investigate the link between PKCd dependent oxidative stress and histone hyperacetylation. Herein we show that exposure of N27 cells to TSA for varying time periods (3-12h) induced a time dependent increase in Bax activation, dissipation of MMP, caspase activation, NADPH oxidase activation, and GSH depletion. These changes preceded the drug induced apoptotic cell death. Intriguingly, a concomitant activation of PCK delta that paralleled histone hyperacetylation was evidenced in TSA treated cells. Moreover, TSA-induced increase in the expression of transcriptional regulators, such as p53, STAT1, and NF-kB, positively correlated with increased expression of pro-apoptotic factors. Notably, down regulation of PKCd levels via ectopic overexpression of a caspase cleavage mutant of PKCd (D327A) or small interference RNA-mediated gene silencing attenuated mitochondrial mediated oxidative cell signaling events, transcription factor activation, histone hyperacetylation, and apoptotic cell death. Collectively, these findings identify PKCδ as a key regulator of TSA-induced hyperacetylation of histones and suggest that oxidative stress mediated proteolytic activation of PKCd contributes to dopaminergic neuronal demise at least in part via deregulation of cellular epigenetic mechanisms (ES10586 and NS065167).

**928** Loss of NF-kB p50 Amplifies Microglia Priming in the Aged Brain

T. Taetzsch, S. Brookins, S. Levesque, C. McGraw and M. L. Block. Virginia Commonwealth University, Richmond, VA.

Excessive and chronic microglial activation has been implicated in degeneration of dopaminergic (DA) neurons in the substantia nigra (SN) during Parkinson’s disease (PD). Aging, a key risk factor for PD, is associated with enhanced sensitivity of microglia to pro-inflammatory stimuli, but the mechanisms are poorly understood. NF-kB p50 is a regulator of inflammation and NF-kB p50 expression is reduced in post mortem SN tissue of Lewy Body Dementia patients, supporting a role for loss of NF-kB p50 function in neurodegeneration. To examine the consequences of loss of NF-kB p50 function in microglial activation, 1.5-2.0 month old NF-kB p50⁻/⁻ and NF-kB p50⁺/+ mice were injected with LPS (5mg/kg, IP). Expression of the pro-inflammatory genes TNFα and IL-1β in the midbrain as well as serum TNFα levels were higher in LPS treated NF-kB p50⁻/⁻ mice at 3h post-injection. Kinetics studies demonstrated that TNFα and iNOS expression is increased at 6h and 12h, but not 3h post-LPS treatment in NF-kB p50⁻/⁻ mixed glia cultures, implicating NF-kB p50 in resolution of the glial pro-inflammatory response. Consistent with this premise, NF-kB p50⁻/⁻ cultures expressed lower levels of the M2 marker arginase-1 in response to LPS, indicating impairment of the resolution of iNOS activation. To examine how loss of NF-kB p50 function affects microglial activation in the aged brain, 1.5-3.0 and 16-18 month old male mice (NF-kB p50⁻/⁻ & NF-kB p50⁺/+ ) were injected with LPS IP. Aged LPS treated NF-kB p50⁻/⁻ mice had the highest levels of serum TNFα as well as midbrain TNFα and IL-1β expression at 3h. Furthermore, higher numbers of microglia with activated morphology were observed in the SN of aged LPS treated NF-kB p50⁻/⁻ mice. These results support that loss of NF-kB p50 function increases neuroinflammation and microglial activation, impairs pro-inflammatory resolution and that these effects are further magnified by aging.
929 Exploring Gene-Environment Interactions Implicated in Parkinson’s Disease Using a Paraoquat and Maneb Model in Drosophila
V. Nunez1, C. A. Martin2 and D. Krantz3. 1Society and Genetics, University of California, Los Angeles, Los Angeles, CA, 2Neuroscience, University of California, Los Angeles, Los Angeles, CA and 3Molecular Toxicology, University of California, Los Angeles, Los Angeles, CA.

Parkinson’s disease (PD) is a neurodegenerative disease characterized by the loss of dopaminergic neurons and a loss in both motor and non-motor functions. Overexpression and mutations of the alpha-synuclein gene in humans has been linked to familial forms of Parkinson’s disease. However, inheritable forms of PD are rare. The vast majority of PD cases are sporadic, thus, disease progression likely relies on an individual’s genetic background and/or environmental exposures. Exposure to environmental toxins, such as pesticides or heavy metals, has been shown to increase the risk of developing PD in humans. In particular, prolonged exposure to the pesticides paraoquat and mane has also been shown to increase the risk of PD up almost two fold. Interestingly, individuals with variants in the alpha-synuclein gene were shown to be at increased risk of PD, compared to control, when they were exposed to pesticides. The complex nature of gene-environment interactions in sporadic PD has made it difficult to understand disease etiology using traditional rodent models. Thus, our lab has developed a paraoquat and maneb model of PD in Drosophila melanogaster, which is amenable to multiple genetic modifications which can be easily combined with various environmental toxin exposures. In our model, survival and motor ability significantly decreased when exposed to paraoquat alone or with paraoquat and maneb combined. Dopaminergic cell counts decreased only when exposed to both paraoquat and maneb. Additionally, we assessed the dopaminergic cell counts, survival curves and climbing assay of our model in the presence of over-expression of human mutant alpha-synuclein. Thus our work confirms epidemiological data in addition to further exploring implicated gene-environment interactions.

930 The Parkinson’s Disease-Linked Pesticide Ziram Causes Deregelation of the Synapse
C. A. Martin1 and D. Krantz2. 1Molecular Toxicology, University of California, Los Angeles, Los Angeles, CA and 2Neuroscience, University of California, Los Angeles, Los Angeles, CA.

Exposures to environmental toxins, such as pesticides, have long been implicated in neurodegenerative diseases such as Parkinson’s disease (PD). Recent epidemiological studies demonstrate that chronic exposure to the pesticide ziram results in over a two-fold increase in the risk of contracting PD. PD is a devastating disease that affects millions of people worldwide. PD patients suffer from an irreversible and progressive loss of dopaminergic neurons that results in motor deficits as well as impairment of other non-motor functions regulated by dopamine such as mood, sleep, smell and digestion. The molecular and physiological changes in dopaminergic neurons that precede cell death and disease are unclear, particularly in the case of sporadic disease onset, which accounts for the vast majority of PD cases. Our aim was to investigate how exposure to the PD-linked pesticide ziram may alter neuron physiology and behavior. By using the well-characterized Drosophila neuromuscular junction (NMJ) preparation, we were able to assess for the first time ziram’s affect in an intact synapse. The large array of live-imaging genetic reagents available in the fly allowed for us to quantify ziram’s affect on the essential neuronal processes of synaptic vesicle release, reuptake and action potential dependent calcium influx. We report that ziram alters synaptic behavior at both excitatory, glutamatergic terminals and modulatory, aminergic terminals at the Drosophila NMJ. Interestingly, aminergic terminals are particularly sensitive to disruption by ziram exposure, resulting in a decrease in the rate of dendritic outgrowth. Additionally, we observe spontaneous depolarization of aminergic, but not glutamatergic, nerve terminals in the presence of ziram. We hypothesize that chronic exposure to ziram results in preferential deregelation of aminergic terminals and may be responsible for its link to PD in the human population.

931 Mitochondrial DNA Damage and Dysfunction and Their Effects on Dopaminergic Neurodegeneration after Chemical Insult in Caenorhabditis elegans
C. P. Gonzalez, I. T. Ryde and J. N. Meyer. Nichols School of the Environment, Duke University, Durham, NC.

Mitochondrial dysfunction has been linked to neurodegenerative diseases including Parkinson’s Disease (PD). Neurons are cells with a high energy demand, and as a result are hypothesized to be particularly vulnerable to mitochondrial dysregulation. We investigated dopaminergic neuron viability after chemical insult in Caenorhabditis elegans strains with gene knockouts of pink-1 and pdr-1, which are involved in mitochondrial dynamics. These genes are the nematode homologs of the human genes PINK1 and PARK2 which when mutated cause familial PD. The four cephalic dopaminergic neurons were visualized with fluorescent microscopy, and assigned a score based on the extent of damage observed. Each neuron was scored from 0 to 2, with zero representing an intact dendrite and 2 representing the highest level of neurodegeneration observed. The strain BY200 (dat-1;GFP) was used as wild type for the strains UA226 (dat-1;GFP; pink-1) and UA227 (dat-1;GFP; pdr-1), all generously provided by Guy Caldwell (University of Alabama). After 6-hydroxydopamine (6-OHDA) exposure, both mutant strains showed different levels of neurodegeneration compared to wild type, with the pink-1 mutant exhibiting less neuronal damage than wild type. We also performed quantitative polymerase chain reaction (QPCR) after 6-OHDA exposure and observed significant levels of DNA damage to both nuclear and mitochondrial genomes. This genotoxic effect of 6-OHDA could be in part responsible for the degeneration observed in dopaminergic neurons after exposure to this chemical. Previous results obtained in the laboratory indicate that knockdown of pink-1 inhibits removal of mitochondrial DNA (mtDNA) damage, presumably inducing mitochondrial fusion and functional complementation and potentially explaining the resistance to neurodegeneration observed in the pink-1 mutant. Further studies are being performed to fully characterize the fate of mtDNA damage induced by environmental toxicants and its effect on neuronal viability and mitochondrial health.

932 Identification of Novel Genes and Epigenetic Mechanisms in C. elegans Models of Idiopathic Parkinson’s Disease
W. Li, N. M. VanDuyn1, J. Trinidad2 and R. M. Nasj1. Pharmacology and Toxilogoy, Indiana University School of Medicine, Indianapolis, IN and 1Chemistry, Indiana University, Bloomington, IN.

Background: Idiopathic Parkinson’s disease’s (PD) is an oxidative stress-related disorder that result in abnormal dopamine (DA) signaling and cell death. Although the origin of the pathogenesis in PD remains unclear, costallatory evidence suggests both genetic and environmental contributions. Recently we have shown that the PD-associated transcription factor SKN-1/Nrf2 is expressed in C. elegans DA neurons and inhibits PD-associated DA neurodegeneration. Aims/Objectives: In this study we asked what are the genes, molecular pathways, and mechanism involved in DA neuron vulnerability to PD-associated toxicants. Methods: We utilized reverse genetics, biochemical assays, immunofluorescence, transgenic C. elegans, RT-PCR, Western analysis, mass spectrometry, and behavioral and neuronal morphology analysis to characterize expression, localization and the role that SKN-1, IDN-1, and post-translational modifications play in 6-OHDA-, rotenone-induced neuronal death. Results: In this study we demonstrate that IDN-1 mutants render DA neuron up to 10-fold more resistant to the neurotoxics relative to WT. We show that IDN-1 is expressed in DA neurons, and IDN-1 overexpression results in a 2-fold increase DA neuron vulnerability. We also show that DA neuron vulnerability is affected by transcriptional and post-translational modifications of involving these and other proteins identified using RNAi affects DA neuron vulnerability. Conclusions: This study identifies novel genes and molecular pathways involved in DA neuron vulnerability in PD, and shows that common epigenetic mechanism modulate DA neuron vulnerability to PD-associated neurotoxicants. Support: NIEHS ES014459 and ES003299 to RN, and EPA STAR Graduate Fellowship to NVD.

933 LRRK2 Transgenic Rats Exhibit Heightened Sensitivity in a Colitis Model
J. Leg1, J. Park2, C. H. Kim2 and L. Cannon2. 1School of Health Sciences, Purdue University, West Lafayette, IN and 2Comparative Pathobiology, Purdue University, West Lafayette, IN.

Accumulating evidence suggests that chronic systemic inflammation is associated with the pathophysiology of Parkinson’s disease (PD). Leucine-rich repeat kinase 2 (LRRK2) has been identified as the gene most frequently mutated in autosomal dominant familial PD. LRRK2 is also a major susceptibility gene for inflammatory bowel disease (IBD) and has an immunoregulatory function. Pathological functions of LRRK2 in both IBD and PD are not well understood. The goal of this project was to examine how potential interactions between IBD and PD models might be mediated by LRRK2. In a preliminary study, BAC transgenic (TG) rats expressing human G2019S mutated LRRK2 or wild-type (WT), littermate controls were exposed to daily dextran sodium sulfate (DSS), 2.5-5% W/V in drinking water) over 21 days to induce experimental colitis. Rats were scored using the total daily activity index (DAI), including body weight loss, stool score and fecal occult blood test, was quantified. At day 21, after euthanizing the brains were removed and processed for neurotransmitter analysis and histology. Also, the blood and gastrointestinal tract were collected for immunological determination. DSS-treated LRRK2
Parkinson’s disease (PD) is a progressive motor disease of unknown etiology. The motor impairments of PD arise from selective degeneration of dopaminergic (DA) neurons in the substantia nigra pars compacta (SNc). These DA neurons project to the striatum (CPu) to release dopamine. Clinical symptoms of Parkinsonism emerge when more than half of the dopaminergic nerve terminals are damaged in the striatum. In the current therapeutic in vivo mouse model study, we used TUDCA as a neuroprotectant and L-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) as neurotoxicant. TUDCA is a molecular chaperone which modulates cell death by interrupting classic pathways of apoptosis, modifying the expression of certain Bcl-2 family members, as well as NF-kB activity. In the present study mice were divided into three groups (Saline/Probencid [250mg/kg, control], MPTP [25mg/kg-10 doses+Probencid, positive control] and TUDCA+MPTP [200mg/kg+25mg/kg, treatment group]). Using immunohistochemical and analytical chemistry techniques, we showed that the SNc and CPu are significantly protected from MPTP induced damage after TUDCA treatment compared to MPTP + Probencid group. Tyrosine hydroxylase and dopamine transporter immunoreactivity in the ventral midbrain SNc and striatum are more protected from MPTP damage in TUDCA treated mice compared to its positive controls. Microglial activation, depletion of striatal fibers and dopamine and the development of motor deficits are significantly less in TUDCA treated group. Together, our results suggest that new mechanisms may be involved in the pathogenesis of PD and that might be exploited in the development of novel therapeutics aimed at slowing or halting neurodegeneration in patients with PD.

G2019S transgenic rats (DSS-TG) showed significantly increased DAi compared to DSS-treated wild type (DSS WT) or untreated rats (control). Surprisingly, neurotransmitter analysis showed that WT animals exhibited decreased striatal dopamine and DOPAC in response to DSS, with TG animals showing no such response. Serotoninergic neurotransmission was not affected. Further, immunohistochemistry data suggest that DSS-WT animals also exhibit decreases in striatal tyrosine hydroxylase levels, in the absence of overt dopaminergic terminal loss. Here again, TG animals did not exhibit such a response. In summary, rats expressing G2019S LRRK2 exhibited heightened clinical sensitivity in a colitis model and did not exhibit adaptive changes in nigrostriatal dopamine transmission observed in WT animals treated with DSS. More studies are needed to confirm these initial observations.

Ceftriaxone Ameliorates L-DOPA-Induced Dyskinesia, a Side Effect of Parkinson’s Disease Treatment

T. Chotibut, V. Fields and M. F. Salvatore. Pharm., Tox. & Neuroscience, LSUHSC, Shreveport, LA.

Parkinson’s disease (PD) is a neurodegenerative disease characterized by motor impairment arising from the loss of dopaminergic neurons. Currently, pharmacological dopamine (DA) replacement with L-DOPA is the gold-standard treatment for PD. Unfortunately, chronic L-DOPA therapy induces abnormal involuntary movements termed L-DOPA-Induced-Dyskinesia (LID) in over 90% of PD patients over time. Furthermore, once dyskinesia manifests, it occurs with every subsequent exposure to L-DOPA. The prevalence and permanence of LID makes L-DOPA’s side effect profile a highly relevant clinical obstacle especially given the primary role L-DOPA plays in PD treatment. Glutamate mediates excitatory signal transduction and in excess (excitotoxicity), can contribute to loss of DA neurons in PD. Thus, suppression of glutamate-mediated excitotoxicity could prolong the longevity of nigrostriatal neurons in PD progression. The beta-lactam antibiotic, Ceftriaxone (cef), increases the expression of GLT-1, a glutamate transporter responsible for glutamate clearance in the CNS. We examined whether Cef could ameliorate dyskinesia when given 7 days post lesion in a 6-OHDA LID model. Chronic Cef (200mg/kg ip) significantly delayed and attenuated dyskinesia in 6-8 month male Sprague Dawley rats compared to saline. Striatal GLT-1 expression was also increased in both Cef and Cef + L-DOPA treated rats compared to L-DOPA suggesting a cef-induced increase in synaptic glutamate clearance.

Tyrosine hydroxylase (TH), a marker for DA, was measured in the lesioned striatum. Compared to its contralateral control, Cef treated rats had the highest remaining striatal TH with 81%, L-DOPA + Cef had 55%, and L-DOPA had 18%. Our data suggest that chronic Cef + L-DOPA may not only halt TH destruction, but also potentially reverse striatal TH loss in a 6-OHDA LID model. Given that Cef is already FDA-approved, these data support the repositioning of the antibiotic based on its ability to not only mitigate dyskinesia severity, but also protect against further DA loss in a Parkinson’s disease rodent model.

Quercetin Treatment Protects Progressive Nigral Dopaminergic Neuronal Degeneration in Cell Culture and MitoPark Animal Models of Parkinson’s Disease by Activating PKD1 Signaling

Mitochondrial dysfunction has been implicated as a key player in the pathogenesis of Parkinson’s disease (PD). The MitoPark mouse, a transgenic mitochondrial impairment model recently developed by specific inactivation of Tfam in dopaminergic neurons, spontaneously exhibits progressive behavioral deficits and neurodegeneration, recapitulating several features of PD. Since non-motor symptoms are now recognized as key features of the pre-symptomatic stage of PD, we monitored the clinically relevant motor and non-motor symptoms of PD from 8-24 wks of age in MitoPark and C57 wild type mice. As expected for MitoPark mice, motor defects begin around 12 weeks and become severe by 18-24 wks. Interestingly, nortok MitoPark mice showed memory deficits before female mice, beginning at 8 wks and becoming most severe between 20-24 wks, as determined by Morris Water Maze. When compared to age-matched naïve C57 black mice, MitoPark mice exhibited olfactory deficits in novel and social scent tests as early as 12 wks. MitoPark mice between 16-24 wks spent more time immobile in forced swim and tail suspension tests, and made fewer entries into open arms of the Elevated Plus Maze, indicating a depressive- and anxiety-related phenotype, respectively. Preliminary analyses revealed that sleep disturbances and gastrointestinal problems may also be present in MitoPark mice. Collectively, our results indicate that MitoPark mice progressively exhibit deficits in cognitive learning and memory, olfactory discrimination, sleep latency, and anxiety- and depressive-like behaviors. Thus, MitoPark mice can serve as an invaluable model for studying motor and non-motor symptoms in addition to studying pathology in PD (supported by NIH grants ES10586 and NS074443 and NS039958).

Oxidative stress has been associated with many neurological diseases including Parkinson’s disease (PD). Therefore, identifying cell signaling mechanisms associated with oxidative stress is critically important to the development of new treatment strategies for PD. We have recently identified a novel oxidative stress-associated signaling pathway in which protein kinase D1 (PKD1) plays a major compensatory survival role in dopaminergic neurons. Therefore, we adopted a rationale based pharmacological screening approach to identify activators of PKD1 using dopaminergic neuronal cell model. Herein, we identified quercetin, a natural flavonoid widely found in vegetables and fruits as effectively activate PKD1 protective signaling. Western blotting analysis revealed that quercetin treatment significantly induced the phosphorylation and activation of PKD1 as well as CREB and Akt phosphorylations in MN9D dopaminergic neuronal cells. Activation of Akt, however, was inhibited by siRNA knockdown of PKD1, suggesting that Akt acts as a downstream target of PKD1 signaling during quercetin treatment. Results from qRT-PCR, Western blot analysis, mtDNA content analysis, and Mitotracker assay experiments revealed that quercetin can induce mitochondrial biogenesis in MN9D cells. Importantly, quercetin treatment protected against 6-OHDA-induced neurotoxicity in MN9D cells. Next, we evaluated the neuroprotective efficacy of quercetin against the progressive neurodegenerative process by using MitoPark mouse model of PD. Administering quercetin (25 mg/kg) once daily to 12-week-old MitoPark mice via oral gavage for 6 weeks significantly reversed behavioral deficits, striatal dopamine depletion, and TH neuronal cell loss in MitoPark mice. Our findings suggest that quercetin, by virtue of its ability to activate the PKD1-mediated neuroprotective signaling, is a promising neuroprotective drug candidate for the treatment of PD (NIH NS74443).
methylation as a result of Pb exposure with levels of SAM and the enzymes involved (SAM) and its role in epigenetic reprogramming. We compare changes in histone methylation, and on the methyl donor S-adenosylmethionine (Alashwal et al., 2012, Dosunmu and Zawia, 2013). It is also known that epigenetic alterations in the expression of genes associated with Alzheimer's disease (Wu et al., 2008; Hui et al., 2012; Syed and Zawia, 2013). Accumulation of Aβ-β amyloid plaques in the neurpathological hallmark of Alzheimer’s disease (AD) that is primarily genetic in nature, or late onset Alzheimer’s disease (LOAD) which is sporadic and affects 90% of those diagnosed with AD. Epidemiological data seem to suggest that both LOAD and late-onset dementia have early origins. Previous work in our lab has shown that early life exposure to Pb results in higher BPb levels for Taq1_T and Apa1_C (p<0.06), whereas Bsm1_C allele in Caucasians (p=0.009) was associated with higher BPb. NAb had a high prevalence in HD (>50%), anti-NF-L, GFAP and MBP the most prevalent. Based on genotype stratifications, Bsm1_C (1) and Taq1_C (1) (homozygotes and heterozygotes) had higher levels of anti-NF-L, NF-H and GFAP (p=0.01-0.05). Bsm1_C genotype, only, was associated with a nearly two-fold increase in the odds of anti-NF-M presence (p=0.02), the NAb best correlated (r=0.24, p=0.008) with Pb, although BPb did increase the odds of anti-MBP detection (OR: 1.13, CI: 1.034-1.232, p=0.003). Overall, multivariate regression revealed that Pb was a significant determinant of anti-NF-M, GFAP and MBP titers (p=0.04, 0.03, 0.005, respectively). Although vitamin D is neuroprotective, VDR SNPs have been associated with ND. In addition, VDR SNP, particularly the major Bsm1_C allele, as well as Taq1_T, alleles have been shown to promote Pb accumulation, an observation confirmed here. Taken together, this study indicates that NAb may be useful for detection of ND in environmentally and genetically vulnerable populations and suggests that heavy metals, like Pb, may contribute to ND in HD patients.

Alzheimer’s disease (AD) is a neurodegenerative disorder and is the most common type of dementia, and is the sixth leading cause of death in the United States. It presents as two forms, either early onset Alzheimer’s disease (EOAD) that is primarily genetic in nature, or late onset Alzheimer’s disease (LOAD) which is sporadic and affects 90% of those diagnosed with AD. Alzheimer’s disease (AD) is one of the most common neurodegenerative disorders. Accumulation of Aβ-containing amyloid plaque is a neuropathological hallmark of Alzheimer’s disease (AD) but inflammatory process triggered by Aβ deposition and microglia activation is significantly related to the pathogenesis of AD. Studies on brain tissues of the patients with AD show the elevated levels of pro-inflammatory cytokines such as IL-1β, IL-6, and TNF-α. Our research studies have shown the therapeutic potential of curcumin in neurodegenerative diseases including AD through its antioxidant, anti-inflammatory and anti-β protein aggregation effects. However, the effect of curcumin on microglia functions and its underlying mechanism is not elucidated yet. The aim of this study was to investigate the anti-inflammatory properties of curcumin on LPS-stimulated microglia cells and its effect on microglia’s functions. We previously demonstrated inhibition of a High Mobility Group Box 1 (HMGB1) in LPS-stimulated microglia BV2 cells improves the phagocytosis ability in these cells. Our current study demonstrated that pre-treatment with 5μM curcumin suppresses LPS-induced proliferation and HMGB1 overexpression in BV2 cells that corresponds with markedly decreased the expressions of Toll like receptor 4 (TLR4). Moreover, administration of curcumin significantly improved the LPS-induced phagocytic impairment in BV2 cells. The present results propose curcumin, which inhibits HMGB1/TLR4 in microglia cells may offer a novel and probable benefit against AD-associated neuro-inflammation.
ubiquitination, nucleotide- and metal ion-binding. A profile of gene expression related to EAE and aging was exhibited, suggesting that monitoring of these genes may be a main subject of possible targets for treatment of the disease.

942a Toxicology of Targeted Drug Delivery to the Midbrain for Parkinson’s Disease Treatment
R. Grondin1, Y. Ai1, P. A. Hardy1, M. T. Butt2, G. A. Gerhardt1, D. M. Gash1, D. A. Burncrot3 and Z. Zhang1. 1Anatomy & Neurobiology, University of Kentucky, Lexington, KY, 2Tox Path Specialists, LLC, Frederick, MD and 3David H. Koch Institute, Cambridge, MA. Sponsor: M. Voce.

Direct drug administration into the brain parenchyma offers a high degree of targeting, while reducing the risks of unwanted side-effects by limiting systemic exposure. Drug delivery to the midbrain region remains a challenge. Here, we used an investigational catheter and cranial anchor system coupled to implanted programmable pumps to continuously infuse 5mM gadopentetate dimeglumine (Magnevist®) into the substantia nigra (SN) of female rhesus monkeys to lay the foundation for delivering drug therapies to the midbrain region. Flow rate tolerability of either 0.1 μL/min to the right SN for 14 days or 0.2 μL/min to the left SN for 14 days was assessed by monitoring clinical observations, body weights and histopathological examinations of the striatum and midbrain regions. Evaluation of post-surgical MRI indicated that the placement of each intranigral catheter was within a 2-mm radius from the intended surgical target and that all catheters were patent, as evidenced by the presence of Magnevist® at the catheter tip. The volume of distribution achieved in the midbrain region with Magnevist® infused at a rate of 0.2 μL/min was greater than that achieved at 0.1 μL/min by nearly 2-fold. There were no indications of toxicity as noted in clinical observations and body weight values. Histopathological evaluations indicated that the catheter tip was placed in or near the SN pars compacta region in all animals. There was no evidence of infection at any of the catheter sites and no difference between the two infusion rates with respect to changes indicating inflammation. There was no discernible difference regarding the microglial reaction at the two different infusion rate sites. There was no detectable decrease of tyrosine hydroxylase staining in the striatum in any of the sections and no detectable necrosis of neurons in the SN pars compacta region. Our data support that direct drug delivery to the midbrain maybe used for the treatment of Parkinson’s disease.

942b Studying Aspects of Parkinson’s Disease in a Zebrafish Model of Ziram Toxicity
A. Lulla1,2, L. Barnhill1,2, M. Stahl1, A. G. Fitzmaurice1,2, S. Li1 and J. Bronstein1,2. 1Molecular Toxicology, UCLA, Los Angeles, CA and 2Neurology, UCLA, Los Angeles, CA.

Parkinson’s disease (PD) is the second most common neurodegenerative disease. Genetic causes of PD account for 5% of cases suggesting that the environment has a role in disease etiology. Epidemiological studies indicate that exposure to pesticides increases the risk for PD. We previously found that exposure to ziram increases the risk of developing PD in humans and causes selective dopaminergic cell toxicity, inhibition of the ubiquitin proteasome system (UPS), and increased γ-synuclein levels in primary neuronal cultures. Here we utilize zebrafish embryos (ZF, Danio rerio) to investigate the mechanisms of ziram’s toxicity. ZF embryos were exposed to ziram at an environmentally relevant concentration (50μM), A transgenic ZF line expressing green fluorescent protein driven by vesicular monoamine transporter protein 2 (VMAT2) promoter was used to study the effects of ziram on amineergic neurons. Embryos treated with 50μM ziram were found to have a reduction of VMAT-GFP expressing neurons by approximately 30%. Ziram was not toxic to non-DA sensory neurons. Additionally, exposure to ziram resulted in a 1.58% increase in expression of TH. The closest ZF homologue to human α-syn is ZF γ-syn (synz), which was found to aggregate when overexpressed in ZF. Treatment with 50μM ziram resulted in an increase in synz expression as measured by western blot. Knockdown of synz via antisense was found to protect against ziram’s dopaminergic cell toxicity, resulting in approximately 75% attenuation of VMAT-GFP expressing neuronal death. The mechanism by which ziram increases ZF γ-syn appears to involve inhibition of protein degradation pathways, as concentrations as low as 1μM ziram inhibited the UPS. In a preliminary experiment a 6 fold increase in fluorescence of LC3, a marker of autophagy was observed for embryos treated with ziram. These studies demonstrate that ziram toxicity is at least partially mediated by synuclein and add to the understanding the etiology PD.

942c In-Depth Toxicogenomic Analysis of a Dopamine Transporter Knockout Animal: Transporter-Associated Behavioral and Signaling Changes in a C. elegans Parkinson’s Disease Model
B. M. Ness1, N. VanDyke1, J. Duet4, J. Trinidade1, W. Li1 and G. Wong1. 1Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN, 2Chemistry, Indiana University, Bloomington, IN, 3Bionics, Kuopio University, Kuopio, Finland and 4Biological Sciences, Ohio University, Athens, OH.

Background: The loss of DA from basal ganglia results in the devastating neurological disorder Parkinson’s disease (PD). DA transporters (DAT) regulate synaptic DA availability and play a role in neuronal vulnerability, yet the molecular modulators associated with DAT are poorly defined. Aims/Objectives: In this study we determined which genes are involved in DAT-associated gene expression and neuronal vulnerability. Methods: We utilized RNA-seq, microarrays, behavioral and biochemical assays, immunofluorescence, transgenic C. elegans, RT-PCR, LC-MS, HPLC, Western analysis, and neuronal morphology analysis to characterize DAT-associated gene and protein expression, post-translational modifications, and toxicant-associated DA neuron vulnerability. Results: Approximately 20,000 genes were analyzed. Over 54 genes were overexpressed in the DAT knockout strain and 33 genes were under expressed. These genes were strongly biased to water homemostasis, cation transport, and G-protein mediated signalling. Specifically, tyrosine hydroxylase (TH), the rate limiting step for DA synthesis, as well as DA is significantly reduced (approximately 50%) as determined by RNAseq, immunofluorescence, Western analysis, and HPLC. DAT knockout animals also displayed mechano-sensory-associated movement defects. Furthermore, 6-OHDA treated DAT knockout animals showed a dramatic change in gene expression (44 genes enriched in oxidative phosphorylation, eycotysis, and GTPase function) relative to WT suggesting novel pathways involved in 6-OHDA mediated toxicity independent of DAT. Conclusion: This study describes a novel whole genome analysis of the role that the DAT and associated genes and signalling pathways play in DA neuron vulnerability that may provide useful therapeutic targets to inhibit PD-associated cellular pathologies.

942d Altered Expression of Amyloid Beta (Aβ) Deposit-Related Molecules in the Aging Brain
D. Kim, J. Park and B. Choi. Preventive Medicine, Chung-Ang University, Seoul, Republic of Korea.

Alzheimer’s disease (AD) is most common form of dementia characterized by the presence of Aβ plaque and neurofibrillary tangles. Aging is the main risk factor for AD. However, the underlying mechanisms are not completely understood. We focused the alteration of the expression related to Aβ production, degradation and transport in the different age rats. We used Sprague-Dawley male rats at ages 7, 26, 52, 96 weeks. We analyzed the protein expression of amyloid precursor protein (APP), beta-site APP-cleaving enzyme 1 (BACE1), neprilysin (NEP), and insulin degrading enzyme (IDE) in the hippocampus and low-density lipoprotein receptor-related protein 1 (LRP1) and receptor for advanced glycation end products (RAGE) in the brain capillary endothelium (BCE) using Western blot. The LRP1 expression in BCE of 96-week rats were lower than 26- and 52-week rats, however higher than 7-week rats. The RAGE expression in BCE was positively associated with age. However, other molecules, such as APP, BACE1, NEP and IDE in HC did not change according to aging. These results imply that age is related with reduction of Aβ transportation. It might lead to accumulation of Aβ in brain extracellular space.

942e Changes of Tight Junctions in the Blood-Brain Barrier Are Mediated by α2B5-35-RAGE Interaction
E. Cuevas1, H. Rojas-Hernandez2, S. Lantz-McPeak1, M. G. Paule1, O. Gu3, C. Gonzalez1, S. Z. Imam1, J. Kanungo1 and S. E. Al1. 1Division of Neurotoxicology, NCTR, Jefferson, AR and 2Laboratorio de Fisiología Celular, Universidad Autonoma de San Luis Potosi, San Luis Potosi, SLP, Mexico.

Recently, we demonstrated that microinjection of α2B5-35 into the rat hippocampus produces neurotoxicity mediated by advanced glycation end products (RAGE). It has been demonstrated that RAGE interact with amyloid β-peptide (Aβ) and mediate Aβ transport across the blood-brain barrier (BBB), contributing to the deposition of Aβ in the brain. However, molecular mechanisms underlying Aβ-RAGE interaction-induced alterations in the BBB are poorly understood. In order to determine whether the toxicity induced by α2B5-35-RAGE interaction is involved in tight junction disruption at the blood-brain barrier (BBB), a primary culture of rat brain microvessel endothelial cells (rBMVEC) were created by enzy-
matic digestion and differential centrifugation as an in vitro model of the BBB. Confluent mVEC monolayers (cultured 10-14 days) were treated with AJ25-35 or AJ35-25 (as control) at 20 μM for 24 hours. RAGE, occludin, and claudin-5 expression were measured by Western blotting. Cytotoxicity was evaluated using a lactate dehydrogenase (LDH) assay for cell death, an XTT (2,3-bis(2-methoxy-4-nitro-5-sulfophenyl)-2H-tetrazolium-5-carboxanilide) assay for mitochondrial function, and detection of 2’, 7’-dichlorofluorescin diacetate (DCFH-DA) to measure ROS production. AJ25-35 produced an increase in RAGE and occludin; and a decrease in claudin-5 expression. Significantly decreased mitochondrial function and increased oxidative stress (ROS production) with no effect on LDH leakage were also observed. These data suggest that AJ25-35-RAGE interaction induced toxicity involved increased occludin and decreased claudin-5 expression. Further studies are underway to determine if these events are associated with disruption in the permeability of the BBB.

**Evaluation of an In Vitro Assay for the Detection of Skin Irritants in Medical Devices**

C. Nyce and A. Y. Sawyer. Corporate Preclinical Development and Toxicology, BD, Research Triangle Park, NC.

The objective of this work is to identify alternative in-vitro methods to screen medical device materials for the presence of skin irritants. Current testing for the presence of skin irritants is done exclusively using a rabbit animal model. Medical device extracts or materials are exposed to the skin of the animal. The material is removed and the affected skin area is observed daily for 3 days and evaluated for erythema and edema. Efforts seeking to improve upon this model by eliminating or reducing the number of animals used in such testing while maintaining or improving sensitivity in identifying such irritants is a focus of ISO TC/219 a standards organization for the Biological Evaluation of Medical Devices. A cultured human skin tissue model, EpiDerm, (Mattek Corporation) allows the direct exposure of test materials to the cultured skin. This model recently demonstrated acceptable performance as a part of the ECVM international validation study for the in vitro identification of chemical irritants. This cultured human skin model is now being evaluated for its ability to identify irritants present in extracts of medical materials and devices. Medical device and device materials present unique problems as the irritants exist within a solid material and are generally present in low levels. We adapted the model protocol and evaluated multiple materials for their irritancy po-

tential. Essentially, the cultured skin tissue was exposed to solvent material extracts for 24 hours. The extract was removed and the skin tissue was allowed to recover for 24 hours. MTT uptake was used to determine irritancy potential (cell cytotoxicity); 50% of control. In addition, IL-1α production was determined via ELISA, to detect increased expression as compared to controls. We have identified 2 materials, when extracted in non-polar solvents, Buna O-rings and Vicryl, that demonstrate an irritancy potential with elevated (≥ 1.5 fold) IL-1α production. This is the first successful demonstration of the use of this in vitro methodology for the identification of irritants in device materials.

**In Vitro Skin Irritation Testing: Characterization of Mid-Range Tissue Viability**

B. Lundell1, C. Dingee1, Y. Huang2, J. Li2 and D. M. Colleluori2. 1AppTec, St. Paul, MN and 2WuXi AppTec, Philadelphia, PA. Sponsor: R. White.

Introduction

In vitro skin irritation testing is gaining acceptance to replace animal testing. Poor-intra assay reproducibility for chemicals with viabilities in the mid-range can potentially hamper classification near the prediction threshold of 50%. This in vitro study characterized a test article having poor-intra-assay reproducibility in the 30-70% range.

Materials and Methods

Based on testing of medical device extracts, triplicate wells of EpiDerm™ were exposed to 100 μl of test material for 24 hours. After washing, wells were processed for histology or tissue viability. Test materials were Dulbecco’s phosphate buffered saline (DPBS, negative control), 0.125% sodium lauryl sulfate (SLS) in DPBS (positive control), 5.25% lactate acid (LA) in DPBS and 5.0% LA in DPBS. After exposure, culture medium was harvested for analyses of human Interleukin 1 alpha (IL-1α), Interleukin 1 Receptor Antagonist (IL-1RA), Interleukin 8 (IL-8) and Leukemia Inhibitory Factor (LIF) using Quantikine® ELISA kits. Data were shown as mean ± SD. Values were compared to the negative control using student’s t test. A (p) value of less than 0.05 was considered statistically significant.

Results

The controls gave expected viabilities, 100 ± 4.9% and 18.3 ± 2.3%. Exposure to 3.25% LA decreased viability to the mid-range and demonstrated poor reproducibility (mean 47.7 ± 30.7%). Exposure to 5.0% LA consistently decreased viability to the low range (mean 8.2 ± 0.9%).

The levels of IL-8, IL-1α and IL-1α were significantly increased and LIF levels were below the limit of detection for all treatments. Poor-intra-assay reproducibility with 3.25% LA was confirmed for viability, IL-1α, and histology. Of the biomarkers evaluated, IL-1α was more sensitive to the treatment of SLS than LA.

Conclusions

Poor-intra assay variability associated with in vitro skin irritation testing is a true chemical response, not technical artifact. Establishing threshold levels for proinflammatory biomarkers may aid in classification of chemicals with viabilities near the prediction threshold of 50%.

**Does Leaching of Bisphenol A (BPA) from Dental Composites Contribute to Neuropsychological Deficits in Children? An Evaluation of Plausibility**

J. E. Reynolds1, L. H. Moilanen1, E. Hope1 and J. K. Dalman2. 1Medical Department, 3M Company, St. Paul, MN and 23M ESPE, 3M Company, St. Paul, MN.

Composite dental restorations are placed in more than 10 million U.S. children each year with significant benefits for oral health. Two recent publications have suggested that BPA leached from dental composites contributes to neuropsychological deficits based on a review of the methodology used in the studies, as well as review of published literature describing dental composite composition, evidence for BPA release from dental composites, and known toxicokinetic and toxicological properties of BPA. Possible misclassification of subjects, confounding, and lack of statistical robustness weaken the strength of the study conclusions. Published data indicate that BPA exposure from dental materials occurs primarily from trace amounts of residual BPA in composite monomers synthesized from BPA. Exposure might also occur by enzymatic degradation of certain dental monomers by esterases. Measured dental-related BPA exposures are small (ng/kg-day) and of acute duration. Bioavailable BPA from dental composites is likely rapidly metabolized and excreted, minimizing exposure. At present, a specific mechanism to explain the putative neuropsychological effects of trace levels of BPA has not been articulated. Based on the weight of the examined evidence, the plausibility of neuropsychological deficits in children caused by BPA release from dental composites is low.

**Potential Confounders of Bisphenol A Analysis in Dental/Orthodontic Materials**

E. Hope1, D. R. Reed2 and L. H. Moilanen1. 1Medical Department, 3M, Saint Paul, MN and 2Corporate Research and Development Analytical Chemistry Laboratory, 3M, Saint Paul, MN.

Bisphenol-A (BPA)-based dental/orthodontic ingredients such as Bisphenol-A diglycidyl ether dimethacrylate (Bis-GMA) may contain trace levels of BPA as a chemical synthesis residue. Accurate determination of BPA in final product formulations is essential for reliable health risk assessments. A cured Bis-GMA-based material representative of commercial dental products was extracted according to international guidelines for medical devices. The extraction solvent was spiked with d16BPA as an internal standard. Sample processing followed expert recommendations for minimizing BPA sample contamination. Extracts were analyzed for BPA using high performance liquid chromatography (HPLC) with either ultraviolet (UV) or Multiple Reaction Monitoring (MRM) detection. The BPA concentrations appeared about 30-fold higher using HPLC-UV vs. HPLC-MRM. Full scan liquid chromatography/mass spectrometry (HPLC/MS) was used to elucidate the different results, and showed a compound co-eluting with BPA which interfered with LC/UV analysis. The co-eluting compound derived from ethyl-4-dimethyl aminobenzoate, a co-initiator used by many dental product manufacturers. These results highlight the potential difficulties in accurate analysis of BPA in complex mixtures such as dental product extracts. Both good separation methodology and a detection method with high specificity and sensitivity are important to avoid incorrect assignment of extractables, and consequent inaccurate quantification of BPA.
New Multipoire Contact Lens Solution (MPS) formulations are required to demonstrate disinfection efficacy, stability, biocompatibility, preclinical and clinical safety in accordance with recognized national and international standards. Specific in vitro tests include medium elution, agar overlay, neutral red uptake for cytotoxicity, colony formation for proliferation, and MTX/TXT assays for metabolic activity. Different parameters used in testing, such as cell line sensitivity, detection response to toxicants, exposure time, and MPS dilution, can lead to contradictory results between various in vitro studies and suggest a lack of correlation to clinical results. This study evaluates the correlation among in vitro models for assessing cytotoxicity and biocompatibility of MPS containing contaminant polyhexamethylene biguanide (PHMB). The biological effects of MPS were evaluated following USP Direct Contact test and Colony Formation Assay (ISO 10993-5) in mouse (L-929) and hamster (V79) fibroblast, respectively, and Cell Viability Assay by alamarBlue in human corneal epithelial cells (HCEC). The dose-dependent effects and uptake-release kinetics of PHMB by contact lens materials were evaluated. Results of the USP Direct Contact test indicated that MPS-induced cytotoxicity are dependent upon the lens PHMB uptake and release profiles. MPS cytotoxicity effects on V79 fibroblasts demonstrated a concentration-dependent response, where cytotoxicity increased with MPS concentrations (1.25%, 2.5%, 5%, and 10%) after long-term exposure (7 days) while MPS concentrations at 100%, 75%, and 50% in HCEC showed a shorter time exposure dependency (15-60 minute) when evaluated at alamarBlue Cell Viability Assay. These results indicate that correlations between preservative concentration-response curves and lens uptake-release profiles should be considered as part of the battery of tests to demonstrate MPS biocompatibility.

The use of printing inks in cardiac leads was evaluated following the 2013 FDA draft guidance on the "Use of International Standard ISO 10993, "Biological Evaluation of Medical Devices - Part 1: Evaluation and Testing". Cardiac leads are used for defibrillation and resynchronization therapies in heart failure patients. Cardiac leads are contacting parts (i.e., tubes) were 70.39cm² (12.8mg) and 20.06 cm² (8.4mg) to the presence of cobalt. Safety concern over C.I. Pigment Blue 28 was due to the particle count and size. An average of 5,019 particles <788 m, with a maximum of 8,350 particles <788 m, that determines particulate count and size. An average of 5,019 particles <788 m, with a maximum of 8,350 particles <788 m, was calculated to be less than 0.8 mg/day. Therefore, chemical safety risk of the extractable amount of cobalt above the method detection limit (MDL) of 0.8 μg/L (ppb) for cobalt, which corresponds to a MDL of 0.3μg C.I. Pigment Blue 28. From this analytical data, the worst case total exposure was calculated to be less than 0.8 μg of C.I. Pigment Blue 28 per device, which was at least 112 times less than the threshold of toxicological concern (TTC) value of 90μg/day. Therefore, chemical safety of the extractable amount of C.I. Pigment Blue 28 from OptiCross under exaggerated conditions is assessed to be acceptable.
for limited-duration, blood-contacting devices (75,000 particles ≥10μm). Because the device category is limited duration and breached or compromised surface contact per ISO 10993-1, the size and number particles present on the device are acceptable and did not adversely impact the test results of the sensitization and intracutaneous reactivity biocompatibility tests.

**952 High-Density Polyethylene Controls in Toxicological Implant Studies**

J. Trausch and R. D. White, WuXi AppTec, St. Paul, MN.

Implant toxicity studies for medical devices require controls that are similar in size, shape, and configuration to the test article. USP High Density Polyethylene (HDPE) is commonly used as a reference material (negative control) for implant studies when a predicate device control is not available, or not feasible for the study design. HDPE controls are matched as closely as possible to test articles by size, shape, and surface area. However, limitations in commercially available USP HDPE often preclude a close geometrical match to a test article, leading to concerns regarding the use of controls and test articles of unmatched dimensions and surface areas in medical device implant toxicity studies. A recent 13 week implantation toxicity study in rabbits compared the clinical pathology and histopathology of animals implanted with a test article to animals implanted with HDPE of two different dimensions and surface areas. Bilateral intramuscular implants were made in 24 animals. Eight test group animals were implanted with bar-shaped stainless steel /nitinol implants approximately 1 x 0.1 x 0.1 cm in size and a surface area of 0.4 cm². One group of eight control animals were implanted with USP HDPE of the same dimensions and surface area as the test article, and a second group of eight control animals were implanted with USP HDPE of a flat rectangular shape, 1 x 1.25 x 0.1 cm in size with a surface area of 3.0 cm². All animals were terminated after thirteen weeks. Gross necropsy, hematology, clinical chemistry, and histopathology of local and systemic tissues were evaluated and compared for each of the three groups. No significant differences were seen in clinical pathology parameters or local and systemic tissue reactions between the two control groups, or between the test group and either control group. Based on these results, using HDPE negative controls unmatched in size, shape and surface area to the test article does not significantly affect the clinical pathology or histopathology evaluation of subchronic intramuscular implantation toxicity studies in rabbits.

**953 Infusion Pump Accuracy Assessment: Weighing Syringes and IV Bags Not Necessary As Secondary Accuracy Check on Infusion Studies**

L. Hudgens, J. K. Herman, K. Rasmussen, N. West and A. N. Alexander, Nonclinical Safety Assessment, Covance Laboratories Inc, Madison, WI.

It is common in some academic and preclinical safety assessment labs to weigh syringes and intravenous (IV) dosing bags pre and post dose administration to confirm dose delivery on infusion studies as a secondary accuracy check. This practice is very laborious, especially for preclinical studies using hundreds of animals, and difficult to document to GLP standards. We chose to assess the accuracy of several commercially available syringe and peristaltic infusion pumps to determine if weighing syringes and IV bags was necessary to confirm dose delivery. Surgically catheterized dogs and rats were infused using a tethered infusion apparatus and external peristaltic or syringe infusion pumps for three dosing cycles at various dose rates to mimic typical preclinical intermittent safety assessment infusion studies. Syringes and IV bags were weighed pre- and post-dose administration and dose volume delivered computed by subtracting the two values and employing a density correction for saline. The calculated dose volume was compared to the dose delivery volume listed on the infusion pump display screen. Percent of theoretical volume delivered was calculated for each animal on each dosing day. A total of 226 rats and 30 dogs were infused for three dosing cycles over 17 days. A total of 2096 syringe doses and 338 IV bag doses using peristaltic pumps were administered over the course of the study. At a threshold of +/-10% of theoretical, 98.7% of the doses listed on the infusion pump met acceptance criteria compared to the calculated dose volume for syringe pumps (99.4% for peristaltic pumps). At a threshold of +/- 5% of theoretical, the correlation was 90% and 77.8%, respectively. The accuracy of the syringe and peristaltic infusion pumps exceeded expectations and were comparable with acceptance criteria of other laboratory equipment used on GLP studies. Therefore, there is no scientific rationale for recording syringe weights pre- and post-dose delivery as a secondary infusion pump accuracy check.

**954 Comparison of Optical Coherence Tomographic and Histopathological Retinal Images and Investigation of Age-Related Change in Retinal Thickness in Cynomolgus Monkeys**

Purpose: Optical coherence tomography (OCT) captures images of ocular fundi non-invasively in real time, based on light reflected from surfaces of interest. In this study, retinal thickness was measured in cynomolgus monkeys using OCT and histopathological (HP) images, and the results were compared to investigate the utility of OCT. Age-related changes in retinal thickness were also investigated with OCT.

Methods: For comparison of OCT and HP (eyeballs were fixed in a mixture of 3% glutaraldehyde/2.5% formalin), 10 male monkeys (age: 3–5 years) with no history of retinal disease were used. Retinal thickness was measured using OCT and HP images at the mid point between the optic papilla and macula, in total and for the following 10 layers: internal limiting membrane (ILM), nerve fiber layer (NFL), ganglion cell layer (GCL), inner plexiform layer (IPL), inner nuclear layer (INL), outer plexiform layer (OPL), outer nuclear layer (ONL), external limiting membrane (ELM), photoreceptor cell (PR), and retinal pigment epithelial layer (RPE). For investigation of age-related change, retinal thickness was measured using OCT for each of the 10 layers in 40 female monkeys (10 animals/age at 1, 5, 10 and 13 years). These data were analyzed statistically.

Results: No difference was noted in total retinal thickness (approx. 340 μm) between OCT and HP images. GCL, INL and OPL were thinner (approx. 30–40%), and IPL and ONL were thicker (approx 50%), in OCT images than HP images. With increase in age, NFL thickness decreased by 23% (1 vs. 13 years) and ONL and INL showed a tendency toward decrease in thickness. IPL, OPL, GCL and RPE showed a tendency toward increase in thickness from 5 years; PR, ILM and ELM showed no age-related change in thickness.

Conclusion: Ocular examinations and evaluations in cynomolgus monkeys with OCT should be carried out taking differences between OCT and HP measurements and age-related change in retinal thickness into consideration.

**954a Creating a Holistic Extractables and Leachables (E&L) Program for Biotechnology Products**

K. L. Li1, A. Mire-Slius1,2 and B. Cherney1,2,1 Corporate Environmental, Health and Safety, Amgen Inc., Thousand Oaks, CA and 2Corporate Quality, Amgen Inc., Thousand Oaks, CA.

The risk mitigation of extractables and leachables (E&L) presents significant challenges to regulators and drug manufacturers with respect to the development, as well as the lifecycle management of drug products. A holistic program is proposed, using a science- and risk-based strategy for testing E&L for primary containers, drug delivery devices and single-use systems for the manufacture of biotechnology products. The strategy is phase-appropriate, progressing from extractables testing for material screening/selection/qualification through leachables testing of final products. The strategy is designed primarily to ensure patient safety and product quality of biotechnology products.

The holistic program requires robust extraction studies using model solvents, with careful consideration of solvation effect, pH, ionic strength, temperature, product contact surface and duration. From a wide variety of process- and product-contact materials, these extraction studies have identified and quantified over 200 organic extractable compounds. The commonly observed compounds are siloxanes, fatty acid amides and methylcylates. The extractables profiles often show degradation products of the chemical additives. Toxicology assessments have been conducted on these compounds using risk-based decision analysis. Safety thresholds have been derived, as appropriate, for the majority of these compounds. Analysis of safety thresholds has helped to establish action thresholds to target and monitor high risk compounds in drug products on stability until expiry. Action thresholds serve to trigger quality investigations to determine potential product impact.

The holistic program also has in place processes to assess the impact of E&L compounds to product quality attributes and risk for immunogenicity. This science- and risk-based approach for primary drug containers and drug delivery devices is also suitable for single-use systems when justified with a historical knowledge base and understanding of the manufacturing processes of biotechnology products.
Cobalt-chromium (CoCr) alloys have long been used in metal-containing hip implants because of their biocompatibility. Like all implant materials, CoCr alloys undergo some degree of wear and corrosion in vivo, and as a result implant patients typically have blood and tissue Co and Cr(III) concentrations that are a few-fold higher than background levels associated with dietary intake. Although to date epidemiology studies do not indicate an increased incidence of cancer in patients with hip implants, questions continue to be raised about the potential cancer risk posed by CoCr-containing implants. This analysis was conducted to determine whether the existing toxicology data support epidemiological findings. We evaluated the results of over 60 in vitro genotoxicity assays in human cell lines treated with Co and Cr(III) ions and particulate; endpoints included chromosomal aberrations, micronuclei formation, DNA breakage, and oxidative DNA damage. The in vitro concentrations at which genotoxic effects occurred (and did not occur) in these studies were compared to tissue concentrations of Co and Cr(III) that we conservatively estimated would exist in patients with normal functioning CoCr metal-on-metal (MoM) hip implants (wear rates of 1 mm3/year). For metal particulates, we found that in general, the minimum concentrations required to cause genotoxic effects in vitro (10–108 µg/ml) were more than 1,000-fold higher than those likely present in tissues of implant patients; similar results were obtained for studies on Co and Cr(III) ionic solutions. Thus, exposures to CoCr wear debris from MoM prostheses would not likely be genotoxic in vivo, and this is consistent with cancer epidemiology studies conducted to date.
been implicated in neurodegenerative diseases and cancer, yet the mechanisms by which it act have remained largely unknown. As an α,β-unsaturated aldehyde, acrolein could react nucleophilic amino acid residues such as lysine in susceptible proteins. The fact that histone proteins are rich in lysines raised the possibility that acrolein targets lysine residues in histone tails, affecting their physiological posttranslational modifications. Because appropriate histone lysine modifications are crucial for genome function, the formation of acrolein-histone adducts should have significant impact on cellular processes. Biochemical and Mass Spectrometry analyses show that acrolein forms adducts with some but not all lysines on histone proteins in vitro and in vivo and preferentially reacts with free histones rather than with nucleosomal histones. Cellular fractionation analyses reveal that acrolein exposure specifically inhibits acetylation of N-terminal tails of cytosolic histones H3 and H4, modifications that are important for nuclear import and chromatin assembly. Notably, acrolein exposure compromises the delivery of histone H3 into chromatin and increases chromatin accessibility as measured by Chromatin Immunoprecipitation, suggesting that acrolein may perturb histone-nuclear exchange. Changes in nucleosome occupancy at several genomic loci are correlated with transcriptional responses to acrolein exposure. We propose that reacting with newly synthesized but not yet modified histones thereby affecting histone modification and chromatin assembly pathway represents a novel mechanism whereby certain environmental factors interact with the genome and influence genome function.

954g Multifocal Defects in the Hematopoietic and Lymphoid Compartments in Mice Dosed with a Broad BET Inhibitor

Bromo and extra terminal (BET) proteins (BRD2, BRD3, BRD4 and BRD7) are epigenetic transcriptional regulators required for efficient expression of growth promoting, cell cycle progression and anti-apoptotic genes. Through their bromodomains, these proteins bind to acetylated lysine residues of histones and are recruited to transcriptionally active chromatin. Inhibition of the BET-histone interaction provides a tractable therapeutic strategy to treat diseases that may have epigenetic dysregulation. JQ1 is a small molecule that blocks BET interaction with histones. It has been shown to decrease proliferation of patient-derived multiple myeloma in vitro and decrease tumor burden in vivo in xenograft mouse models. While targeting BET appears to be a viable and efficacious approach, the safety profile of BET inhibition is largely unknown. In this study, we used JQ1 as a tool molecule to explore the potential safety issues related to BET inhibition, and provide early de-risking of the target. Mice dosed with JQ1 at efficacious exposures develop multifocal defects in the lymphoid and immune cell compartments. At higher doses, JQ1 was not tolerated and resulted in significant body weight loss in mice, which were subsequently euthanized early in the study. Flow cytometry analysis of lymphoid tissues showed a decrease in both B and T lymphocytes and a concomitant decrease in peripheral white blood cells were confirmed by hematology & histopathology. Further investigation is required to determine if these toxic effects are associated with BET inhibition or more specifically related to the chemical structure of JQ1.

954h Sex-Dependent Effects of Lead and Prenatal Stress on Histone Modifications in Frontal Cortex and Hippocampus of the Developing Brain

Sex-dependent differences characterize the response of the brain to lead (Pb) and prenatal stress (PS), but the molecular mechanisms are unknown. This study examined the potential epigenetic basis of Pb±PS effects on expression of sexually dimorphic histone modifications, H3K9/14Ac (associated with gene activation) and H3K9Me3 (associated with gene silencing), in frontal cortex (FC) and hippocampus (HIPP) in males and females at 2 developmental periods (PN0, PN6). FC appeared more vulnerable than HIPP, effects of Pb±PS, but neither alone were seen in males; effects were prominent at PN6 but not P0. Histone modifications are involved in many aspects of brain development including neurogenesis, synapse formation, and cell differentiation/migration. Sex differences in histone modification may underlie different functional outcomes from Pb±PS in males and females. ES021534-01

955 Global DNA Methylation Profiling of Hepatocellular Carcinomas from Ginkgo biloba Extract-Treated and Vehicle Control B6C3F1 Mice

Epigenetic modifications, such as DNA methylation, play an important role in the development of hepatocellular carcinoma (HCC). In a recent NTP 2-year carcinogenicity bioassay, chronic exposure of B6C3F1 mice to Ginkgo biloba extract (GBE) resulted in a high incidence of HCC. To better understand the gene-specific methylation alterations in HCC due to GBE exposure, we performed global methylation profiling on HCC from GBE exposed mice (GBE-HCC; n = 5), spontaneous HCC from vehicle control mice (spont-HCC; n = 5), and age-matched normal liver from vehicle control mice (VN; n = 5), in order to identify differentially methylated regions (DMRs) in HCC from GBE exposed animals. The global methylation profiling included 20,404 promoter regions and 15,988 annotated CpG islands, and methylation changes were correlated to corresponding transcriptomic changes. Compared to VN liver, 1400 CpG sites in GBE-HCC and 849 CpG sites in spont-HCC were differentially methylated (DM; P < 0.01). Compared to spont-HCC, 138 CpG sites were DM in GBE-HCC (P < 0.01). Using pyrosequencing, we confirmed promoter-specific hypomethylation of the Myc oncogene in GBE-HCC compared to spont-HCC (P < 0.001), with a corresponding increase in gene expression showing significant negative correlation with methylation changes (r = -0.93; P = 0.01). In addition, we also confirmed hypermethylation of tumor suppressors (Spry2, Cdkn2a, Dusp5) in GBE-HCC compared to spont-HCC (P < 0.001) with a corresponding decrease in gene expression. In conclusion, we have identified DMRs in promoter CpG islands of relevant cancer genes altered in GBE-HCC compared to spont-HCC, suggesting that such promoter CpG island DMRs could be used to differentiate treatment-related tumors from background, spontaneous tumors in cancer bioassays. Furthermore, these data provide additional understanding of the underlying epigenetic mechanisms of chemical carcinogenesis in animals and their relevance to human health and hazard identification.

956 Hepatic Epigenome Controls the Severity of Liver Injury in Mice Induced by a Choline- and Folate-Deficient Diet
V. Trinhvak, T. Han, J. C. Fuscoe, F. A. Beland and I. Pogribny. 1Division of Biochemical Toxicology, FDA-NCTR, Jefferson, AR and 2Division of Systems Biology, FDA-NCTR, Jefferson, AR.

The importance of epigenetic changes in etiology and pathogenesis of disease has been increasingly recognized. However, the role of epigenetic alterations in the genesis of nonalcoholic fatty liver disease (NAFLD) and cause of variations in individual susceptibilities to this disease are largely unknown. In the present study we investigated whether or not the epigenetic profile of normal liver affects the severity of NAFLD-associated liver injury. Male WSB/EiJ and A/J inbred mice were maintained on either control or choline- and folate-deficient (CDF) diets for 12 weeks and the status of DNA methylation and histone H3 lysine 4 trimethylation (H3K4me3) was determined using whole genome methylated DNA immunoprecipitation (MeDIP) and H3K4me3-chromatin immunoprecipitation (ChIP)-on-chip techniques. Feeding the CDF diet for 12 weeks caused significantly greater liver injury in WSB/EiJ mice as compared to A/J mice. MeDIP analysis shows that the greater vulnerability of WSB/EiJ mice was associated with a hypomethylated liver phenotype. This was evidenced by a greater number of hypomethylated Cpg domains than hypermethylated Cpg regions, 3429 and 471, respectively, and consequently a high hypomethylated/hypermethylated Cpg domain ratio in DNA isolated from normal livers of WSB/EiJ mice. In contrast, DNA isolated from normal livers of A/J mice contained approximately an equal number of hypomethylated and hypermethylated Cpg regions, 2044 and 1856, respectively. ChIP-on-chip analysis showed differential hypomethylation of H3K4me3 enrichment throughout the genome in the normal livers of WSB/EiJ and A/J mice, but it was not associated with the extent of the CDF diet-induced liver injury. Interestingly, feeding a CDF diet caused opposite effects on DNA methylation: increased methylation in the livers of H3K9Me3 levels. These results suggest that Pb±PS alters H3 acetylation/trimethylation early during development in a sex-dependent manner, leading to potential errors in transcriptional regulation. FC appeared more vulnerable than HIPP. Enhanced effects of combined Pb±PS were seen only in males; effects were prominent at P0 but not P6. Histone modifications are involved in many aspects of brain development including neurogenesis, synapse formation, and cell differentiation/migration. Sex differences in histone modification may underlie different functional outcomes from Pb±PS in males and females. ES021534-01
957 Epigenetic Alterations in the Livers of Fisher 344 Rats Exposed to Furan

Furan is a volatile heterocyclic compound widely used in the chemical manufacturing industry. It is also found in a variety of common cooked foods consumed by adults and infants. Lifetime exposure to furan causes liver tumors in rats and mice (NTP, 1993); however, the mechanisms of the furan hepatocarcinogenicity are still unclear. The goal of the present study was to investigate whether or not the exposure to furan causes epigenetic alterations in rat liver. Male Fisher 344 rats were treated by gavage with different doses of furan (0, 0.92, 2.0, or 4.4 mg/kg body weight/bw/day) dissolved in corn oil. The exposure of Fisher 344 rats to furan produced dose- and time-dependent epigenetic changes in the livers consisting of alterations in the global pattern of histone lysine methylation and acetylation, gene-specific methylation, and altered expression of chromatin modifying genes. Specifically, there was a sustained decrease in the levels of histone H3 lysine 9 and H4 lysine 20 trimethylation in the livers after 180 and 360 days of furan exposure, and a marked reduction of histone H3 lysine 9 and H3 lysine 56 acetylation after 360 days of treatment at 4.4 mg/kg/bw/day. These histone modification changes were accompanied by a reduced expression of related Suv39H1, Prdm2, and Suv4-20h2 histone methyltransferases, Ep300 histone acetyltransferase, and an up-regulation of Sir6 histone deacetylase. The exposure to furan at doses 0.92, 2.0, and 4.4 mg/kg/bw/day caused global demethylation of hepatic DNA after 360 days of treatment. Additionally, furan at 2.0, and 4.4 mg/kg/bw/day doses induced hypermethylation-dependent down-regulation of the Rassf1a tumor suppressor gene in the livers after 180 and 360 days of treatment. In summary, these findings indicate possible involvement of dose- and time-dependent epigenetic modifications in the hepatotoxicity and carcinogenicity of furan.

958 Genome-Wide DNA Methylation Changes Influence Gene Expression in Arsenic-Transformed Human Prostate Cells

NextGen sequencing provides genome-wide coverage at base-pair resolution of DNA alterations for environmentally-related diseases, like cancer. In this study, methylated DNA was affinity-enriched, bisulfite treated and sequenced for high-resolution detection of differential methylation in arsenic-transformed, CàE-PÉ cells derived from normal, RWPE-1 human prostate cells. We hypothesized that changes in methylation status might change gene expression in CàE-PÉ cells and contribute to malignancy. A total of 74,844 million bisulfite-treated DNA sequenced reads (100bp, paired end) were produced. Analysis focused on the most differentially methylated bases (cytosines), termed DMBs, and showed a >50% change in methylation state. We organized DMBs into structural units of differentially methylated clusters (DMCs), as short regions with 4 or more DMBs. More than 7,000 DMCs were found in the two cell lines. There were >500 genes with at least one DMC in the promoter region for which >40 hypermethylated cytosines and 10 hypomethylated sites have been independently validated by 454 pyrosequencing. However, only 25% of all DMBs were found within CpG islands or shores while the majority of DMBs were not data. Data suggest that CpG-based platforms (e.g. CpG bead arrays) may underrepresent the methylene and not be fully capable of measuring differential methylation. Additionally, RNA-Seq showed a large increase in KRAS mRNA in CàE-PÉ cells compared to RWPE-1. KRAS is a well-known oncogene whose enhanced activity (mutated forms) or increased mRNA levels can be upregulated in many types of tumors. While no mutations were seen in KRAS mRNA in either cell line, other oncogenic mechanisms may have occurred that play a major role in malignant conversion to form CàE-PÉ cells. We believe these data will offer insights into epigenetic effects of arsenic carcinogenesis and a technical approach to studying epigenetic mechanisms.

959 Environmental Health Disparities in the Age of Epigenetics

Over the past decades, genome-wide association studies have identified certain genetic loci for numerous diseases and traits. However, genetic variations identified to date account for only a small proportion of disease phenotypes. Growing evidence suggests that environmental exposures can influence human disease risk through the accumulation of epigenetic modifications. This general hypothesis provides a broad umbrella to examine how the environment “gets under skin” among selected racial, ethnic and/or socioeconomic groups. We systematically reviewed published literature and propose the “neighborhood-specific” epigenome analysis as a promising approach to study environmental health disparities. In this treatise, environment is characterized in the broad sense of “non-genetic” factors including social, biological, chemical and physical stressors. The hypothesis suggests that understanding the complex interactions between genes, the environment and chronic disease requires the examination of the role of epigenetics in regulating genetic susceptibility to environmental stressors. The slow progress in understanding disparities in disease susceptibility may be in part related to the fact that studies have not considered the cumulative effect of environmental exposure to both chemical and non-chemical stressors on genetic substrates. “Geographical neighborhood-specific” epigenetic markings can potentially be used as a tool to investigate proposed mechanisms to account for well documented racial and ethnic disparities in health. Additionally, by considering neighborhood-specific epigenetic profiling, one could then identify novel targets for population-based prevention efforts. Through proposed neighborhood-specific epigenome analysis and approaches, we provide considerable insight into the causes of health disparities and their potential prevention and intervention strategies.

960 Cadmium Alters Histone Modifications in Mouse Embryonic Stem Cells

S. R. Gaethia and F. A. Baril. Pharmaceutical Sciences, St. John’s University College of Pharmacy, Queens, NY.

Epigenetic changes in histone modifications due to cadmium exposure early in life results in pathologies observed during adulthood. We tested the effects of low dose acute Cd exposure on cell viability, total histone protein (THP) production, histone acetylation and deacetylation at multiple sites, cell cycle progression in mouse embryonic stem (mES) cells. Exposure to 10 μM Cd altered cell cycle progression at 1-h and 24-h (± recovery) but differentiation patterns were affected only during 72-h exposures. In addition, flow cytometry data demonstrated that Cd IC25 concentration decreased the number of cells appearing in the S-phase and reduced newly synthesized DNA during acute exposures, whereas cell differentiation is inhibited during chronic exposures in mES cells. Also, we previously showed that Cd alters THP production and H3K27me1 levels (Gaethia et al., 2012), suggesting chromatin damage and transcriptional changes. Whereas H3K27me1 is a precursor to H3K27me2/3, we analyzed the effects of Cd using 2-stage hepatocarcinogenesis model using 2-Stage Hepatocarcinogenesis Model.
962 Effect of THC on Genome-Wide Histone Methylation in Immune Cells
X. Yang, V. L. Hegde, J. Zhang, P. S. Nagarkarati and M. Nagarkarati. PMI-SOM, University of South Carolina, Columbia, SC.

Despite the fact that marijuana may have beneficial medical effects in patients with certain diseases, increasing evidence indicates that marijuana suppresses immune function. Therefore marijuana use may increase susceptibility to infection and some types of cancer. To further investigate the effect of marijuana on immune function, we used an animal model to determine the role of Δ9-tetrahydrocannabinol (THC), the major effective component in marijuana, in epigenetic modification of genes in immune cells. Since epigenetic modification plays a critical role in immune cell differentiation and lineage commitment, we sought to investigate whether THC alters global histone methylation. Using ChiP-Seq technology, we compared genome-wide histone H3K4, H3K27, H3K9 and H3K36 trimethylation patterns between THC and vehicle treated activated popliteal lymph node cells. Our results show that THC treatment leads to the association of active modification signals with Th2 cytokine genes and suppressive modification signals with Th1 cytokine genes. These results suggest that THC inhibits Th1 cells while promoting Th2 cells through histone modification. At the genomic level, a significant amount of histone methylated regions are altered by THC. Functional classification of these histone methylation associated genes shows that these differentially associated genes are involved in various cellular functions, from cell cycle to metabolism, suggesting that THC regulates global gene expression in immune cells through histone modification. (Supported in part by NIH grants P01AT003961, R01AT066888, R01ES019133, R01MH094755, P20RR02684 and VA Merit Award BX001357)

963 Prenatal Exposure to TCDD Triggers Epigenetic Modifications Including DNA Methylation and microRNA Induction That Target Genes Which Regulate Immune Functions
N. P. Singh1, X. Yang1, U. Singh1, J. Zhang1, I. K. Abbas1, M. Nagarkarati1 and P. S. Nagarkarati2. 1Pathology, Microbiology, and Immunology, University of South Carolina School of Medicine, Columbia, SC and 2Epidemiology and Biostatistics, University of South Carolina, Columbia, SC.

TCDD (2,3,7,8-tetrachlorodibenzo-p-dioxin) is a potent aryl hydrocarbon receptor (AhR) ligand and an environmental contaminant. Prenatal exposure to TCDD is well known to cause thymic atrophy as well as alterations in T cell differentiation, the precise mechanisms of which are unclear. In the current study, therefore, we investigated the role played by epigenetic mechanisms in regulating the immunotoxic effects of TCDD following prenatal exposure. To this end, pregnant mice on gestational day 14, were injected with TCDD (5 μg/kg) and on postnatal day 4, the thymus were harvested and high-throughput microRNA (miR) and genome-wide MeDIP methylation arrays were performed. We observed more than 69 miRs to be up- or down-regulated greater than 2 fold in fetal thymocytes post TCDD exposure when compared to controls. We validated the expression of several miRs by performing Real-Time PCR. The data obtained from miR arrays of fetal thymus post-TCDD exposure demonstrated changes in miR profile that affected expression of important genes such as, AhR, CYP1A1, Foxp3, IL-17, Fas and Fasl, which are known to regulate signaling, toxicity, apoptosis, thymic atrophy, and immunosuppression caused by TCDD. The data obtained from methylation arrays, upon further analysis, showed significant differences in methylation status of specific genes such as AhR, CYP1A1, IFN-γ, IL-4, FoxP3, and IL-17 in thymus following prenatal exposure to TCDD. We also noted induction of regulatory T cells and suppression of Th17 cells. Together, our studies suggest that prenatal exposure to TCDD triggers significant alterations in miRs as well as methylation status of a wide range of genes that regulate the immune functions (Supported in part by NIH grants P01AT003961, R01ES019133, R01MH094755, P20RR02684 and VA Merit Award BX001357).

964 Physiological Effects of Developmental Lead (Pb) Exposure on Weight, Food Intake, Body Fat, and Insulin in Mice
C. Faulk, A. K. Barka, B. N. Sánchez, Z. Zhang, O. S. Anderson, K. E. Peterson and D. Dolinoy. Environmental Health Sciences, University of Michigan, Ann Arbor, MI.

Developmental exposure to lead (Pb) can have persistent effects on physiology and has been associated with lower body weight in human infants and later onset obesity in mice. Epigenetic reprogramming of transposons and imprinted genes during development is a plausible mechanism linking early exposures and physiological changes later-in-life. Mouse dams (n=49) were randomized to one of four groups where drinking water was supplemented 2 weeks prior to mating, through weaning, with 0 (control), 2.1 (low), 16 (medium), or 32 (high) ppm Pb. We measured 18 outcomes in offspring (n=30 control, n=28 low, n=35 medium, and n=29 high): physiological measures at 3, 6, and 9 mos of age, and epigenetic drift in tail DNA from weaning to 10 mos. We estimated average, sex-specific changes in physiological outcomes over time and their differences across exposure using repeated measures models adjusted for within-litter and within-mice correlations. Overall both sexes exhibited increased energy expenditure (p<0.0001) as well as increased food intake (p<0.0001) compared to controls. Similarly, body weight increases were found in males at medium (p<0.004) and high (p<0.029) exposure, whereas overall, total body fat increased in males and decreased in females (both p<0.0001). However, relative to controls, insulin was increased only in males at the medium level (p<0.05). We measured linear trends in relative methylation shift over time vs. exposure level using a linear mixed model. Epigenetic drift measured at the transposon linked metastable epiallele, CbpPlAP had significant, exposure-dependent increases over time (p<0.02). In general, imprinted genes increased in methylation over time but had locus-specific responses to Pb. For example, Igf2 showed no association with Pb, while Igfl2 exhibited increased methylation with Pb (p=0.045), and H19 displayed moderately increased methylation with Pb (p=0.085). Perinatal Pb exposure has both physiological and epigenetic effects over life course in mice that vary by sex and locus.

965 Effect of 2, 3, 7, 8-Tetrachlorodibenzo-p-Dioxin (TCDD) Exposure on the Expression of DNMT Genes during Development in Zebrafish (Danio rerio)
E. Kuo1,2, Z. Yu1, S. I. Karchner1 and N. Aluru1. 1Biology, Woods Hole Oceanographic Institution, Woods Hole, MA, 2Stanford University, Stanford, CA and 3New England Biolabs, Ipswich, MA.

DNA methylation is one of the most important epigenetic modifications involved in the regulation of gene expression. Recent studies have demonstrated that environmental toxicants can affect normal development by altering DNA methylation patterns. However, the mechanisms of action of these chemicals are poorly understood. Hence, we tested the hypothesis that developmental exposure to TCDD affects DNA methyltransferase (DNMT) gene expression patterns. To address this hypothesis, zebrafish embryos were exposed to 5 nM TCDD for one hour from 4 to 5 hours post-fertilization (hpf) and sampled at 12, 24, 48, 72 and 96 hpf to determine DNMT gene expression patterns and global methylation patterns. Results demonstrate that TCDD upregulates DNMT1 gene expression, whereas DNMT3 genes (DNMT3a1, 3b1, 3b4) are downregulated following exposure. These results suggest that TCDD exposure may impact both maintenance and de novo methylation. To characterize the TCDD effects, we screened the 2 kilobase region of the DNMT gene promoters for xenobiotic response elements (XRE). We identified at least one XRE in each DNMT promoter. We are characterizing the function of these XREs in in vitro luciferase reporter assays. Furthermore, we are quantifying global DNA methylation levels using liquid chromatography to correlate changes in gene expression with methylation patterns. Funding for this project was provided by WHOI Ocean Life Institute and NIH grant P01ES021923 and National Science Foundation Grant OCE-1314642 through the Woods Hole Center for Oceans and Human Health.
Adult exposure to water pollutant trichloroethylene (TCE) in drinking water has been shown to induce autoimmune hepatitis in female MRL+/+ mice. This was accompanied by expansion of activated/memory CD4+ T cells that secreted increased levels of IFN-γ. Several aspects of normal and autoreactive CD4+ T cell function, including differentiation and cytokine production, are regulated by gene-specific alterations in DNA methylation. In the current genetic study transcriptomics and toxicogenomics were used to define time-dependent alterations in gene expression and related DNA methylation in CD4+ T cells from MRL+/+ mice exposed to TCE for up to 40 weeks. Naïve and memory/activated subsets of CD4+ T cells were examined separately. We observed differential DNA methylation in CD4+ T cells from TCE and control mice. These TCE-induced alterations in DNA methylation were CpG-, time-, and subset-specific. The alterations encompassed genes important in CD4+ T cell differentiation, cell cycle proliferation and cytokine production. This study is the first to document that low level adult exposure to TCE induces temporal, specific, and potentially functionally important, epigenetic alterations in CD4+ T cells.

Nickel, an environmental carcinogen, is a widely used metal and release of nickel compounds into atmosphere occurs during various stages of industrial processes. Nickel compounds have been conclusively shown to induce lung and nasal cancers in humans. In spite of its proven carcinogenicity, the mutagenic potential of nickel is very low. Therefore, nickel-induced carcinogenesis appears to be initiated predominantly by non-genotoxic mechanisms. It has been shown earlier that exposure to nickel alters the levels of various epigenetic modifications and growing evidence points to epigenetic dysregulation as a major outcome of nickel exposure. However, the mechanistic basis of nickel-induced epigenetic alterations is not fully understood. In this study, using ChIP-Seq, we comprehensively analyzed NGC2-induced alterations to several activating and repressive histone modification marks on a genome-wide scale in the immortalized non-cancerous human lung epithelial, BEAS-2B cells. Using RNA-Seq, we detected hundreds of genes with altered expression due to nickel exposure. A large majority of these genes had altered epigenetic profiles in their promoters and gene body regions indicating the extent of epigenetic alterations induced by nickel. Interestingly, the nickel-induced alterations to histone modification marks were not only limited to promoters and regulatory regions of the genome, but also extended to large genomic regions. Taken together, our results indicate disruption of chromatin structure as an important mechanism in nickel-induced gene expression alterations, which could potentially lead to carcinogenesis. We believe that our findings will serve not only as a model to understand the mechanism involved in epigenetic alterations induced by an environmental carcinogen, but also help comprehend how epigenetic aberrations contribute to carcinogenesis. Supported by National Institutes of Health grants R01ES023174 and P30ES002620.

Hexavalent chromium [Cr(VI)] is a potent human carcinogen. Occupational exposures have been associated with increased risk of respiratory cancer. Increasing evidences suggest that multiple mechanisms might contribute to Cr(VI) induced carcinogenesis, including DNA damage, genomic instability, and epigenetic modulation. As an important epigenetic regulator of gene expression, DNA methylation in the promoter region of genes is inversely correlated to gene transcription. Aberrant DNA methylation in the gene promoter region has been found in many human tumors, which is responsible for their silencing. Previous studies on chromium-induced human cancer revealed a decreased expression of MLH1 and p16 that was accompanied by an increased DNA methylation in their promoter region, indicating that chromium was able to silence tumor suppressor genes by modulating DNA methylation status. To further investigate the effect of chromium on DNA methylation of other tumor suppressor genes, we analyzed the promoter methylation of 22 tumor suppressor genes in workers from a chromate factory and referent subjects using EpiTect Methyl II PCR array. Among 22 tumor suppressor gene promoters whose hypermethylation was frequently observed in many human cancers, three genes (WIP1, APL, and MLH1) exhibited elevated promoter DNA methylation in chromate workers compared to referent subjects. Multiple linear regression analysis indicated a positive correlation between promoter DNA methylation of these three tumor suppressor genes and the levels of Cr(VI) in air and in the red blood cells. Our studies have identified new target tumor suppressor genes that were silenced in human by chromate through epigenetic regulation.

Mechanisms underlying alcohol induced immunotoxicity are poorly understood. Fasl, plays a critical role in regulating physiologic as well as pathologic apoptotic death of CD4+ T cell and the immune response. Although transcriptional regulation of Fasl has been extensively studied, the role of epigenetic mechanisms is only poorly understood. Accordingly, immunotoxic effects of alcohol on promoter histone modifications regulating Fasl gene expression in human primary CD4+ T cells were examined. Effect of stimulation and alcohol exposure on Fasl promoter-histone modifications was examined in chromatin samples prepared from CD4+ T cells obtained from non-alcoholic and alcohol abusing study subjects by quantitative chromatin immunoprecipitation (ChIP) analysis. In comparison to normal CD4+ T cells, alcohol exposure significantly increased transcriptionally permissive trimethylation at histone H3 lysine 4 (H3K4me3), with a coordinate decrease in transcriptionally repressive trimethylation at H3 lysine 9 (H3K9me3). Commensurate with the decrease in H3K9me3, the acetylation of H3K9 (H3K9ac) which is an essential modification for transcriptional activation and is mutually exclusive to methylation, was further increased upon alcohol exposure. Notably, increase in H3K9ac was determined to be critically regulated by the p300 histone acetyltransferase (p300/ HAT). Further, in correspondence with transcriptionally germine histone modifications, alcohol enhanced the recruitment of relevant transcription factors and RNA polymerase II to the Fasl promoter, which correlated with increased Fasl expression and apoptotic death. Overall, these data identify the dynamic interplay between promoter H3K4 and H3K9 methylation and acetylation as a significant mechanism regulating Fasl gene expression in alcohol-induced immunotoxicity.
Epigenetic regulation of gene expression plays a pivotal role in the orchestration of immune responses and may impact their vigor, quality or longevity. Chemical allergens can be broadly divided into two categories: contact allergens (e.g. dinitrochlorobenzene; DNCB) and respiratory allergens (e.g. trimellitic anhydride; TMA) that health effects in human due expose to PAHs had been augmented since last decade. Several health effects related to exposure of different PAHs, including benzo(a)pyrene (BaP), were reported as asthma, genotoxicity, altered neurodevelopment and interestingly highlight the proinflammatory effects. Recently, it has been observed that the main epigenetic mechanisms such as DNA methylation, histone modification and microRNAs are be able to respond to external factors as pollutants. In this work we explored if BaP be able to modify two epigenetic mechanisms. We found that miRNAs expression are altered due BaP exposure in human MNC in vitro.

Epigenetic regulation of dopamine transporter expression is the key regulator of dopaminergic transmission and is a target of several xenobiotics, including pesticides and pharmaceutical agents. Therefore, determination of the mechanisms by which DAT expression is regulated may provide insight into the actions of these compounds on the nervous system. Using in silico analyses, we identified regions within the DAT promoter which may contribute to its regulation at the mRNA level. The DAT promoter is CpG rich, indicating potential regulation by DNA methylation. Additionally, the lack of a conserved TATA box suggests regulation by histone acetylation. To determine the relative roles of DNA methylation and histone acetylation, we utilized a rat dopaminergic cell line (N27) to probe the responsiveness of the DAT to manipulations by inhibitors of DNA methyltransferases (DNMT) and histone deacetylases (HDAC). Inhibition of DNMTs using 5-aza-2-deoxycytidine led to a 1.25-fold increase in DAT mRNA expression. This was confirmed by siRNA experiments. However, valproate exposure increased DAT mRNA expression by up to 10-fold. To confirm the mechanism of HDAC inhibitor-mediated increase in DAT mRNA, chromatin immunoprecipitation assays were used to determine proteins recruited to the DAT promoter following valproate treatment. Data demonstrate a 4-fold increase in acetylation of histone 3 on lysines 9 and 14 (H3K9/K14ac) in the DAT promoter. Together, these results indicate that histone acetylation appears to be a plausible mechanism for DAT regulation by valproate and perhaps, by other xenobiotics. Support provided by NIEHS grants P30ES005022, R01ES051991, T32ES007148.
promoter was hypomethylated (11%) in the epithelium of the small intestine, whereas the UGT1A10 promoter was hypermethylated (89%) in hepatocytes. A luciferase assay revealed that the methylation of the UGT1A10 promoter by SsII methylase abrogated transactivity even with overexpressed Cdx2 and HNF1β. The UGT1A10 promoter was highly methylated (86%) in liver-derived HuH-7 cells, where UGT1A10 is not expressed. In contrast, the UGT1A10 promoter was hardly methylated (19%) in colon-derived LS180 cells, where UGT1A10 is expressed. Treatment with 5-aza-2’-deoxycytidine (5-Aza-dC), an inhibitor of DNA methylation, resulted in an increase in UGT1A10 mRNA expression only in HuH-7 cells. Moreover, the overexpression of HNF1β and Cdx2 further increased CUGT1A10 mRNA only in the presence of 5-Aza-dC. Collectively, we found that DNA hypermethylation would interfere with the binding of HNF1β and Cdx2, resulting in the defective expression of UGT1A10 in human liver. Thus, epigenetic regulation is a crucial determinant of the tissue-specific expression of UGT1A10.

Conclusion: Skin manifestation showed positive association with whole genome DNA methylation in a dose-dependent manner while other biomarkers did not indicate any. The underlying mechanisms and physiologic implications of the increased skin manifestation need further study.

Perfluorooctanoic acid (PFOA) is a stable man-made compound with many industrial and commercial uses. Recently, however, concern has been raised that it may induce various toxicological effects such as hepatotoxicity, immunotoxicity, and developmental toxicity. Because levels of circulating microRNAs (miRNAs) can be altered in several clinical diseases, they may serve as potential novel biomarkers. Here, we explored differences in the profiles of circulating miRNAs in mice after PFOA exposure. Using TaqMan miRNA arrays, we determined that the levels of 24 circulating miRNAs were altered in mice dosed with PFOA at 1.25 mg/kg/d and 73 were altered in mice dosed with 5 mg/kg/d. Eight miRNAs, namely miR-28-5p, miR-32-5p, miR-34a-5p, miR-122-5p, miR-192-5p, miR-200c-3p, miR-26b-5p and miR-199a-3p, were further validated using TaqMan Real-Time PCR assays. Results were consistent with those obtained from the TaqMan miRNA arrays, except for miR-199a-3p. The most remarkable of the circulating miRNAs (miR-26b-5p and miR-199a-3p) were also up-regulated in the serum of occupational workers in our previous epidemiological study. We also found similar patterns in mice exposed to PFOS and the observed increase of circulating miRNAs may not only be specific for PFOA but also for PFOS and even other PFASs. These results demonstrated that circulating miRNA profiles were altered after exposure to high concentrations of PFOA and miR-28-5p, miR-32-5p, miR-122-5p, miR-192-5p, and miR-26b-5p in serum may be potential biomarkers of PFOA induced toxicological effects, especially in occupational exposed people.

Correlation between Whole Genome DNA Methylation and Biomarkers of Arsenic Toxicity in Arsenic-Exposed Populations of West Bengal, India

M. Majumder1, U. B. Dasgupta2, D. N. GuhaMazumder3 and N. Das1. 1Dept. of Molecular Biology, Surenradhath College, Kolkata, West Bengal, India, 2Dept. of Life Science and Biotechnology, Jadavpur University, Kolkata, West Bengal, India and 3DNfRM Foundation, Kolkata, West Bengal, India.

Background: Arsenic is a potent environmental toxicant. Number of individuals in West Bengal, India are endemically exposed to inorganic arsenic, far above the acceptable limit (10μg/L). Though Pigmentation, keratosis are the specific skin lesions characteristic of chronic arsenic toxicity, various systemic manifestations are there over and above skin lesions, like chronic lung diseases, skin, lung urinary bladder cancer. Despite being recommended as a Group 1 carcinogen, arsenic is a poor in vitro mutagen in both bacterial and mammalian systems. Thus, epigenetic mechanisms of carcinogenesis (hyper/hypo methylation of DNA) has been invoked. Arsenic exposure may result in global DNA hypermethylation in human; still the association between DNA methylation and the known biomarkers of arsenic toxicity remains to be determined.

Objective: The objective of the study presented here is to find if there is any correlation between biomarkers of arsenic toxicity like skin manifestation score, arsenic intake, hair and urinary arsenic deposition, smoking and tobacco chewing habit, gender with whole genome DNA methylation in exposed individuals of West Bengal. Method: PBL DNA quantification and methylation, plasma and urinary arsenic concentrations, smoking habit and skin manifestation were assessed in a study population, in the district of Nadia, West Bengal. Genomic DNA methylation was measured by using ELISA-based assay. An Institutional Ethical committee (IRB) meeting was held to review the project in depth and approved. Result: Our data indicated positive correlation between whole genome DNA methylation and skin score (p=0.004).

1,3-Butadiene (BD) is a widely used industrial chemical and a ubiquitous environmental pollutant that is a known human carcinogen. Although genotoxicity is an established mechanism of the carcinogenicity of BD, epigenotoxicity has also been observed in livers of mice exposed to the chemical. To better understand the molecular mechanisms associated with BD effects in other tissues, we evaluated BD genotoxicity and epigenotoxicity in both target (lung and liver) and non-target (kidney) tissues of butadiene-induced carcinogenesis. We hypothesized that epigenotoxic effects may explain, at least in part, the tissue-specific differences in BD carcinogenicity in mice. Male C57BL/6 mice were exposed to 0 or 425 ppm of BD by inhalation (6 hr/day, 5 days/week) for 2 weeks. For assessment of genotoxic and epigenetic alterations, we evaluated THB-Gua adducts and bis-N7G-BD crosslinks, and levels of histone and DNA methylation, respectively. Liver and lung tissues of BD-exposed mice exhibited DNA damage as well as epigenetic alterations indicative of genomic instability. Marked genotoxic effects of BD were also observed in the kidneys, but epigenetic alterations clearly differed in this non-target tissue as compared to liver and lung. Specifically, trimethylation of histones H3K9, H3K27, and H4K20, all marks of condensed heterochromatin and transcriptional silencing, was increased in the kidneys of treated mice as compared to controls. These modifications may represent a post-repair chromatin restoration response at sites of DNA damage and present a potential mechanistic explanation for the lack of tumor susceptibility of this non-target tissue. These results indicate that tissue-specific epigenetic alterations are associated with tissue specificity in carcinogenesis, even in cases of known genotoxic carcinogens.

T. Han, C. Moland, V. Vijay, K. Wang, J. C. Kwekel, Y. G. Desai and J. C. Tuson. Personalized Medicine Branch, Division of Systems Biology, National Center for Toxicological Research/FDA, Jefferson, AR.

Epigenetic modifications of DNA, such as methylation of cytosine, play a critical role in regulating miRNA expression, miRNA levels, and cellular development, and have been linked to human diseases such as cancer. The role of epigenetics in toxicological development and diseases has not been thoroughly reviewed; however, there is a lack of a comprehensive study to understand the epigenetic effects on liver disease susceptibility and response to xenobiotics at different life stages. Furthermore, these epigenetic changes may serve as biomarkers for disease progression. Recent advances in high throughput technologies make it possible to monitor the methylation aberrations at the whole genome level. In this study, liver tissues from both sexes of Fischer 344 rats at 2, 5, 6, 8, 15, 21, 52, 78, and 104 weeks of age were examined for sex- and age-specific alterations in DNA methylation using Roche 385k rat promoter methylation microarrays. The raw image data were extracted and analyzed by DEVA software (v1.2.1) to determine the methylation changes in these samples. Tukey’s biweight mean centering normalization was applied before downstream analysis. One-way ANOVA was used to identify differences between groups. Principal component analysis indicated that there are greater sex differences than age difference in terms of methylation patterns. Within each sex, the results also showed methylation changes occurring from early age through old age. In contrast, the differences between 52wk, 78wk, and 104wk animals were much smaller in male animals compared to female animals, in which there were greater differences between 52wk and older animals. The number of methylated sites was very similar between different groups although there was variability in the chromosomal sites. These age- and sex-related differences in DNA methylation may provide insights in susceptibility to liver disease, adverse drug events and their progression.

Epigenomic changes induced by environmental factors are important for the acquired phenotype. It is thought that degree of its variability is small and that its deviation is large among individuals. Since no appropriate method has been available to quantify CpG-methylation frequency (MF) in a genome-wide manner in terms of accuracy, precision, and cost, we developed a novel method (methylation site display (MSD)-AFLP) and then applied this method to examine influence of bisphenol-A (BPA) exposure on DNA methylation in mouse tissues. MSD-libraries prepared by digestion with different pairs of adapter were used to obtain AFLP-chart data of the DNA methylation of C57BL/6j mice tissues (liver, kidney and hippocampus). Many CpG-sites suspected to be the tissue-specific differentially methylated regions (tDMRs) were detected by 16-selective primer sets. Nucleotide sequences adjacent to these methyl-CpG sites were determined and the MF was analyzed by MSRE-PCR to confirm the precision of the AFLP analysis. The differences of the MF among tissues were almost identical in the both methods. Additionally, AFLP data from Ss11-treated genomic DNA was used to calculate MF from MSD-AFLP. Many CpGs showing less than 5% of statistically significant tissue-specific difference and less than 10% of degree of variability were detected, suggesting that MSD-AFLP is a highly precise analytical method. Finally, hippocampus DNAs from male pups exposed to 200 mg/kg BPA (n=6) in utero and from control pups (n=6) were analyzed by MSD-AFLP. No statistically significant change of MF by BPA exposure was detected in 43,840 CpGs, despite using the full 256-selective primer sets. Our newly developed method will provide accurate values in MF and be useful to screen unknown subtle differences of methyl-CpGs in a genome-wide manner. In addition, nearly no influence of in utero BPA exposure on DNA methylation was observed in mouse hippocampus.
indeed a skin irritant, as evidenced by PMN and inflammatory macrophage infiltration and activity. Furthermore, characteristic inflammation may be dependent on genetic background.

980 Comparative In Vivo and Ex Vivo Toxicity Studies of Wildfire Particulate Matter

Inhalation of particulate matter (PM) generated from biomass burning is of concern particularly as the frequency and severity of wildfires have been increasing. Size-fractionated PM samples (ultrafine, <0.2 µm; fine, 0.2-2.5 µm; coarse, 2.5-10 µm) were collected downwind from a peat-bog wildfire in Eastern North Carolina from 6/26/2008 – 7/11/2008 when the fire was smoldering (ENCF-1), or at a later time from 8/8/2008 – 8/19/2008 after the fire had been controlled but not fully extinguished (ENCF-4). Wildfire PM samples were extracted in methanol for toxicity studies and chemical analysis, and then given by oropharyngeal aspiration to mice at 100 µg/50 µl saline or cultured with lung tissue slices for 11 µg per lung slice (8 mm diameter). At 4 h and 24 h post-exposure, biomarkers of lung injury and inflammation were assessed in lung lavage fluid from mice, and in conditioned medium from the lung slices. In addition, lung slices were also exposed to wildfire PM pre-treated with the endotoxin inhibitor (polymyxin B). The results showed that both ENCF-1 and -4 coarse PM had 4-8 times greater endotoxin content than the fine and ultrafine PM. Moreover, only the coarse PM significantly increased neutrophils and biomarkers of inflammation (e.g., interleukin-6) in the lung lavage fluid at any time point, and similar patterns of pro-inflammatory effects were observed in the lung tissue slice model. Finally, the inflammatory effects in the lung slices were significantly diminished after exposure to the PM pre-treated with polymyxin B. We conclude that exposure to wildfire coarse PM caused substantial acute toxicity in the mouse lung in association with endotoxin content, and that the lung slice ex vivo model provides a good alternative for in vivo lung toxicity testing. (This abstract does not represent U.S. EPA policy).

981 The Impact of Endotoxins in African Dust: Cause for Inflammatory Response

M. G. Ortiz-Martinez and B. D. Jimenez-Velez. Biochemistry and Center for Environmental and Toxicological Research, University of Puerto Rico-Medical Sciences Campus, San Juan, Puerto Rico.

African Dust Events (ADE) are believed to be associated with respiratory diseases such as asthma in Puerto Rico. Particle pollution in the form of PM10 contained in windblown dust is known to possess bacterial molecules such as endotoxins (ENX) as part of its biological components. ENX are able to signal the activation of pro-inflammatory genes through the Toll-like receptors (TLR2, 4) signaling pathway. We had demonstrated that ENX in PM10 from an urban and rural site were in part responsible for the release of IL-6 and IL-8 from human bronchial epithelial cells (BEAS-2B). The use of a specific ENX inhibitor (polymyxin B) indicates ENX are responsible for increase in TLR4 mRNA expression and transcription factor, nuclear factor kappa (NF-κB) activation (preliminarily). Tagman® Real-Time PCR, antibody based and transcription factor assays were employed for these outcomes. We report here that urban extracts are more proficient in the induction of pro-inflammatory responses than rural extracts. Results highlight ENX as important constituents of PM10 ADE-induced cellular effects in vitro with particular contribution at the urban site. Also, these findings suggest the influence of local PM10 sources on dust reaching a Puerto Rican urban site and how it is capable of stimulating the molecular mechanism of Toll-like receptors in BEAS-2B. Support provided by MBRS-RISE Grant R25GM061838.

982 Addition of a Methoxymethyl Side Chain into p-Phenylenediamine Yields 2-Methoxy-Methyl-p-Phenylenediamine, a Hair Dye with Reduced Skin Sensitizing Properties

C. Goebel1, J. Troutman1, H. Hennig2, H. Rothé3, H. Schlatter1, G. Grote1 and B. M. Blomberg2. 1Central Product Safety, Procter & Gamble, Dormstadt, Germany, 2Central Product Safety, Procter & Gamble, Cincinnati, OH and 3Environmental Toxicology, Trier University, Trier, Germany.

p-Phenylenediamine (PPD) and p-toluidinediamine (PTD) are the most important hair dye primary intermediates for oxidative hair coloring and are regarded as the key drivers of hair dye allergy. Adding a methoxymethyl side chain to the PPD molecule yields the derivative 2-methoxy-methyl-p-phenylenediamine (ME-PPD) with reduced sensitizing properties compared to PPD and PTD. ME-PPD showed an attenuated innate immune response when analyzed for its protein reactivity and dendritic cell activation potential. In the local lymph node assay (LLNA) in mice, the concentration of ME-PPD needed to induce lymphocyte proliferation 3-fold above background (EC3 value) was 4.3%, indicating a moderate skin sensitizing potency, whereas EC3 values of 0.1 and 0.17% correspond with an extreme to strong potency for PPD and PTD. Quantitative risk assessment (QRA) of the skin sensitizing potency of ME-PPD under hair dye usage conditions indicated an allergy induction risk negligible compared to PPD or PTD.

983 Comparison of Different Sampling Methods for Assessment of Biological Activity of Dust from Moisture Damaged Buildings

J. Tirkkonen1, K. hutudden1, M. Täubel2, H. Leppänen1, A. Hyvärinen2 and M. Hirvonen1. 1Department of Environmental Sciences, University of Eastern Finland, Kuopio, Finland and 2Department of Environmental Health, National Institute for Health and Welfare, Kuopio, Finland. Sponsor: M. Viluksela.

The poor quality of indoor air in the moisture damaged buildings leads to several kinds of symptoms and diseases. There is an evident need for better tools to measure the severity of the damage. In this study, the aim was to compare sampling methods for analysis of biological activity of dust in moisture damaged and reference school buildings. Two kinds of samples were collected in one moisture damaged and one reference school: three active air samples (Button sampling, 4L/min) for five days during working hours, and six settled dust box samples during a two week period. All dust samples were weighed and then extracted directly into cell culture medium. The toxicity testing was done by exposing RAW 264.7 mouse macrophages to three dilutions of dust samples for 24 hours. After the exposure, the viability of the cells and production of inflammatory mediators nitric oxide (NO) and cytokine tumor necrosis factor (TNF) α were measured. The amount of dust was smaller in the damaged school compared to the reference school. The biological activity of the actively collected dust was slightly higher in the sample collected from the moisture damaged school, but the small amount of material in the sample limited the assay. A similar, clearer trend could be seen in the settled dust samples, and the difference was even more pronounced when the sampling sites within the schools were compared according to the damage observations. The results indicate that the biological activity of the dust collected with these sampling methods seems to be higher in the water damaged school compared to reference school, but the method may not differentiate the buildings reliably enough for the needs of risk assessment. Further testing of different sampling approaches should be done to improve the method.

PS984 Role of ROS and HMGB1 in Chemical Allergen-Induced IL-18 Production in Human Keratinocytes

E. Corsini, V. Galiberti, C. Galli and M. Marinovich. DiSeF, Università degli Studi di Milano, Milan, Italy.

We have recently identified the possibility to use interleukin-18 (IL-18) production for the in vitro identification of contact allergens. Previously, we demonstrated a role for oxidative stress, NF-κB and p38 MAPK activation (PPD)-induced IL-18 production. The purpose of this study was to characterize the molecular mechanisms underlying allergen-induced IL-18 production, in order to identify the cellular source of reactive oxygen species (ROS) and the danger signals involved. Selective inhibitors were used to characterize the source of ROS and to identify the damage-associated molecular pattern molecules (DAMPs) triggered by contact allergens. The human keratinocyte cell line NCTC2544 was exposed to three contact allergens, dihydroxy PPD, 2,6-dinitrochlorobenzene and cital in the presence or absence of diphenylethylenequinone (DPQ), aliquoteine and rotenone to identify
the source of ROS, and to anti-TLR4 antibody and glycyrizic acid to characterize the DAMPs. In the case of PPD, the induction of IL-18 can be modulated by rotenone, allopurinol and DPI, indicating the involvement of different sources of ROS. In the case of DNCh, rotenone completely prevents the induction of IL-18, suggesting a central role of mitochondria-derived ROS, while for citral DPI completely prevents the induction of IL-18, indicating the central of NADPH oxidase. Allergen-induced IL-18 involves the activation of the inﬂammasome and TLR4, as it can be modulated by the caspase inhibitor Z-VAD FMK and anti-TLR4 antibody. As DAMPs, we demonstrated the ability of all allergens tested to induce the release of HMGB1 (high mobility group box-1) and its sequence by glycyrizic acid significantly modulate PPD-induced IL-18 production and completely prevents DNCh and citral-induced IL-18, conﬁrming the role of HMGB1. Overall, we found that different intracellular source of ROS are triggered by contact allergens and an important role for HMGB1 in chemical allergen-induced IL-18 production was demonstrated.

985 Human Skin Explants: An Alternative Method to Assess Allergenic Potential of Chemicals

1DEB Group, Denby, United Kingdom, 2PREVOR Laboratory, Valmondois, France, 3Bio-Ec Laboratory, Longjumeau, France and 4Department of Dermatology, UCSF Medical School, San Francisco, CA.

Aims of the study
This study is aimed to assess predictive allergenic potential of chemical through a histological expertise of the general morphology of the skin after staining according to Masson trichrome and by the counting of Langerhans cell as after immunostaining of CD1a. The study is also an opportunity to develop a model for evaluation of protective creams against professional chemical allergens.

Method
84 human skin explants from abdominoplasty. 8 allergens frequently used at work-placed were evaluated: Tetramethylthiram disulﬁde, 2-Mercapto benzothiazole, Benzyl carbamate, Bisphenol, Ethyl acrylile Koشر, Araldite 506 epoxy Resin, Hevein (latex) and Formaldehyde 30 %. The allergens stayed in contact with the skin for 24 hours. 3 series were compared: the 8 allergens as positive control, cream excipient, creams with different potential protective agents. Epidermic Langerhans cells were stained with a monoclonal anti-CD1a antibody (IM590, clone O10, Beckman Coulter) for one hour, then enhanced with a streptavidin/biotin system (Vector, PK-7200) and at the end revealed using VIP (Vector, SK-4600). The mean number per centimetre of epidermic Langerhans cells was calculated to objective their migration as a proof of skin sensitization.

Results
In our operating conditions, allergenic tested molecules in contact with the skin for 24 hours induce Langerhans cells migration. When the skin was pre-treated with excipient or skin protective cream, less signiﬁcant migration of the Langerhans cells was induced by the allergens (p < 0.05).

Conclusion
This method is efficient to show the hypersensitivity potential of known chemical allergen. It could be useful “for alternative to animal testing” for skin sensitization. It also could be a model for testing skin protective creams.

986 Comparing Lymphocyte Subsets in the Mouse Allergy Model and Local Lymph Node Assay by Multiparameter Flow Cytometry

A validated animal model is needed to predict the potential of drugs administered by oral or parenteral routes to produce hypersensitivity reactions (HR). Recently, the mouse allergy model (MAM) was developed as a predictive model where subcutaneous injection of drugs associated with HR in the clinic produce a marked increase in the cellularity of the draining lymph nodes (LN). The murine local lymph node assay (LLNA) has been used extensively as a tool to predict for contact HR but does not appear to predict for systemically administered drugs. In the LLNA, topical application of contact sensitizers to the ears of mice causes an increase in cell counts in draining LN. The objective of this study was to compare the responses in the MAM and LLNA to determine if similar mechanisms may be involved in driving these responses. The MAM and LLNA assays were performed and the draining LN lymphocyte subsets and surface marker expression of CD62L/L-selectin and CCR7 were evaluated by flow cytometry. In the MAM, amoxicillin (100 mg/kg) treatment resulted in a proportional increase in absolute counts of CD4 and CD8 T cells and B cells, whereas a significant (2-fold) increase in the percentage of B cells was observed in the LLNA with 0.25% Dinitrofluorobenzene (DNFB)

987 Identification and Frequency of Naı́ve T Lymphocytes Specific for Penicillin: Implication in Drug-Allergy

M. Pallardı́, M. Azoury1, N. Scortet2, C. Nhım1, D. Joseph1, S. Delarue-Cochin1, S. Dellut2, B. Mailleır3, R. Weaver4 and N. D. Claude5.
1UMR996, Université́, Château-nil-Maléry, France, 2UMR CNRS8076, Université́, Château-nil-Maléry, France, 3Platine Pharma Service, Lyon, France, 4SINOPRO, Ibé-Tec, CEA, Saclay, France and 5Institut de Recherches Internatio-nalı́e Servier, Suresnes, France.

Allergic reactions to drugs are unpredictable and have many side effects. According to the hapten theory, these compounds are capable to bind to proteins and form immunogenic complexes. Antigen presenting cells, such as dendritic cells (DC), internalize haptenized complexes, digest them into peptides and present them on HLA molecules to drug-specific T cells inducing an immune response. Knowing that drugs provoke IgE mediated hypersensitivity reactions in treated patients, the CD4+ T-cell response to benzyl-penicillin (BP) was investigated. The aim of the study was to determine the size of the BP-specific naive CD4+ T-cell repertoire, and to identify peptide epitopes haptenized with BP and presented to T cells via HLA-II molecules.

Since BP is known to bind covalently to proteins, human serum albumin (HSA)-BP bio-conjugates were synthesized at basic pH and BP-binding sites on HSA were identified using mass-spectrometry. 12 peptides of 15 mer long including the identified BP binding sites were synthesized. naïve CD4+ T cells from non-allergic donors were stimulated once a week with autologous DC loaded with HSA-BP or with peptide-BP to amplify respectively HSA-BP- or peptide-BP-specific T cells. Activation of specific CD4+ T cells was detected using interferon-γ EлиSpot and their frequency was calculated.

The results of the CD4+ T-cell response to BP were as follows: - Detection of BP-specific CD4+ T cells in 12/13 tested donors with a mean frequency of 0.26 cells/million of CD4+ T cells
- Identification of 17 binding sites of BP on HSA
- Specific naïve CD4+ T cells recognized 5 specific peptides, from HSA, haptenated by BP.

This study showed the capacity of HSA-BP to be recognized by naïve T-cells from multiple donors and the possibility to identify epitopes involved in the allergic reaction to BP.

Azoury M. & Scortet N.: Contributed equally to this work.

988 Molecular Profile Analysis of Allergenic Acid Hydrolyzed Wheat Protein

1National Institute of Health Sciences, Tokyo, Japan, 2National Institute of Technology and Evaluation, Tokyo, Japan and 3Sagamihara National Hospital, Sagamihara, Japan.

Hydrolyzed wheat protein (HWP; hydrolyzed gluten) is used in various products worldwide. Several cases of systemic wheat allergy caused by HWP have been reported, including wheat-dependent exercise-induced anaphylaxis following sensitization to HWP in cosmetics in Japan. Moreover, an increasing number of studies have shown that HWP can induce IgE-mediated hypersensitivity by skin contact and/or food ingestion. It is considered that these allergic manifestations result from deamidated gluten in HWP. However, the relationship between the essential molecular properties of HWP and its allergenicity remains unknown.

In this study, we prepared several HWPs with different degrees of acid hydrolysis (0.1 N hydrochloric acid treatment at 100°C for 0.5, 1, 3, 6, 9, 12, and 24 h). In profiling analysis of these HWPs, size exclusion chromatography showed that the average molecular weight of HWP decreased depending on the extent of acid hydrolysis. In contrast, proteomics analysis showed that the deamidation level increased depending on the extent of acid hydrolysis, and this level reached a plateau after 6 h of hydrolysis. The allergenicity of gluten and two HWP (0.5- and 9-h hydrolysis sample) was compared by transdermal administration to BALB/c mice. Among these HWPs, the 0.5-h hydrolysis sample showed significantly increased

SOT 2014 Annual Meeting 257
antigen-specific serum IgE: titer. After skin sensitization for 4 weeks, intraperitoneal injection of this HWP caused active systemic anaphylaxis, resulting in marked decrease in rectal temperatures, increase in anaphylaxis scores, and increase in plasma histamine levels. The effect of skin sensitization with gluten and 9-h hydrolysis samples was significantly weaker than that with the 0.5-h hydrolysis sample. In conclusion, we demonstrated that allergenic HWP has specific molecular properties and the results showed that it may be possible to reduce the risk of skin sensitization to HWP by extensive acid hydrolysis.

989 Impact of Aggregation on Immunogenicity: Relevance for Biopharmaceuticals
K. Ratiani1, J. Derrick1, R. Thorpe2, M. Wadhwa2, L. Kimber2 and R. J. Dearman1, 1Faculty of Life Sciences, Manchester University, Manchester, Greater Manchester, United Kingdom and 2Institute for Biological Standards and Control, Potter Bar, United Kingdom.

The clinical use of protein therapeutics has increased dramatically over the last decade. One important safety issue with such molecules is the development of anti-drug antibodies in patients that may cause adverse events or may reduce efficacy of the protein therapeutic. Protein aggregation can be associated with the induction of vigorous immune responses, for example with certain preparations of interferon-β. As a result, regulatory guidelines recommend screening for and minimizing protein aggregation during bioprocessing, despite a lack of understanding regarding the mechanisms and the size/nature of problem aggregates that can trigger such responses. In the current experiments a humanized single chain Fv (scFv) antibody fragment expressed by E. coli was purified using Protein A affinity chromatography (monomeric fraction; mean diameter 7nm). Reproducible aggregates within the subvisible particle size range (mean diameter 190nm) were formed by incubation at 40°C for 20 min at pH 7.0. Antibody responses induced in BALB/c strain mice by intraperitoneal exposure to the monomeric fraction or the aggregated scFv (1 mg/ml) were characterised. Sera were analysed for protein specific total IgG and IgG1 and IgG2a subclasses by enzyme-linked immunosorbant assay. Immunisation with both forms of scFv induced relatively vigorous IgG1 and IgG1 antibody responses of equivalent magnitude. However, the aggregated fraction stimulated significantly higher titers of IgG2a antibody than did the monomeric fraction. Tiers were independent of whether aggregated or monomeric protein was used a substrate in the analysis. Thus, aggregated protein induces a preferential Th1 type response (IgG2a) whereas the monomer elicits a selective Th2 response (IgG1/IgG2a). Th1 responses are typically mounted against intracellular bacteria and viruses, suggesting that the aggregated protein may stimulate polarized Th1 responses by mimicking the repetitive structures found in viruses.

990 Allergen-Induced Langerhans’ Cell (LC) Migration: Role of Interleukin (IL)-1β
L. Eaton1, O. Metryka1, R. Roberts1, L. Kimber2 and R. J. Dearman1, 1Manchester University, Manchester, United Kingdom and 2Safety Assessment, AstraZeneca, Alderley Park, United Kingdom.

Epidermal LC play key roles in the initiation and regulation of immune and allergic responses. LC migration induced in mice by topical exposure to the contact allergen oxazolone (Ox) requires two independent cytokine signals delivered by UVB, trauma) are dependent upon the local availability of TNF-α. These data also contrasts with the prevailing view that all LC migratory stimuli (allergens, irritants, concentrations are very high, LC migration is independent of TNF-α. This

991 Cytokine Fingerprinting for Chemical Respiratory Allergens: Use of a Nonstandard Vehicle
R. J. Dearman and I. Kimber. Manchester University, Manchester, United Kingdom.

We have demonstrated previously that prolonged (13 day) topical exposure of BALB/c mice to the reference contact allergen 2,4-dinitrochlorobenzene (DNCB), or to the reference respiratory allergen trimellitic anhydride (TMA) induces selective type 1 or type 2 cytokine secretion profiles, respectively. Similar divergent cytokine expression patterns have been shown for a number of other contact allergens (such as formaldehyde, isoeugenol) and respiratory allergens (including disocyanates). In these experiments, compounds have been formulated exclusively in the standard local lymph node assay acetonoeol oil (AOO) vehicle for topical exposure. In the current experiments, responses provoked by respiratory sensitizers formulated in dimethyl formamide (DMF) have been examined. Mice were exposed topically allergen over a 13 day period, 13 days after the initiation of exposure, draining auricular lymph node cells (LNC) were isolated. Single cell suspensions were prepared and cultured; cytokine secretion profiles were measured. Initial experiments with DNCB and TMA formulated in either AOO or DMF revealed that, with the exception of interleukin (IL)-4 which was recorded at low levels in TMA/DMF treated animals, TMA treatment induced a type 2 phenotype with high levels of IL-5, 10 and 13 and relatively low levels of interferon-gamma when formulated in either vehicle. The converse type 1 pattern was provoked by DNCB exposure independent of vehicle, however, cytokine levels were more variable and patterns less divergent when DMF was used. Cytokine fingerprinting experiments conducted with additional respiratory sensitizers (chloramine T; reactive dyes) formulated in DMF revealed the expected type 2 phenotype. These data suggest that the measurement of induced cytokine secretion profiles in the BALB/c strain mouse provides a robust method for hazard identification and characterization of respiratory chemical allergens. Furthermore, DMF is an appropriate alternative vehicle although AOO is still the vehicle of choice.

992 Interleukin (IL)-1 Expression by Dendritic Cells (DC): Evidence for Intracellular Degradation
I. Kimber1, J. Ainscough1, G. Gerberick2 and R. J. Dearman1, 1Manchester University, Manchester, United Kingdom and 2Procter & Gamble, Cincinnati, OH.

DC play pivotal roles in the development of immune and allergic reactions, including skin sensitization, the commonest form of immunotoxicity. A key event in contact allergy is the production of the proinflammatory cytokine IL-1β. This cytokine is not secreted via the classical pathway, instead, independent signals are required. The first induces up-regulation of pro-IL-1β, and the second drives cleavage and secretion of the bioactive molecule. The intracellular regulation of expression of this cytokine in immature (day 8) mouse bone marrow (BM) DC has now been characterized. Cells were stimulated with lipopolysaccharide (LPS; 0.1µg/ml) and the IL-1α and β content of supernatants (secreted cytokine) and cell lysates (intracellular cytokine) was analyzed by ELISA. The impact of cycloheximide (CHX), the proteasome inhibitor MG132 and the autophagy inhibitor 3-methyladeninde (3-MA) on IL-1β production was examined. The role of ubiquitination was examined by IL-1β immunoprecipitation and Western blotting. LPS treatment stimulated a marked increase in intracellular IL-1β, peaking at ~8hr and declining rapidly thereafter. There was no concomitant detection of secreted product, indicating that in the absence of a second signal, LPS-induced IL-1α and β were rapidly degraded. Using a 1hr CHX (10µg/ml) pulse to inhibit de novo translation revealed a 4-hr lag before IL-1β degradation was detected. Treatment with MG132 (10µM), but not with 3-MA (10µM), inhibited significantly IL-1β degradation without impacting cell viability. Furthermore, following MG132 inhibition of degradation, Western blotting with anti-ubiquitin antibodies revealed an accumulation of ubiquitinated IL-1β. Thus, IL-1α and β are degraded in an ubiquitin-proteasome paradigm of protein degradation and this process is initiated following DC activation in the absence of secretion. Therefore, the regulation of IL-1α proteasomal degradation may control the vigor of IL-1α secretion, and ultimately may influence the potency of pro-inflammatory responses.

993 Enteropathogenic Escherichia coli As a Mucoassociated Exosome Extends Epithelial NF-kB Activation via Macrophage Inhibitory Cytokine 1
H. Choi and Y. Moon. Department of Biomedical Sciences, Pusan National University School of Medicine and Immunoregulatory Therapeutics Group in Brain Busan 21 Project, Vangans, Republic of Korea.

Commensal bacterial community shifts in the pathogenic colonic environment and chronic colonization of mucoassociated Escherichia coli (MAEC) has been linked to chronic colonic inflammatory diseases. Enteropathogenic Escherichia coli...
(EPEC) is one of commonly identified MAEC in inflammatory bowel disease patients. The aim of this study is to address the contribution of MAEC colonization to human inflammatory signals such as nuclear factor kappa B (NF-κB). The present study was conducted to investigate the prolonged epithelial responses to persistent EPEC infection via NF-κB activation. EPEC infection led to sustained activation of NF-κB signal in mouse intestinal epithelial cells in vitro and in vivo, which was positively associated with a type III secretion system, whereas early NF-κB is regulated. Moreover, prolonged NF-κB activation was found to be a part of macrophage inhibitory cytokine 1 (MIC-1)-mediated signaling activation, a novel link between NF-κB signaling and infection-associated epithelial stress. Furthermore, both EPEC-induced MIC-1 and NF-κB signaling mediated epithelial survival by enhancing the expression of cyclin D1, a target of NF-κB. In summary, the results of the present study suggest that MIC-1 serves as a mediator of prolonged NF-κB activation, which is critical in maintaining gut epithelial integrity in response to EPEC-induced injury. This work was supported by the National Science Foundation of China, the National Natural Science Foundation of China, the National Key Research and Development Program of China, and the National Health and Family Planning Commission of the People’s Republic of China.

PS 994 The Role of Endothelin-1 in Endotoxin-Triggered Release of Placental Proinflammatory Cytokines

P. R. Mahajan1, R. Donepudi1, F. Einstein3 and S. E. Reznik1, 2, 3
1Pharmacological Sciences, St. John’s University, Jamaica, NY, 2Pathology, Albert Einstein College of Medicine, Bronx, NY and 3Obstetrics and Gynecology, Albert Einstein College of Medicine, Bronx, NY. Sponsoring Institution: L. Trombetta.

Background: Premature delivery occurs in 12% of all births and accounts for 60 to 80% of perinatal mortality in non-anomalous infants. Despite advances in obstetrics and neonatology, there is no FDA approved therapy for preterm labor. We have shown that the ECE-1 inhibitor, phosphorhamdomid, the selective endothelin receptor A antagonist, BQ-123 and a novel synthetic ET A receptor antagonist synthesized by our group rescue mice from LPS-induced PTB. Finally, we have been able to prevent PTB in LPS-stimulated animals, using RNA silencing, by hydrodynamic transfection of E15 mice with ECE-1 RNAi.

Objective: Our aim was to test the hypothesis that ET-1 contributes to the cause of preterm birth by up-regulating pro-inflammatory cytokines.

Methods: Chorionic villous explants from full term human placenta obtained by Cesarean delivery were cultured under aseptic conditions and were divided into four groups: sham, endotoxin-treated, endotoxin plus low concentration BQ-123-treated, and endotoxin plus high concentration BQ-123-treated. Explant supernatants from all groups were collected 24 hours after the addition of LPS and evaluated for changes in levels of interleukin 1 β (IL-1 β) and tumor necrosis factor α (TNF α) by Western blot analysis.

Results: Villous explants treated with LPS released significantly higher amounts of both IL-1 β and TNF α into culture media than sham explants. This pro-inflammatory response was reversed, in a concentration-dependent fashion, with the ET A receptor antagonist, BQ-123.

Conclusion: IL-1 β and TNF α, pro-inflammatory cytokines closely linked to infection-associated PTB, are ET-1 dependent. The mechanism of action of ET-1 blocking agents in tocolysis involves decrease ET-1-dependent release of these mediators. Further evaluation of inflammatory mediators affected by ET-1 action may lead to the identification of novel targets for preventive therapy for PTB.

PS 995 Classical and Alternative Activation of Cyanobacterium Anaeroba sp. Lipopolysaccharide (LPS)-Treated Rat Brain Microglia

C. Osterbauer1, D. MacAdam1, M. L. Hall1, D. Feher2, P. Williams1 and A. M. Mayer1
1Pharmacology, Midwestern University, Downey Grove, IL and 2Chemistry and Biochemistry, University of Hawaii at Manoa, Honolulu, HI.

Cosmopolitan Gram-negative cyanobacteria may contaminate freshwater by releasing toxins, such as lipopolysaccharide (LPS), thus affecting human health. We reported that cyanobacterium Anaeroba sp. LPS (AnaLPS) elicited classical activation of rat microglia (BMP) and MIP-1α (CCL3) and IL-6 release in vitro (The Toxicologist CD 132 (S-1), 2013). We hypothesized that AnaLPS activates classical and alternative activation of BMG in vitro and concomitant release of cytokines and chemokines. AnaLPS was prepared by hot phenol/water extraction. E. coli LPS (EcoliLPS) 026:B6 from Difco Lab, Detroit, MI was used as a positive control. BMP were isolated from neonatal rats, and treated in vitro in a concentration-dependent manner with either AnaLPS or EcoliLPS for 18 hours at 35.9 °C. Cytokines and chemokines were determined by Milliplex® MAP rat cytokine/chemokine multiplex immunoassays. Results were the following: EcoliLPS and AnaLPS stimulated concentration-dependent and statistically significant release of (a) Pro-inflammatory cytokines: IL-6, IL-1β, TNF-α; (b) Pro-inflammatory chemokines: MIP-2(CXCL2) > CINC(CXCL1) > MIP-1α (CCL3) > MCP-1(CCL2) > IP-10(CXCL10) > RANTES(CCL5); and (c) The Anti-inflammatory cytokine: IL-10, at > 1ng/ml. EcoliLPS and 10 ng/ml AnaLPS. We thus conclude that an 18 hour in vitro treatment with AnaLPS stimulated both classical and alternative activation of rat brain microglia, but was considerably less potent than EcoliLPS. Continued investigation of the mechanism responsible for the differential response observed between EcoliLPS and AnaLPS on BMG is ongoing in our laboratory.

Financial support by Midwestern University and the University of Hawaii at Manoa is gratefully acknowledged.

PS 996 Behavioral and Neurochemical Alterations in Adult Mice with Low-Chronic Inflammation Caused by Repeated Peripheral Lipopolysaccharide Exposure

S. Krishna1, C. A. Dodd1, 2 and N. M. Filipovic1
1Physiology and Pharmacology, Univ. of Georgia, Athens, GA and 2Biology, Fort Valley State University, Fort Valley, GA.

Sickness behavior following acute inflammation, modeled by acute peripheral lipopolysaccharide (LPS) administration, can later transition into depressive behavior. In light of the limited information on the impact of chronic peripheral inflammation on the development of depressive behavior and other behavioral alterations and on their persistence after inflammatory stimuli exposure termination, this study assessed behavioral and neurochemical effects of chronic (25 weeks), low dose (0.25 mg/kg body weight; twice weekly) peripheral (intraperitoneal) LPS exposure in adult male C57BL/6 mice. Behavioral tests were performed 6 and 12 weeks post LPS/saline treatment as well as in mice exposed to 13-week LPS/saline treatment followed by an 11-week period without any treatment. Following sacrifice (at 13 and 25 weeks), striatal concentrations of dopamine, serotonin and their metabolites were analyzed. LPS-exposed mice were hypoactive in the open field after 6 weeks, whereas significant hyperactivity was observed in the 12 week LPS and 13 week LPS+11 week off groups. Similar biphasic responses were observed in the time in the center of the open field arena between the 6 week LPS (decreased) and 13 week LPS+11 week off groups (increased), suggestive of increased and decreased anxiety, respectively. In forced swim test, mice exhibited significant increase in the immobility time (depressive behavior) at all three time points. Neurochemistry data are still being analyzed. Above findings demonstrate that chronic peripheral inflammation initially causes decreased locomotion and increased anxiety, followed by persistent hyperactivity and decreased anxiety. Notably, chronic low-dose LPS-induced depressive behavior appears early and persists long after termination of LPS exposure. Collectively, these data emphasize the need to pay more attention on the lasting behavioral alterations induced by chronic peripheral inflammation. Supported by: R01ES016965 (NIEHS).

PS 997 Sex Differences in Gene Expression Profiles in Individuals with Idiopathic Pulmonary Fibrosis Potential Targets of Xenoestrogens?

1Physiological Sciences, University of Florida, Gainesville, FL, 2Bayer CropScience LP, Research Triangle Park, NC, 3Epidemiology, Bioinformatics, and Environmental Health, University of Memphis, Memphis, TN and 4Environmental and Global Health, University of Florida, Gainesville, FL.

Epidemiological studies suggest sex-specific trends in the prevalence and mortality of idiopathic pulmonary fibrosis (IPF) and chronic obstructive pulmonary disease (COPD). While the expression of several immune and extracellular matrix (ECM) genes in the lung have been well characterized in these diseases, investigations aimed at elucidating their sex-specific expression by disease type and severity, and the evaluation of hormone-related genes, has not been well studied. To begin to examine sex-specific expression profiles we performed targeted analysis of 48 genes, those involved in inflammation, ECM remodeling and hormonal processes, in lung tissues from males and females with mild or medium severity IPF or COPD. Results revealed a subset of genes that are differentially expressed among sex, disease type and severity. The most significant observations were the increased expression primarily of ECM genes in medium severity IPF (CATHK, COL1A1, COL3, MMP1, MMP1, MMP7, IL1RN) compared to mild IPF and COPD. Results suggested sex-specific gene expression profiles in individuals with IPF and COPD. Interestingly, two genes, CH3L1 and MMP7 showed a significant interaction of sex and disease in individuals with IPF. While there were no significant differences in any of the hormonal genes between the IPF groups, ESR1 and AR expression levels were higher and lower, respectively, compared to COPD samples. Based on these data we are investigating a role for (xeno)estrogens in the transcriptional control of these select genes in lung epithelial cells through modulation of the nuclear and membrane
estrogen receptor. Overall, these results highlight molecular targets that could play a role in differential trends in lung disease incidence and severity between men and women and their influence by contaminants with hormonal activity.

### 998 S-Nitrosoglutathione Reductase (GSNOR) Activity Is Differentially Regulated within Macrophage Phenotypes

C. Guo, J. Gow, M. Govindraj and A. Gow. Rutgers University, Piscataway, NJ.

Macrophages (Mφ) play a crucial role in innate immunity. Upon stimulation, Mφ are divided by two main phenotypes, classic (M1) and alternative (M2) activation, distinguished by their functional patterns. M1 Mφ produce large amount of NO, which reacts with glutathione (GSH) to form S-nitrosoglutathione (GSNO). GSNOR can transnitrosate the thiol residues of proteins to form S-nitrosothiols (SNO), with functional consequences. GSNOR reductase (GSNOR) reduces the SNO moiety in the presence of NADH to regenerate GSH and produce hydroxyamine. It is a major regulator of intracellular SNO content. We hypothesized that GSNOR activity is regulated within Mφ activation in order to regulate SNO accumulation within phenotypic differentiation. We have utilized LPS or IL-4 to stimulate a M1 or M2 phenotype respectively in a range of Mφ cultures including RAW264.7, Raw blue, bone marrow derived Mφ (BMDM) and alveolar Mφ. Incubation of all Mφ with LPS dramatically increased iNOS expression and NO production in all cell systems. IL-4 induced arginase but not iNOS expression. LPS induced M1 Mφ had increased SNO content and SNO-proteins as determined by Cu-Cys reduction assay and biotin-switch. IL-4 reduced total intracellular SNO content and SNO-proteins. LPS treatment decreased Mφ GSNOR expression within 1-6 hours, while IL-4 treatment stimulated expression of GSNOR. These changes were matched by reduced GSNOR activity within cellular lysates. LPS mediated increased in iNOS expression were associated with increased NO production in Raw blue cells, and the NF-kB inhibitor CAPE reduced iNOS expression in Raw264.7 cells. However, CAPE had no effect on GSNOR expression, suggesting that GSNOR expression is NF-kB independent. These changes were not specific to cell lines as they were also observed in BMDM and alveolar Mφ. SNO regulation in Mφ in the different phenotypes suggests that SNO plays an important role in Mφ activation. Regulation of GSNOR activity may provide novel therapeutic avenues within inflammatory disease. Supported by NIH HL086621.

### 999 Salvia plebeia Extract Alleviates Inflammatory Response in Murine Arthritis Model and Human Rheumatoid Synovial Fibroblasts

J. Choi, M. Jin, J. Je and S. Kim. Pharmacology, School of Medicine, Kyungpook National University, Daegu, Republic of Korea.

Salvia plebeia R. Br (S. plebeia) has been used for the treatment of a variety of inflammatory diseases and anti-oxidant as an oriental folk medicine. In this study, we investigated the effects of S. plebeia extract (SPE) on inflammatory arthritis and underling mechanisms of action. We used a collagen-induced arthritis (CIA) model in BALB/c mice by immunized with type II collagen. SPE was orally administrated during 5 weeks of arthritis induction. Oral administration of SPE decreased arthritis symptoms such as, physiologic arthritis score, footpad thickness, histopathologic changes in addition to serum IgG1 and IgG2a levels. SPE inhibited TH1/TH2/TH17 cytokine CD4+ T lymphocytes expansion in draining lymph node, expression of inflammatory mediator cytokines, matrix metalloproteinase (MMP)-1 and MMP-3 in the ankle joint tissue. To define the underlying mechanisms of action, tumor necrosis factor-α stimulated rheumatoid arthritis synovial fibroblasts were used. SPE significantly suppressed the expression of inflammatory cytokines and MMP-1 by the down-regulation of nuclear factor-kB and mitogen-activated protein kinases. Taken together, the results indicate that SPE has therapeutic efficacy for chronic inflammatory arthritis, suggesting that SPE might be a candidate for the treatment of RA.

### 1000 Optimization and Evaluation of Metabolite Extraction Methods for Untargeted Metabolomic Study by LC-QTOF/MS for the Evaluation of Effects of 12-Dimethylmythene on RAW264.7 Murine Macrophages

J. Berkbigler. Center For Environmental Medicine, Colorado State University, Fort Collins, CO.

Advances in accurate mass spectrometry, better data analysis software and availability of biological pathway databases have allowed for more accurate untargeted metabolomic investigations. The purpose of this study was to optimize the harvest, extraction and LC-QTOF/MS parameters for the metabolic evaluation of the effects of 12-dimethylmythene (12-DIM) on RAW264.7 murine macrophages. 12-DIM is part of a family of potential anti-inflammatory compounds isolated from Brassica vegetables, such as broccoli, kale and brussel sprouts, and a metabolomics study will evaluate the potential for anti-inflammatory properties of 12-DIM. The optimal harvesting and extraction procedure was chosen with cold methanol and cell scraping, compared to the standard trypsin/ethylendiaminetetraacetic acid (EDTA) treatment. Four different extraction methods were compared to elucidate the highest efficiency for intracellular and extracellular metabolite extraction, including: methanol/chloroform/water, methanol/chloroform/0.1% formic acid, methanol/chloroform and methanol/water. Extraction with cold methanol/chloroform was found to extract the most definable molecular features. The ideal mobile phases were found to be water/0.1% formic acid and methanol, which gave a better chromatographic baseline as compared to acetonitrile. The source parameters including: nebulizer, sheath gas temperature, gas flow, gas temperature and the fragmentor for the LC-QTOF/MS were also optimized. These refined parameters provided sensitive and reproducible quantification and extraction of cellular metabolites from RAW264.7 macrophage cells for a global metabolomics study of the effects of 12-DIM.

### 1001 Nebulized Thiocyanate Attenuates Inflammation and Oxidative Stress in the Airway and Liver of ENaC Mice

J. D. Chandler1,2, E. Min1, J. Huang1, D. P. Nichols1 and B. J. Day1,2.

1DEOHs, National Jewish Health, Denver, CO and 2Pharmaceutical Sciences, University of Colorado, Denver, CO.

The pseudohalide thiocyanate (SCN-) has been implicated in innate immune function in mammals but less is known about its impact on inflammation and oxidative stress. The pseudohalide thiocyanate (SCN-) has been implicated in innate immune function in mammals but less is known about its impact on inflammation and oxidative stress. SCN- is dysregulated in cystic fibrosis (CF), a disease marked by chronic airway inflammation. Previously, we have shown that nebulized SCN- decreases inflammatory and bacterial burden in B6 mice infected with P. aeruginosa while sparing the antioxidant glutathione (GSH). To investigate the role of SCN- in pathogen-independent inflammation, we administered nebulized SCN- or normal saline vehicle to ENaC mice, a phenotypic model of CF, and wild type littermate controls. Nebulized SCN- significantly decreased airway neutrophil infiltration concurrent with rescue of the ratio of GSH to oxidized glutathione (GSSG) in airway leukocytes and epithelial lining fluid (ELF) of ENaC mice compared to control. Similarly, nebulized SCN- rescued the GSH/GSSG ratio in lung and liver tissue of ENaC mice to levels comparable to littermate controls. These results demonstrate that SCN- directly impacts pathogen-free airway inflammation and attenuates oxidative stress with both local and systemic protective effects. These results are supported mechanistically by the ability of SCN- to scavenge hypohalous acids, strong oxidants produced by neutrophils, forming a less reactive oxidant (hydroxyamine) that we have previously demonstrated is safely metabolized by mammalian cells. Our findings support nebulized SCN- as a potential pharmacologic agent in diseases of chronic inflammation such as CF. Continuing studies will investigate the effect of nebulized SCN- during chronic infection of ENaC mice and littermates and changes in cytokine characteristics that may affect neutrophil trafficking. This work was supported by NIH grant R01 HL084469 and a Cystic Fibrosis Foundation Research Grant.

### 1002 Redox Cross-Talk between Myeloid-Derived Suppressor Cells and Dendritic Cells in Cancer: Accumulation of Oxygenated Lipid Droplets and Suppression of Antigen Cross-Presentation

V. A. Tsviv1,2, W. Cao3, A. Amoscato1,2, J. Loomen3, D. Gabrilovich1 and V. E. Kagan1,2.

1EOH, University of Pittsburgh, Pittsburgh, PA; Center for Free Radical Antioxidant Health, University of Pittsburgh, Pittsburgh, PA and 3The Wistar Institute Cancer Center, Philadelphia, PA.

Accumulation of myeloid-derived suppressor cells (MDSCs), and expansion of immature dendritic cells (DCs) with aberrant cross-presentation – are important immunological abnormalities in cancer. While interactions between these cells are recognized as contributors to the failed anti-tumor immunity, their molecular mechanisms remain elusive. Excessive formation of lipid droplets (LDs) affects DCs immune functions. We show that DCs from tumor-bearing mice or treated with tumor explant supernatants (EL4, MC38) contained oxygenated neutral lipids: triglycerides (oxTAGs), free fatty acids (oxFFAs) and cholesterol esters (oxCE). LC-ESI-MS/MS revealed that oxTAGs were represented by a spectrum of truncated molecular species 39:1; 39:0; 41:1; 41:0; 45:2; 41:1; 43:0; 45:2 with functional consequences. GSNO reductase (GSNOR) reduces the SNO moiety in the presence of NADH to regenerate GSH and produce hydroxylamine. It is a major regulator of intracellular SNO levels. We hypothesized that GSNOR activity is regulated within Mφ activation in order to regulate SNO accumulation within phenotypic differentiation. We have utilized LPS or IL-4 to stimulate a M1 or M2 phenotype respectively in a range of Mφ cultures including RAW264.7, Raw blue, bone marrow derived Mφ (BMDM) and alveolar Mφ. Incubation of all Mφ with LPS dramatically increased iNOS expression and NO production in all cell systems. IL-4 induced arginase but not iNOS expression. LPS induced M1 Mφ had increased SNO content and SNO-proteins as determined by Cu-Cys reduction assay and biotin-switch. IL-4 reduced total intracellular SNO content and SNO-proteins. LPS treatment decreased Mφ GSNOR expression within 1-6 hours, while IL-4 treatment stimulated expression of GSNOR. These changes were matched by reduced GSNOR activity within cellular lysates. LPS mediated increased in iNOS expression were associated with increased NO production in Raw blue cells, and the NF-kB inhibitor CAPE reduced iNOS expression in Raw264.7 cells. However, CAPE had no effect on GSNOR expression, suggesting that GSNOR expression is NF-kB independent. These changes were not specific to cell lines as they were also observed in BMDM and alveolar Mφ. SNO regulation in Mφ in the different phenotypes suggests that SNO plays an important role in Mφ activation. Regulation of GSNOR activity may provide novel therapeutic avenues within inflammatory disease. Supported by NIH HL086621.

1003 Signaling Role of Cardiolipin Externalization in Elimination of Damaged Mitochondria in Lung Epithelial Cells

Euhoe University of Pittsburgh, Pittsburgh, PA.

Bacterial pneumonia triggers an exuberant host response characterized by excessive inflammation, oxidative stress, and epithelial cell damage culminating in the acute respiratory distress syndrome (ARDS). In ARDS, virulent bacterial pathogens directly damage host cells, activate innate immune responses, and trigger a burst in reactive oxygen species resulting in epithelial cell death. However, specific pathways involved in the evolution of epithelial injury with attendant release of novel damage signals remain elusive. We suggested that one critical damage signal is mitochondrial cardiolipin (CL). We found that mitochondria and reduced levels of distal mitochondrial protein markers were detectable in murine models of bacterial pneumonia. In addition, we demonstrated that early on after bacterial infection of murine lung epithelial cells (MLE15), CL transmigrates from the IMM to OMM; the unmasked externalized CL serves as a novel signal for mitophagy. A typical inducer of mitophagy, carbonyl cyanide m-chlorophenylhydrazone (CCCP) — acting as a protonophoric uncoupler — induced CL externalization to the OMM in MLE15 cells. This was evidenced by a robust decrease of the ratio of CL in the IMM and OMM from 18.6±0.3 in control MLE15 cells to 3.7±1.4 after treatment with CCCP. The externalization of CL was accompanied by activation of autophagy (LC3-II/I conversion) and decreased levels of mitochondrial marker proteins (TIM40, TIM23 and MnsSOD) — consistent with mitophagy activation. CCCP-induced mitophagy in MLE was also confirmed by co-localization of mitochonldria and lysosomes. Manipulations of CL levels or proteins involved in CL externalization (PLS3R) affected sensitivity of MLE to pro-mitophagial stimulation. These data are compatible with a hypothesis that externalized CL acts as an “eat-me” signal in depolarized mitochondria. Supported by NIH E00106, U19 A008821, and NIOSH OH008282.

1004 Resveratrol Protects against a Mouse Model of Multiple Sclerosis via Regulation of T Cell miRNA Expression

K. Orr Gandy, P. S. Nagarkatti and M. Nagarkatti.

Pathology, Microbiology and Immunology, University South Carolina School of Medicine, Columbia, SC.

Resveratrol is a plant-derived phytoalexin with antioxidant, anti-carcinogenic and anti-inflammatory actions. Resveratrol has been extensively studied in cancer and in cardiovascular disease and has recently emerged as a potential therapeutic for the treatment of various inflammatory diseases. In this study, we evaluated the mechanistic effects of resveratrol on the pathogenesis of a mouse model of multiple sclerosis, experimental autoimmune encephalitis (EAE). We hypothesized that resveratrol protects against myelin oligodendrocyte peptide (MOP35-55)-induced neuroinflammation via regulation of T cell microRNA (miRNA) expression. Analysis of miRNA expression in CD4+ T cells from brains of EAE mice revealed significant up-regulation of miR-12-124, -125, -132, -138 and -155 with resveratrol treatment. Predicted and validated target genes were chosen for further examination based on gene ontology and functional analysis. miRNAs and target gene expression were validated by qRT-PCR. We found that resveratrol treatment leads to miRNA-mediated down regulation of genes essential for cell cycle progression (Rb1 and Cyclin D1) and growth and proliferation (p38 and Sphingosine Kinase 1) in CD4+ T cells. We also found that resveratrol decreases immune cell infiltration into the brain and impairs activation. While studies evaluating the impact of resveratrol on immune cells in the periphery exist, few studies have examined its effect on T cells in the target organ, the brain. Given the established neuroprotective effects and the rapidly growing anti-inflammatory properties, resveratrol is emerging as an ideal candidate for the treatment of multiple sclerosis and other neuroinflammatory diseases. Supported in part by NIH grants P01AT003961, R01AT008361, R01AT006888, R01ES019313, R01MH094755, P20RR032684 and VA Merit Award BX001357.

1005 CCR2 Regulates Proinflammatory Macrophage Migration into the Liver during Acetaminophen (APAP)-Induced Hepatotoxicity

M. Mandal1, R. Sun1, S. Lad1, H. Choi2, L. D. Laskin2 and D. L. Laskin2.

Pharmacology & Toxicology, Rutgers University, Piscataway, NJ and Robert Wood Johnson Medical School, Rutgers University, Piscataway, NJ.

Inflammatory macrophages (MP) have been shown to play an important role in APAP-induced hepatotoxicity. Mechanisms mediating their accumulation in the liver have not been established. The C-C chemokine receptor, CCR2 has been shown to regulate inflammatory cell trafficking into injured tissues. In the present studies, we analyzed the phenotype of MP migrating into the liver following APAP intoxication and the role of CCR2 in this response. Mice were fasted overnight prior to administration of APAP (300 mg/kg, i.p.) or PBS. Liver, spleen and bone marrow (BM) were collected 24-96 h later and analyzed by flow cytometry. APAP caused a time-dependent increase in CD11b+Ly6C+ pro-inflammatory MP in the liver, but a transient decrease in CD11b+Ly6C+ anti-inflammatory/wound repair MP. Loss of CCR2 significantly reduced CD11b+Ly6C+ cells accumulating in the liver in response to APAP. We previously showed that the spleen is a source of hepatic inflammatory MP. Following APAP administration, increases in CD11b+Ly6C+ monocytes were observed in the spleen, with no effect on CD11b+Ly6C+ monocytes. Loss of CCR2 reduced numbers of pro-inflammatory monocytes in the spleen. In contrast, no differences were observed in monocyte subsets in the BM between wild type (WT) and CCR2/-/- mice. We also identified a subpopulation of CD11b+Ly6G+Ly6C+ myeloid derived suppressor cells (MDSC) in the liver and spleen of WT mice, which decreased 72 and 96 h after APAP. In contrast, in CCR2/-/- mice, MDSC increased within 24 h of APAP, remaining elevated for 72-96 h. Taken together, these results indicate that CCR2 plays a role in the emigration of CD11b+Ly6C+ pro-inflammatory MP into the liver from BM and spleen following APAP hepatotoxicity. Moreover, loss of CCR2 results in increased MDSC in the liver which may contribute to tissue repair. Supported by NIH ES007148, ES004738, CA132624, AR050575, and ES005022.

1006 Collagen Synthesis and Degradation Are Enhanced in Chronic Bacterial-Induced Prostatic Inflammation

I. Wong, P. Hutson and W. Bushman.

University of Wisconsin-Madison, Madison, WI.

Benign prostatic hyperplasia (BPH) is a common disorder in aging men. Prostatic inflammation-induced fibrosis is suggested to be a major contributor of BPH etiology. Collagen deposition was increased in our previously described mouse model of bacterial prostatic inflammation. The goal of this study is to investigate the synthesis and degradation of newly synthesized collagen in bacterial-induced prostatic inflammation.

Adult C3H/HeOuJ male mice were transurethrally instilled 200ul of 2x106/ml of uropathogenic E. coli 1677 or saline to induce prostatic inflammation. Prostates were harvested to perform immunohistology at selected timepoint following infection. To measure collagen synthesis, mice were injected with 15µg of 3H-proline on day 0, 5, 12, 19, 26 post-installation. Prostates were harvested 2 days after 3H-proline injection. To measure collagen degradation, mice were injected with 15µCi of 3H-proline every 2 days for 28 days. Prostates were harvested on day 0, 4, 8, 15, 22, 29, 36, 57, 78, 113 after the last injection of 3H-proline. The incorporation of 3H-hydroxyproline was determined by measuring 3H radioactivity using a liquid scintillation counter.

Collagen synthesis was significantly increased in the infected prostates between 5 and 7 days, and 12 and 14 days post-installation. Immunostaining to determine collagen-producing cell revealed that there were abundant CD45+Vimentin+ fibrocytes coexpressing with the collagen synthesizing enzyme prolyl hydroxylase in the infected prostates on day 7 after infection. The newly synthesized collagen in prostatic inflammation was less stable than that in the saline-instilled prostates. The half-life of collagen in the saline prostates was 18.6 days while collagen in the infected prostates had a half-life of 15.7 days.

Our study showed that increased collagen turnover and the presence of fibrocytes characterize prostatic fibrosis in bacterial-induced inflammation. This finding provides a basis for future study to elucidate the cellular and molecular mechanisms of collagen deposition in inflammation-associated prostatic diseases.
The use of cellulosic biofuels can potentially reduce our carbon footprint. However, they may have unintended ecological and health effects such as increased competitiveness and allergenicity. Climate change may impact the quality or quantity of allergens produced in elevated temperatures. The goal of these studies was to 1) develop a method to assess the potential allergenicity of the various grass components to which workers will be exposed and 2) determine if there are differences based on grass growth temperature (gt).

The biofuel grass components (leaves, flowers/stems, anthers, pollen) of *Sorghum bicolor* and *Fusarium virgatum* were extracted in an excess of 0.2 mM Tris pH 8. Following centrifugation the supernatant was concentrated and protein content assayed. Female BALB/c mice were dosed 4X over a 4 week period by intratracheal aspiration to a pool of equal protein amounts from each of the component extracts/species(gt) to induce an IgE antibody response. Three days after the final exposure the mice were exsanguinated and the blood pooled by species and gt.

Western blots of the component extracts were probed with species(gt) specific serum for IgE reactivity. IgE reactive proteins were identified only in pollen extracts. Blots of *S. bicolor* pollen extract identified 2 IgE reactive protein bands. Grass gt had no apparent effect on IgE reactivity (densitometry). Blots of *P. virgatum* pollen identified 4 IgE reactive protein bands in the control gt extract and 5 additional protein bands in the high gt extract. There was a reduced intensity in the 4 common *P. virgatum* protein bands in the control gt extract compared to the high gt extract. This limited dataset suggests that pollen is the most relevant source of allergenic proteins and that elevated growth temperatures may alter the IgE reactive profile for some but not all species.

(2) Polycyclic aromatic hydrocarbons (PAHs) comprise several hundred compounds with different carcinogenic potentials and are invariably found in mixtures. Due to a lack of data, risk estimations for PAH mixtures are usually based on those for benzo[a]pyrene (B[a]P). Individual substances within PAH mixtures, however, may influence genotoxic properties and act synergistically or antagonistically. In the present study we examined influences on the formation of B[a]P-specific anti-B[a]P-7,8-diol-9,10-epoxide (anti-BPDE) DNA-adducts by pyrene. Human A549 lung cancer cells were exposed to B[a]P (0.01-10 μM), pyrene (0.01-10 μM), or binary mixtures of 1 μM B[a]P + pyrene (0.01-10 μM) for 24 h. Specific anti-BPDE-DNA-adducts were determined in terms of the B[a]P-petrol 1-1 by HPLC with fluorescence detection. Additionally, changes in cytochrome P450 1A1/1B1 (CYP1A1/1B1) activities were measured in intact cells utilizing a luminescence-based assay. B[a]P alone led to a concentration-dependent formation of anti-BPDE-DNA-adducts after 24 h, with maximum adduct rates at 1 μM. After co-incubation with 1 μM B[a]P + 0.01 μM pyrene, adduct rates were enhanced compared to 1 μM B[a]P alone. But, with further increasing pyrene-concentrations in the binary mixtures, anti-BPDE-DNA-adduct rates decreased compared to 1 μM B[a]P alone. All changes in DNA-adduct formation were accompanied by similar changes in CYP1A1/1B1 activities. Incubation with pyrene only resulted in concentration-dependent decreases of CYP1A1/1B1 enzyme activities. Our results show that genotoxicity of B[a]P is systematically modulated by pyrene, but, not unidirectional in terms of increasing or decreasing genotoxicity. The observed effects were closely related to the bioactivation of B[a]P. These findings are important especially with respect to the fact that PAH mixtures to which humans are exposed vary in their compositions.

(3) Toxicological evaluation and risk assessment of chemical mixtures using a factorial design allows us to estimate not only main effects but also toxin interactions. This study evaluated individual and combined effects of four common Fusarium mycotoxins, DON (2μM), NIV (2μM), ZEA (40μM) and FB1 (40μM) on immunological defense mechanisms of intestinal epithelial cells (IECs) using pro-inflammatory cytokine synthesis (IL1β, IL1p, IL6, IL8, TNFα and MCP-1), antimicrobial peptide (pBD-1 and pBD-2) synthesis and secretion on porcine intestinal epithelial IPEC-J2 cells, as well as secretory mucin (MUC5AC and MUC5B) synthesis and secretion. The study also evaluated inflammatory cytokine synthesis (IL1β, IL6, IL8, TNFα (up to 22-fold), IL6 (up to 2.6-fold), IL8 (up to 20.5-fold), TNFα (up to 21-fold) and MCP-1 (up to 24.5-fold), anti-BPDE-DNA-adduct rates constantly decreased compared to 1 μM B[a]P alone. All changes in DNA-adduct formation were accompanied by similar changes in CYP1A1/1B1 activities. Incubation with pyrene only resulted in concentration-dependent decreases of CYP1A1/1B1 enzyme activities. Our results show that genotoxicity of B[a]P is systematically modulated by pyrene, but, not unidirectional in terms of increasing or decreasing genotoxicity. The observed effects were closely related to the bioactivation of B[a]P. These findings are important especially with respect to the fact that PAH mixtures to which humans are exposed vary in their compositions.
ative risk assessment for children, this work is to derive comparable benchmark doses (BMD) for SVOCs acting on the reproducitve system through the same mode of action.

The choice of chemicals was based on: detection frequency (>10%) in French dwellings, availability of data on the mechanism / mode of action for reproductive toxicity, and availability of comparable dose-response relationships (in terms of species, route and window of exposure). Lower bound of 95% confidence interval of BMDs corresponding to a decrease in 10% and 50% of serum testosterone were derived using BMDs software (US EPA, 2013).

Among 51 SVOCs previously selected, 12 (6 phthalates, 1 polybromodiphenyl-ether, 3 pesticides, benzo[a]pyrene and benophen A) have been described to act on the Leydig cells by inhibition of an enzyme activity responsible of testoste-ron production, resulting in a decrease in serum testosterone levels. Only 7 have suf-ficient and comparable data to derive BMDs. Considering the decrease of serum tes-terone levels, benzo[a]pyrene has the most potent toxicity (BMDs’ lower bounds: 0.0023-0.015mg/kg BW/d) and benzylbutylphthalate has the least potent toxicity (BMDs’ lower bounds: 52.73 - 364.89mg/kg BW/d). Relative potencies ranked as: benzo[a]pyrene > bisphenol A > 2,2,4,4-tetrafluorobiphenyl-ether > permethrin > diethylphthalate > cypermethrin > benzylbutylphthalate.

The main limitation for a cumulative risk assessment remains the lack of compara-ble toxicological data but this approach allows taking into account pollutants from diverse chemical families, with similar mode of action. These BMDs make possible a cumulative risk assessment for children exposed in indoor, in view to protect them from reproductive effects in adulthood.

### 1010 Human Health Hazard Assessment of Hydroprocessed Esters and Fatty Acids (HEFA) Bio-Based Jet Fuels

The 2007 Office of the Secretary of Defense Assured Fuels Initiative directed the pursuit of domestically produced alternative fuels for military use to decrease dependence on foreign oil sources. Although bio-based jet fuels are similar to petro-leum-derived JP-8, the traditional military fuel, the overall chemical composition is different. Therefore, potential health effects must be studied during development of alternative jet fuels. The body of toxicological data for Hydroprocessed Esters and Fatty Acids (HEFA) fuels from feedstocks including Camelina seed (HEFA-C), tallow (HEFA-T) and mixed animal fats and oils (HEFA-F) were exam-ined in order to develop an occupational exposure limit (OEL) for HEFA fuels. Dermal irritation studies showed that HEFA fuels are less irritating or equivalent to JP-8. Mutagenicity and genotoxicity assays were negative. Acute and short-term inhalation studies resulted in transient effects at low levels that were not seen in the 90-day inhalation study; additional reproductive endpoints were negative and no significant neurobehavioral effects were observed based on functional observa-tional battery and motor activity tests. Sensory irritation assays never reached 50% respiratory depression at saturation doses. HEFA toxicity data were compared with toxicity data from synthetic parathion kerosene (SKP) alternative jet fuel and petro-leum derived JP-8. A comparative OEL for HEFA fuels was developed that concurs with the current JP-8 OEL (200 mg/m³).

### 1011 Xenobiotic Mixtures Decrease Human Hepatic Gluconeogenesis and Glucose Oxidation

A. Leblanc, E. Blanc, A. Ambolet-Camoit, C. Benelli, S. Bortoli, R. Barouki, and M. Aggerbeck.

Epidemiological studies have shown that exposure to certain xenobiotics is associ-ated with an increased prevalence of metabolic diseases. Since humans are exposed to mixtures of xenobiotics detoxified by the liver, we used two xenobiotics, both en-docrine disruptors and persistent organic pollutants, which use different signaling pathways, to study hepatic energy metabolism: 2,3,7,8 tetrachlorodibenzo-p-dioxin (TCDD), which uses the AhR, and α-endosulfan, an organochlorine pesticide, which acts via the PXR and/or the estrogen receptor.

Treatment with either TCDD or α-endosulfan decreases, in vitro, the expression of hepatic glucose metabolism genes even at low doses and decreases hepatic gluconeogenesis and glucose oxidation. Chronic exposure of individuals to low doses of xenobiotics might significantly affect hepatic carbohydrate metabolism and be a contributing factor in the development of the metabolic syndrome.

### 1012 Studying the Impact of Volatile Organic Chemical Coexposures on the Urinary Excretion of Their Metabolites in Human Volunteers

It is common practice to assess volatile organic compounds (VOCs) exposure by monitoring their corresponding urinary metabolite, assuming no interactions between co-exposed chemicals. There is a dearth of information concerning the im-pact of VOC co-exposure on the excretion of metabolites used for biomonitoring.

The objective of this study was to collect metabolite excretion data and parent compound kinetics from inhalation exposures in human of four common VOCs (i.e. chloroform [CHL], toluene [TOL], ethylbenzene[EBZ] and m-xylene [XYL]). Five human volunteers were exposed by inhalation to 18 different combinations of chemicals (single, in binary combination with chloroform, or all 4 VOCs) at 1/4 or 1/8 TLV for 6 hours each with a week of interval between each exposure. Parent compounds were measured in exhaled air and blood samples taken during and following exposures. Metabolites, such as o-cresol (TOL), mandelic acid (EBZ), m-methylyluric acid (XYL) and 2,4-dimethylphenol (XYL) were quantified in urine (collected during and after exposure) after derivatization. No interactions were observed in exhaled air between exposures. No statistically significant interac-tions were observed on metabolites except for 2,4-dimethylphenol, which showed a decrease of 25% to 36% in total excreted amount in the presence of CHL alone or in the presence of all VOCs in air. Although average total amount of o-cresol ex-creted is increased by 50-72% when co-exposed to EBZ and XYL in air, and CHL in drinking water, this was not shown to be statistically significant. More effort will be place to understand the contradictory mixture interaction (i.e., decreased xylene blood levels but decreased metabolite excretion). These data will help to develop and validate an interactions-based physiologically-based pharmacokinetic modeling approach to assess VOCs exposure from urinary biomonitoring data.

### 1013 Pharmaceutical, Metal, and Ammonia Mixtures: Widespread Additive Toxicity in Zebrafish Larvae

Urban and industrial effluents (e.g. wastewater, agricultural and mining effluents) can introduce many contaminants into our aquatic ecosystems. Indeed, multiple contaminants in a single polluted site is the norm. Aquatic life has little say in the matter and are susceptible to contaminant exposure, given their constant contact with the aqueous environment. The acute toxicities of a variety of environmental contaminants were examined using the larval stage of a model organism, the ze-brafish (Danio rerio; 4–8 days post fertilization). Toxic interactions were observed between metals such as nickel, cadmium and copper. For example, sublethal copper exposure (6% of the copper LC50 or 13% of LC01) decreased the cadmium 96 h LC50 by 47%. In addition, pharmaceuticals in the environment are a growing con-cern and selective serotonin reuptake inhibitors (SSRIs) are particularly toxic to fish. Fluoxetine (ProzacTM) and sertraline (ZoloftTM, LustralTM) mixtures displayed additive toxicity; sublethal Fluoxetine (one-third of the LC50, 40% of the LC01) decreased the sertraline LC50 by 46%. Most surprising, however, were the observations that mixtures of acutely toxic environmental contaminants from different chemical classes also displayed additive toxicity. For example, ethinyl estradiol (EE2; bioactive estrogen in the female oral contraceptive pill) displayed additive toxicity with copper and sertraline. Similarly, sublethal amphetamine (a component of fertilizer) increased the toxicities of sertraline and Fluoxetine. Mixtures were typically additive or greater than additive. In the search for a common toxic mechanism, it was discovered that larvae exposed to metals, SSRIs or ammonia (around their respective LC50s) all experienced whole body ion loss. Decreases were greatest for Na+ as high as 39% in 48 h. Water quality criteria should ulti-mately recognize additive toxicity in order to protect our aquatic ecosystems.
1014 Assessing Neurological Risks from Oral Exposure to Mixtures of Organophosphorus (OP), Carbamate, and Pyrethroid Insecticides

P. McClure1 and H. Pohl2, 1SRC, Inc., East Syracuse, NY and 2US Public Health Service ATSDR, Atlanta, GA.

Data on interactions were evaluated to develop approaches to screening level assessments of human neurological hazard from oral exposure to mixtures of OP, carbamate, and pyrethroid insecticides. PubMed and Toxline were searched for data on interactions among 34 OPs, 16 pyrethroids, and 14 carbamates. Using ATSDR’s 2004 binary weight-of-evidence framework, the following determinations were made: 1) There are inadequate data to assess the direction of possible interactions between pyrethroids and carbamates; 2) There is some evidence for dose-additive action between pyrethroids and OPs, but only at near lethal levels in rodents; and 3) There is evidence for dose-additive action for carbamates and OPs on neurological endpoints in rats [brain cholinesterase and associated thermoregulatory endpoints]. Additionally, pituitary-elaboration kinetics was unchanged in humans exposed to low doses of pirimicarb and chlorpyrifos-methyl. Overall, the evidence is not compelling to move from a dose-additive approach. Dose-additivity most closely describes the joint toxic action of adverse neurological effects from oral exposures to mixtures of OPs, carbamates, or pyrethroids. A relative potency factor (RPF) Hazard Index approach would be an appropriate approach using RPFs and index chemicals determined by the USEPA Office of Pesticide Programs (EPA RPF) Hazard Index approach would be an appropriate approach using RPFs and index chemicals determined by the USEPA Office of Pesticide Programs (EPA 2006, 2007, 2011) and provisional oral Minimal Risk Levels for index chemicals of each class.

1015 Potential Toxicity of Electronic Cigarette Liquids and Aerosols As Measured by Four In Vitro Assays

R. Leverette, M. Mistra, R. T. Cooper and M. B. Bennett. Technology Development/Life Sciences, Lorillard Tobacco Company, Greensboro, NC.

The popularity of electronic cigarettes (E-cig) continues to increase worldwide, with several major tobacco companies entering the E-cig market. A typical E-cig delivers a flavored propylene glycol or glycerol based aerosol, with or without nicotine, via vaporization by a battery-powered heating element. Currently, data regarding the potential toxicity of E-cigs is limited. To further our understanding, an in vitro battery of established assays was used to examine the mutagenicity (Ames), cytotoxicity (Neutral Red Uptake; NRU), genotoxicity (Micrococcus; MN) and inflammatory (IL-8 release) response of a set of glycerol-based commercial E-cigs, specifically the neat E-cig liquids, pad-collected aerosol extracts and freshly generated whole aerosols. Pad-collected smoke condensates and whole smoke from traditional tobacco burning cigarettes (3R4F, 1R5F and one commercial cigarette) were included for comparison. All E-cigs and traditional cigarettes were smoked under Canadian Intense parameters (55 mL puff volume, 2 second puff duration, 30 second puff interval, 100% blocked air dilution). At the levels tested, exposures with neat E-cig liquids and pad-collected aerosol extracts showed no-to-extremely low activity in the Ames, NRU, MN and IL-8 assays when compared to responses from the traditional tobacco burning cigarettes. Results with E-cig samples without nicotine were very similar in all assays, indicating that the presence of nicotine, at the levels tested, did not significantly contribute to any cytotoxic and genotoxic effects observed at high doses. Whole aerosol exposures are ongoing, but preliminary results (Ames) show no activity. Overall, results from this study indicate, under the experimental conditions utilized, E-cigs do not produce any meaningful toxic effects when compared to traditional cigarettes, as measured by the four in vitro endpoints used in this study.

1016 Concentration Addition and Toxic Equivalent Factors: When Do They Apply?

T. Webster. Dept Environmental Health, Boston University School of Public Health, Boston, MA.

Dose addition/concentration addition (CA) is the principle criterion used in toxicology for judging interaction of compounds that act via similar mechanisms. Deviations from CA are then said to display synergy (more properly, greater than CA) or antagonism (less than CA). Following Berenbaum and others, by CA we mean that one compound can substitute for another at a constant ratio at any constant effect level. This is equivalent to having linear isoboles: the contours of the joint dose-response surface are straight lines. It is not widely understood that Toxic Equivalence Factors (TEFs) is a special case in which the dose ratio is the same at all effect levels (isoboles are then parallel which they need not be in the more general case). Confusion has crept into the literature as a result. Indeed, some alternative definitions of concentration addition lead to strange results. First, suppose that $f_A(a)$ describes the dose-response curve for compound A and $f_B(b)$ for compound B. Let the mathematical inverses of these functions be $g_A(E)$ and $g_B(E)$, respectively: they tell us the dose of A alone or B alone needed to achieve any given effect level E. One alternative definition of CA calculates the combined effect of A and B under no interaction as $f_A(g_A(fb(b)))$ or $f_B(g_B(fa(a)))$. We show that these two expressions are equal only under the TEF case; in other situations they can lead to different isoboles. Second, it has been claimed that joint dose-response surfaces with linear isoboles are rare. It is widely known that TEFs apply when the joint response of A and B is $f_A(a^*b)$ where $r$ is the relative potency of B compared to the reference compound A. While it can be shown that this is the only situation where TEFs apply, it places little restriction on the types of dose-functions $f_A(a)$ and $g_B(b)$. Finally, we might ask what kinds of joint dose-response functions obey CA. It can be shown that applying another function $h(E)$ to a response function changes the height of the response function but not the shape of its isoboles. Hence the kinds of dose-response-functions which can obey CA is enormous.

1017 Toxicology and Risk Assessment of Chemical Mixtures

M. Krishan and A. Kreter, ILSI, North America, Washington, DC.

Evaluation of potential health risk from simultaneous exposure to multiple chemicals has been one of the major challenges for toxicology research and risk assessment (RA). Terminology and problem formulation is complex and the framework for mixture RA varies greatly among different agencies. As part of the International Life Sciences Institute North America Technical Committee on Food and Chemical Safety, 2013 Summer Fellowship Program, we analyzed current methods to achieve the following: 1) Describe the landscape of RA for chemical mixtures; 2) Characterize differences in RA frameworks; and 3) Assess regulatory acceptance of these frameworks with a focus on food mixtures. Review of literature was conducted for mixture RA paradigms used by US federal agencies, non-profit organizations (WHO, IPCS) and international agencies (EU). There are significant overlaps and differences between paradigms and there appears to be no single unified method, is apparent from our research. US EPA’s original framework forms the basis of most of the globally accepted methods for mixture RA. Whole mixture, sufficiently similar mixture or component-based approaches are used for mixture RA depending on data availability. Differences in hazard assessment approaches were found among agencies, including differences in criteria (e.g., mode of action, health outcome) for grouping chemicals in assessment groups. WHO, IPCS and EU recommend the use of a tiered approach and dose additivity as the default approach. We developed a framework based on a food mixture scenario to select the set of parameters to guide use of appropriate RA methods. These parameters include target population, exposure routes, availability of data on the exposure levels and toxicity interactions for the whole mixture or individual components. Future methods could incorporate high throughput screening data (e.g., toxicogenomics and bio-monitoring) to improve risk characterization of food mixtures. Considering the current challenges in food mixtures such as heavy metals, pesticides and migrants from packaging, a case study was done to compare different methods and test their applicability to food safety assessments.

1018 The Modulation of Antioxidant Enzyme Activities and Glutathione Levels in the Livers of Mice after Subchronic Exposure to Mixtures of Dichloroacetate and Trichloroacetate

E. Hassoun and J. M. Cease, Pharmacology, University of Toledo, Toledo, OH.

Dichloroacetate (DCA) and trichloroacetate (TCA) are drinking water chlorination byproducts that were found to be hepatotoxic/hepatocarcinogenic in rodents. Mixtures of the compounds were previously found to induce additive or greater than additive effects on various biomarkers of oxidative stress (OS) in the hepatic tissues of B6C3F1 male mice after subchronic exposure, and that was suggested to modulate the hepatotoxicity/hepatocarcinogenic outcomes of the compounds. In order to determine the role of antioxidant enzymes and glutathione (GSH) on the effects of the mixtures, groups of male B6C3F1 mice were treated daily, by gavage, with 3 different doses of DCA (7.5, 15 and 30 mg/kg/day), 3 different doses of TCA (12.5, 25, and 50 mg/kg/day) and 3 different mixtures (Mix I, Mix II and Mix III) of the compounds for 13 weeks. The concentrations of the compounds in Mix I, II and III, respectively corresponded to those producing approximately 15%, 25% and 35% of maximal induction of OS by the individual compounds in the subchronic studies. The mice were euthanized at the end of the treatment period and livers were assayed for the activities of superoxide dismutase, catalase, glutathione peroxidase and glutathione level. While the individual compounds effects on the enzyme activities and glutathione were demonstrated as either suppression or stimulation, the mixture effects were demonstrated as the net effects of the two compounds in mixtures. The results indicate significant contribution of the antioxidants to the outcome of OS in the livers of B6C3F1 mice after long term exposure, and that the effects of mixtures of the compounds are different from...
those produced by the individual compounds. Hence, mixtures of DCA and TCA may result in modulation of the hepatotoxic/hepatocarcinogenic outcomes of the individual compounds. (Supported by NIH/NIEHS grant # R15ES013706-01A2)

1018a Cumulative Toxicity of an Environmentally Relevant Mixture of Nine Regulated Disinfection By-Products in a Multigenerational Rat Reproductive Bioassay

Disinfection of water has advanced public health by decreasing waterborne disease. Disinfectants react with organic materials in the water to form complex mixtures of disinfection by-products (DBPs). While a large unknown fraction remains, >600 DBPs have been identified. Most prevalent in chlorinated water are trihalomethanes (THMs) and halocarbons (HAAs); 4 THMs (chloroform, bromodichloromethane, chlorodibromomethane, bromoform) and 5 HAAs (chloroacetate, dichloroacetate, bromoacetate, dibromoacetate) are regulated by EPA as a group at 80 µg/L and 60 µg/L, respectively. This is the first multigenerational reproductive toxicity bioassay in animals with a drinking water mixture of the regulated THMs and HAAs. At realistic proportions, a mixture was prepared at 0, 500x, 1000x, and 2000x of EPA’s maximum contaminant levels (MCLs). Timed-pregnant Sprague-Dawley rats (P0 generation) were exposed from gestation day 0 until weaning of the F1 offspring. Weanlings continued in their treatment groups, were examined for reproductive endpoints and bred to produce F2 litters. Pre- and postnatal survival was unaffected. F1 pup weights were unaffected at birth but reduced at 2000x on postnatal day (PND) 6 and at ≥1000x on PND 21. Males at 2000x had a small but significantly increased incidence of retained nipples and effects on sperm motility. Onset of puberty showed dose-related delays at 1000x and 2000x. F1 estrous cycles, breeding, and fertility were unaffected and F2 litters showed no effects on pup weight, or prenatal or neonatal survival. Histologically, P0 dams had nephropathy and adrenal cortical pathological at 2000x. In sum, while puberty was delayed at DBP concentrations ≥1000x and males at 2000x had retained nipples and altered sperm motility, exposure at these concentrations to an environmentally realistic mixture of 9 regulated DBPs did not affect F1 animals’ ability to reproduce. (This abstract does not reflect EPA policy.)

1018b Toxicity Testing of Water, Air, and Soil near Mountaintop Removal Mining Sites in the Southern Coalfields of West Virginia Using In Vitro Methods—What the Data Can Tell Us

L. M. Crossley1, W. Orem1, C. DeVera1, K. Charles1, M. Varonka1, A. Bates1, T. Westphal1, A. Kolker1, C. Tatu2, and N. Geboy1.
